

Figure 7. Western spadefoot localities within the Fanita Ranch and Magnolia Subunits and the number of overlapping fires that have occurred since 1910. Western spadefoot occurrence records are from Dudek (2017).

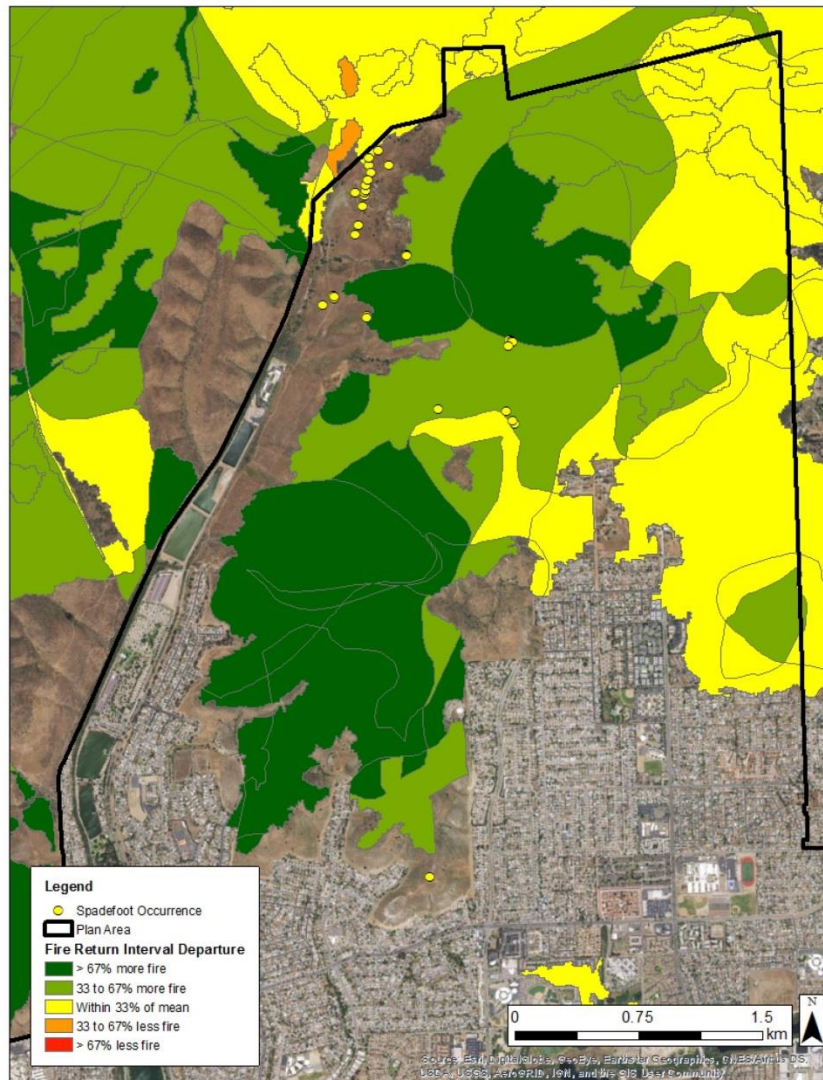

Figure 8. Western spadefoot localities within the Fanita Ranch and Magnolia Subunits and the Fire Return Interval Departure rating based on pre-European fire patterns and vegetation type. Western spadefoot occurrence records are from Dudek (2017).

