Re: Health Effects of Respirable Crystalline Silica in Blasting Dust
Newland Sierra Project – San Diego County

This letter report summarizes potential health effects associated with expected respirable crystalline silica emissions from blasting that will occur at the subject project.

1.0 INTRODUCTION

Respirable crystalline silica means crystalline silicon dioxide with aerodynamic diameter less than four microns (0.0004 cm). Silica or quartz is ubiquitous in nature. Most silica is amorphous and is therefore not crystalline as these two terms are mutually exclusive. Most dust generated by construction dust sources including blasting is greater than 4 microns and therefore too large to be respirable. Respirable crystalline silica constitutes a de minimis fraction of dust from these sources and does not represent a significant health risk to neighbors of these types of projects.

In order to result in toxic effects the silica needs to crystalline, smaller than 4 microns, and inhaled. This letter discusses the potential for the confluence of these conditions and shows that the health risk from crystalline silica is less than significant.

2.0 TOXICOLOGY OF CRYSTALLINE SILICA

Inhalation of crystalline silica initially causes respiratory irritation and an inflammatory reaction in the lungs. Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and emphysema. Levels to which workers (e.g., miners, sandblasters) may be exposed have been shown to cause cancer.

Acute exposures to high concentrations cause cough, shortness of breath, and pulmonary alveolar lipoproteinosis (acute silicosis). In a report on the hazards of exposure to crystalline silica, the American Thoracic Society (1997) stated: “Studies from many different work environments suggest that exposure to working environments contaminated by silica at dust levels that appear not to cause roentgenographically visible simple silicosis can cause chronic airflow limitation and/or mucus hypersecretion and/or pathologic emphysema.”

Other researchers also concluded that "chronic levels of silica dust that do not cause disabling silicosis may cause the development of chronic bronchitis, emphysema, and/or small airways disease that can lead to airflow obstruction, even in the absence of radiological silicosis." Fibrotic lesions associated with crystalline silica have also been found at autopsy in the lungs of granite workers who lacked radiological evidence of silicosis. (OEHHA, 2015).

Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and emphysema. Silica exposure has been implicated in autoimmune diseases (rheumatoid arthritis, scleroderma, systemic lupus erythematosus) in gold miners and granite workers and in the causation of kidney disease in some occupations, possibly by an immune mechanism. (OEHHA, 2015).

Several studies have reported "environmental silicosis", cases where the silicosis occurs in the absence of an industry usually associated with the disease. In one of the stronger examples, Saiyed et al. (1991) investigated non-occupational pneumoconiosis in Ladakh, India, high in the western Himalayas where there are no mines or industries. The prevalence of pneumoconiosis corresponded with the severity of dust storms and the presence or absence of chimneys in the kitchens (i.e., ventilated cooking). Without chimneys (Chushot), dust concentrations in kitchens averaged 7.5 mg/m3 during cooking periods. The free silica content of the dust storms was 60-70%. The authors suggested that exposure to free silica from dust storms and to soot from cooking with domestic fuels caused the pneumoconiosis. Such exposures in this and other studies might be considered to be non-industrial but occupational, since the subjects studied by Saiyed et al. (1991) were involved in the domestic work of cleaning and cooking (USEPA, 1996). In any case, the exposures were very high and thus similar to some occupational exposures. (OEHHA, 2015).

3.0 REGULATORY STATUS OF CRYSTALLINE SILICA

Crystalline silica is widely used in industry and has long been recognized as a major occupational hazard, causing disability and deaths among workers in several industries. In 1997, the International Agency for Research on Cancer rated respirable crystalline silica a Class 1 carcinogen based exclusively on worker exposure levels and epidemiology (IARC, 2012). In 2005, OEHHA adopted the Toxicity Summary for respirable crystalline silica which states:

> "In 1997, IARC classified respirable crystalline silica in Class 1, a Known Human Carcinogen, based on occupational epidemiologic studies. However, chronic RELs are not based on cancer endpoints. Further, there is no approved cancer potency factor for silica."

In other words, adverse health effects or endpoints other than cancer were used by OEHHA to determine the chronic non-cancer reference exposure level (REL). For purposes of health risk assessment using State of California AB2588 Air Toxics Hot Spot Program methods, respirable crystalline silica is not a carcinogen. Concentrations to which the public may be exposed are unexpected to give rise to cancer. Accordingly, OEHHA developed the chronic, non-cancer REL. CalOSHA developed the cancer protective permissible exposure level (PEL) for worker exposures. Both OEHHA and CalOSHA thresholds are presented in Table 1.

Table 1. Regulatory Exposure Levels for Crystalline Silica

Agency	Applicability	Concentration ($\mu g/m^3$)	Basis
OEHHA	Environmental exposures to respirable dust.	3	Non-cancer health effect, annual average exposure.
CalOSHA	Worker exposures to respirable dust.	100	Carcinogenic health effect. 8 hour time weighted average exposure.

4.0 EMISSIONS FROM BLASTING

Blasting emissions were calculated by Dudek to be approximately 56 lb PM_{10}/blast and 3.2 lb $PM_{2.5}$/blast based on approximately 0.9 acres affected per blast (Attachment 1). The PM_4 crystalline silica emissions are approximately 5% of the PM_{10} (Attachment 2) emissions or 2.8 lb/day. Blasting is expected to occur at two to three day intervals. There would be no more than one blast per day.

5.0 DISPERSION AND CONCENTRATION OF AIRBORNE DUST

Blasting will occur in the center of the Project site and along roads within the Project site. Figure 1 shows the wind rose and aerial photograph of the site. Air dispersion modeling for blasting was not undertaken because the Gaussian dispersion models (i.e., AERMOD) assume steady state conditions which are not appropriate for an event like blasting. Other models that could be used to evaluate a “puff” type source require input that is not feasible to obtain for this project.

The windrose presents the direction from which the wind is blowing. The size of each sector represents the frequency that wind blows from each direction. Wind is calm approximately 27% of time and 48% of time wind is from the west or southwest. 46% of the time wind is between 1 and 4 knots and 24% of time wind is between 4 and 7 knots. Wind exceeding 7 knots occurs less than 3% of the time. The average wind for the dataset is 2.59 knots (i.e., 3 mph) from the west-southwest.

Winds at 3 mph are relatively light creating a stable atmosphere. Under such conditions the plume of dust from blasting would be expected to remain intact for a longer distance than if greater wind speeds were present. The larger particles of dust would fall out of the atmosphere relatively close to the source as compared to the distance under higher wind conditions. Smaller respirable particles are less influenced by wind and are considered to behave as a neutrally buoyant gas. Respirable particles will remain in the atmosphere for many miles downwind.

Although low wind conditions result in more cohesive plumes and greater ground level concentrations, other conditions would have the opposite effect resulting in increased dispersion of the plume and lower concentrations. Specifically, the terrain is rough which increases vertical mixing as wind travels along the terrain. In addition, the plume has a large initial volume which means that it is already somewhat dispersed both vertically and laterally due to the nature of the source.

The most influential aspect of the blasting on receptor concentrations is the short lived nature of the emissions. The duration of exposure is brief. For instance, a plume that is generated by one-acre square area blasted would have initial length and width of approximately 200 ft. At the average wind speed, the plume would pass through a point in space in approximately one minute. The amount of dust inhaled would be limited by the brief

exposure and variability of blasting locations combine to produce a chronic effect from blasting emissions such that is would be unlikely that conditions of repeat exposure would occur frequently.

Finally, concentrations of pollutants in air decrease rapidly with increasing distance from the source. Given the relatively large distances between blasting activities and receptors, compliance with worker safety standards should also ensure that concentrations off-site are not significant.

6.0 MEASUREMENT OF RESPIRABLE CRYSTALLINE SILICA

Respirable crystalline silica has been measured by air districts and others near hard rock quarries that produce construction aggregates. The subject site is located in an area that is designated by the State to contain significant quantities of mineral resources. The primary bedrock unit onsite is Cretaceous-aged Granitic rock. (Leighton and Associates, 2015).

The Azusa Rock facility in South Coast AQMD is a hard rock mine which performs blasting to extract granitic rock (California Division of Conservation, 1988). SCAQMD performed monitoring of the particulate matter and respirable crystalline silica concentrations near Azusa Rock (SCAQMD, 2008). The SCAQMD concluded that "crystalline silica results show that for the duration of the study, no samples exceeded the non-cancer chronic reference exposure level of 3 $\mu g/m^3$ as PM_4 established by the State of California. The maximum 24-hour reported value for crystalline silica was 1.3 $\mu g/m^3$, with an average of 0.5 $\mu g/m^3$." (SCAQMD, 2008, p. 7). The concentrations measured include emissions from blasting and many other activities that occur at the facility.

7.0 FATE OF DUST DEPOSITED NEAR RECEPTORS

Dust that is deposited near receptors is unlikely to result in exposure to respirable crystalline silica for the following reasons:

1. The vast majority of deposited material is too large to be respirable.
2. The small amount of respirable dust that may be deposited, would need to be re-entrained into the air in order to be a hazard.
3. There are no processes taking place at receptors that would reduce the size of particles deposited making them smaller, respirable particles.

