Re: Health Effects of Respirable Crystalline Silica in Blasting Dust
Newland Sierra Project – San Diego County

This letter report summarizes potential health effects associated with expected respirable crystalline silica emissions from blasting that will occur at the subject project.

1.0 INTRODUCTION

Respirable crystalline silica means crystalline silicon dioxide with aerodynamic diameter less than four microns (0.0004 cm). Silica or quartz is ubiquitous in nature. Most silica is amorphous and is therefore not crystalline as these two terms are mutually exclusive. Most dust generated by construction dust sources including blasting is greater than 4 microns and therefore too large to be respirable. Respirable crystalline silica constitutes a de minimis fraction of dust from these sources and does not represent a significant health risk to neighbors of these types of projects.

In order to result in toxic effects the silica needs to crystalline, smaller than 4 microns, and inhaled. This letter discusses the potential for the confluence of these conditions and shows that the health risk from crystalline silica is less than significant.

2.0 TOXICOLOGY OF CRYSTALLINE SILICA

Inhalation of crystalline silica initially causes respiratory irritation and an inflammatory reaction in the lungs. Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and emphysema. Levels to which workers (e.g., miners, sandblasters) may be exposed have been shown to cause cancer.

Acute exposures to high concentrations cause cough, shortness of breath, and pulmonary alveolar lipoproteinosis (acute silicosis). In a report on the hazards of exposure to crystalline silica, the American Thoracic Society (1997) stated: “Studies from many different work environments suggest that exposure to working environments contaminated by silica at dust levels that appear not to cause roentgenographically visible simple silicosis can cause chronic airflow limitation and/or mucus hypersecretion and/or pathologic emphysema.”

Other researchers also concluded that “chronic levels of silica dust that do not cause disabling silicosis may cause the development of chronic bronchitis, emphysema, and/or small airways disease that can lead to airflow obstruction, even in the absence of radiological silicosis.” Fibrotic lesions associated with crystalline silica have also been found at autopsy in the lungs of granite workers who lacked radiological evidence of silicosis. (OEHHA, 2015).

Silicosis results from chronic exposure; it is characterized by the presence of histologically unique silicotic nodules and by fibrotic scarring of the lung. Lung diseases other than cancer associated with silica exposure include silicosis, tuberculosis/silicotuberculosis, chronic bronchitis, small airways disease, and emphysema. Silica exposure has been implicated in autoimmune diseases (rheumatoid arthritis, scleroderma, systemic lupus erythematosus) in gold miners and granite workers and in the causation of kidney disease in some occupations, possibly by an immune mechanism. (OEHHA, 2015).

Several studies have reported "environmental silicosis", cases where the silicosis occurs in the absence of an industry usually associated with the disease. In one of the stronger examples, Saiyed et al. (1991) investigated non-occupational pneumoconiosis in Ladakh, India, high in the western Himalayas where there are no mines or industries. The prevalence of pneumoconiosis corresponded with the severity of dust storms and the presence or absence of chimneys in the kitchens (i.e., ventilated cooking). Without chimneys (Chushot), dust concentrations in kitchens averaged 7.5 mg/m3 during cooking periods. The free silica content of the dust storms was 60-70%. The authors suggested that exposure to free silica from dust storms and to soot from cooking with domestic fuels caused the pneumoconiosis. Such exposures in this and other studies might be considered to be non-industrial but occupational, since the subjects studied by Saiyed et al. (1991) were involved in the domestic work of cleaning and cooking (USEPA, 1996). In any case, the exposures were very high and thus similar to some occupational exposures. (OEHHA, 2015).

3.0 REGULATORY STATUS OF CRYSTALLINE SILICA

Crystalline silica is widely used in industry and has long been recognized as a major occupational hazard, causing disability and deaths among workers in several industries. In 1997, the International Agency for Research on Cancer rated respirable crystalline silica a Class 1 carcinogen based exclusively on worker exposure levels and epidemiology (IARC, 2012). In 2005, OEHHA adopted the Toxicity Summary for respirable crystalline silica which states:

> “In 1997, IARC classified respirable crystalline silica in Class 1, a Known Human Carcinogen, based on occupational epidemiologic studies. However, chronic RELs are not based on cancer endpoints. Further, there is no approved cancer potency factor for silica.”

