Mitigation Measure M-GCC-7
Attachment “A”

Part 3 of 3: Verra

PREFACE

During the Village 13 Project's implementation phase and prior to the County's issuance of Project-related grading and building permits, the County shall reference and use Mitigation Measure M-GCC-7 Attachment "A" to determine whether the Project is proposing to use eligible carbon offset project types to meet its CEQA mitigation obligations under mitigation measures M-GCC-7 and M-GCC-8. This Preface describes the contents of Attachment "A."

Mitigation Measure M-GCC-7 Attachment "A" contains copies of the manuals used by the Climate Action Reserve, American Carbon Registry and Verra to administer their carbon offset programs. Each manual contains the foundational principles and standards deployed by the registries to ensure that their carbon offset programs achieve high standards of environmental integrity. As such, the manuals contain generally applicable GHG reduction accounting guidelines; rules and procedures for carbon offset project registration, implementation, and verification; and, standards for the development of protocols and methodologies. The registries' program manuals are updated from time to time; reference should be made to the current iteration of each manual, as needed.

Mitigation Measure M-GCC-7 Attachment "A" also contains all of the carbon offset protocols and methodologies of these three registries that the County has determined to be eligible for use when reducing GHG emissions pursuant to mitigation measures M-GCC-7 and M-GCC-8 of the Village 13 Project's EIR. While the following bulleted summary is not an exhaustive listing of the types of information contained in protocols and methodologies, each of the Attachment "A" protocols and methodologies routinely provide the following type of information:

- A description of the specific carbon offset project type, and associated definitional parameters;
- Eligibility rules pertaining to project location, start date, the crediting period, the additionality tests, and regulatory compliance;
- A description of the GHG assessment boundary and rules for quantifying both baseline and project emissions; and,
- Project monitoring and reporting requirements, including related verification standards.

The County of San Diego has reviewed and determined that the protocols and methodologies included in Attachment "A" establish and require carbon offset projects to comply with standards designed to achieve additional, real, permanent, quantifiable, verifiable and enforceable reductions. In making this determination, the County reviewed the registries' program manuals, the registries' websites (which provide additional background information on each protocol and methodology, including comments from interested members of the public and experts in the field), and the registries' protocols and methodologies included herein. As such, when implementing mitigation measures M-GCC-7 and M-GCC-8, the Village 13 Project shall procure offsets only from the carbon offset project types authorized by the Attachment "A" protocols and methodologies.

The Attachment "A" protocols and methodologies are periodically updated by the registries, pursuant to their established processes, in response to public comments, on-the-ground experience, and technological, scientific and regulatory developments. Updates ensure no reduction in efficacy and environmental integrity, in accordance with the registries' program manuals. Related iterations of the protocols and methodologies for the carbon offset project types listed herein may be used. However, protocols and methodologies for carbon offset project types that are not listed herein cannot be utilized by the Village 13 Project, absent additional evaluation and action by the County of San Diego.

MITIGATION MEASURE M-GCC-7
ATTACHMENT "A"

TABLE OF CONTENTS

** As provided in mitigation measures M-GCC-7 and M-GCC-8, the protocols and methodologies, and other related documents contained in this Attachment are periodically updated by the registries, pursuant to their established processes, in response to public comments, on-the-ground experience, and technological, scientific and regulatory developments. Related iterations of the protocols and methodologies for the carbon offset project types listed herein may be used during the mitigation implementation phase. However, protocols and methodologies for carbon offset project types that are not listed herein cannot be utilized, absent additional County evaluation and action.*

Program Guide

19 September 2019

v4.0

ABOUT VERRA

Verra supports climate action and sustainable development through the development and management of standards, tools and programs that credibly, transparently and robustly assess environmental and social impacts, and drive funding for sustaining and scaling up these benefits. As a mission-driven, non-profit (NGO) organization, Verra works in any arena where we see a need for clear standards, a role for market-driven mechanisms and an opportunity to achieve environmental and social good.

Verra manages a number of global standards frameworks designed to drive finance towards activities that mitigate climate change and promote sustainable development, including the Verified Carbon Standard (VCS) Program and its Jurisdictional and Nested REDD+ framework (JNR), the Verra California Offset Project Registry (OPR), the Climate, Community & Biodiversity (CCB) Standards and the Sustainable Development Verified Impact Standard (SD VISta). Verra is also developing new standards frameworks, including LandScale, which will promote and measure sustainability outcomes across landscapes. Finally, Verra is one of the implementing partners of the Initiative for Climate Action Transparency (ICAT), which helps countries assess the impacts of their climate actions and supports greater transparency, effectiveness, trust and ambition in climate policies worldwide.

CONTENTS

1 INTRODUCTION

The Verified Carbon Standard (VCS) Program provides a global program and standard for GHG emission reduction and removal projects and programs. It uses as its core the requirements set out in *ISO 14064-2:2006, ISO 14064-3:2006 and ISO 14065:2013*. The *VCS Program Guide* (this document) is the overarching program document and provides the rules and requirements governing the VCS Program, and describes the constituent parts of the program such as the project and program registration process, the Verra registry system, the methodology approval process, and the accreditation requirements for validation/verification bodies.

1.1 Version

VCS Program editions are labeled with a version number and program documents are correspondingly version controlled. *VCS Version 4* is the fourth working version of the VCS, having been preceded by *VCS Version 1* (the initial version), *VCS 2007* and *VCS 2007.1* (which were two releases of the same version, but with the latter version incorporating the agriculture, forestry and other land use (AFOLU) specifications), and *VCS Version 3*.

VCS Version 4 was released on 19 September 2019 and becomes the applicable version with immediate effect, except where grace periods were set out for particular requirements.

VCS Version 4 is comprised of all the program documents labeled v4.x, where x is a running number starting at zero. Individual program documents may be updated from time-to-time, as developments require, and their version numbers will be incremented using the v4.x format. Such updated documents still form part of version 4 and the VCS Program edition should be referred to as *VCS Version 4* regardless of the version numbers of the individual program documents. Where documents are updated, an appendix to the document will clearly state the updates made and their effective date. VCS Program stakeholders will be informed of the updates and the updates will also be catalogued on the Verra website. Readers shall ensure that they are using the most current version of this and all other program documents.

Note that errata documents may also be issued on a periodic basis to correct typographical errors in text, equations or figures in VCS Program documents or methodologies. In addition, clarification documents may be issued to provide additional guidance on the VCS Program rules or methodological requirements. Errata and clarification documents are posted to the Verra website alongside the relevant program document or methodology, and are effective on their issuance date. Project proponents and validation/verification bodies shall apply and interpret the VCS Program rules and methodological requirements consistent with any errata and clarifications. Errata and clarifications will be incorporated into the next issued version of the relevant program document or methodology.

New versions of the VCS Program will be issued on a periodic basis when major edition updates are required. Development of new versions of the program will include public stakeholder consultation and will be announced on the Verra website and to VCS Program stakeholders.

The VCS Program documents for previous versions of the VCS Program are available on the Verra website and these should be referred to for the rules and requirements under such previous versions of the VCS Program.