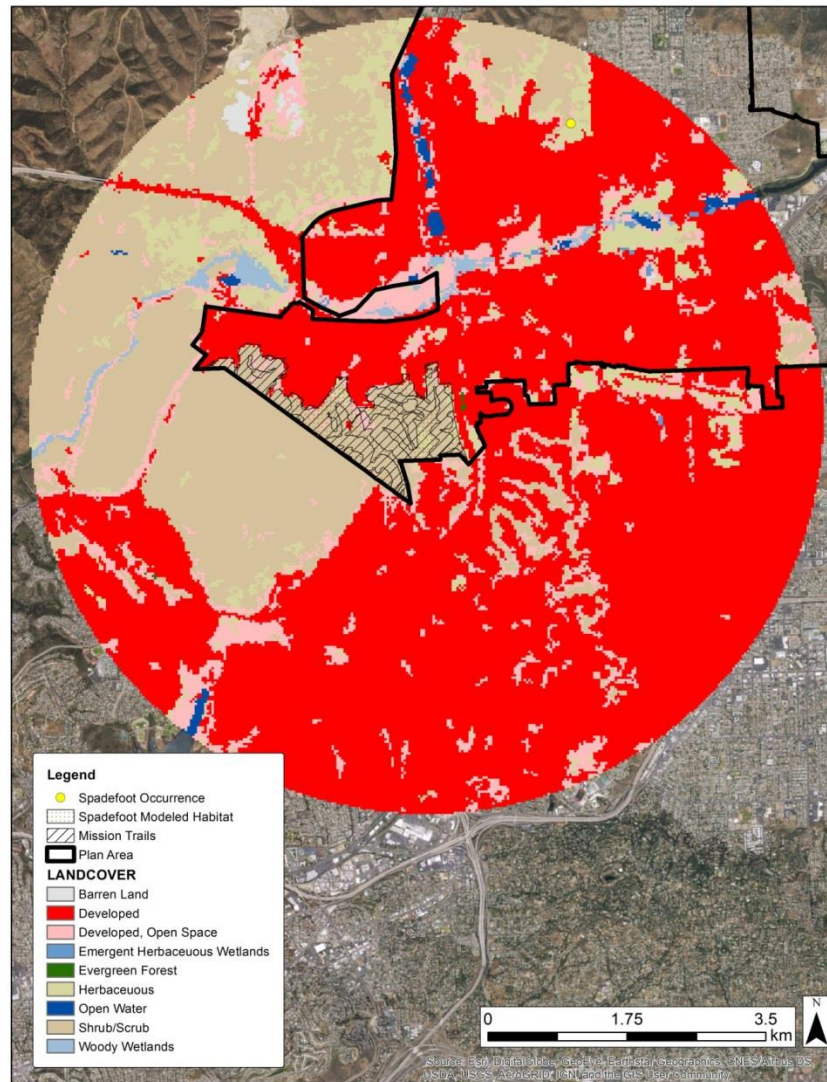

Figure 9. Land cover characterization in the Mission Trails Subunit within a 5,000 meter buffer around the predicted habitat suitable for western spadefoot. Nearly 60% of the area is developed. Western spadefoot occurrence records are from Dudek (2017).