In other words, adverse health effects or endpoints other than cancer were used by OEHHA to determine the chronic non-cancer reference exposure level (REL). For purposes of health risk assessment using State of California AB2588 Air Toxics Hot Spot Program methods, respirable crystalline silica is not a carcinogen. Concentrations to which the public may be exposed are unexpected to give rise to cancer. Accordingly, OEHHA developed the chronic, non-cancer REL. CalOSHA developed the cancer protective permissible exposure level (PEL) for worker exposures. Both OEHHA and CalOSHA thresholds are presented in Table 1.

Table 1. Regulatory Exposure Levels for Crystalline Silica

Agency	Applicability	Concentration ($\mu g/m^3$)	Basis
OEHHA	Environmental exposures to respirable dust.	3	Non-cancer health effect, annual average exposure.
CalOSHA	Worker exposures to respirable dust.	100	Carcinogenic health effect. 8 hour time weighted average exposure.

4.0 EMISSIONS FROM BLASTING

Blasting emissions were calculated by Dudek to be approximately 56 lb PM_{10}/blast and 3.2 lb $PM_{2.5}$/blast based on approximately 0.9 acres affected per blast (Attachment 1). The PM_4 crystalline silica emissions are approximately 5% of the PM_{10} (Attachment 2) emissions or 2.8 lb/day. Blasting is expected to occur at two to three day intervals. There would be no more than one blast per day.

5.0 DISPERSION AND CONCENTRATION OF AIRBORNE DUST

Blasting will occur in the center of the Project site and along roads within the Project site. Figure 1 shows the wind rose and aerial photograph of the site. Air dispersion modeling for blasting was not undertaken because the Gaussian dispersion models (i.e., AERMOD) assume steady state conditions which are not appropriate for an event like blasting. Other models that could be used to evaluate a "puff" type source require input that is not feasible to obtain for this project.

The windrose presents the direction from which the wind is blowing. The size of each sector represents the frequency that wind blows from each direction. Wind is calm approximately 27% of time and 48% of time wind is from the west or southwest. 46% of the time wind is between 1 and 4 knots and 24% of time wind is between 4 and 7 knots. Wind exceeding 7 knots occurs less than 3% of the time. The average wind for the dataset is 2.59 knots (i.e., 3 mph) from the west-southwest.

Winds at 3 mph are relatively light creating a stable atmosphere. Under such conditions the plume of dust from blasting would be expected to remain intact for a longer distance than if greater wind speeds were present. The larger particles of dust would fall out of the atmosphere relatively close to the source as compared to the distance under higher wind conditions. Smaller respirable particles are less influenced by wind and are considered to behave as a neutrally buoyant gas. Respirable particles will remain in the atmosphere for many miles downwind.

Although low wind conditions result in more cohesive plumes and greater ground level concentrations, other conditions would have the opposite effect resulting in increased dispersion of the plume and lower concentrations. Specifically, the terrain is rough which increases vertical mixing as wind travels along the terrain. In addition, the plume has a large initial volume which means that it is already somewhat dispersed both vertically and laterally due to the nature of the source.

The most influential aspect of the blasting on receptor concentrations is the short lived nature of the emissions. The duration of exposure is brief. For instance, a plume that is generated by one-acre square area blasted would have initial length and width of approximately 200 ft. At the average wind speed, the plume would pass through a point in space in approximately one minute. The amount of dust inhaled would be limited by the brief

exposure and variability of blasting locations combine to produce a chronic effect from blasting emissions such that is would be unlikely that conditions of repeat exposure would occur frequently.

Finally, concentrations of pollutants in air decrease rapidly with increasing distance from the source. Given the relatively large distances between blasting activities and receptors, compliance with worker safety standards should also ensure that concentrations off-site are not significant.

6.0 MEASUREMENT OF RESPIRABLE CRYSTALLINE SILICA

Respirable crystalline silica has been measured by air districts and others near hard rock quarries that produce construction aggregates. The subject site is located in an area that is designated by the State to contain significant quantities of mineral resources. The primary bedrock unit onsite is Cretaceous-aged Granitic rock. (Leighton and Associates, 2015).