Note that projects, programs and verified carbon units (VCUs) are not labeled in the Verra registry with a specific version of the VCS Program (i.e., projects are not “Version 3 projects” or “Version 4 projects”, and likewise with VCUs). The VCS Program documentation is merely labeled with a version in order to provide version control over the program documents.

1.2 Language

The operating language of the VCS Program is English. The VCS Program documents may be translated into other languages to facilitate local use. However, the English versions of VCS Program documents, and the interpretation of same, shall take precedence over any other language translations.

1.3 Definitions

Definitions as set out in the VCS Program document *Program Definitions*, *ISO 14064-2:2006*, *ISO 14064-3:2006* and *ISO 14065:2013* shall apply to all VCS Program documentation. Note that defined terms in the VCS Program documents, in common with ISO convention, are used without capital first letters.

2 OVERVIEW OF THE VCS PROGRAM

2.1 Program Objectives

The VCS Program establishes the rules and requirements that operationalize the *VCS Standard* to enable the validation of GHG projects and programs, and the verification of GHG emission reductions and removals that can be used both in voluntary and compliance markets. The VCS Program aims to:

1) Establish clear rules and procedures to enable the successful development of GHG projects and programs, and the creation of high quality GHG credits;
2) Create a trusted and fungible GHG credit, the VCU;
3) Stimulate innovation in GHG mitigation technologies and measures as well as procedures for validation, verification and registration, all within a context of quality, credibility and transparency;
4) Provide a secure registry system for all VCUs that offers assurance against double counting and provides transparency to the public;
5) Demonstrate workable frameworks and offer lessons that can be incorporated into other GHG programs and climate change regulation;
6) Provide oversight to ensure that investors, buyers and the market recognizes VCUs as being real, additional and permanent; and
7) Link carbon markets worldwide through a coherent and robust framework.

2.2 Program History

The Climate Group, the International Emissions Trading Association and the World Business Council for Sustainable Development are the partner organizations that founded the VCS Program. The World Economic Forum also partnered in the development of the VCS Program for part of the process. *VCS Version 1* was released on 28 March 2006 as both a consultation document and a standard for use by the market. *VCS Version 2* was released in October 2006 as a consultation document and did not replace *VCS Version 1* as the applicable version. After two years of work, two rounds of public consultation and the work of the 19-member steering committee[1] and seven technical working groups, *VCS 2007* was released on 19 November 2007. *VCS 2007.1*, which incorporated requirements for agriculture, forestry and other land use projects, was released on 18 November 2008. *VCS Version 3* was issued on 8 March 2011. *VCS Version 4* was released on 19 September 2019.

[1] The members of the steering committee were Jan-Willem Bode, Derik Broekhoff, Mike Burnett, Robert Dornau, Steve Drummond, Mitchell Feierstein, Yoshito Izumi, Mark Kenber, Adam Kirkman, Andrei Marcu, Erin Meezan, Ken Newcombe, Mark Proegler, Robert Routliffe, Richard Samans, Marc Stuart, Einar Telnes, Bill Townsend and Diane Wittenberg.

2.3 Program Scope

The VCS Program provides the standard and framework for independent validation of projects and programs, and verification of GHG emission reductions and removals, based on *ISO 14064-2:2006* and *ISO 14064-3:2006*. The scope of the VCS Program covers all those activities related to the generation of GHG emission reductions and removals, including jurisdictional programs and nested REDD+ projects. The scope does not include carbon footprint assessments or carbon neutrality claims.

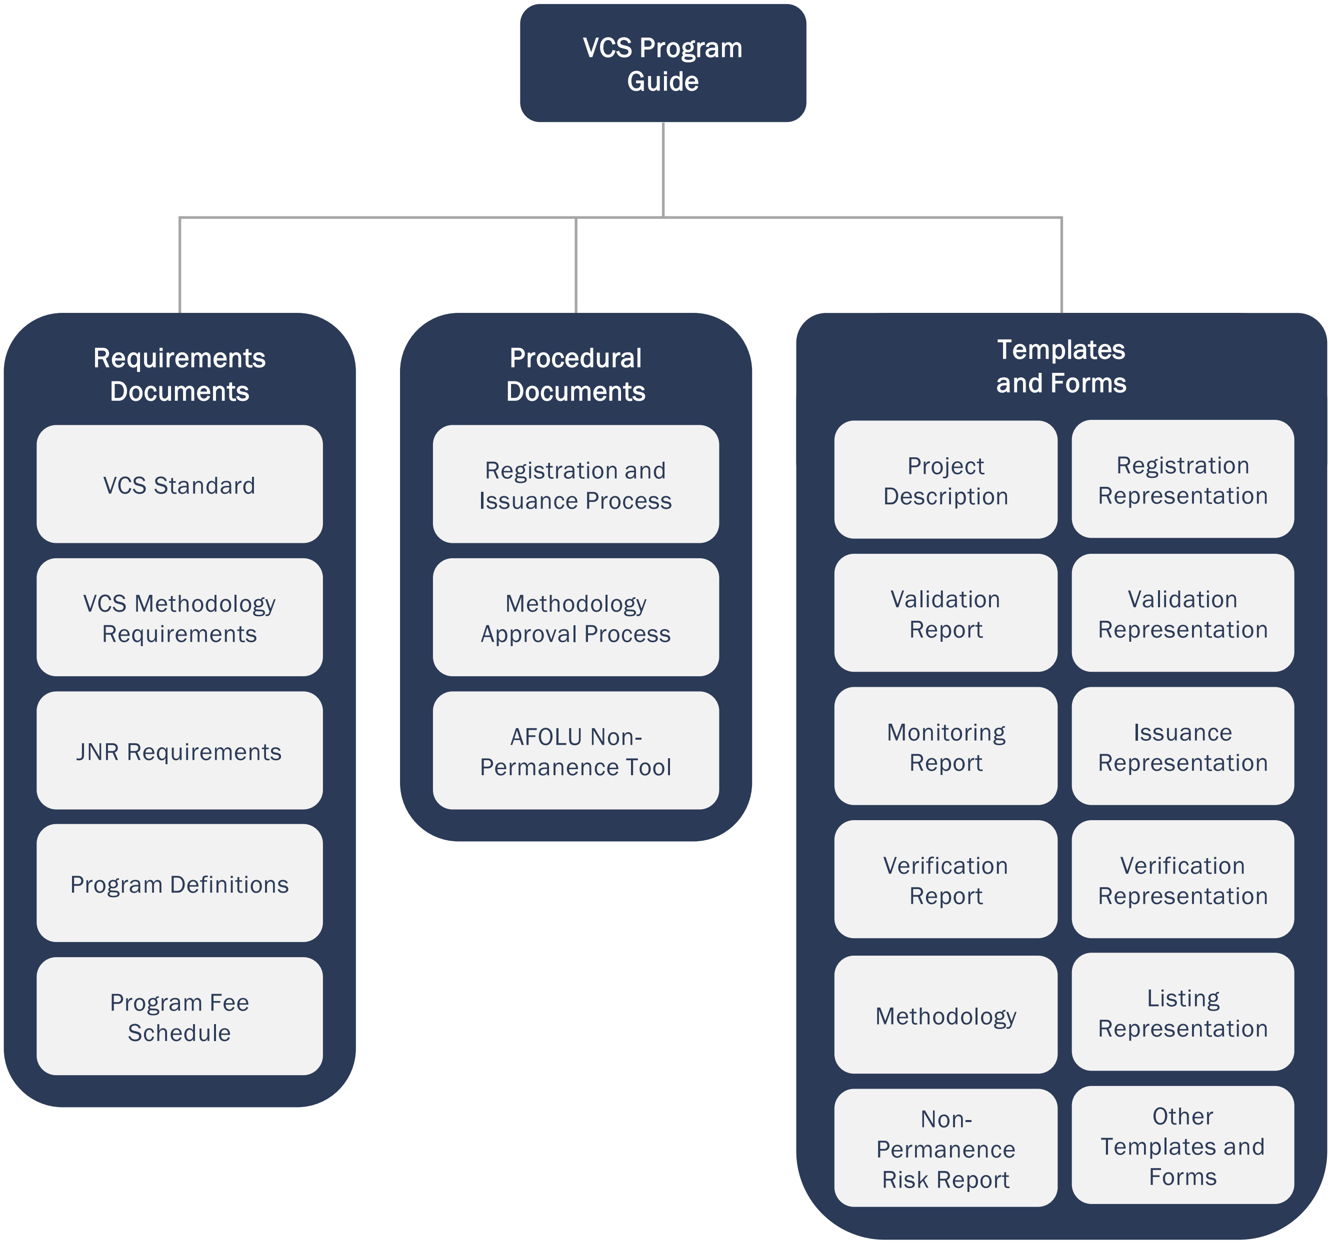
Participation is voluntary and based on objective criteria. The VCS Program is not discriminatory to project proponents, jurisdictional proponents, methodology element developers, validation/verification bodies, or VCU buyers, sellers or brokers.