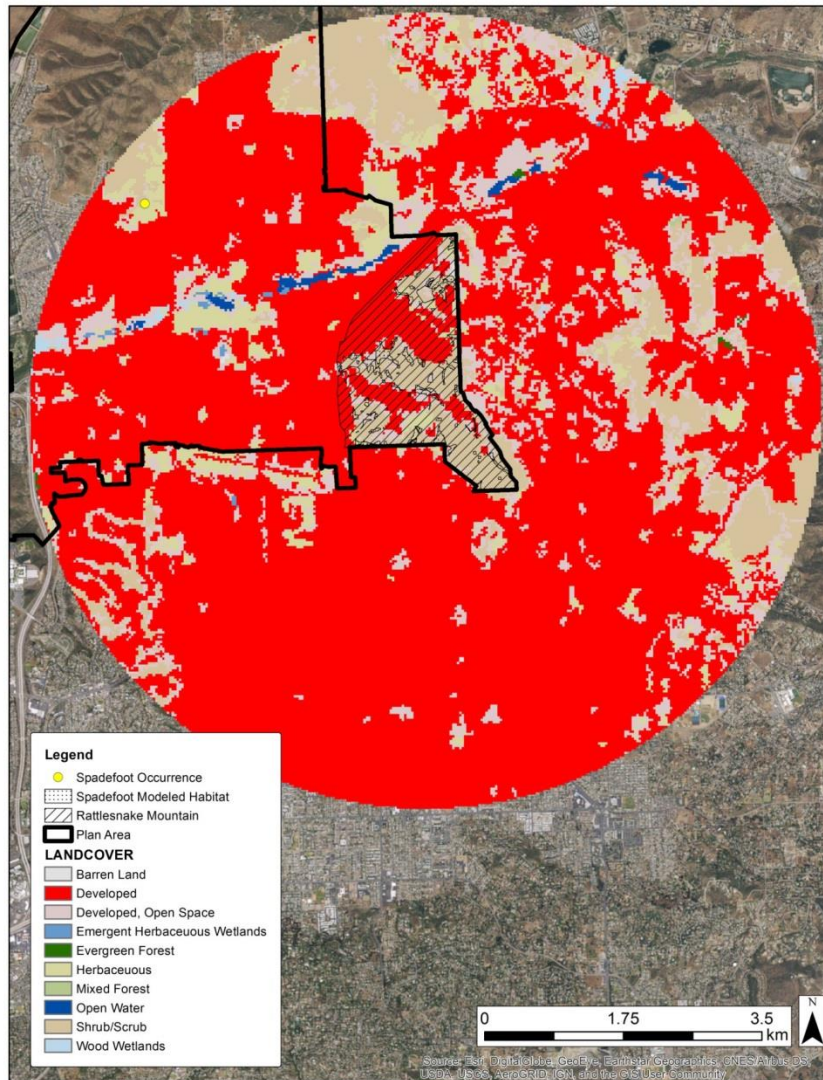

Figure 10. Land cover characterization near the Rattlesnake Mountain Subunit within a 5,000 meter buffer around predicted suitable habitat for western spadefoot. Within the 5,000 m buffer, 73% of the area is developed. Western spadefoot occurrence records are from Dudek (2017).