The Azusa Rock facility in South Coast AQMD is a hard rock mine which performs blasting to extract granitic rock (California Division of Conservation, 1988). SCAQMD performed monitoring of the particulate matter and respirable crystalline silica concentrations near Azusa Rock (SCAQMD, 2008). The SCAQMD concluded that "crystalline silica results show that for the duration of the study, no samples exceeded the non-cancer chronic reference exposure level of 3 $\mu g/m^3$ as PM_4 established by the State of California. The maximum 24-hour reported value for crystalline silica was 1.3 $\mu g/m^3$, with an average of 0.5 $\mu g/m^3$." (SCAQMD, 2008, p. 7). The concentrations measured include emissions from blasting and many other activities that occur at the facility.

7.0 FATE OF DUST DEPOSITED NEAR RECEPTORS

Dust that is deposited near receptors is unlikely to result in exposure to respirable crystalline silica for the following reasons:

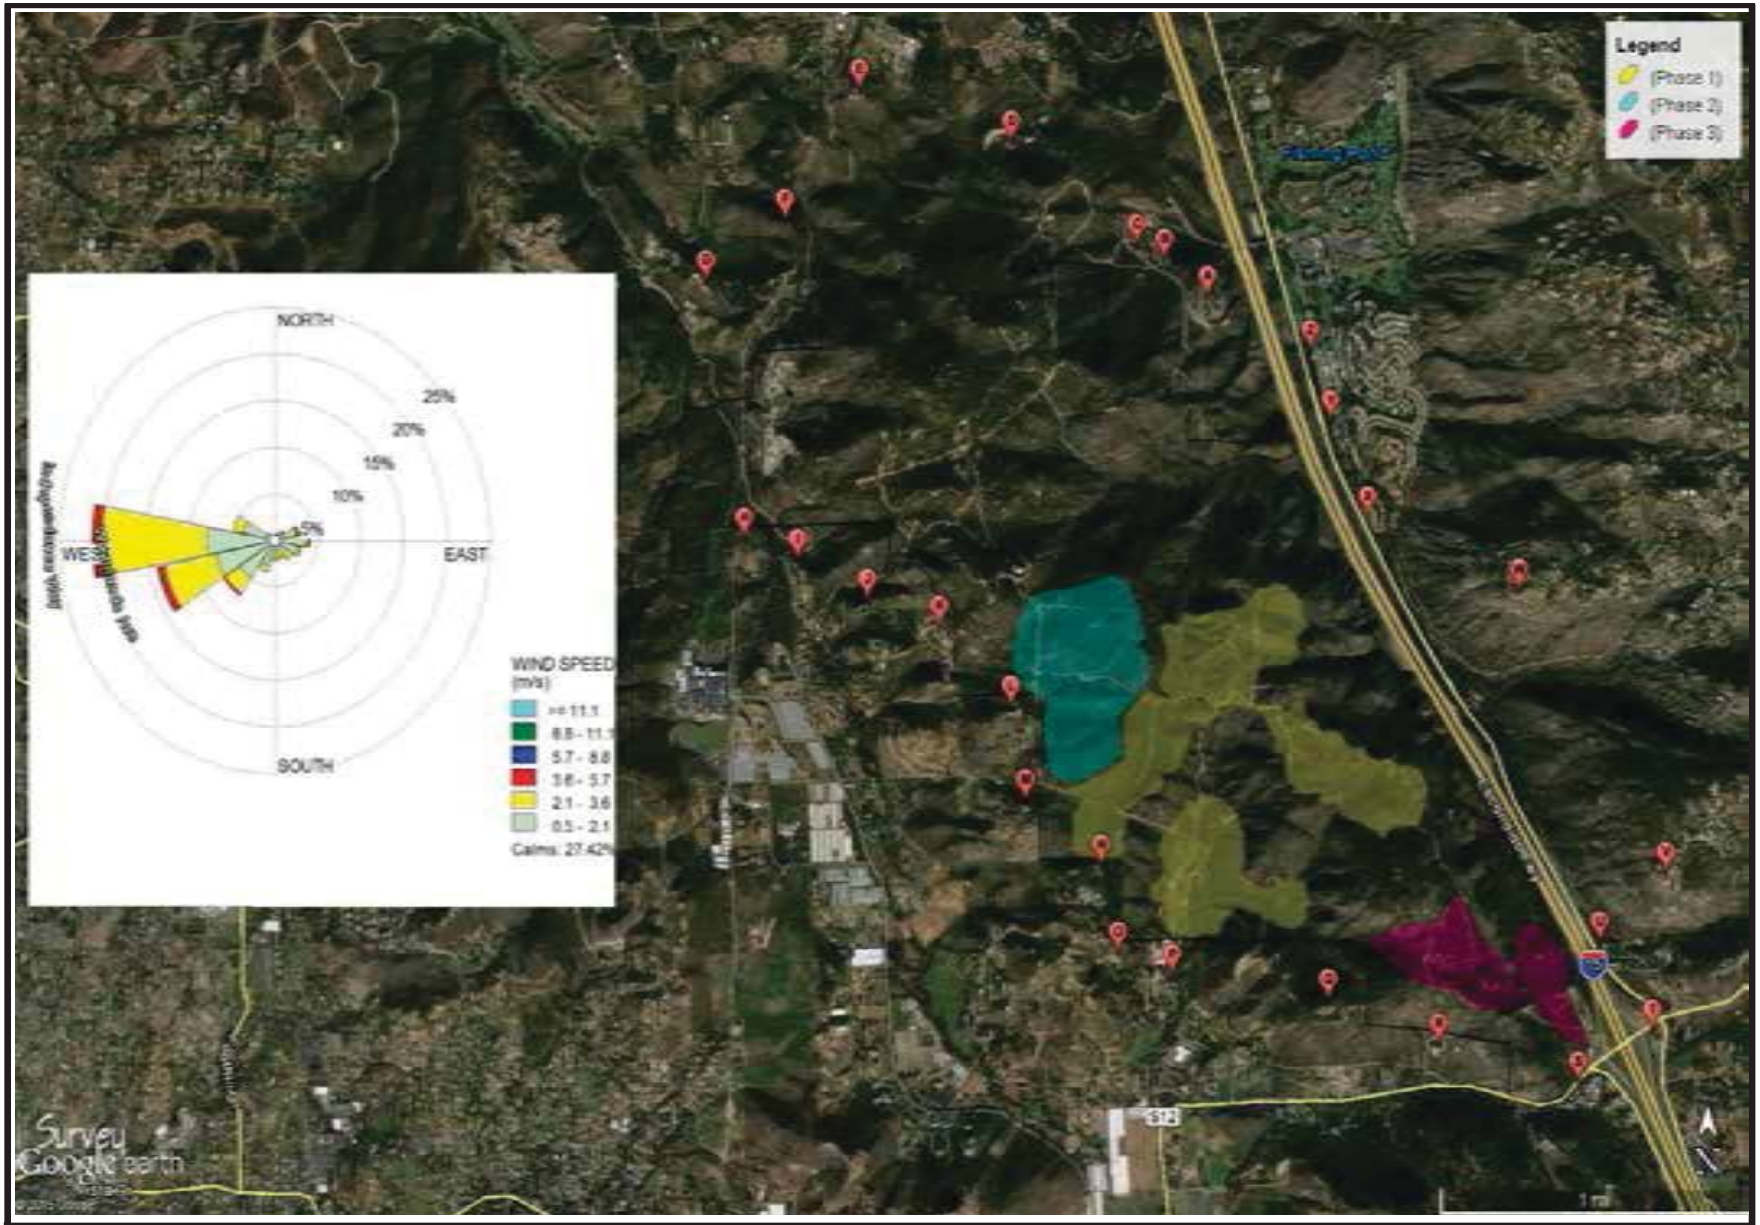
1. The vast majority of deposited material is too large to be respirable.
2. The small amount of respirable dust that may be deposited, would need to be re-entrained into the air in order to be a hazard.
3. There are no processes taking place at receptors that would reduce the size of particles deposited making them smaller, respirable particles.