2.4 Program Documents

The rules and requirements for the VCS Program are set out in the program documents. Projects, programs and methodologies shall meet with all the applicable rules and requirements set out in these documents.

The structure of the program documents is summarized in Diagram 1. The *VCS Program Guide* is the overarching program document, providing the rules and requirements governing the VCS Program and further describing the constituent parts of the program such as the project and program registration process, the Verra registry system, the methodology approval process, and the accreditation requirements for validation/verification bodies. Complementing the *VCS Program Guide* are requirements documents, procedural documents and templates and forms. Verra may issue new documents, as developments in the VCS Program require, and the complete and current list of the program documents is available on the Verra website.

Diagram 1: Program Documents



In addition to the *VCS Program Guide*, the program documents currently include the following:

1) Requirements Documents

   a) *VCS Standard*. Provides the requirements for developing projects and for the validation and verification process.

   b) *Methodology Requirements*. Provides the requirements for developing new methodology elements.

   c) *JNR Requirements*. Provides further requirements for developing jurisdictional REDD+ programs and nested REDD+ projects.

   d) *Program Definitions*. Provides the definitions for terms used in the VCS Program documents.

   e) *Program Fee Schedule*. Provides the fees related to the various parts of the VCS Program.

2) Procedural Documents

   a) *Registration and Issuance Process.* Provides the procedures and rules for registering projects and issuing VCUs.

   b) *JNR Registration and Issuance Process.* Provides the procedures and rules for registering jurisdictional baselines and jurisdictional REDD+ programs, as well as projects nested in jurisdictional programs and standalone projects operating under Scenario 1.

   c) *JNR Validation and Verification Process.* Provides the process and requirements for the validation and verification of jurisdictional baselines and jurisdictional REDD+ programs.

   d) *Methodology Approval Process.* Provides the procedures and rules for approval of VCS Program methodology elements.

   e) *AFOLU Non-Permanence Risk Tool.* Provides the procedure for conducting non-permanence risk analysis and buffer determination for AFOLU projects.

3) Templates and Forms

   a) *VCS Program Templates.* Templates for project descriptions, validation reports, monitoring reports, verification reports and methodologies.

   b) *Representations Templates.* Templates for deeds of representation made by project proponents and validation/verification bodies.

   c) *Forms.* Forms such as for submitting methodology elements under the methodology approval process and for applying to be an AFOLU expert.

The following are normative (referenced) documents for the VCS Program:

1) *ISO 14064-2:2006*, Greenhouse gases – Part 2: Specification with guidance at the project level for quantification, monitoring and reporting of greenhouse gas emission reductions or removal enhancements, ISO, 2006.

2) *ISO 14064-3:2006*, Greenhouse gases – Part 3: Specification with guidance for the validation and verification of greenhouse gas assertions, ISO 2006.

3) *ISO 14065:2013*, Greenhouse gases – Requirements for greenhouse gas validation and verification bodies for use in accreditation or other forms of recognition, BSI, 2007.

4) *The GHG Protocol for Project Accounting* (Chapter 7, guidance related to additionality and common practice), WRI, 2005.

The four standards above are part of the requirements of the VCS Program and their requirements shall be met either by the project proponent (*ISO 14064-2:2006*) or validation/verification body (*ISO 14064-3:2006* and *ISO 14065:2013*). Where there is any conflict between VCS Program documentation and the above normative references, the VCS Program documentation shall take precedence.

The program documents are also complemented by a number of guidance documents. These guidance documents do not set out VCS Program rules and requirements, but they provide additional information to assist with the interpretation of the rules and requirements. It is strongly encouraged that such guidance is followed.

2.5 Roles and Responsibilities

2.5.1 Project and Jurisdictional Proponents

Project and jurisdictional proponents are the entities with overall control and responsibility for projects or programs. A project may have one project or jurisdictional proponent, or there may be a number of project or jurisdictional proponents who collectively have overall control and responsibility for a project or program. Project and jurisdictional proponents establish and operate projects and programs in accordance with the VCS Program rules. They are responsible for providing the project or program description, monitoring report and supporting documentation (including evidence of project ownership or program ownership) to facilitate validation and verification.

Project and jurisdictional proponents sign unilateral representations with respect to their projects or programs and VCUs, and these are made available on the Verra registry. Project proponents assume limited liability for replacement of excess VCUs, as set out in Section 4.2.

Note – In order to aid the readability of the VCS Program documentation, the documents use project and jurisdictional proponent in the singular. For projects and programs with multiple project or jurisdictional proponents, "project proponents" or "jurisdictional proponents" should be substituted in place of "project proponent" or "jurisdictional proponent", as appropriate.

2.5.2 Methodology Element Developers

Methodology element developers are entities that develop methodologies, methodology revisions, modules and tools that are subject to the methodology approval process.

2.5.3 Validation/Verification Bodies

Validation/verification bodies are accredited to:

1) Validate projects and verify GHG emission reductions and removals.

2) Assess methodology elements under the methodology approval process.

Validation/verification bodies are only eligible to carry out work for the sectoral scopes for validation and verification for which they hold accreditation and must sign the required agreement with Verra before they can perform validation or verification in connection with the VCS Program. The list of validation/verification bodies is available on the Verra website.

2.5.4 Verra Registry

The Verra registry is responsible for ensuring that all required project and program documents have been submitted to Verra; issuing and maintaining accounts of VCUs for accountholders; ensuring the seamless flow of VCUs throughout the entire Verra registry system; tracking and reporting the deposit/withdrawal of buffer credits to/from the centrally managed AFOLU pooled buffer account and jurisdictional pooled buffer account; and maintaining custody and records of VCU legal ownership.