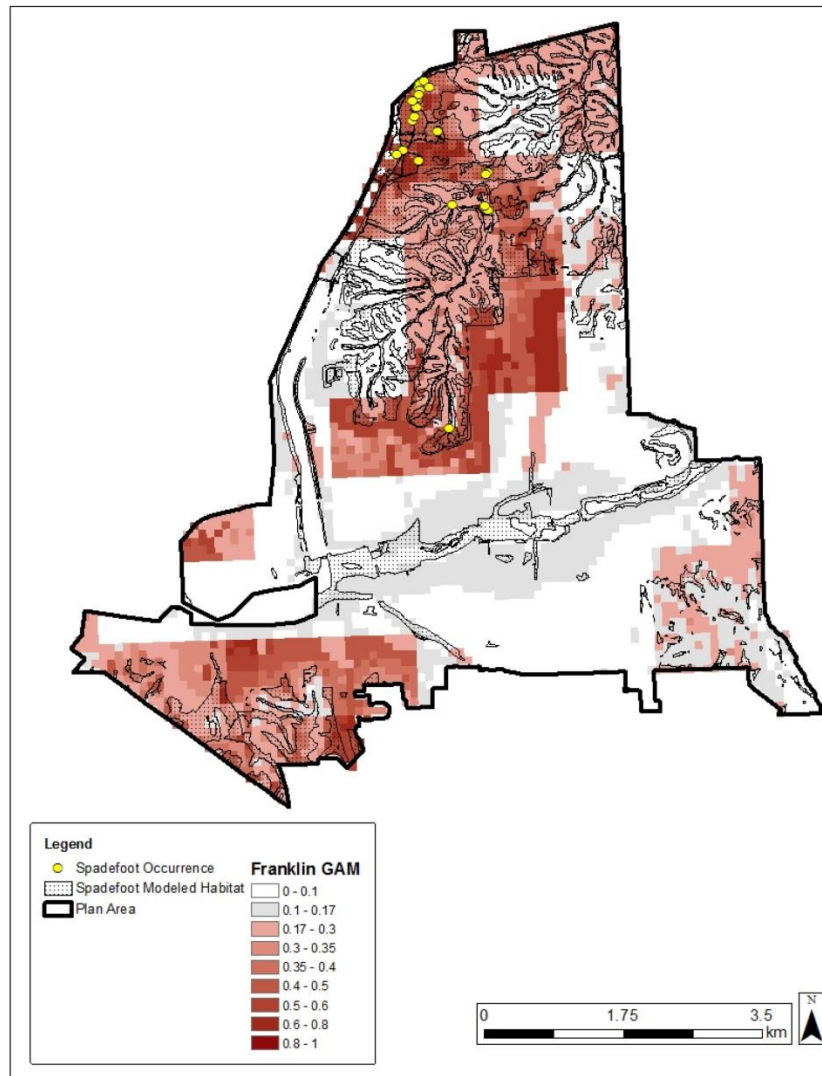

Figure 13. Species distribution model for western spadefoot provided by ICF and that provided by Dr. J. Franklin developed based on the USGS pitfall captures of the species. The General Additive Model (GAM) predicts the probability of western spadefoot occupying the cell. Western spadefoot occurrence records are from Dudek (2017).

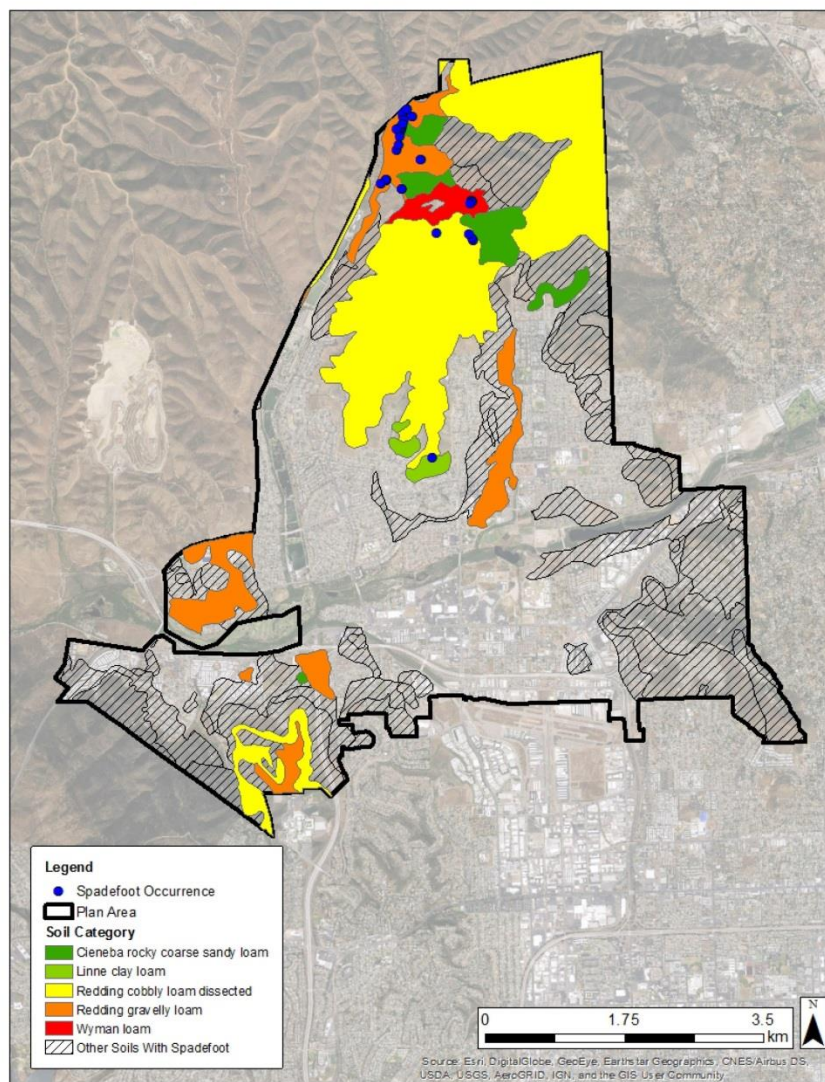

Figure 14. Within the Plan Area, western spadefoot have been found on five different soil categories which exist in the Fanita Rancho, Magnolia, and Mission Trails Subunits. Other soil categories used by spadefoot, based on the USGS pitfall surveys, are also shown. Western spadefoot occurrence records are from Dudek (2017).

