Health Advisory: Expanding Measles Outbreak in the United States and Guidance for the Upcoming Travel Season

Key Messages

- Centers for Disease Control and Prevention (CDC) recently issued a [Health Advisory](#) to inform clinicians of an expanding measles outbreak in Texas and New Mexico.
- Infants aged 6 months or older without evidence of immunity should receive measles-mumps-rubella (MMR) vaccination prior to international travel.
- Measles should be considered when individuals present with an acute febrile illness and maculopapular rash and a history of travel.
- All patients with fever and rash should be screened at the point of entry to a healthcare facility. Providers **should immediately institute airborne precautions** on patients suspected of measles to prevent healthcare associated exposures.
- Immediately report any suspected measles cases to the County Immunization Program.

Situation

On March 7, 2025, the U.S. Centers for Disease Control and Prevention (CDC) released a Health Alert Network (HAN) report on the [Expanding Measles Outbreak in the United States and Guidance for the Upcoming Travel Season](#). More cases are expected as this outbreak continues to expand rapidly. Texas and New Mexico have reported 208 confirmed cases associated with this outbreak (198 in [Texas](#) and 10 in [New Mexico](#)) with two deaths.

Background

In anticipation of increased travel activity over spring and summer season, clinicians should ensure that all individuals 6 months and older are up to date on measles vaccination prior to any international travel, regardless of destination. Additionally, consider measles in the differential diagnosis for anyone with fever and rash who has recently traveled abroad. Delays in identifying and isolating measles cases in health care settings can result in exposures to hundreds of additional contacts.

Actions Requested

1. **Review** the accompanying CDC health alert for additional information and recommendations on measles in the U.S.
2. **Immunize** any U.S. resident older than age 6 months [without evidence of immunity](#) who is planning to travel internationally with the MMR vaccine prior to departure.
 - Infants aged 6 through 11 months should receive one dose of MMR vaccine before departure. Infants who receive a dose of MMR vaccine before their first birthday should receive two more doses of MMR vaccine, the first of which should be administered when the child is age 12 through 15 months and the second at least 28 days later.

- Children aged 12 months or older should receive two doses of MMR vaccine, separated by at least 28 days.
 - Teenagers and adults without documented measles immunity should receive two doses of MMR vaccine separated by at least 28 days.
3. **Consider** measles in the differential diagnosis of febrile rash, especially among patients with a history of recent international travel or domestic travel through an international airport.
 4. **Isolate** suspected measles cases immediately, ideally in an airborne infection isolation room (AIIR) if available.
 5. **Report** suspected measles cases immediately to the County Immunization Program during office hours by calling (866) 358-2966 (press 5 at the prompt) Monday-Friday 8AM-5PM and (858) 565-5255 after hours and on weekends.

Emergency Preparedness and Response

Expanding Measles Outbreak in the United States and Guidance for the Upcoming Travel Season

Distributed via the CDC Health Alert Network

March 7, 2025, 2:00 PM ET

CDCHAN-00522

Summary

The Centers for Disease Control and Prevention (CDC) is issuing this Health Alert Network (HAN) Health Advisory to notify clinicians, public health officials, and potential travelers about a measles outbreak in [Texas](#) and [New Mexico](#) and offer guidance for prevention and monitoring. As of March 7, 2025, Texas and New Mexico have reported 208 confirmed cases associated with this outbreak (198 in [Texas](#) and 10 in [New Mexico](#)). As a part of this outbreak, two deaths have been reported: one in [Texas](#) and one in [New Mexico](#). More cases are expected as this outbreak continues to expand rapidly.

With spring and summer travel season approaching in the United States, CDC emphasizes the important role that clinicians and public health officials play in preventing the spread of measles. They should be vigilant for cases of febrile rash illness that meet the measles [case definition](#) and share effective measles prevention strategies, including vaccination guidance for international travelers.

The risk for widespread measles in the United States remains low due to robust U.S. immunization and surveillance programs and outbreak response capacity supported by federal, state, tribal, local, and territorial health partners. **Measles-mumps-rubella (MMR) vaccination remains the most important tool for preventing measles.** To prevent measles infection and spread from imported cases, all U.S. residents should be up to date on their MMR vaccinations, especially before traveling internationally, regardless of the destination.