8.0 CONCLUSION

In summary, long term exposure to ambient respirable crystalline silica concentrations greater than 3 $\mu g/m^3$ causes silicosis and other adverse health effects. Steady state air dispersion models that are normally used to evaluate project impacts are not well suited to predicting concentrations from blasting. Input data for other dispersion models that would produce meaningful results are not feasible to obtain for this project.

The winds at the Project site are predominantly from the west-southwest and so receptors located east of the Project would be most affected by dust from blasting activities. It would take approximately 1 minute for a dust plume to pass by a receptor, during which time the receptor would take a few breaths. The amount of dust inhaled would be limited by the brief exposure and the variability of blasting locations should result in few repeat exposures that could combine to produce a chronic effect from inhalation of blasting emissions.

Materials being blasted at the Project are granitic and similar to those blasted at hard rock quarries. Specifically SCAQMD monitored respirable crystalline silica near the Azusa Rock Quarry and found that average concentrations were 0.5 µg/m^3 or 6 times less than the REL. This concentration included emissions from blasting and other sources on-site. Accordingly, concentrations that Project receptors will be exposed too should also be acceptable.



Lastly, deposition of crystalline silica at nearby receptors will consist of large particles that are not respirable. There are no processes at receptors that would reduce the size of the particles to respirable and thereby create an inhalation hazard. Thus, deposited crystalline silica is not considered to be the source of significant health risk.

Please call me or Rob Dal Farra at (805) 275-1515 if you have any questions or if you need additional information.

ABSTRACT

The California Construction and Industrial Minerals Association and the National Stone, Sand, & Gravel Association have sponsored tests at three sand and gravel plants in California to compile crystalline silica emission factors for particulate matter (PM) of aerodynamic diameter of 4 μm or less (PM_4) and ambient concentration data. This information is needed by industrial facilities to evaluate compliance with the Chronic Reference Exposure Level (REL) for ambient crystalline silica adopted in 2005 by the California Office of Environmental Health Hazard Assessment. The REL applies to PM_4 respirable PM. Air Control Techniques, P.C. sampled for PM_4 crystalline silica using a conventional sampler for PM of aerodynamic diameter of 2.5 μm or less ($PM_{2.5}$), which met the requirements of 40 *Code of Federal Regulations* Part 50, Appendix L. The sample flow rate was adjusted to modify the 50% cut size to 4 μm instead of 2.5 μm. The filter was also changed to allow for crystalline silica analyses using National Institute for Occupational Safety and Health (NIOSH) Method 7500. The particle size-capture efficiency curve for the modified Appendix L instrument closely matched the performance curve of NIOSH Method 0600 for PM_4 crystalline silica and provided a minimum detection limit well below the levels attainable with NIOSH Method 0600. The results of the tests indicate that PM_4 crystalline silica emissions range from 0.000006 to 0.000110 lb/t for screening operations, tertiary crushers, and conveyor transfer points. The PM_4 crystalline silica emission factors were proportional to the crystalline silica content of the material handled in the process equipment. Measured ambient concentrations ranged from 0 (below detectable limit) to 2.8 μg/m³. All values measured above 2 μg/m³ were at locations upwind of the facilities being tested. The ambient PM_4 crystalline silica concentrations measured during this study were below the California REL of 3 μg/m³. The measured ambient concentrations in the PM_4 size range are consistent with previously published ambient crystalline silica data applicable to the $PM_{2.5}$ and PM of aerodynamic diameter of 10 μm or less (PM_{10}) size ranges.

IMPLICATIONS

Mineral processing facilities need PM_4 crystalline silica emission factor data to evaluate compliance with the 3 μg/m³ Chronic REL for PM_4 ambient crystalline silica adopted in 2005 by the California Office of Environmental Health Hazard Assessment. Emission tests at three sand and gravel plants have provided PM_4 crystalline silica data for screens, crushers, and conveyors. Mineral processing facilities can use the emission factor data to evaluate compliance with the stringent ambient PM_4 crystalline silica limit.

INTRODUCTION

Crystalline Silica Emission Factors of Particulate Matter of Aerodynamic Diameter of 4 μm or Less

There are no previously published data concerning particulate matter (PM) of aerodynamic diameter of 4 μm or less (PM_4) crystalline silica emissions from aggregate producing plants or other mineral industry sources. The PM_4 crystalline silica emission factors can be estimated based on published data concerning emission factors for PM of aerodynamic diameter of 10 μm (PM_{10}) or 2.5 μm ($PM_{2.5}$) or less for aggregate producing plants.[1–9] The U.S. Environmental Protection Agency (EPA) AP42 Section 11.19-2 emission factors for tertiary crushers, screens, and conveyor transfer points indicate that the $PM_{2.5}$ emissions range from 0.000013 to 0.000100 lb/t of stone. The AP42 Section 11.19-2 PM_{10} emission factors for these three types of processing equipment range from 0.000046 to 0.00074 lb/t.