2.5.5 VCU Buyers, Sellers and Brokers

Buyers, sellers and brokers are companies, organizations or individuals who transact VCUs or facilitate the transaction of VCUs.

2.5.6 Verra

The VCS Program is managed by Verra, which is an independent, non-profit organization incorporated under the laws of the District of Columbia in the United States. Verra is responsible for managing, overseeing and developing the program. It maintains an impartial position in the market and does not develop projects, programs or methodologies, nor does it provide validation, verification or consulting services.

One of Verra's roles is in respect of overseeing and ensuring the integrity of projects, programs and VCUs in the Verra registry system. Verra conducts reviews of project and program registration and VCU issuance requests. Verra is also responsible for overseeing the validation/verification bodies operating under the VCS Program. Where Verra identifies shortcomings in a validation/verification body's performance, it may provide feedback and require the validation/verification body to address non-conformities.

Verra reserves the right not to register projects and programs, or issue VCUs where it deems that they are not in compliance with the VCS Program rules or may otherwise impact the integrity of the VCS Program or the functioning of the broader carbon market, and to delist projects, programs and VCUs where it deems that they have not been registered or issued in accordance with the VCS Program rules. Verra also reserves the right to take action against validation/verification bodies in accordance with the provisions set out in the agreements signed with Verra. The rights and obligations for validation/verification bodies are set out in such agreements.

Verra is also responsible for managing the methodology approval process, and it reserves the right to not accept methodology elements into the process, not approve methodology elements, or review and update, put on hold or withdraw approved methodology elements where it deems that they are not in compliance with the VCS Program rules, would sanction politically or ethically contentious project activities, or may otherwise impact the integrity of the VCS Program or the functioning of the broader carbon market.

Verra may convene steering committees, advisory committees or working groups to support its work in specific areas. These groups draw in expertise from outside the organization to develop and support specific elements of the VCS Program. A full list of steering committees and working groups is available on the Verra website.

3 VCS PROGRAM CRITERIA FOR GHG PROJECTS AND PROGRAMS

All projects and programs shall meet the requirements set out in the *VCS Version 4* program documents.

GHG emission reductions and removals verified under the VCS Program and issued as VCUs shall meet the following principles:

Real
All GHG emission reductions and removals and the projects or programs that generate them must be proven to have genuinely taken place.

Measurable
All GHG emission reductions and removals must be quantifiable using recognized measurement tools (including adjustments for uncertainty and leakage) against a credible emissions baseline.

Permanent
Where GHG emission reductions or removals are generated by projects or programs that carry a risk of reversibility, adequate safeguards must be in place to ensure that the risk of reversal is minimized and that, should any reversal occur, a mechanism is in place that guarantees the reductions or removals will be replaced or compensated.

Additional
GHG emission reductions and removals must be additional to what would have happened under a business-as-usual scenario if the project had not been carried out.

Independently Audited
All GHG emission reductions and removals must be verified to a reasonable level of assurance by an accredited validation/verification body with the expertise necessary in both the country and sector in which the project is taking place.

Unique
Each VCU must be unique and must only be associated with a single GHG emission reduction or removal activity. There must be no double counting, or double claiming of the environmental benefit, in respect of the GHG emission reductions or removals.

Transparent
There must be sufficient and appropriate public disclosure of GHG-related information to allow intended users to make decisions with reasonable confidence.

Conservative
Conservative assumptions, values and procedures must be used to ensure that the GHG emission reductions or removals are not over-estimated.

4 VERRA REGISTRY

The Verra registry provides the public interface to all project, program and VCU information. VCU serial numbers are generated by the registry, which ensures uniqueness of projects, programs and VCUs. In addition, the Verra registry provides full transparency on project and program documentation, together with information on project and jurisdictional proponents, VCU issuance and retirement, the AFOLU pooled buffer account and the jurisdictional pooled buffer account.

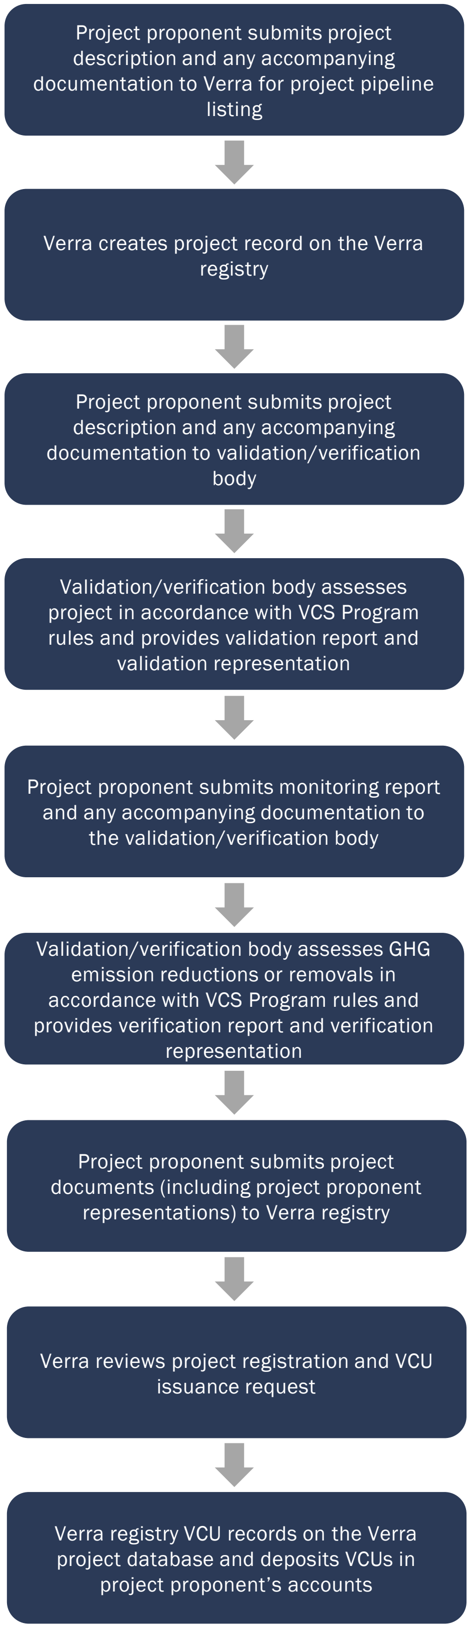
The AFOLU pooled buffer account holds non-tradable buffer credits to cover the non-permanence risk associated with AFOLU projects. It is a single account that holds the buffer credits for all projects. The account is subject to a periodic reconciliation, as set out in the VCS Program document *VCS Standard*. Likewise, the jurisdictional pooled buffer account holds the non-tradable buffer credits to cover the non-permanence risk associated with jurisdictional REDD+ programs and nested projects.

The Verra registry provides accountholder services and is the entry point into the registry system for project and jurisdictional proponents, and VCU buyers and sellers. Such market participants open an account with the Verra registry and project and program registration and VCU issuance is initiated with the Verra registry.

The Verra registry is responsible for ensuring that projects and programs are registered and VCUs are issued in accordance with the VCS Program rules; providing services for holding, transferring and retiring VCUs; managing AFOLU and jurisdictional buffer credits; and providing custodial services for VCUs and maintaining records of VCU legal ownership.