Appendix 1

Dudek Data

The previous round of data on western spadefoot within the Plan Area was collected and provided by Dudek (2017). The data provided by Dudek appear accurate based on recent visits to the sites. 243 pools were mapped by Dudek, consisting of both natural pools and road rut pools (Figure 1.1). Western spadefoot were only documented in the Fanita Ranch Subunit (Figure 5 through Figure 13). The vernal pools that Dudek mapped in the north end of the Fanita Ranch Subunit are consistent with those found during the 2017 visits. The western spadefoot occurrence and pool mapped near the south end of the Fanita Ranch Subunit was also visited in 2017, but no western spadefoot were detected, they had already metamorphosed and left the pool by the time the pool was visited in 2017. One additional occupied road-rut pool was detected, which was not surprising as there was another 12 years of disturbance on the dirt roads since the last survey, so additional pools could form over this time.

Figure 1.1 Potential western spadefoot breeding pools documented by Dudek (2017) in the Fanita Ranch Subunit. Both natural and road rut pools were mapped.

Appendix 2

USGS Site Visit: 9 Feb, 2017

The USGS, City of Santee, and ICF visited the modeled habitats in the Mission Trails Subunit and the northwest side of the Fanita Ranch Subunit. The habitat in the Mission Trails Subunit did seem like suitable habitat as modeled, but no western spadefoot were observed. There were several small pools of water but no sign that western spadefoot had bred at the site this year. Adjacent habitat outside the Plan Area might support pools and adults could be present within the Plan Area at this site. At the Fanita Ranch Subunit, multiple pools (road ruts) contained western spadefoot tadpoles (SCHA). Baja chorus frogs (HYRE), western skinks (EUSK), and fairy shrimp were also documented.

Figure 2.1 GPS track and species records from the north end of the Fanita Ranch Subunit (Points correspond to Table 2.1 below). Species are: EUSK – western skink, HYRE – Baja chorus frog, and SCHA – western spadefoot.

Figure 2.2 Western spadefoot tadpoles in a roadside pool.

Table 2.1 Summary table for species observations on 9 February, 2017.
Species are: EUSK – western skink, SCHA – western spadefoot, and HYRE – Baja chorus frog.

Point	Species	Age	Number observed

9	EUSK	Adult	2

Appendix 3

USGS Site Visit: 13 March, 2017

USGS visited the site to assess the developmental progress of the tadpoles and to collect tissue for genetic analysis. The same area at the north end of the Fanita Ranch Subunit was visited and an effort was made to get to the western spadefoot sites identified by Dudek in 2005(Dudek, 2017). The western spadefoot location at the south end of the Fanita Ranch Subunit was also surveyed.

Biotelemetry Data for Golden Eagles (*Aquila chrysaetos*) Captured in Coastal Southern California, February 2016–February 2017

By Jeff A. Tracey¹, Melanie C. Madden¹, Jeremy B. Sebes¹, Peter H. Bloom², Todd E. Katzner¹, and Robert N. Fisher¹

Abstract

Because of a lack of clarity about the status of golden eagles (*Aquila chrysaetos*) in coastal southern California, the USGS, in collaboration with local, State, and other Federal agencies, began a multi-year survey and tracking program of golden eagles to address questions regarding habitat use, movement behavior, nest occupancy, genetic population structure, and human impacts on eagles. Golden eagle trapping and tracking efforts began in September 2014. During trapping efforts from September 29, 2014, to February 23, 2016, 27 golden eagles were captured. During trapping efforts from February 24, 2016, to February 23, 2017, an additional 10 golden eagles (7 females and 3 males) were captured in San Diego, Orange, and western Riverside Counties. Biotelemetry data for 26 of the 37 golden eagles that were transmitting data from February 24, 2016, to February 23, 2017 are presented. These eagles ranged as far north as northern Nevada and southern Wyoming, and as far south as La Paz, Baja California, Mexico.