8.0 CONCLUSION

In summary, long term exposure to ambient respirable crystalline silica concentrations greater than 3 $\mu g/m^3$ causes silicosis and other adverse health effects. Steady state air dispersion models that are normally used to evaluate project impacts are not well suited to predicting concentrations from blasting. Input data for other dispersion models that would produce meaningful results are not feasible to obtain for this project.

The winds at the Project site are predominantly from the west-southwest and so receptors located east of the Project would be most affected by dust from blasting activities. It would take approximately 1 minute for a dust plume to pass by a receptor, during which time the receptor would take a few breaths. The amount of dust inhaled would be limited by the brief exposure and the variability of blasting locations should result in few repeat exposures that could combine to produce a chronic effect from inhalation of blasting emissions.

Materials being blasted at the Project are granitic and similar to those blasted at hard rock quarries. Specifically SCAQMD monitored respirable crystalline silica near the Azusa Rock Quarry and found that average concentrations were 0.5 $\mu g/m^3$ or 6 times less than the REL. This concentration included emissions from blasting and other sources on-site. Accordingly, concentrations that Project receptors will be exposed too should also be acceptable.

Lastly, deposition of crystalline silica at nearby receptors will consist of large particles that are not respirable. There are no processes at receptors that would reduce the size of the particles to respirable and thereby create an inhalation hazard. Thus, deposited crystalline silica is not considered to be the source of significant health risk.

Please call me or Rob Dal Farra at (805) 275-1515 if you have any questions or if you need additional information.

ABSTRACT

Fu The California Construction and Industrial Minerals Association and the National Stone, Sand, & Gravel Association have sponsored tests at three sand and gravel plants in California to compile crystalline silica emission factors for particulate matter (PM) of aerodynamic diameter of 4 μm or less (PM_4) and ambient concentration data. This information is needed by industrial facilities to evaluate compliance with the Chronic Reference Exposure Level (REL) for ambient crystalline silica adopted in 2005 by the California Office of Environmental Health Hazard Assessment. The REL applies to PM_4 respirable PM. Air Control Techniques, P.C. sampled for PM_4 crystalline silica using a conventional sampler for PM of aerodynamic diameter of 2.5 μm or less ($PM_{2.5}$), which met the requirements of 40 *Code of Federal Regulations* Part 50, Appendix L. The sample flow rate was adjusted to modify the 50% cut size to 4 μm instead of 2.5 μm. The filter was also changed to allow for crystalline silica analyses using National Institute for Occupational Safety and Health (NIOSH) Method 7500. The particle size-capture efficiency curve for the modified Appendix L instrument closely matched the performance curve of NIOSH Method 0600 for PM_4 crystalline silica and provided a minimum detection limit well below the levels attainable with NIOSH Method 0600. The results of the tests indicate that PM_4 crystalline silica emissions range from 0.000006 to 0.000110 lb/t for screening operations, tertiary crushers, and conveyor transfer points. The PM_4 crystalline silica emission factors were proportional to the crystalline silica content of the material handled in the process equipment. Measured ambient concentrations ranged from 0 (below detectable limit) to 2.8 μg/m³. All values measured above 2 μg/m³ were at locations upwind of the facilities being tested. The ambient PM_4 crystalline silica concentrations measured during this study were below the California REL of 3 μg/m³. The measured ambient concentrations in the PM_4 size range are consistent with previously published ambient crystalline silica data applicable to the $PM_{2.5}$ and PM of aerodynamic diameter of 10 μm or less (PM_{10}) size ranges.

IMPLICATIONS

Mineral processing facilities need PM_4 crystalline silica emission factor data to evaluate compliance with the 3 μg/m³ Chronic REL for PM_4 ambient crystalline silica adopted in 2005 by the California Office of Environmental Health Hazard Assessment. Emission tests at three sand and gravel plants have provided PM_4 crystalline silica data for screens, crushers, and conveyors. Mineral processing facilities can use the emission factor data to evaluate compliance with the stringent ambient PM_4 crystalline silica limit.

INTRODUCTION

Crystalline Silica Emission Factors of Particulate Matter of Aerodynamic Diameter of 4 μm or Less

There are no previously published data concerning particulate matter (PM) of aerodynamic diameter of 4 μm or less (PM_4) crystalline silica emissions from aggregate producing plants or other mineral industry sources. The PM_4 crystalline silica emission factors can be estimated based on published data concerning emission factors for PM of aerodynamic diameter of 10 μm (PM_{10}) or 2.5 μm ($PM_{2.5}$) or less for aggregate producing plants.[1–9] The U.S. Environmental Protection Agency (EPA) AP42 Section 11.19-2 emission factors for tertiary crushers, screens, and conveyor transfer points indicate that the $PM_{2.5}$ emissions range from 0.000013 to 0.000100 lb/t of stone. The AP42 Section 11.19-2 PM_{10} emission factors for these three types of processing equipment range from 0.000046 to 0.00074 lb/t.

These emission factors provide a starting point for evaluating possible PM_4 crystalline silica emission factors. It is reasonable to expect the PM_4 total emission factors to be between the $PM_{2.5}$ and PM_{10} emission factors. The PM_4

Crystalline Silica;Emission Factors;Aggregate Producing Facilities;PM_4;Testing

crystalline silica emission factors will depend on the crystalline silica content of the PM_4 total PM.

Ambient Crystalline Silica Concentrations

No PM_4 ambient concentration or emission factor data have been published. All previous crystalline silica ambient concentration data applied to the $PM_{2.5}$, PM_{10}, and/or PM of 15-μm or less (PM_{15}) size ranges.

One of the first studies of ambient crystalline silica concentrations was conducted by Davis et al.[10] This study focused on urban areas. Ambient crystalline silica concentrations were measured in 22 urban areas using dichotomous samplers that separate ambient PM into the 0- to 2.5-μm range ("fine PM") and the 2.5- to 15-μm range (termed here as "coarse/supercoarse PM"). Davis et al. measured mean 24-hr average ambient crystalline silica concentrations ranging from 0.9 to 8 $\mu g/M^3$ in the coarse/supercoarse size range. Crystalline silica was 1–9% of the coarse/supercoarse PM and 0–2.6% of the fine (<2.5 μm) PM.

EPA[11] used the data of Davis et al. to derive estimates of the annual average crystalline silica levels in urban areas. The city-specific crystalline silica content values were multiplied by annual average PM_{10} concentrations in these areas to estimate the annual average PM_{10} crystalline silica levels. EPA also calculated an annual average of 1.9 $\mu g/m^3$ with a range of 0.8–5 $\mu g/m^3$ in the PM_{10} size range. The crystalline silica content in the $PM_{2.5}$ size range was consistently less than 1 $\mu g/m^3$ because of the low crystalline silica content of the $PM_{2.5}$ PM and the low total concentration of $PM_{2.5}$ PM.

In 2000, the National Stone, Sand, & Gravel Association (NSSGA) sponsored upwind-downwind studies of ambient crystalline silica concentrations at four stone crushing plants processing high-quartz-content rock.[12] Air Control Techniques, P.C. used Rupprecht & Patashnick Co, Inc. Federal Reference Method (FRM)-2000 samplers that fully met the stringent design and operating specifications of 40 *Code of Federal Regulations* (CFR) Part 50, Appendix L.[13] The measured 8-hr working-shift PM_{10} crystalline silica concentrations at the collocated downwind PM_{10} samplers ranged from 1 to 10.9 $\mu g/m^3$. These values are similar to the range of mean 24-hr concentration values of 0.9–8 $\mu g/m^3$ for 24-hr concentrations measured by Davis et al. in the coarse/supercoarse size range. The measured upwind and downwind concentrations were similar. The crystalline silica levels of 5.07–6.24% by weight of the PM_{10} were similar to the 4.9 ± 2.3% levels in coarse/supercoarse PM reported by Davis et al.

Various other studies have provided limited data for urban, rural, and industrial areas. Puledda[14] measured PM_{10} crystalline silica levels in Rome, Italy of 0.11–2.27 $\mu g/m^3$. These levels were 1.7–3.4% of the measured PM_{10}. Norton and Gunter[15] measured PM_{10} crystalline silica levels averaging 10% in Moscow, ID. They also extracted PM from PM_{10} samples from numerous areas throughout Idaho and estimated crystalline silica levels to be between 7 and 16% of PM_{10} in various urban and rural areas in Idaho. Various other studies described by EPA[11] at urban, rural, and industrial areas indicated 24-hr average crystalline silica levels and crystalline silica contents in PM_{10} that were similar to those in Davis et al.,[10] Air Control Techniques, P.C.,[12] Puledda,[14] and Norton and Gunter.[15] These other studies include Schipper,[16] Goldsmith,[17] Chow et al.,[18] Chow,[19] and Chow.[20] Only the study of Shakari and Holmen[21] reported crystalline silica levels and PM_{10} crystalline silica contents outside of the range of the various papers summarized above. There are insufficient data in Shakari and Holmen to identify the possible reasons for the differences between their data and other studies.