Project and jurisdictional proponents (or other eligible entities, as set out in the VCS Program documents *Registration and Issuance Process* and *JNR Registration and Issuance Process*) request listing and registration of projects and programs, and VCU issuance, with the Verra registry. Diagram 2 outlines the project life cycle and registration process, which is similar to the program life cycle and registration process. Once the project or program has been validated and the GHG emission reductions or removals verified, the project or jurisdictional proponent submits the relevant documents to the Verra registry. Verra conducts a completeness review of the documents, and may conduct a further accuracy review to assess compliance with the VCS Program rules. Where it is determined that the project or program complies with the VCS Program rules, Verra uploads the documents to the public Verra registry and issues VCUs into the project or jurisdictional proponent's account. Note that validation and verification may be undertaken simultaneously, with registration and issuance of the VCUs occurring at the same time, or validation may occur before verification, with registration occurring before any subsequent issuance of VCUs.

Diagram 2: Project Life Cycle and Registration Process



The process and detailed rules and requirements for project pipeline listing, program listing, project and program registration, and VCU issuance are set out in the VCS Program documents *Registration and Issuance Process* and *JNR Registration and Issuance Process*.

4.1 VCS Program Fees

Verra charges fees to cover administration costs, at the rates set out in the VCS Program document *Program Fee Schedule*.

4.2 VCU Liability And Statute Of Limitations

Registered projects and issued VCUs are subject to review by Verra, as set out in the VCS Program document *Registration and Issuance Process*. Project proponents are responsible for compensating for excess VCU issuance where Verra deems, acting reasonably, that there has been a material erroneous issuance of VCUs in respect of a project, as a result of the fraudulent conduct, negligence, intentional act, recklessness, misrepresentation or mistake of the project proponent. A statute of limitations applies, whereby Verra can only require such compensation in relation to any verification completed after 8 April 2014 and up to the later of:

1) 6 years after the date of issuance of the relevant VCU; or
2) 12 months after the date upon which any second verification report with respect to the relevant VCU is accepted on the Verra registry.[2]

[2] The relevant VCU will be issued following acceptance of a verification report for a project. For some types of AFOLU projects in particular, verification cycles may be longer than 6 years. In this regard, if the second verification report shows a VCU has been erroneously issued, Verra will have an additional 12 months to deal with that issue. Note also that where a VCU is erroneously issued from the last verification report of a project, Section 4.2(1) applies.

5 VCS PROGRAM ACCREDITATION

Validation/verification bodies are eligible to provide validation and verification services under the VCS Program if they have signed the required agreement with Verra and are:

1) Accredited under a VCS-approved GHG program[3]; or
2) Accredited under *ISO 14065:2013* for scope VCS by an accreditation body that is a member of the International Accreditation Forum;

The validation/verification body shall hold such accreditation or approval for validation or verification (as applicable) for the sectoral scope(s) applicable to the methodology applied to the project. Where the methodology falls under more than one sectoral scope, the validation/verification body shall hold accreditation or approval for validation or verification (as applicable) for all relevant sectoral scopes.

Where the validation/verification body holds accreditation or approval for the verification for the relevant sectoral scope(s) but does not hold accreditation or approval for validation, it may validate project description deviations and inclusion of new project activity instances in grouped projects at the time of verification, under the following circumstances:

1) It holds accreditation or approval for validation in at least one other sectoral scope.
2) It has completed validation of at least five projects under the VCS Program or an approved GHG program, and such projects have been registered under the relevant program.
3) The validation activity does not entail the validation of a project description deviation that impacts the applicability of the methodology, additionality or the appropriateness of the baseline scenario (see the *VCS Standard* for further information on such deviations).

Validation/verification bodies are also eligible to conduct assessments (validation) of methodology elements under the methodology approval process. The validation/verification body shall hold accreditation for validation for the sectoral scope(s) applicable to the methodology. Where the methodology falls under more than one sectoral scope, the validation/verification body shall hold accreditation for validation for all relevant sectoral scopes.

To apply to become an approved validation/verification body with the VCS Program, organizations must complete a *Verra Validation/Verification Body Application Form* and submit the signed application, along with any supporting evidence (as required by the application) to secretariat@verra.org.

A list of validation/verification bodies approved to undertake validation and verification services under the VCS Program is available on the Verra website.

[3] Note that accreditation under an approved GHG program shall be recognized only until such time as Verra determines that a sufficient number of validation/verification bodies are accredited under other recognized accreditation pathways, or two years from the date of release of VCS Version 4, whichever is earlier. After such date, all validation/verification bodies must be accredited through another approved accreditation pathway.

6 METHODOLOGY APPROVAL PROCESS

The methodology approval process is the process by which methodologies, methodology revisions, modules and tools (including additionality tools, performance benchmarks and technology benchmarks), are approved under the VCS Program. Such methodology elements are subject to review by Verra, a global stakeholder consultation hosted on the Verra website and independent assessment by one validation/verification body, before final approval by Verra.

The full rules and requirements for methodology elements with respect to the methodology approval process are set out in the VCS Program document *Methodology Approval Process*.

6.1 Review of Approved VCS Methodology Elements

Verra may periodically review methodology elements approved under the VCS Program to ensure they continue to reflect best practice and scientific consensus. This includes ensuring that methodology elements approved under the program are consistent with any new requirements issued by Verra and that methodology elements have appropriate criteria and procedures for addressing all VCS Program requirements and are consistent with emerging best practice and scientific consensus. As a result, Verra may need to update, put on hold or withdraw a methodology element. The procedure through which Verra may review approved VCS Program methodology elements and take appropriate action is set out in the VCS Program document *Methodology Approval Process*.

6.2 Compensation for Methodology Developers

Methodology developers are eligible to receive compensation for methodologies approved under the VCS Program.

Compensation will be paid according to the number of VCUs issued to projects using the methodology or a revision of the methodology, at the rate and in accordance with the payment terms set out in the VCS Program document *Program Fee Schedule*. Compensation is payable with respect to VCUs issued on or after 15 June 2010. Methodology developers may elect not to receive compensation by notifying Verra at any time.

Where Verra sanctions the consolidation of a number of methodologies, the compensation due to the developer of the consolidated methodology and the underlying methodologies respectively will be determined on a case-by-case basis by Verra.

Where an eligible methodology is withdrawn or put on hold, compensation remains payable in respect of continuing issuance of VCUs to registered projects that have applied the methodology or a revision of the methodology.

Only methodologies developed under the VCS Program methodology approval process are eligible for the compensation mechanism. Developers of methodology revisions, modules and tools are not compensated under the mechanism.

Note – Project proponents pay the same VCU issuance levy regardless of the methodology applied to the project. Verra pays any compensation to the methodology developer out of the VCU issuance levy it receives.