Background

As of March 6, 2025, a total of [222 measles cases](#) have been reported by twelve U.S. jurisdictions this year: Alaska, California, Florida, Georgia, Kentucky, New Jersey, New Mexico, New York City, Pennsylvania, Rhode Island, Texas, and Washington; 201 of which occurred in New Mexico and Texas. Most of the 222 cases are among children who had not

received the MMR vaccine. There have been three outbreaks, with an outbreak defined as three or more related cases, reported in 2025, and 93% of cases are outbreak-associated. For comparison, 16 outbreaks were reported during 2024 and 69% of cases were outbreak-associated.

[Measles](#) is a highly contagious viral illness that typically begins with fever, cough, coryza (runny nose), and conjunctivitis (pink eye), lasting 2-4 days prior to [rash](#) onset. Measles can cause severe health complications, including pneumonia, encephalitis (inflammation of the brain), and death. The virus is transmitted by direct contact with infectious droplets or by airborne spread when an infected person breathes, coughs, or sneezes. Measles virus can remain infectious in the air and on surfaces for up to 2 hours after an infected person leaves an area.

Infected people are contagious from 4 days before the rash starts through 4 days afterward. The incubation period for measles, from exposure to fever, is usually about 7–10 days, and from exposure to rash onset is usually about 10–14 days (with a range of 7 to 21 days).

Recommendations for Healthcare Professionals

- Ensure all patients without other evidence of immunity, especially those planning international travel, are up to date on [MMR vaccine](#) per routine ACIP recommendations:
 - Children are recommended to receive 2 doses of MMR. The first dose is given at 12–15 months of age and the second is given at 4–6 years of age before school entry.
 - Infants 6 months of age or older can receive MMR prior to international travel or in outbreak settings (see below). MMR is not licensed for children <6 months of age.
 - Adults not at high risk of exposure are recommended to have at least 1 documented dose of MMR in their lifetime, or other evidence of immunity (e.g., positive measles immunoglobulin G (IgG)). Adults at [high exposure risk](#), including students at post-secondary institutions, healthcare workers, and international travelers, should have two documented doses.
- Ensure patients who reside in areas with an ongoing measles outbreak follow state and local guidance. [Texas Department of State Health Services \(DSHS\)](#) [↗](#) has issued the following recommendations for the affected counties in Texas:
 - Infants 6 through 11 months receive an early dose of MMR vaccine (i.e., infant dose). Subsequent doses should follow CDC's recommended childhood schedule:
 - Another dose at 12 through 15 months of age.
 - A final dose at 4 through 6 years of age.
 - Children older than 12 months who have not been vaccinated should receive one dose immediately and follow with a second dose at least 28 days after the first. Children older than 12 months with one prior dose should receive an early second dose of MMR vaccine separated by at least 28 days.
 - Teenagers and adults previously vaccinated with one dose of MMR vaccine should receive a second dose. Those with no [evidence of immunity](#) should receive one dose of MMR vaccine immediately and follow with a second dose at least 28 days later.
- Ensure all U.S. residents older than age 6 months without [evidence of immunity](#) who are [traveling internationally](#) receive MMR vaccine prior to departure:
 - Infants 6 through 11 months of age should receive one dose of MMR vaccine before departure. Infants who receive a dose of MMR vaccine before their first birthday should receive 2 more doses of MMR vaccine; the first of which should be administered when the child is 12 through 15 months of age and the second at least 28 days later (generally at age 4-6 years of age but can be administered sooner if indicated).
 - Children 12 months of age or older should receive two doses of MMR vaccine, separated by at least 28 days.
 - Teenagers and adults without evidence of measles immunity should receive two doses of MMR vaccine separated by at least 28 days.
- Be aware that some patients may develop a mild rash reaction in the 3 weeks following MMR vaccination. This does not typically require testing or public health intervention since a person with a rash due to a vaccine reaction is not infectious. If a symptomatic person who has been recently vaccinated also has a known or suspected measles

exposure, consultation and additional testing may be required from the local or state health department to evaluate for acute measles.