On the basis of the available ambient crystalline silica data, the study participants concluded that there was a need for a monitoring technique having a minimum detectable limit of 0.3 $\mu g/m^3$. This is at or below the concentrations anticipated in this project. This minimum detectable concentration is also 10% of the California Relative Exposure Limit. An evaluation of National Institute for Occupational Safety and Health (NIOSH) Method 0600 used for in-plant industrial hygiene tests indicated that this method was not sufficiently precise at the necessary detection limit. Accordingly, the California Construction and Industrial Minerals Association (CalCIMA) and NSSGA sponsored the development of a more accurate and precise PM_4 crystalline silica monitoring method for this project. Information concerning the development of the PM_4 crystalline silica monitoring method on the basis of the validated $PM_{2.5}$ test method is described in the project report.[22]

TEST LOCATIONS AND PROCEDURES

PM_4 Crystalline Silica Measurement Test Locations

Study participants selected facilities for testing on the basis of (1) the representativeness of a vibrating screen, tertiary crusher, and conveyor transfer point of other California plants; (2) the representativeness of the crystalline silica content of the minerals processed; (3) the accessibility of the equipment for testing; (4) the capability to isolate the process unit tested from adjacent process units; and (5) the geographical location. The plants included the Service Rock Products, Inc. plant in Barstow; the Vulcan Materials, Inc. Carroll Canyon plant near San Diego; and the Teichert Aggregates, Inc. Vernalis plant near Tracy. These plants had crystalline silica levels ranging from 16.5 to 35.3% by weight in the minerals being processed.

PM_{10} data were compiled to provide a comparison of measured PM_4 crystalline silica emissions with measured PM_{10} emissions. The scope of the programs at each of these three facilities included PM_{10} emission factor tests on the crushers, vibrating screens, and conveyor transfer points.

The specific sources tested at Barstow included (1) a 16- by 5-ft flat vibrating screening operation, (2) a short-head crusher, and (3) a conveyor transfer point. The equipment tested at Carroll Canyon included (1) a 16- by 8-ft flat vibrating screen, (2) a set of two cone crushers, and (3) a conveyor transfer point. The sources tested at Vernalis included (1) a 20- by 8-ft triple deck sloped vibrating screen, (2) a set of two cone crushers, and (3) a conveyor transfer point. Water sprays controlled all of the units with the exception of the Carroll Canyon cone

018272

crushers. A fabric filter supplemented wet suppression control at the Carroll Canyon cone crushers.

PM_4 Crystalline Silica Measurement Procedures

The PM_4 crystalline silica emission concentrations were measured using TECO Model 2000 FRMs modified to have a 50% cut point of 4 μm rather than 2.5 μm. This monitoring method was developed for CalCIMA and NSSGA by Air Control Techniques, P.C. in accordance with a protocol submitted to the California Air Resources Board in July 2005. The authors consider this method to be an extension of the $PM_{2.5}$ ambient monitoring procedures specified by EPA in 40 CFR Part 50, Appendix L because of the use of identical sampling equipment, sampling procedures, and quality assurance procedures.

The main adjustment necessary to an Appendix L qualifying instrument is a change in the 50% cut size of this instrument from $PM_{2.5}$ to PM_4. The 50% cut size was adjusted by reducing the sample airflow rate into the TECO sharp cut cyclone to 11.1 L/min from the 16.67 L/min used for $PM_{2.5}$ monitoring. The adequacy of the cut size was confirmed using National Institute for Standards and Technology (NIST) traceable microspheres.

A calculated sampling time of 1–3 hr was required to meet the minimum detection limits of NIOSH 7500 for crystalline silica during tests on the process equipment. These sampling time estimates were based on (1) the NIOSH Method 7500 detection limit of 5 μg, (2) the TECO FRM 2000 sample gas flow rate of 11.1 L/min that was used to collect PM_4, and (3) the estimated crystalline silica content of the stone material being processed. Crystalline silica was detected in all but one filter sample, which confirmed the adequacy of the 1- to 3-hr sampling periods used in the study. The filter samples were weighted at R.J. Lee Group, Inc. using a microbalance and analyzed for crystalline silica using NIOSH Method 7500.

The fugitive PM_{10} PM emissions from the process equipment sources tested in Barstow were measured using a TECO tapered element oscillating microbalance (TEOM) in accordance with EPA Reference Method IO-3. For the tests at Carroll Canyon and Vernalis, the fugitive PM_{10} PM emissions were measured using TECO Model 2000 FRMs modified for PM_{10}.

Sampling arrays designed based on EPA Method 5D (40 CFR Part 60, Appendix A) captured process equipment PM_4 crystalline silica emissions. The mass fluxes

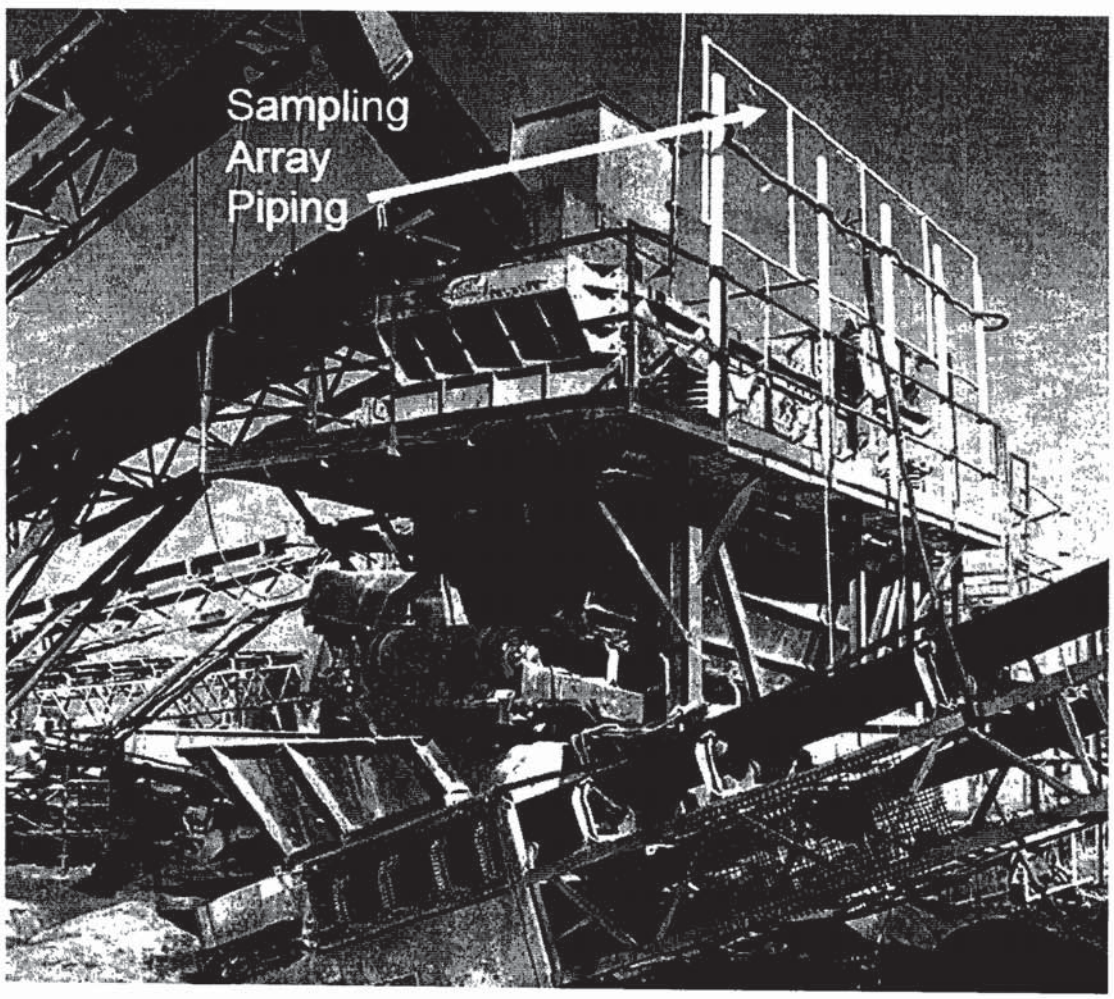

Figure 1. Side view of the sampling array on the downwind side of the vibrating sizing screen at the Barstow plant.

Figure 2. South-side view of sampling array on downwind side of the conveyor transfer point at the Barstow plant.

of PM_4 and PM_{10} fugitive PM through the arrays were calculated by multiplying the total area of the array by the ambient wind speed and the measured PM_4 and PM_{10} concentrations.