Introduction

Growing uncertainty about the status of golden eagles (*Aquila chrysaetos*) in southern California has highlighted the need for ecological information that will allow local managers to evaluate and mitigate the effects of human activities on this species (Scott, 1985; Harlow and Bloom, 1989). Depending on the season, the population of golden eagles in California is typically comprised of resident adult territorial breeders, adult floaters, locally fledged juvenile and subadults, as well as migrants with origins from more northerly or southerly latitudes. A better understanding of the current distribution, status, foraging requirements, and population characteristics of golden eagles can help to manage golden eagle habitat and threats/stressors to each nesting territory in coastal southern California. Recent work has been completed in the Mojave Desert and the Tehachapi Mountains in southern California, but nothing previously from the coastal areas (Braham and others, 2015; Poessel and others, 2016). The U.S. Geological Survey (USGS) in collaboration with U.S. Fish and Wildlife Service (FWS), California Department of Fish and Wildlife (CDFW), Bureau of Land Management (BLM), and San Diego Management and Monitoring Program (SDMMP) began a multi-year survey and tracking program of golden eagles to address questions regarding habitat use, movement behavior, nest occupancy, genetic population structure, and human impacts on eagles. This report presents golden eagle capture and biotelemetry data from February 24, 2016, through February 23, 2017. Capture and biotelemetry data for November 22, 2014, to February 23, 2016, are available in Tracey and others (2016).

2 Biotelemetry Data for Golden Eagles Captured in Coastal Southern California, February 2016–February 2017

Methods

Biotelemetry

Once captured, each eagle was given an eagle ID for this study, a USGS Bird Banding Laboratory leg band (if it did not already have one), and a Global Positioning System (GPS) transmitter that sends data over the mobile phone network (a GPS-GSM transmitter; Lanzone and others, 2012). The eagle ID consists of a four-letter code for the species, a two-letter code for the county of capture, and an “F” or “M” followed by a numeral (with up to two leading zeros) to indicate the sex and capture order of the individual. For example, the first female eagle captured in San Diego County was given an eagle ID of GOEA-SD-F001. We use the county code OC for Orange County and RV for Riverside County.

Standard morphological measurements and samples were taken from each captured eagle. Measurements included (1) weight, (2) hallux and culmen, and (3) characteristics of the primary and secondary flight feathers. Samples included (1) blood samples for genetic and lead testing, (2) swabs of the eyes, mouth, and cloaca for chlamydia testing by University of California, Davis; and (3) two to four feathers for lead, stable isotope, and genetic testing. For the health of the eagle, rapid processing and release took precedence over collecting measurements and samples. Thus, in some cases we did not collect weight measurements or take blood samples for field lead testing in favor of properly attaching the GPS-GSM unit and releasing the eagle in a timely manner. When time and the ambient temperatures permitted, eagles were tested in the field for lead toxicity using a LeadCare® II testing unit. If lead testing results were greater than 60 µL/dL, we planned to deliver the eagle to Scott Weldy DVM (Orange County Bird of Prey Center, Serrano Animal & Bird Hospital) for therapy. All samples were collected under Dr. Peter Bloom’s scientific collecting permit (Bloom Biological, Inc.) and delivered to the appropriate parties (University of California, Davis Wildlife Health Center, Todd Katzner of USGS, and Andrew DeWoody of Purdue University—each of whom is permitted to receive samples). No samples were retained in California by USGS. Any request for results of analysis of these samples should be directed to the individual or organization to whom the samples were delivered. Sex was determined based on body size, weight, and measurements of the hallux and culmen and will be confirmed genetically. Age was estimated based on molt patterns (Bloom and Clark, 2001).

Each captured eagle was fitted with a Cellular Tracking Technologies (CTT™) CTT™-1070a GPS-GSM telemetry unit (Dunstan, 1972; Kenward, 1985; Lanzone and others, 2012).