- Consider measles as a diagnosis in anyone with fever ($\geq 101^{\circ}\text{F}$ or 38.3°C) and a generalized maculopapular rash with cough, coryza, or conjunctivitis who has recently traveled internationally, or domestically to a region with a [known measles outbreak](#), or has other known or suspected exposure to measles.
- If you suspect measles:
 - **Isolate:**
 - **Isolate patients with suspected measles immediately**, ideally in a single-patient airborne infection isolation room (AIIR), or in a private room with a closed door until an AIIR is available. Patients with suspected measles should not remain in the waiting room or other common areas of a healthcare facility
 - **Protect healthcare providers** against measles by adhering to Standard and airborne precautions when evaluating confirmed or suspect cases, regardless of their vaccination status. Healthcare providers without presumptive evidence of measles immunity who are exposed to measles should be excluded from work from day 5 after the first exposure until day 21 following their last exposure and offered post-exposure prophylaxis, as appropriate.
 - Healthcare systems should ensure all healthcare providers have presumptive evidence of immunity to measles, ensure they can rapidly retrieve healthcare provider immunization status in case of exposures and offer postexposure prophylaxis when indicated.
 - Offer measles testing outside of facilities to avoid possible transmission in healthcare settings. Call ahead to ensure immediate isolation for patients referred to hospitals for a higher level of care.
 - **Notify:** Immediately notify state, tribal, local, or territorial health departments ([24-hour Epi On Call contact list](#) [↗](#)) about any suspected case of measles to ensure rapid testing and investigation. States report measles cases to CDC.
 - **Test:** [Laboratory confirmation](#) [📄](#) should be pursued for all patients with suspected measles. CDC recommends collecting either a nasopharyngeal (NP) swab or throat (OP) swab for reverse transcription polymerase chain reaction (RT-PCR) testing as well as a blood specimen for serology testing from all patients with clinical features compatible with measles. Collecting a urine specimen along with an NP/OP swab may improve sensitivity of testing.
 - **Manage:**
 - **Post-exposure prophylaxis (PEP):** In coordination with local or state health departments, provide appropriate measles PEP to close contacts without evidence of immunity, as soon as possible after exposure, either with MMR vaccine (within 72 hours) or immunoglobulin (within 6 days). The choice of PEP is based on elapsed time from exposure or medical contraindications to vaccination.
 - **Supportive care:** There is no specific antiviral therapy for measles. Medical care is supportive to help relieve symptoms and address complications such as pneumonia and secondary bacterial infections. Consistent with guidance from the [American Academy of Pediatrics](#) [↗](#), [vitamin A](#) may be administered to infants and children in the United States with measles as part of supportive management. Children with severe measles, such as those who are hospitalized, should be managed with vitamin A. Vitamin A should be administered under the supervision of a healthcare provider and is not a substitute for vaccination. [Overuse of Vitamin A can lead to toxicity](#) [↗](#) and cause damage to the liver, bones, central nervous system, and skin. Pregnant women should avoid taking high levels of vitamin A as it has been [linked to severe birth defects](#) [↗](#).

Recommendations for State and Local Health Departments

State and local health departments have the lead in investigating measles cases and outbreaks.

- Report measles immediately (within 24 hours) to CDC (measlesreport@cdc.gov) and through the [National Notifiable Disease Surveillance System \(NNDSS\)](#). Measles is a nationally notifiable disease.
- Establish measles case reporting within hospitals and to public health authorities.
- Record and report details about cases of measles, including close contacts and locations visited while infectious (i.e. 4 days before and after rash onset).

- Conduct active surveillance for any additional cases and facilitate transportation of specimens immediately to confirm diagnosis if measles is identified.
- Enhance outreach and communications to under-vaccinated communities through trusted messengers.
- Consider utilizing state-based [syndromic surveillance](#) to monitor for changes with healthcare seeking behavior for febrile rash illness or vitamin A toxicity.

Recommendations for Domestic Travelers to Outbreak Areas and International Travelers

- Talk to your doctor about the MMR vaccine, especially if you or your child plan to travel to an area with an ongoing outbreak or internationally. Two doses of MMR vaccine provide better protection (97%) against measles than one dose (93%).
- Check your [destination](#) and CDC’s [Global Measles Travel Health Notice](#) for more travel health advice if you plan to travel internationally, including countries measles outbreaks have been reported.
- After domestic travel to an area with an ongoing outbreak or international travel, watch for signs and symptoms of measles for 3 weeks after returning to the United States. If you or your child gets sick with a rash and a high fever, call your healthcare provider. Tell them you traveled to an area where they identified measles or another country and whether you or your child had received MMR vaccine.

For More Information