7 LINKING TO OTHER GHG PROGRAMS

To recognize work that has gone into developing other credible GHG programs, the VCS Program has a process for approving GHG programs that meet VCS Program criteria. A GHG program shall demonstrate compliance with VCS Program principles and requirements through a gap analysis and the Verra Board will make the final decision on whether to approve the GHG program. Approval of a GHG program under the VCS Program has three implications:

1) GHG credits under the approved GHG program may be cancelled and issued as VCUs (converted into VCUs).
2) Validation/verification bodies under the approved GHG program are approved for validation and verification under the VCS Program (for the corresponding sectoral scopes for validation and verification respectively, and provided they have signed the required agreement with Verra).
3) Methodology elements under the approved GHG program may be used for developing projects under the VCS Program.

The list of approved GHG programs is available on the Verra website, together with any specific conditions or further clarifications with respect to the scope of approval.

7.1 Gap Analysis Methodology and Process

The approval of other GHG programs is based on the principle of full compatibility with the VCS Program. A gap analysis process is applied on a case-by-case basis to determine the other GHG program's compliance with VCS Program principles and requirements and to assess whether the GHG emission reductions or removals issued under the GHG Program are fully compatible with VCUs issued under the VCS Program.

Any party may initiate a gap analysis of another GHG program with the VCS Program. All relevant documentation in relation to the GHG program shall be provided to Verra, with appropriate authorization secured.

The onus is on the GHG program to demonstrate that it meets the VCS Program criteria. The costs of the assessment are borne by the GHG program or whoever initiates the gap analysis.

Based on the gap analysis report, the Verra Board will make a decision on whether to approve the full GHG program or elements of the program.

7.2 Review of VCS Program-Approved GHG Programs

Approved GHG programs are reviewed periodically by Verra. Any changes made by an approved GHG program which may affect its compatibility with the VCS Program shall be communicated immediately to Verra. In the event that it is considered that the changes lead to non-conformity with the VCS Program, the Verra Board may decide to suspend or terminate its recognition of the approved GHG program. Any projects approved under the GHG program prior to such Verra Board decision will not be affected by the suspension or termination.

8 COMPLAINTS AND APPEALS PROCEDURE

Project proponents, validation/verification bodies, methodology element developers and other stakeholders (including interested stakeholders) may submit enquiries to Verra at any time. In addition, the VCS Program provides a complaints and appeals procedure as set out in the Verra *Appeals, Complaints and Conduct Policy* available on the Verra website.

A VERRA STANDARD

VCS Standard

19 September 2019

v4.0

ABOUT VERRA

Verra supports climate action and sustainable development through the development and management of standards, tools and programs that credibly, transparently and robustly assess environmental and social impacts, and drive funding for sustaining and scaling up these benefits. As a mission-driven, non-profit (NGO) organization, Verra works in any arena where we see a need for clear standards, a role for market-driven mechanisms and an opportunity to achieve environmental and social good.

Verra manages a number of global standards frameworks designed to drive finance towards activities that mitigate climate change and promote sustainable development, including the Verified Carbon Standard (VCS) Program and its Jurisdictional and Nested REDD+ framework (JNR), the Verra California Offset Project Registry (OPR), the Climate, Community & Biodiversity (CCB) Standards and the Sustainable Development Verified Impact Standard (SD VISta). Verra is also developing new standards frameworks, including LandScale, which will promote and measure sustainability outcomes across landscapes. Finally, Verra is one of the implementing partners of the Initiative for Climate Action Transparency (ICAT), which helps countries assess the impacts of their climate actions and supports greater transparency, effectiveness, trust and ambition in climate policies worldwide.

CONTENTS

1 INTRODUCTION

The *VCS Standard* provides a global standard for GHG emission reduction and removal projects and programs. It uses as its core the requirements set out in *ISO 14064-2:2006*, *ISO 14064-3:2006* and *ISO 14065:2013*. The three principal documents of the program are the *VCS Program Guide,* the *VCS Standard,* and the *VCS Methodology Requirements*. The *VCS Program Guide* describes the rules and requirements governing the VCS Program and further describes the constituent parts of the program such as the project and program registration process, the Verra registry system, the methodology approval process and the accreditation requirements for validation/verification bodies. The *VCS Standard* provides the requirements for developing projects and programs, as well as the requirements for validation, monitoring and verification of projects, programs and GHG emission reductions and removals. The *VCS Methodology Requirements* provides the rules and requirements for developing new VCS methodologies. The *VCS Program Guide* should be read before using the *VCS Standard* or the *VCS Methodology Requirements*.

Verra recognizes the kind agreement of the International Organization for Standardization (ISO, www.iso.org) to allow inclusion of critical clauses of *ISO 14064-2:2006* and *ISO 14064-3:2006* in the VCS Program documentation to facilitate comprehension. In particular, the sections in this document on project and methodology requirements include text drawn from *ISO 14064-2:2006* clause 5 and *ISO 14064-3:2006* clause 4.9, amended where necessary to fit the context of the VCS Program.

1.1 Version

All information about version control under the VCS Program is contained in the *VCS Program Guide*.

This document will be updated from time-to-time and readers shall ensure that they are using the most current version of the document. Where external documents are referenced, such as the *IPCC 2006 Guidelines for National GHG Inventories*, and such documents are updated, the most recent version of the document shall be used.

Previous versions of the VCS Program may have included different rules and requirements than those set out in this version. Previous versions of the *VCS Standard* and other VCS Program documents are archived and available on the Verra website.

1.2 Language

The operating language of the VCS Program is English. The project and program description, validation report, monitoring report, verification report and all other documentation (including all and any appendices) required under the VCS Program shall be in English.

2 VCS PROGRAM SPECIFIC ISSUES

2.1 Scope of VCS Program

2.1.1 The scope of the VCS Program includes:

1) The six Kyoto Protocol greenhouse gases.
2) Ozone-depleting substances.
3) Project activities supported by a methodology approved under the VCS Program through the methodology approval process.
4) Project activities supported by a methodology approved under a VCS approved GHG program, unless explicitly excluded under the terms of Verra approval.
5) Jurisdictional REDD+ programs and nested REDD+ projects as set out in the VCS Program document *Jurisdictional and Nested REDD+ (JNR) Requirements*.

The scope of the VCS Program excludes projects that can reasonably be assumed to have generated GHG emissions primarily for the purpose of their subsequent reduction, removal or destruction. The VCS Program also excludes the following project activities under the circumstances indicated in Table 1, below.

Table 1: Excluded Project Activities

Activity	Non-LDC[1]		LDC	
	Large scale[2]	Small scale[2]	Large scale	Small scale
Activities that reduce hydrofluorocarbon-23 (HFC-23) emissions	Excluded	Excluded	Excluded	Excluded
Grid-connected electricity generation[3]	Excluded	Excluded	Excluded	

[1] Least Developed Country, as designated by the United Nations.
[2] Small-scale and large-scale designations are as per CDM definitions for same.
[3] "Grid-connected electricity generation" means the generation of electricity primarily for delivery to a national or regional grid. Generation of electricity primarily for delivery to a micro-grid (i.e., a localized grid that facilitates the delivery of electricity to discrete and often remote sets of infrastructure that do not otherwise have reliable access to electricity) is not included in this definition, and such project activities are eligible under the scope of the VCS Program.

using hydro power plants/units				
Grid-connected electricity generation using wind, geothermal, or solar power plants/units	Excluded	Excluded		
Utilization of recovered waste heat for, *inter alia*, combined cycle electricity generation and the provision of heat for residential, commercial or industrial use	Excluded	Excluded		
Generation of electricity and/or thermal energy using biomass. This does not include efficiency improvements in thermal applications (e.g., cook stoves).	Excluded	Excluded		
Generation of electricity and/or thermal energy using fossil fuels, including activities that involve switching from a higher carbon content fuel to a lower carbon content fuel	Excluded	Excluded		
Replacement of electric lighting with more energy efficient electric lighting, such as the replacement of incandescent electrical bulbs with CFLs or LEDs	Excluded			
Installation and/or replacement of electricity transmission lines and/or energy efficient transformers	Excluded			

For example, and to illustrate the mechanics of this table, large-scale grid-connected hydroelectric projects are excluded in all cases. However, a small-scale grid-connected hydroelectric project would be eligible where located within an LDC.