The arrays for the vibrating screens, tertiary crushers, and conveyor transfer points were mounted within 5 ft of the locations of PM entrainment by ambient air. Because of this close spacing of the arrays to the source, the "plume" did not have time to substantially disperse in the horizontal or vertical direction. Accordingly, the dispersing PM was captured from the sources even as the ambient winds shifted direction within an angle of approximately 90°.

Each sampling array had more than 100 sampling points. This substantially exceeds the 30 sampling points specified in EPA Method 5D for testing open-top sources. The area monitored by the sampling array exceeded the area subject to dispersion of the PM on the downwind side of the process unit being tested. Each array consisted of manifolds having equally spaced nozzles for air sampling. The gas transport velocities through all sampling tubes and ductwork were above a minimum of 3200 ft/min to prevent any gravitational settling of dust. The sampling manifolds and ductwork were visually inspected after each test run. Following each set of emission tests, the sampling array piping and flex ducts were disassembled and checked for solids deposits. No deposits were present in any sections of the sampling system. Wind speed data and wind direction data demonstrated that each test run was consistent with study requirements.

Each of the array sampling manifolds was ducted together to yield a single sample gas stream. This gas stream flowed through a round duct 12 in. in diameter with sampling ports for a TECO FRM 2000 (modified for PM_4) sampling head and a PM_{10} sampling head. This duct size was the minimum necessary to accommodate the relatively large inlet heads for the TECO FRM 2000 and the TEOM. The gas velocity through the portion of the duct with the sampling ports for the monitoring instruments was less than 10 mph to be consistent with typical ambient wind velocities.

The actual sample gas flow rates through the sampling arrays provided near-isokinetic sampling velocities in the nozzles of the sampling arrays. The nozzles provided isokinetic sampling velocities equal to or lower than 110% at an average ambient wind speed of 5 mph. At isokinetic sampling rates below 100%, there is a slight bias to higher-than-true PM_4 concentrations because of the inertia of the PM_4 particles; however, this isokinetic effect is small for PM_4 particles because of their extremely low mass. Figures 1–3 show the sampling array arrangements. F1-3

The ambient airflow rate through each array was calculated based on the area of the array and the measured ambient wind speed. The tests were conducted only when the ambient winds were moving across the process being tested and through the downwind array. The adequacy of fugitive dust capture by the array was documented on a continuous basis using visible wind direction indicators and on an intermittent basis using a nephelometer continuous PM concentration analyzer inside and outside of the array.

018274

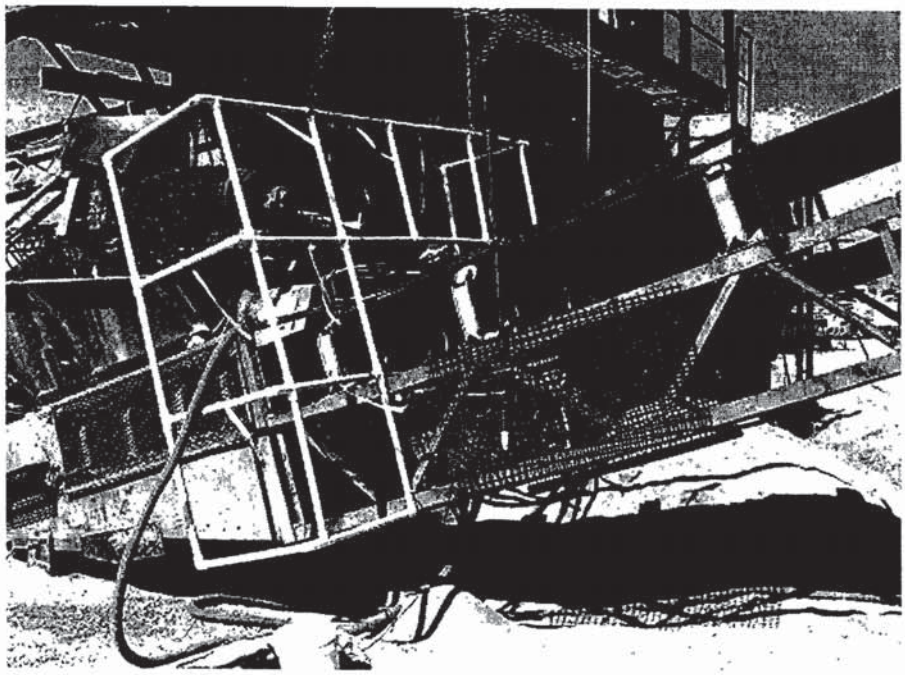

Figure 3. Close-up view of the sampling orifices in the conveyor transfer point array at the Carroll Canyon plant.

As part of this testing program, meteorological monitoring stations were installed to measure the following parameters during the process equipment test programs.

- Average and peak wind speeds
- Wind direction
- Ambient temperature

The sample gas velocities and volumetric flow rates through the main sampling duct during the PM_4 and PM_{10} tests were determined according to the procedures outlined in EPA Reference Method 2.

The authors believe that this fugitive dust capture technique provides the most accurate means possible to quantify fugitive dust emissions without affecting the rate of fugitive dust emissions and without interfering with safe plant operations.

PM_4 Emission Factor Test Program Process Data

During each of the test runs, study participants compiled data concerning the process operating conditions and the characteristics of the materials being handled.

- Crystalline silica content of aggregate being processed through the tested units
- Material moisture content (% wt)
- Material particle size distribution (sieve analyses)
- Material throughput (t/hr)

Ambient PM_4 Crystalline Silica Measurements

The PM_4 crystalline silica ambient concentrations were measured using TECO Model 2000 FRMs adjusted for PM_4 monitoring. Two Model 2000 FRMs were located

Table 1. PM_{10}, PM_4, and PM_4 crystalline silica emission factors at Barstow.

		Emission Factor Values (lb/t) of Stone Throughput		
Equipment Tested	**Emission Factor**	**Measured Value**	**Ambient Upwind Equivalent[b]**	**Emission Factor**
Vibrating screen	PM_{10}	0.000167[a,c]	NA[c]	0.000167[a,c]
	PM_4	0.000079[c]	NA[c]	0.000079[c]
	PM_4 crystalline silica	0.000006[c]	NA[c]	0.000006[c]

	PM_4 crystalline silica	0.000111	0.000028	0.000083
Conveyor transfer point	PM_{10}	0.000625	0.000050	0.000575
	PM_4	0.000402	0.000050	0.000352
	PM_4 crystalline silica	0.000035	0.000006	0.000029

Notes: [a]PM_{10} emission factors were calculated based on TEOM data. [b]Ambient levels of PM_4 PM and PM_4 crystalline silica upwind of the units tested were subtracted from the emission factors to account for material not emitted by the source. [c]Ambient levels of PM and crystalline silica upwind of the vibrating screens were not subtracted because the upwind samplers were below the elevation of the screens; therefore, the air quality at this elevation was not necessarily representative of air quality on the inlet side of the screen.

Table 2. PM_{10}, PM_4, and PM_4 crystalline silica emission factors at Carroll Canyon.

Equipment Tested	Emission Factor	Emission Factor Values (lb/t) of Stone Throughput: Measured Value	Ambient Upwind Equivalent	Emission Factor

on the downwind side of the facility at a location immediately adjacent to the plant fence line. A single upwind Model 2000 FRM was located on the upwind side of the facility.

These instruments were operated for 24 hr and obtained sample volumes of 16 m^3. R.J. Lee Group, Inc. (RJL) weighed the filter samples using a microbalance and analyzed for crystalline silica using NIOSH Method 7500.

RESULTS

Emission Factor Test Results

The PM_{10}, PM_4, and PM_4 crystalline silica emission factors for the equipment sources measured at the three facilities are presented in Tables 1–3. The emission factors presented in the column on the right were calculated by subtracting the measured downwind concentrations from the measured upwind (ambient) concentrations. T1-3

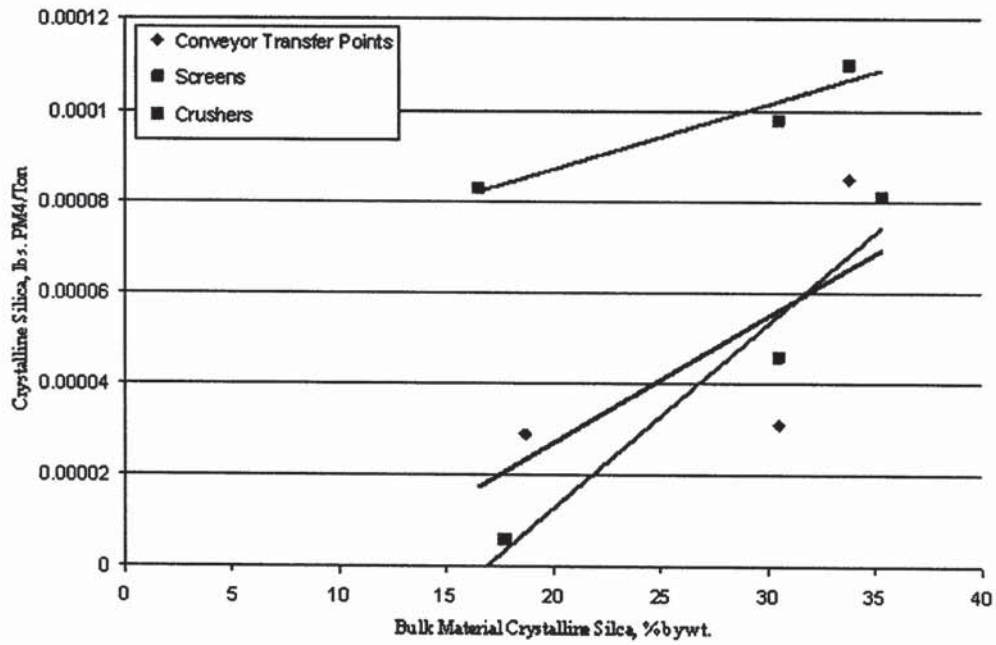

Figure 4. Relationship between bulk material crystalline silica content and the PM_4 crystalline silica emission factor.