These emission factors provide a starting point for evaluating possible PM_4 crystalline silica emission factors. It is reasonable to expect the PM_4 total emission factors to be between the $PM_{2.5}$ and PM_{10} emission factors. The PM_4

Crystalline Silica;Emission Factors;Aggregate Producing Facilities;PM_4;Testing

crystalline silica emission factors will depend on the crystalline silica content of the PM_4 total PM.

Ambient Crystalline Silica Concentrations

No PM_4 ambient concentration or emission factor data have been published. All previous crystalline silica ambient concentration data applied to the $PM_{2.5}$, PM_{10}, and/or PM of 15-μm or less (PM_{15}) size ranges.

One of the first studies of ambient crystalline silica concentrations was conducted by Davis et al.[10] This study focused on urban areas. Ambient crystalline silica concentrations were measured in 22 urban areas using dichotomous samplers that separate ambient PM into the 0- to 2.5-μm range ("fine PM") and the 2.5- to 15-μm range (termed here as "coarse/supercoarse PM"). Davis et al. measured mean 24-hr average ambient crystalline silica concentrations ranging from 0.9 to 8 $\mu g/M^3$ in the coarse/supercoarse size range. Crystalline silica was 1–9% of the coarse/supercoarse PM and 0–2.6% of the fine (<2.5 μm) PM.

EPA[11] used the data of Davis et al. to derive estimates of the annual average crystalline silica levels in urban areas. The city-specific crystalline silica content values were multiplied by annual average PM_{10} concentrations in these areas to estimate the annual average PM_{10} crystalline silica levels. EPA also calculated an annual average of 1.9 $\mu g/m^3$ with a range of 0.8–5 $\mu g/m^3$ in the PM_{10} size range. The crystalline silica content in the $PM_{2.5}$ size range was consistently less than 1 $\mu g/m^3$ because of the low crystalline silica content of the $PM_{2.5}$ PM and the low total concentration of $PM_{2.5}$ PM.

In 2000, the National Stone, Sand, & Gravel Association (NSSGA) sponsored upwind-downwind studies of ambient crystalline silica concentrations at four stone crushing plants processing high-quartz-content rock.[12] Air Control Techniques, P.C. used Rupprecht & Patashnick Co, Inc. Federal Reference Method (FRM)-2000 samplers that fully met the stringent design and operating specifications of 40 *Code of Federal Regulations* (CFR) Part 50, Appendix L.[13] The measured 8-hr working-shift PM_{10} crystalline silica concentrations at the collocated downwind PM_{10} samplers ranged from 1 to 10.9 $\mu g/m^3$. These values are similar to the range of mean 24-hr concentration values of 0.9–8 $\mu g/m^3$ for 24-hr concentrations measured by Davis et al. in the coarse/supercoarse size range. The measured upwind and downwind concentrations were similar. The crystalline silica levels of 5.07–6.24% by weight of the PM_{10} were similar to the 4.9 ± 2.3% levels in coarse/supercoarse PM reported by Davis et al.

Various other studies have provided limited data for urban, rural, and industrial areas. Puledda[14] measured PM_{10} crystalline silica levels in Rome, Italy of 0.11–2.27 $\mu g/m^3$. These levels were 1.7–3.4% of the measured PM_{10}. Norton and Gunter[15] measured PM_{10} crystalline silica levels averaging 10% in Moscow, ID. They also extracted PM from PM_{10} samples from numerous areas throughout Idaho and estimated crystalline silica levels to be between 7 and 16% of PM_{10} in various urban and rural areas in Idaho. Various other studies described by EPA[11] at urban, rural, and industrial areas indicated 24-hr average crystalline silica levels and crystalline silica contents in PM_{10} that were similar to those in Davis et al.,[10] Air Control Techniques, P.C.,[12] Puledda,[14] and Norton and Gunter.[15] These other studies include Schipper,[16] Goldsmith,[17] Chow et al.,[18] Chow,[19] and Chow.[20] Only the study of Shakari and Holmen[21] reported crystalline silica levels and PM_{10} crystalline silica contents outside of the range of the various papers summarized above. There are insufficient data in Shakari and Holmen to identify the possible reasons for the differences between their data and other studies.