2.2 Principles

2.2.1 The application of principles is fundamental in ensuring that GHG-related information is a true and fair account. The principles below shall provide the basis for, and shall guide the application of, the VCS Program rules and requirements.

Principles taken from ISO 14064-2:2006, clause 3.

Relevance
Select the GHG sources, GHG sinks, GHG reservoirs, data and methodologies appropriate to the needs of the intended user.

Completeness
Include all relevant GHG emissions and removals. Include all relevant information to support criteria and procedures.

Consistency
Enable meaningful comparisons in GHG-related information.

Accuracy
Reduce bias and uncertainties as far as is practical.

Transparency
Disclose sufficient and appropriate GHG-related information to allow intended users to make decisions with reasonable confidence.

Conservativeness
Use conservative assumptions, values and procedures to ensure that net GHG emission reductions or removals are not overestimated.

Note – Accuracy should be pursued as far as possible, but the hypothetical nature of baselines, the high cost of monitoring of some types of GHG emissions and removals, and other limitations make accuracy difficult to attain in many cases. In these cases, conservativeness may serve as a moderator to accuracy in order to maintain the credibility of project and program GHG quantification.

2.3 Timing of Crediting

2.3.1 VCUs shall not be issued under the VCS Program for GHG emission reductions or removals that have not been verified.

2.3.2 Project activities are eligible for immediate crediting of future avoided emissions under the conditions set out below, which shall be addressed at the level of the methodology:

1) The project immediately avoids future streams of GHG emissions as a result of an upfront intervention that permanently precludes further emissions from the source. VCUs shall be issued only after such an intervention has occurred and the GHG emission reductions have been verified. Examples of such activities include projects that destroy chlorofluorocarbons recovered from refrigeration equipment thereby immediately precluding their future release into the atmosphere, and composting projects that divert organic waste from landfill sites thereby immediately precluding future methane emissions. A REDD project would not qualify for immediate crediting because future streams of GHG emissions are not permanently precluded.

2) The physical processes that would generate GHG emissions in the absence of an intervention are well-understood, stable and quantifiable. Models used to simulate such processes shall meet the requirements for such models set out in the VCS Program document *VCS Methodology Requirements*. Any default factors associated with input parameters shall meet the requirements set out for such default factors in the VCS Program document *VCS Methodology Requirements*.

3) VCUs may be issued only for GHG emissions avoided over a ten-year period, even if such GHG emissions are likely to have continued over a longer period of time under the baseline scenario. For example, a composting project that diverts organic waste from a landfill site would be eligible for crediting (in relation to a specific amount of composted organic waste) for the GHG emissions that would have occurred at the landfill site over a ten-year period, and any emissions that would have occurred beyond the ten year period (in relation to the specific amount of composted organic waste) are not eligible. Note that in this particular example the ten-year rule applies to the specific amount of composted organic waste and the usual rules on duration of the project and project crediting period still apply.

2.3.3 ODS projects are eligible for immediate crediting of future avoided emissions and methodology elements may use such a crediting model.

Note – Crediting of ODS projects shall still be in relation to the baseline scenario. In many cases, methodology elements will credit projects for all of the ODS destroyed by the project (minus any project emissions and leakage). However, it is possible that projects could destroy ODS from existing stockpiles and only a portion of the ODS would have been emitted under the baseline scenario. For example, if the baseline scenario includes use of the ODS to service existing equipment and a certain proportion of such ODS would be recovered and destroyed at the end of that equipment's life (whether voluntarily or due to regulation), then the volume of credits granted to the project shall reflect this.

2.4 AFOLU Non-Permanence Risk and Pooled Buffer Account

2.4.1 Non-permanence risk in Agriculture, Forestry, and Other Land Use (AFOLU) projects is addressed through the use of a project risk analysis, using the *AFOLU Non-Permanence Risk Tool*, which determines a number of credits to be deposited in the AFOLU pooled buffer account. The pooled buffer account holds non-tradable buffer credits to cover the non-permanence risk associated with AFOLU projects. It is a single account that holds the buffer credits for all projects.

Buffer credits are cancelled to cover carbon known, or believed, to be lost. As such, the VCUs already issued to projects that subsequently fail are not cancelled and do not have to be "paid back". All VCUs issued to AFOLU projects (as with all projects) are permanent. The VCS approach provides atmospheric integrity because the AFOLU pooled buffer account will always maintain an adequate surplus to cover unanticipated losses from individual project failures and the net GHG benefits across the entire pool of AFOLU projects will be greater than the total number of VCUs issued.

The full rules and procedures for AFOLU projects with respect to non-permanence risk are set out in Section 3.2.

2.4.2 The AFOLU pooled buffer account is subject to periodic reconciliation. Reconciliation is based on a review of existing AFOLU verification reports and an assessment of project performance. This process will identify the projects that have failed or underperformed and seek to identify their common characteristics. The risk analysis criteria and buffer withholding percentages, set out in the VCS Program document *AFOLU Non-Permanence Risk Tool*, will be adjusted accordingly to ensure that there are always sufficient buffer credits in the AFOLU pooled buffer account to cover project losses. Any changes to the tool will not be retroactive (i.e., they will apply only to future non-permanence risk assessments).

2.4.3 Project risk analyses will be subject to periodic review by Verra. This process consists of a review of a sample of AFOLU project risk reports to identify any inconsistencies in the process and application of the *AFOLU Non-Permanence Risk Tool* and assessment of same by validation/verification bodies. The risk analysis criteria and risk ratings set out in the tool may be adjusted, to ensure consistent and accurate application of the tool. Any changes to the tool will not be retroactive (i.e., they will apply only to subsequent non-permanence risk analyses).

2.5 AFOLU Leakage Assessments

2.5.1 Project market leakage assessments will be subject to periodic review by Verra. This process consists of a review of a sample of AFOLU projects' leakage assessments to identify any inconsistencies in the process and application of the leakage requirements in Sections 3.14.7–3.14.9 and the VCS Program document *VCS Methodology Requirements,* and assessment of same by validation/verification bodies. The leakage requirements set out in the *VCS Methodology Requirements* may be adjusted to ensure consistent and accurate application. Any changes to the leakage requirements will not be retroactive (i.e., they will apply only to subsequent leakage assessments).

3 PROJECT REQUIREMENTS

This section sets out the rules and requirements for projects under the VCS Program. Specific requirements for AFOLU and ODS projects are set out throughout this section, as these project types may encounter unique circumstances related to project implementation, monitoring and other matters, which must be addressed.