T4 As indicated in Table 4, the crystalline silica PM_4 emission factors range from 3.21 to 7.95% of the PM_{10} emission factors. This is a useful ratio because it compares the PM_4 crystalline silica emissions with PM_{10} emissions for which data are often available.

The plant-to-plant differences in PM_4 crystalline silica emission factors are primarily due to the crystalline silica content of the material being handled. As indicated F4 in Figure 4, the bulk material crystalline silica content is responsible for most of the variance in the data. However, it is important to note that because of the small number of test values (three), it is not possible to demonstrate that the relationship between PM_4 crystalline silica emission factors and bulk crystalline silica content is significant at the 90% confidence level.

A less consistent relationship was observed for the conveyor transfer point tests. The reduced emission factor value for the Carroll Canyon plant (30.5% crystalline silica point) is probably due to the high aggregate throughput of this unit. It is theorized that at very high throughputs, some of the stone in the flowing material stream is shielded from attrition and, therefore, does not contribute to emissions. Despite this one test value, there appears to be a relationship between PM_4 crystalline silica emission factors and the crystalline silica content of the bulk material.

An alternative approach for summarizing the PM_4 crystalline silica concentrations is to compile average values for the datasets for the crushers, screens, and con- T5 veyor transfer points tested. Table 5 includes average values based on the data from the three plants provided in Tables 1–3.

T6 Table 6 summarizes the crystalline silica fraction of the total PM_4. These data demonstrate that the crystalline silica content of the PM_4 material is considerably lower than the crystalline silica content measured in the bulk samples recovered from each unit tested. On the basis of an average of the tests at the three plants, the PM_4 crystalline silica content is 44% of the bulk material crystalline silica content. It is apparent that the crystalline silica content of the rock is not as prone to attrition size reduction as other constituents in the aggregate.

The process equipment PM_4 crystalline silica emission factors summarized in Tables 1–6 are consistent with previously published emission factors for $PM_{2.5}$ and PM_{10} from similar process units. The PM_4 crystalline silica emission factors are intended for use as input data to dispersion models to evaluate annual average PM_4 concentrations at plant fence lines.

Ambient PM_4 Crystalline Silica Concentrations

Ambient concentrations of PM_4 crystalline silica were measured during 3 consecutive 24-hr periods at the

Table 5. Average emission factors from Barstow, Carroll Canyon, and Vernalis: combined dataset.

Carroll Canyon and Vernalis plants. Two collocated TECO FRM samplers modified for PM_4 crystalline silica measurement operated at a location downwind of the quarry and processing equipment. A single TECO FRM instrument for PM_4 crystalline silica monitoring operated at a location upwind of the entire facility being tested. Meteorological monitoring stations were placed at the upwind and downwind locations. The results of the ambient monitoring tests demonstrated that the plants operated at levels well below the 3-$\mu g/m^3$ REL value. Tables 7 and 8 summarize the results for the Carroll Canyon and Vernalis plants, respectively.

The differences between the upwind and downwind ambient PM_4 crystalline silica concentrations are small. The slightly higher upwind values observed during several of the test days are due to emissions from unpaved roads near the upwind monitoring sites.

Quality Assurance/Quality Control Procedures for PM_4 and PM_{10} Sampling

All of the PM_4 crystalline silica concentration tests conducted with modified Appendix L samplers included quality assurance (QA)/quality control (QC) procedures established by EPA for IO-1.3 (TEOMs) and 40 CFR Part 50, Appendix L (TECO FRM 2000s). The QA/QC data indicated that the TECO PM_4 samplers, the TECO PM_{10} samplers, and the TECO TEOM monitor used for PM_4 and PM_{10} monitoring performed extremely well throughout the three test programs.

All of the PM_4 concentration samplers used for emission factor testing and ambient air monitoring met all of the pre- and post-test requirements concerning filter temperature, ambient temperature, barometric pressure, sample flow, and sample gas stream leak rates.

A TEOM monitor was used during the tests at Barstow for the emission factor tests of the tertiary crusher, the vibrating screen, and the conveyor transfer point. The TEOM monitor satisfied the pre- and post-test QA requirements concerning ambient temperature, barometric pressure, sample flow, and sample gas stream leak rates.

SUMMARY

PM_4 crystalline silica emission factors measured using an Appendix L-based filter sampler ranged from 0.000006 to 0.000110 lb/t of stone processed in vibrating screens, tertiary crushers, and conveyor transfer points. The measured PM_4 crystalline silica emissions ranged from 3.21 to 7.95% of the simultaneously measured PM_{10} emission factors. The PM_4 crystalline silica emissions measured in this study appeared to be related to the crystalline silica content of the mineral being handled. The concentration of crystalline silica in PM_4 PM averaged 44% of the crystalline silica content of the bulk mineral.

Ambient concentrations of PM_4 crystalline silica were measured upwind and downwind of the facilities during the emission factor test programs. The measured ambient concentrations of PM_4 crystalline silica ranged from below the detectable limit of 0.3 $\mu g/m^3$ to 2.8 $\mu g/m^3$. These concentrations are well below the California REL of 3 $\mu g/m^3$.

EXECUTIVE SUMMARY

Purpose

In a letter dated April 12, 2005, the city of Duarte requested the AQMD to examine potential air quality impacts of quarry operations in the area. Specifically, the city requested that the AQMD conduct particle matter (PM) sampling in the community. The AQMD worked with the city to identify a suitable sampling location and deployed a PM_{10} sampler at Royal Oaks Elementary in Duarte beginning in August 2005. In October 2005, a $PM_{2.5}$ sampler was added at the school and fallout samples were collected at various locations in the community. The AQMD held a town hall meeting on September 21, 2005 to inform the public of the air monitoring program and to hear community concerns. Comments were made that elevated levels of crystalline silica may occur from the quarry activities and are a potential health concern. Subsequent to the meeting, the AQMD initiated air monitoring for crystalline silica. This fourth report details findings for the first three quarters of 2008 and for the entire duration of sampling starting in August 2005 and ending on September 9th 2008. The sampling at Royal Oaks Elementary has established baseline levels of PM_{10}, $PM_{2.5}$, and crystalline silica which may be used to compare future samples.

Sampling

Sampling at Royal Oaks Elementary located in Duarte began in August 2005 with federal reference method (FRM) sampling of PM_{10}. A $PM_{2.5}$ FRM sampler was then added in October 2005. Due to concerns about crystalline silica, an additional PM sampler specific to crystalline silica, was added on May 23, 2006. From the beginning of sampling, a meteorological system has measured and recorded wind speed and direction at the site. The PM and meteorological data are used for comparison to AQMD's air monitoring station (AMS) data collected in Azusa, immediately east of the quarrying and materials handling facility, and to air quality standards established by both the state of California and U.S. EPA.

Key Findings

- The state 24-hour standard for PM_{10} is 50μg/m^3. This standard was exceeded on two sampling days in Duarte and ten sampling days in Azusa during the period of January to September 9th 2008. Average 24-hour PM_{10} concentrations were 28μg/m^3 in Duarte and 35μg/m^3 in Azusa when same sampling dates are compared.

- The federal 24-hour standard for $PM_{2.5}$ is set at 35μg/m^3. This standard was exceeded on two days in Duarte and one day in Azusa during this reporting period. The federal level was exceeded in Duarte on July 5th with a measured value of 60μg/m^3, likely as a result of 4th of July fireworks activities; no sample

was recovered from Azusa on this day. The other day in Duarte exceeding the federal standard occurred on Feb 18th 2008 with a value of 35.3μg/m^3, the same day as Azusa (36.5μg/m^3). $PM_{2.5}$ averaged 14.6μg/m^3 in Duarte compared to 14.4μg/m^3 at the Azusa AMS when same sampling days were compared for the first three quarters of 2008.

- Crystalline silica results show that for the duration of the study, no samples exceeded the non-cancer chronic reference exposure level of 3μg/m^3 as PM_4 established by the State of California. The maximum 24-hour reported value for crystalline silica was 1.3μg/m^3, with an average of 0.5μg/m^3.