The units were attached to the eagles using 11 mm natural tubular Teflon™ tape fed through the attachment holes on the GPS-GSM unit and around the wings to form a “backpack” (Dunstan, 1972; Kenward, 1985). The Teflon™ ribbon is non-abrasive and is the standard method for attaching telemetry units to eagles. If the eagle had other markings or telemetry devices, in addition to a USGS Bird Banding Laboratory (BBL) leg band, we were directed by the BBL to remove them.

Data Filtering

Once data were downloaded from CTT™ servers, the data were formatted (for example, formatting dates and converting text strings with latitude and longitude data into numerical values) and merged with data from prior downloads when needed. We applied two filters to the records to eliminate potentially erroneous locations prior to merging the new data with prior data.

To pass the first filter, six conditions had to be satisfied:

1. Location had to be at least 2D,
2. Horizontal dilution of precision (HDOP) had to be less than or equal to 4,
3. Vertical dilution of precision (VDOP), if available, had to be less than or equal to 4,
4. Longitude values had to be available and be on the interval [−180, 180] degrees,
5. Latitude values had to be available and be on the interval [−90, 90] degrees, and
6. Fixes had to be at least 4 seconds apart (based on discussion with engineers at CTT™).

The second filter depends on distance metrics. To pass the second filter, three conditions had to be satisfied:

1. The start and end location must have passed the first filter (above),
2. Location had to be within UTM zones 10, 11, or 12 and both the start and end location had to be in the same UTM zone (because the UTM coordinates were used to calculate the move distances for step 3 that follows), and
3. Rate of displacement had to be realistic (≤ 89.4 m/s horizontal or ≤ 20.0 m/s vertical).

Biotelemetry Data for Captured Golden Eagles

From September 29, 2014, and February 23, 2017, we baited at 135 different locations in San Diego, Orange, and western Riverside Counties of southern California and captured a total of 37 golden eagles. During this reporting period, February 24, 2016–February 23, 2017, we baited at 64 locations, captured 10 new golden eagles at nine trapping locations, and collected biotelemetry data from a total of 26 golden eagles, including 16 that were captured prior to February 24, 2016 (table 1, fig. 1). For the 16 eagles captured prior to February 24, 2016, see Tracey and others (2016) for a map of the bait sites at which they were captured. Of the eagles for which telemetry data were collected during the reporting period, there were 18 eagles with active transmitters, 2 eagles with transmitters of unknown status, 3 eagles with inactive transmitters, and 3 eagles known to have died (see “Status” column, table 1). An active transmitter is one from which we have received data within the past 10 days. A transmitter with unknown status is one from which we have received data from 11 to 60 days ago, an inactive transmitter

Biotelemetry Data for Captured Golden Eagles 3

is one from which we have not received data in more than 60 days, and a fatality indicates that we have recovered the eagle’s remains. Several eagles with inactive transmitters have been observed alive in the field. Fourteen of the eagles appeared to have had breeding territories, five appeared to have been floaters (that is, adults without a breeding territory), and seven had undetermined territorial behavior (see “Behavior” column, table 1). For territorial adults, the place name of the territory is given in the “Territory Name” column. No telemetry data were collected during this reporting period for 11 golden eagles (4 confirmed fatalities and 7 apparent transmitter failures) that were included in Tracey and others (2016).

A view of the location data over the entire extent of the area used by the golden eagles is shown in figure 2. Note that a lack of eagle data for a particular area does not necessarily imply that it is not used by eagles. We are only tracking a subset of the population of eagles in southern California, so empty areas could still be utilized by eagles that we are not tracking. Location data for 26 captured golden eagles with transmitters that produced telemetry data during the reporting period are shown in figures 3–28.

4 Biotelemetry Data for Golden Eagles Captured in Coastal Southern California, February 2016–February 2017

Table 1. Summary of golden eagles tracked in southern California, February 24, 2016–February 23, 2017.

Figure 28. Location data for eagle G0EA-SD-M015 captured at Table Mountain, San Diego, California, January 28, 2017.

Biotelemetry Data for Captured Golden Eagles 33

A series of photographs of golden eagles are shown at bait sites (figs. 29–30), a telemetered golden eagle being released (fig. 31), and golden eagle cliff nests (figs. 32–34).