On the basis of the available ambient crystalline silica data, the study participants concluded that there was a need for a monitoring technique having a minimum detectable limit of 0.3 $\mu g/m^3$. This is at or below the concentrations anticipated in this project. This minimum detectable concentration is also 10% of the California Relative Exposure Limit. An evaluation of National Institute for Occupational Safety and Health (NIOSH) Method 0600 used for in-plant industrial hygiene tests indicated that this method was not sufficiently precise at the necessary detection limit. Accordingly, the California Construction and Industrial Minerals Association (CalCIMA) and NSSGA sponsored the development of a more accurate and precise PM_4 crystalline silica monitoring method for this project. Information concerning the development of the PM_4 crystalline silica monitoring method on the basis of the validated $PM_{2.5}$ test method is described in the project report.[22]

TEST LOCATIONS AND PROCEDURES

PM_4 Crystalline Silica Measurement Test Locations

Study participants selected facilities for testing on the basis of (1) the representativeness of a vibrating screen, tertiary crusher, and conveyor transfer point of other California plants; (2) the representativeness of the crystalline silica content of the minerals processed; (3) the accessibility of the equipment for testing; (4) the capability to isolate the process unit tested from adjacent process units; and (5) the geographical location. The plants included the Service Rock Products, Inc. plant in Barstow; the Vulcan Materials, Inc. Carroll Canyon plant near San Diego; and the Teichert Aggregates, Inc. Vernalis plant near Tracy. These plants had crystalline silica levels ranging from 16.5 to 35.3% by weight in the minerals being processed.

PM_{10} data were compiled to provide a comparison of measured PM_4 crystalline silica emissions with measured PM_{10} emissions. The scope of the programs at each of these three facilities included PM_{10} emission factor tests on the crushers, vibrating screens, and conveyor transfer points.

The specific sources tested at Barstow included (1) a 16- by 5-ft flat vibrating screening operation, (2) a short-head crusher, and (3) a conveyor transfer point. The equipment tested at Carroll Canyon included (1) a 16- by 8-ft flat vibrating screen, (2) a set of two cone crushers, and (3) a conveyor transfer point. The sources tested at Vernalis included (1) a 20- by 8-ft triple deck sloped vibrating screen, (2) a set of two cone crushers, and (3) a conveyor transfer point. Water sprays controlled all of the units with the exception of the Carroll Canyon cone

018272

crushers. A fabric filter supplemented wet suppression control at the Carroll Canyon cone crushers.

PM_4 Crystalline Silica Measurement Procedures

The PM_4 crystalline silica emission concentrations were measured using TECO Model 2000 FRMs modified to have a 50% cut point of 4 μm rather than 2.5 μm. This monitoring method was developed for CalCIMA and NSSGA by Air Control Techniques, P.C. in accordance with a protocol submitted to the California Air Resources Board in July 2005. The authors consider this method to be an extension of the $PM_{2.5}$ ambient monitoring procedures specified by EPA in 40 CFR Part 50, Appendix L because of the use of identical sampling equipment, sampling procedures, and quality assurance procedures.

The main adjustment necessary to an Appendix L qualifying instrument is a change in the 50% cut size of this instrument from $PM_{2.5}$ to PM_4. The 50% cut size was adjusted by reducing the sample airflow rate into the TECO sharp cut cyclone to 11.1 L/min from the 16.67 L/min used for $PM_{2.5}$ monitoring. The adequacy of the cut size was confirmed using National Institute for Standards and Technology (NIST) traceable microspheres.

A calculated sampling time of 1–3 hr was required to meet the minimum detection limits of NIOSH 7500 for crystalline silica during tests on the process equipment. These sampling time estimates were based on (1) the NIOSH Method 7500 detection limit of 5 μg, (2) the TECO FRM 2000 sample gas flow rate of 11.1 L/min that was used to collect PM_4, and (3) the estimated crystalline silica content of the stone material being processed. Crystalline silica was detected in all but one filter sample, which confirmed the adequacy of the 1- to 3-hr sampling periods used in the study. The filter samples were weighted at R.J. Lee Group, Inc. using a microbalance and analyzed for crystalline silica using NIOSH Method 7500.

The fugitive PM_{10} PM emissions from the process equipment sources tested in Barstow were measured using a TECO tapered element oscillating microbalance (TEOM) in accordance with EPA Reference Method 10-3. For the tests at Carroll Canyon and Vernalis, the fugitive PM_{10} PM emissions were measured using TECO Model 2000 FRMs modified for PM_{10}.

Sampling arrays designed based on EPA Method 5D (40 CFR Part 60, Appendix A) captured process equipment PM_4 crystalline silica emissions. The mass fluxes