- Wind direction at Duarte and AQMD's Azusa air monitoring station (AMS) demonstrates a great deal of similarity for months where data is available. Wind speeds at the Azusa AMS are typically higher than those measured in Duarte.

1.0 INTRODUCTION

This is the fourth and final follow-up to AQMD's report on particulate matter (PM) monitoring conducted at Royal Oaks Elementary School, located in Duarte, California (SCAQMD, 2006). New sampling results in this report cover the first, second, and third quarters of 2008 (January to September 9th 2008). Details regarding background, project discussion, and sampler siting protocols are provided in the 2006 report[1]. For this monitoring period, 76 samples were collected for PM_{10}, 76 samples for $PM_{2.5}$ mass determination and 33 PM_4 samples were collected to determine ambient crystalline silica concentrations. Twenty one of the crystalline silica samples had concentrations greater than the detection limit of $0.4\mu g/m^3$.

2.0 Crystalline Silica

Silica refers to silicon dioxide (SiO2), which occurs naturally in crystalline and amorphous forms. It is exposure to respirable crystalline silica that has been determined to have health impacts. Crystalline silica is the crystalline form of silicon dioxide and is naturally occurring; the most common form of crystalline silica is quartz. Exposure to crystalline silica may result from activities that involve the suspension of respirable crystalline silica into the air; such activities might include mining, quarry work, rock drilling, stonecutting, and abrasive blasting.

Atmospheric sampling for respirable crystalline silica is based on sampling particulate matter with an aerodynamic diameter of 4 micro-meters or less (PM_4). A PM_4 sampler was deployed in May 2006 at Royal Oaks Elementary. This sampler was replaced with a higher flow rate PM_4 sampler at the beginning of January 2007. Samples for PM_{10}, $PM_{2.5}$, and PM_4 are all collected over a one-day, 24-hour period, from midnight to midnight.

There is very little information on ambient levels of PM_4 crystalline silica. In a document dated 1996, U.S. EPA estimated background levels of crystalline silica at $3\mu g/m^3$ of PM_{15}, but has no estimates for PM_4 crystalline silica. An upper bound estimate of 10% for silica in PM_{10} in metropolitan areas was also given, but it was noted that this upper bound is uncertain. Crystalline silica is listed as a Proposition 65 cancer-causing compound by the State of California and has set a non-cancer chronic reference exposure level (REL) of $3\mu g/m^3$ as PM_4. Chronic exposure refers to exposure of 8 years or longer and is not based on a specific sampling period. The National Institute of Occupational Safety and Health (NIOSH) has set a recommended exposure limit of $50\mu g/m^3$ PM_4 averaged over a work shift of 8 to 10 hours.

3.0 ANALYSIS

Analysis for PM mass is conducted in accordance with established U.S. EPA and AQMD methods. The determination of crystalline silica follows AQMD's method. All samples are accompanied with a completed Sample Analysis Request – Chain of Custody Form upon receipt by the AQMD Laboratory. Specific details regarding sampling and analysis protocols can be found in the 2006 AQMD report.

4.0 RESULTS

PM Sampling

Results of PM_{10} sampling for the first, second and third quarters in Duarte and Azusa for 2008 are listed in Appendix A and plotted in Figure 1. PM_{10} data collected since the start of the study are shown in Figure 2 and Appendix D. Results of $PM_{2.5}$ sampling for the first, second, and third quarters in Duarte and Azusa for 2008 are listed in Appendix B and plotted in Figure 3. Data for all $PM_{2.5}$ samples collected since the beginning of the monitoring program are shown in Figure 4 and in Appendix E. All results are based on samples being taken every sixth day for a 24-hour sampling period.

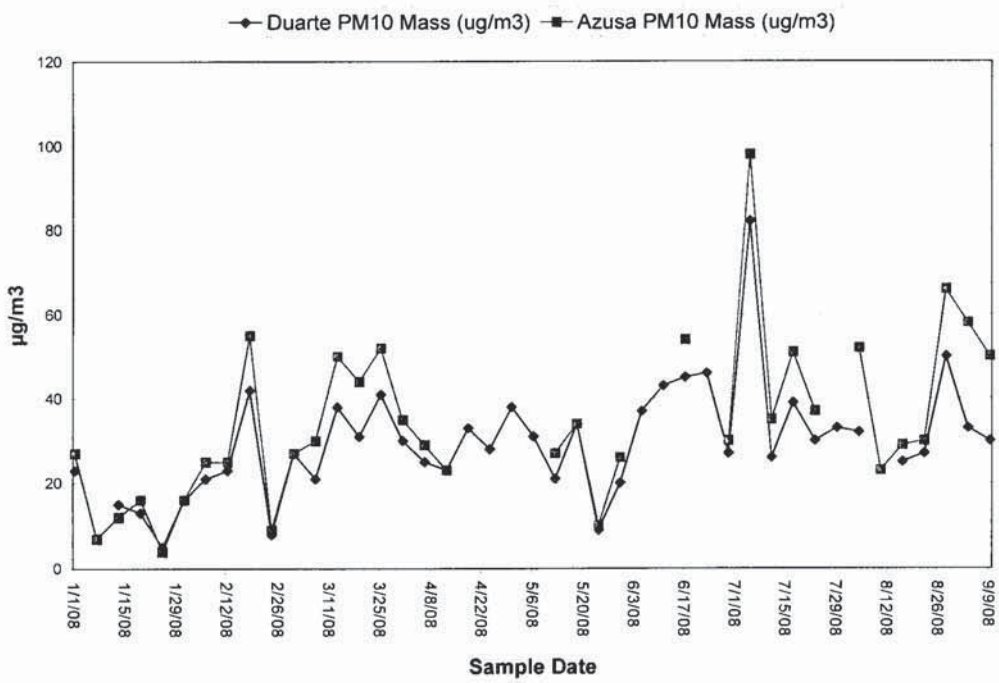

Figure 1. First Three Quarters of 2008 PM_{10} Mass at Duarte and Azusa

For the three quarter period of 2008, the 24-hour PM_{10} data collected at Duarte track well with data collected in Azusa. All sampled PM_{10} concentrations at Duarte and Azusa are below the federal 24-hour standard of 150µg/m^3. The state 24-hour PM_{10} standard of 50µg/m^3 set by the California Air Resources Board was exceeded on two days in Duarte and ten days in Azusa. On the July 5th 2008 sample day, both Duarte (82µg/m^3) and Azusa (98µg/m^3) largely exceeded the state PM_{10} standard; likely a result of Fourth of July fireworks. The average PM_{10} mass concentration during this three quarter period when comparing the same sample days was 28µg/m^3 in Duarte and 35µg/m^3 Azusa.

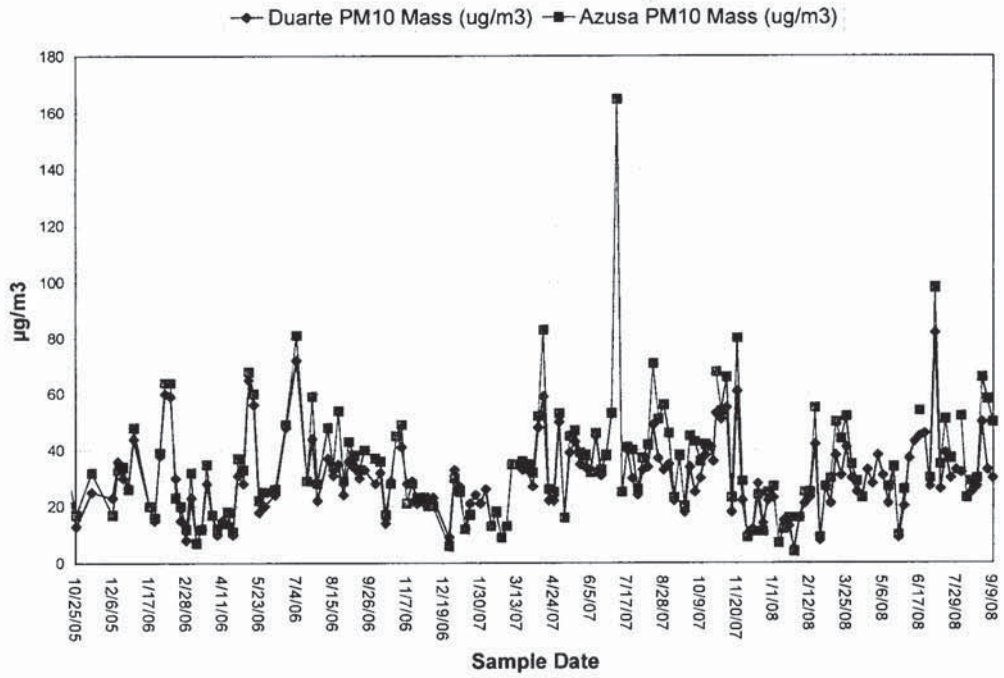

Figure 2. PM_{10} Data at Duarte and Azusa Since Study Inception

$PM_{2.5}$ concentrations at the two sites also track each other very well. The federal 24-hour standard for $PM_{2.5}$ is established at 35µg/m^3. This standard was exceeded on two days in Duarte and one day in Azusa during this reporting period. One day the federal level was exceeded in Duarte occurred on July 5th likely as a result of 4th of July fireworks activities; no sample was recovered from Azusa on this day. The other day in Duarte exceeding the federal standard occurred on Feb 18th 2008, the same day as Azusa. $PM_{2.5}$ averaged 14.6µg/m^3 in Duarte compared to 14.4µg/m^3 at the Azusa AMS when same sampling days were compared.