Figure 29. A golden eagle visits a bait site. Often, eagles are attracted by the activity of other scavengers, such as the common ravens seen here. The photograph was taken by a motion-triggered camera used to monitor the bait site.

Figure 31. A golden eagle being released by biologist Marla Steele (volunteer with BBI) after being captured and fitted with a telemetry unit, January 30, 2017. Photograph by Peter H. Bloom, Bloom Biological, Inc. Used with permission.

Figure 30. A golden eagle at a bait site, October 29, 2016.

Figure 32. Typical golden eagle nesting habitat in our study area, March 15, 2017. The location of the nest is indicated by the red arrow. Photograph by Peter H. Bloom, Bloom Biological, Inc. Used with permission.

Figure 33. A female golden eagle wearing a telemetry unit incubates her eggs, March 15, 2017. The yellow arrow points to the unit. Photograph by Peter H. Bloom, Bloom Biological, Inc. Used with permission.

Figure 34. A female golden eagle with hatchlings, May 12, 2015. Photograph by Peter H. Bloom, Bloom Biological, Inc. Used with permission.

Acknowledgments

We thank the USGS field biologists who have made this project possible, including Jordyn Mulder, Monique Wong, James Molden, Michelle Curtis, Devin Adsit-Morris, Karen Aerni, Nicole Deatherage, Robert Krijgsman, Cary Cochran, Omar Guerra Salcido, Tristan Edgarian, and Wendy Bear. We thank Susan Phillips, Sue Jones, and Keith Miles of USGS for their managerial support. We also thank Bloom Biological Inc. biologists Michael Kuehn, Marcus England, Karly Moore, and Jackie Catino and Wendy Humphrey of Bloom Biological Inc. for administrative support. John Martin, Jeff Wells, Joe Papp, Sharon Coc, Kris Preston, Barbara Kus, Suellen Lynn, Marla Steele, and Dustin Jancke volunteered to assist in eagle trapping. Members of the numerous agencies provided support, including the California Department of Fish and Wildlife (Karen Miner, Tracie Nelson, Jason Price, Carrie Battistone, and Rich Burg, Eddy Kono, Scott Sewell, Randy Botta, Nicholas Peterson, and Hans Sin); the U.S. Fish and Wildlife Service (Susan Wynn, Mary Beth Woulfe, Tom Dietsch, Jill Terp, John Martin, Randy Nagel, Joel Pagel, and Karen Goebel); the Bureau of Land Management (Amy Fesnock, Joyce Schlachter, and Carrie Sahagun), the U.S. Forest Service (Jeff Wells), the County of San Diego (Jennifer Price, Mary Niez, Ranger Walt Schmidtke, Ranger Kyle Icke, and Ranger Roger Covalt), the City of San Diego (Nicole McGinnis, Brent Peterson, and Tim Nguyen), SANDAG/SDMMP (Keith Greer, Paul Fromer, Ron Rempel, Yvonne Moore, Kris Preston, Emily Perkins, and the EMP Working Group), the Irvine Ranch Conservancy (David Raetz, Sherry Fuller, and Jutta Burger), Orange County Parks (John Gump and Sean Bengtson), California State Parks (Ken Kietzer and Michael Puzzo, and Gina Moran), Pala Band of Mission Indians, Corte Madera Ranch, Jerry Crowe FBI Regional Tactical Training Center (El Toro), Santa Margarita Ecological Reserve (Pablo Bryant), Back Country Land Trust, Santa Rosa Plateau Ecological Reserve (Carole Bell), Gonzalo De León (Centro de Investigaciones Biológicas del Noroeste, S.C.), and Amber Craig (Border Patrol), and John and Kim Smiley. We thank Winston Vickers (University of California, Davis) and Jeff Lincer (Researchers Implementing Conservation Action) for their support. We thank Michael Lanzone, Andrew McGann, Sheldon Blackshire, and Jeannine Parvin at Cellular Tracking Technologies for technical support. Finally, Frank Konyn, Robert Van Ommering, Brad Scott, and Steve Stiles provided assistance in acquiring bait.