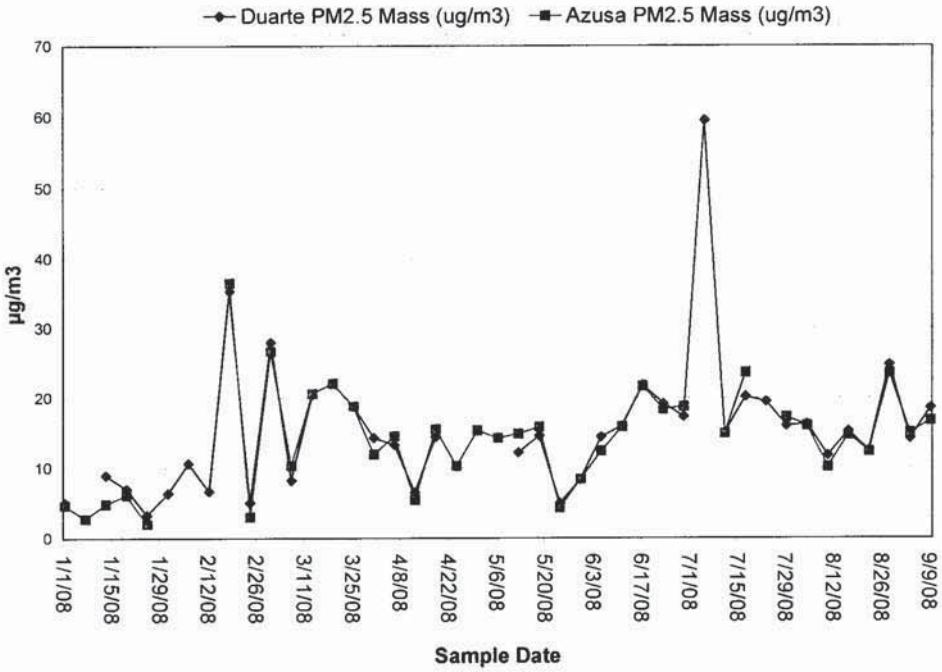

Figure 3. First Three Quarters of 2008 $PM_{2.5}$ Mass at Duarte and Azusa

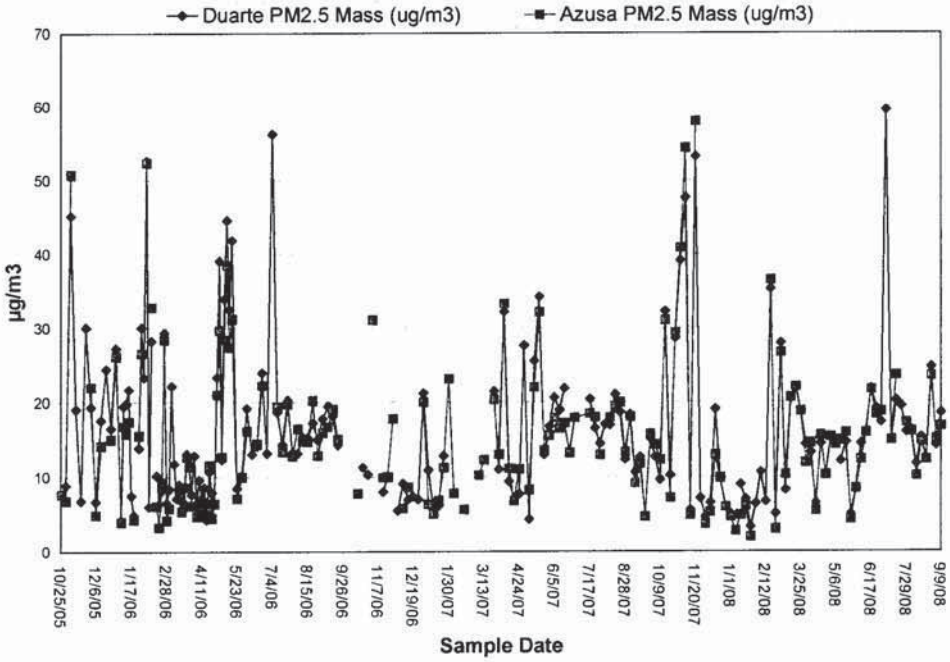

Figure 4. $PM_{2.5}$ Data at Duarte and Azusa Since Study Inception

Crystalline Silica

A crystalline silica non-cancer chronic reference exposure level (REL) of 3μg/m^3 as PM_4 has been set by the State of California. This non-cancer chronic level was not exceeded during the entirety of the study. Likewise, the NIOSH occupational limit of 50μg/m^3, also as PM_4, was not exceeded. For the thirty three samples at or above the non-detection limit of 0.4μg/m^3 PM_4 crystalline silica averaged 0.6μg/m^3 for the period of January 2008 into early September 2008. The average crystalline silica value for the entirety of the study was 0.5μg/m^3 and the highest detected level of crystalline silica was 1.3μg/m^3. Results of crystalline silica sampling in Duarte are shown in Appendix C. Figure 5 presents data in graph form. Data for all samples collected since the start of the study are provided in Figure 6 and in Appendix F. In figures 5 and 6 all data at or below the detection level of 0.4μg/m^3 or 0.3μg/m^3 are plotted at these levels. In Figure 5 the detection limit of crystalline silica from November 2006 through December 2007 was lowered to 0.3μg/m^3 from 0.4μg/m^3.

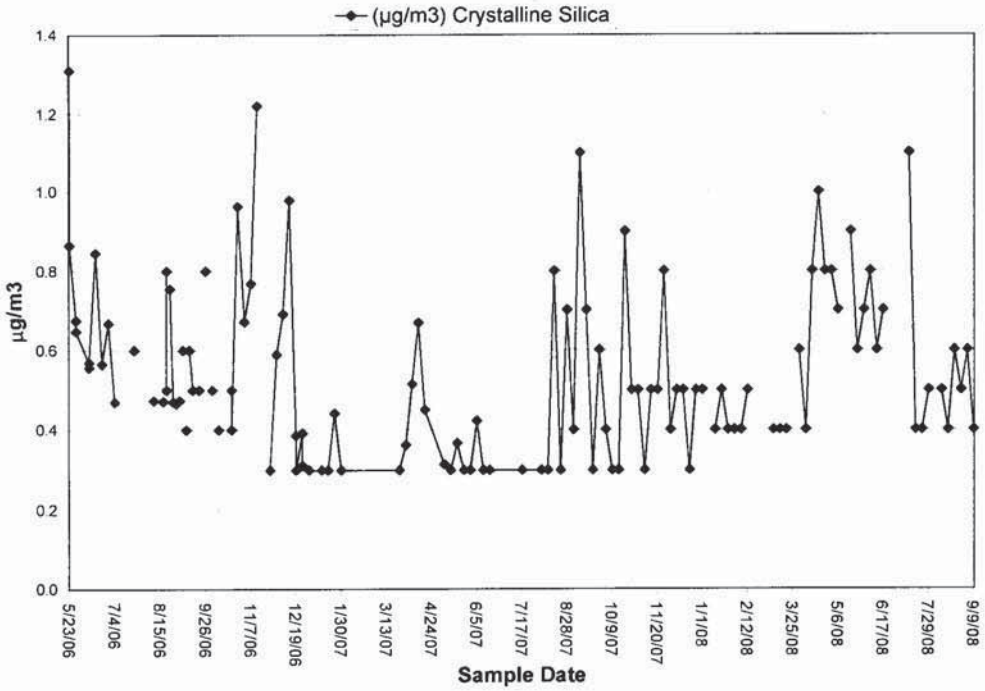

Figure 6. PM_4 Crystalline Silica Data Since Study Inception

Wind Speed and Direction

Wind speed and direction data collected at Royal Oaks Elementary School are averaged on an hourly basis. The information is collected for a month and is then graphically displayed in a "wind rose". Wind roses provide both wind speed and direction information in a fashion that allows for comparison to other monitored locations. For this study, consistent with the PM data, comparison is made to AQMD's Azusa AMS. Sample wind roses for the first three quarters of 2008 are shown in Appendix G. For this reporting period, winds at Duarte and Azusa showed similar patterns when comparable data is available. The wind direction was similar at both sites and as before the wind speed was consistently higher at the Azusa AMS as compared to the Duarte site. Unfortunately for much of the sampling period the wind speed and direction data are not available for the Duarte site. This occurred due to a data logger failure. However, from the data that are available (as shown in Appendix G) as well as historic data, wind patterns are similar at both monitoring sites.

5.0 SUMMARY

For this reporting period of the first three quarters in 2008 and duration of the study; the PM_{10} and $PM_{2.5}$ measurements show similar patterns and concentrations at Duarte and Azusa. PM_{10} concentrations at Duarte and Azusa are below the federal 24-hour standard for PM_{10} of 150μg/m^3. During the first three quarters of 2008, the PM_{10} levels did exceed the state standard of 50μg/m^3 on two days at Duarte and ten days at the Azusa AMS. The federal standard for $PM_{2.5}$ established at 35μg/m^3 was exceeded on two days in Duarte and one day in Azusa during this reporting period. No crystalline silica samples exceeded the REL set by the state and averaged 0.6μg/m^3. All samples were collected over a one day, 24-hour period.

For the duration of the study from August 2005 to September 9th 2008, a total of 319 PM_{10}, 330 $PM_{2.5}$, and 120 PM_4 crystalline silica samples were analyzed. PM_{10} concentrations during the study were all below the federal 24-hour standard of 150μg/m^3. The 24-hr PM_{10} state standard was exceeded five times at Duarte and thirty four times at Azusa. Crystalline silica averaged 0.5μg/m^3 and had a maximum measured value of 1.3μg/m^3 for the duration of the study.

Key Findings

- The state 24-hour standard for PM_{10} is 50μg/m^3. This standard was exceeded on two sampling days in Duarte and ten sampling days in Azusa during the period of January to September 9th 2008. Average 24-hour PM_{10} concentrations were 28μg/m^3 in Duarte and 35μg/m^3 in Azusa when same sampling dates are compared.

- The federal 24-hour standard for $PM_{2.5}$ is set at 35μg/m^3. This standard was exceeded on two days in Duarte and one day in Azusa during this reporting period. The federal level was exceeded in Duarte on July 5th with a measured value of 60μg/m^3, likely as a result of 4th of July fireworks activities; no sample was recovered from Azusa on this day. The other day in Duarte exceeding the federal standard occurred on Feb 18th 2008 with a value of 35.3μg/m^3, the same day as Azusa (36.5μg/m^3). $PM_{2.5}$ averaged 14.6μg/m^3 in Duarte compared to 14.4μg/m^3 at the Azusa AMS when same sampling days were compared for the first three quarters of 2008.

- Crystalline silica results show that for the duration of the study, no samples exceeded the non-cancer chronic reference exposure level of 3μg/m^3 as PM_4 established by the State of California. The maximum 24-hour reported value for crystalline silica was 1.3μg/m^3, with an average of 0.5μg/m^3.

- Wind direction at Duarte and AQMD's Azusa air monitoring station (AMS) demonstrates a great deal of similarity for months where data is available. Wind speeds at the Azusa AMS are typically higher than those measured in Duarte.

6.0 CONCLUDING REMARK

In response to a letter from the City of Duarte requesting AQMD to determine potential impacts of quarrying operations in the area, the AQMD has been monitoring particulate matter (PM) at Royal Oaks Elementary School in Duarte since August 2005. In May 2006 sampling for crystalline silica began. The intent of the sampling was to establish a baseline for ambient PM and crystalline silica concentrations, the baseline was to be established over a one year period.

As of September 9th 2008, all sampling ended at Royal Oaks Elementary due to the need for equipment to be used to address concerns in other communities. Data collected up to this point can be used as a baseline measurement should sampling need to be resumed at Royal Oaks Elementary. The AQMD is committed to working with the city and community of Duarte to resume sampling if determined necessary as a result of expanded quarrying activities or other circumstances.

APPENDIX G

CALINE4 Output Files

CO Hotspots

Mobile-source impacts occur basically on two scales of motion. Regionally, project-related travel will add to regional trip generation and increase the vehicle miles traveled within the local airshed and the SDAB. Locally, project traffic will be added to the City roadway system in the vicinity of the proposed project. If such traffic occurs during periods of poor atmospheric ventilation, is composed of a large number of vehicles "cold-started" and operating at pollution-inefficient speeds, and is operating on roadways already crowded with non-project traffic, there is a potential for the formation of microscale CO "hotspots" in the area immediately around points of congested traffic. Because of continued improvement in vehicular emissions at a rate faster than the rate of vehicle growth and/or congestion, the potential for CO hotspots in the SDAB is steadily decreasing.

Carbon monoxide transport is extremely limited and disperses rapidly with distance from the source. Under certain extreme meteorological conditions, however, CO concentrations near a congested roadway or intersection may reach unhealthy levels, affecting sensitive receptors such as residents, school children, hospital patients, and the elderly. Typically, high CO concentrations are associated with roadways or intersections operating at an unacceptable level of service (LOS). Projects contributing to adverse traffic impacts may result in the formation of CO hotspots. As indicated in the County of San Diego *Guidelines for Determining Significance and Report Format and Content Requirements Air Quality* (County of San Diego 2007), a site-specific CO hotspot analysis should be performed if a proposed development would cause road intersections to operate at or below a LOS E (with intersection peak-hour trips exceeding 3,000).

The project's traffic report evaluated 8 intersections in the project vicinity to assess potential impacts resulting from the proposed project. The results of the traffic analysis show that the following intersections are forecast to be LOS E or worse under existing plus project conditions and would require a CO hotspot analysis per County of San Diego's guidelines.

- Deer Springs Rd. and I-15 NB Ramps
- Deer Springs Rd. and I-15 SB Ramps
- Deer Springs Rd. and Twin Oaks Valley Rd.
- Buena Creek Rd. and Twin Oaks Valley Rd.
- Robelini Drive and South Santa Fe Avenue
- Twin Oaks Valley Rd. and San Marcos Blvd.
- Twin Oaks Valley Rd. and Discover Rd.
- Twin Oaks Valley Rd. and Richmar

The potential impact of the proposed project on local CO levels was assessed at these intersections with the Caltrans CL4 interface based on the CAlifornia LINE Source Dispersion Model (CALINE4), which allows microscale CO concentrations to be estimated along each roadway corridor or near intersections.

The modeling analysis was performed for worst-case wind angle, in which the model selects the wind angles that produce the highest CO concentrations at each of the receptors. The suburban land classification of 100 centimeters was used for the aerodynamic roughness coefficient, which determines the amount of local air turbulence that affects plume spreading. The at-grade option was used in the analysis; for at-grade sections, CALINE4 does not permit the plume to mix below ground level. The calculations assume a mixing height of 1,000 meters, a flat topographical condition between the source and the receptor (link height of 0 meters), and a meteorological condition of little to almost no wind (0.5 meters per second), consistent with EPA guidance. The hourly traffic volume anticipated to travel on each link, in units of vehicles per hour, was based on the proposed project's traffic report (LLG 2016).

The maximum 1-hour CO background concentration of 3.8 ppm, as measured in the Escondido – East Valley Parkway monitoring station 2014 concentrations[1], was assumed in the analysis model. The model provides predicted concentrations in ppm at each of the receptor locations. To estimate an 8-hour average CO concentration, a persistence factor of 0.7, as is recommended for urban locations, was applied to the output values.

The results of the model are shown in Table F-1, CALINE4 Predicted CO Concentrations.

Table F-1
CALINE4 Predicted CO Concentrations

Intersection	Maximum Modeled Impact Year 2020 with Project + Cumulative	
	1 hour (ppm)	*8 hour (ppm)[1]*
Deer Springs Rd. and I-15 NB Ramps	4.3	3.01
Deer Springs Rd. and I-15 SB Ramps	4.8	3.36
Deer Springs Rd. and Twin Oaks Valley Rd.	4.8	3.36
Buena Creek Rd. and Twin Oaks Valley Rd.	4.6	3.22
Robelini Drive and South Santa Fe Avenue	4.3	3.01
Twin Oaks Valley Rd. and San Marcos Blvd.	4.9	3.43
Twin Oaks Valley Rd. and Discover Rd.	4.9	3.43
Twin Oaks Valley Rd. and Richmar	4.4	3.08
Maximum CO Impact	4.9	3.43
County of San Diego Thresholds	*20*	*9*
Threshold Exceeded?	*No*	*No*

Source: CALINE4 (Caltrans 2011).
[1] 8-hour concentrations were obtained by multiplying the 1-hour concentration by a factor of 0.7.

1 CARB. 2014c. *Air Quality Data Statistics.* http://arb.ca.gov/adam.

As shown in Table F-1, maximum CO concentrations predicted for the 1-hour averaging period would be 4.9 ppm, which is below the state 1-hour CO standard of 20 ppm. Maximum predicted 8-hour CO concentrations of 3.43 ppm would be below the state CO standard of 9.0 ppm. As neither the state 1-hour standard nor the 8-hour standard would be equaled or exceeded at any of the intersections studied, potential CO hotspot impacts would be less than significant.