In order to complete the VCS Program certification process, projects must demonstrate how they meet the rules and requirements set out below. Projects must also demonstrate how they have applied an eligible methodology in full. Projects demonstrate their compliance with the VCS Program rules and the applied methodology through the validation and verification processes, which are defined in Section 4 below. Once projects complete the validation and verification processes, they become eligible to request registration and VCU issuance. Note that the full process for requesting project registration and VCU issuance is set out in the VCS Program document *Registration and Issuance Process*.

3.1 General Requirements

Concept

Establishing a consistent and standardized certification process is critical to ensuring the integrity of VCS projects. Accordingly, certain high-level requirements must be met by all projects, as set out below.

Requirements

3.1.1 Projects shall meet all applicable rules and requirements set out under the VCS Program, including this document. Projects shall be guided by the principles set out in Section 2.2.1.

3.1.2 Projects shall apply methodologies eligible under the VCS Program. Methodologies shall be applied in full, including the full application of any tools or modules referred to by a methodology, noting the exception set out in Section 3.13.1. The list of methodologies and their validity periods is available on the Verra website.

3.1.3 Projects and the implementation of project activities shall not lead to the violation of any applicable law, regardless of whether or not the law is enforced.

3.1.4 Where projects apply methodologies that permit the project proponent its own choice of model (see the VCS Program document *Program Definitions* for definition of model), such model shall meet with the requirements set out in the VCS Program document *VCS Methodology Requirements* and it shall be demonstrated at validation that the model is appropriate to the project circumstances (i.e., use of the model will lead to an appropriate quantification of GHG emission reductions or removals).

3.1.5 Where projects apply methodologies that permit the project proponent its own choice of third party default factor or standard to ascertain GHG emission data and any supporting data for establishing baseline scenarios and demonstrating additionality, such default factor or standard shall meet with the requirements set out in the VCS Program document *VCS Methodology Requirements*.

3.1.6 Projects shall preferentially apply methodologies that use performance methods (see the VCS Program document *VCS Methodology Requirements* for further information on performance methods) where a methodology is applicable to the project that uses a performance method for determining both additionality and the crediting baseline (i.e., a project shall not apply a methodology that uses a project method where such a performance method is applicable to the project). Methodologies approved under the VCS Program that use performance methods provide a list of similar methodologies that use project methods (that were approved under the VCS Program or an approved GHG program at the time the performance method was developed). Such lists are not necessarily exhaustive but can serve as the starting point for determining whether a performance method is applicable to the project. Following the approval of a methodology that uses a performance method, projects may use any applicable pre-existing methodology that uses a project method for a six-month grace period.

3.1.7 Where the rules and requirements under an approved GHG program conflict with the rules and requirements of the VCS Program, the rules and requirements of the VCS Program shall take precedence.

3.1.8 Where projects apply methodologies from approved GHG programs, they shall comply with any specified capacity limits (see the VCS Program document *Program Definitions* for definition of capacity limit) and any other relevant requirements set out with respect to the application of the methodology and/or tools referenced by the methodology under those programs.

3.1.9 Where Verra issues new requirements relating to projects, registered projects do not need to adhere to the new requirements for the remainder of their project crediting periods (i.e., such projects remain eligible to issue VCUs through to the end of their project crediting period without revalidation against the new requirements). The new requirements shall be adhered to at project crediting period renewal, as set out in Section 3.8.9.

3.2 AFOLU-Specific Matters

Concept

AFOLU projects may encounter unique circumstances related to project implementation, monitoring and other matters. This section sets out high-level requirements related to such AFOLU-specific matters. Note that additional AFOLU-specific requirements are also set out throughout this document.

Requirements

General

3.2.1 There are currently six AFOLU project categories eligible under the VCS Program, as defined in *Appendix 1 Eligible AFOLU Project Categories* below: afforestation, reforestation and revegetation (ARR), agricultural land management (ALM), improved forest management (IFM), reduced emissions from deforestation and degradation (REDD), avoided conversion of grasslands and shrublands (ACoGS), and wetland restoration and conservation (WRC). Further specification with respect to eligible activities which may be included within methodologies approved under the VCS Program can be found in the VCS Program document *VCS Methodology Requirements.*

3.2.2 Where projects are located within a jurisdiction covered by a jurisdictional REDD+ program, project proponents shall follow the requirements in this document and the requirements related to nested projects set out in the VCS Program document *Jurisdictional and Nested REDD+ Requirements*.

3.2.3 Where an implementation partner is acting in partnership with the project proponent, the implementation partner shall be identified in the project description. The implementation partner shall identify its roles and responsibilities with respect to the project, including but not limited to, implementation, management and monitoring of the project, over the project crediting period.

3.2.4 Activities that convert native ecosystems to generate GHG credits are not eligible under the VCS Program. Evidence shall be provided in the project description that any ARR, ALM, WRC or ACoGS project areas were not cleared of native ecosystems to create GHG credits (e.g., evidence indicating that clearing occurred due to natural disasters such as hurricanes or floods). Such proof is not required where such clearing or conversion took place at least 10 years prior to the proposed project start date. The onus is upon the project proponent to demonstrate this, failing which the project shall not be eligible.

3.2.5 Activities that drain native ecosystems or degrade hydrological functions to generate GHG credits are not eligible under the VCS Program. Evidence shall be provided in the project description that any AFOLU project area was not drained or converted to create GHG credits. Such proof is not required where such draining or conversion took place prior to 1 January 2008. The onus is upon the project proponent to demonstrate this, failing which the project shall not be eligible.

3.2.6 The project proponent shall demonstrate that project activities that lead to the intended GHG benefit have been implemented during each verification period in accordance with the project design. Where no new project activities have been implemented during a verification period, project proponents shall demonstrate that previously implemented project activities continued to be implemented during the verification period (e.g., forest patrols or improved agricultural practices of community members).

3.2.7 For all IFM, REDD, WRC and ACoGS project types, the project proponent shall, for the duration of the project, reassess the baseline every 10 years and have this validated at the same time as the subsequent verification. Baseline projections for deforestation and/or degradation, land conversion, forest management plans and wetland hydrological changes beyond a 10-year period are not likely to be realistic because rates of change in land-use and/or land or water management practices are subject to many factors that are difficult to predict over the long term, hence the need for periodic reassessment of the baseline. The following shall apply with respect to the baseline reassessment:

1) The reassessment will capture changes in the drivers and/or behavior of agents that cause the change in land use, hydrology, sediment supply and/or land or water management practices and changes in carbon stocks, all of which shall then be incorporated into revised estimates of the rates and patterns of land-use change and estimates of baseline emissions.[4]

2) The latest approved version of the methodology or its replacement shall be applied at the time of baseline reassessment.

3) The project description shall be updated at the time of baseline reassessment following the requirements set out in Section 3.8.9(2)(d).

4) Ex-ante baseline projections beyond a 10-year period are not required.

3.2.8 Where ARR, ALM, IFM or REDD project activities occur on wetlands, the project shall adhere to both the respective project category requirements and the WRC requirements, unless the expected emissions from the soil organic carbon pool or change in the soil organic carbon pool in the project scenario is deemed below *de minimis* or can be conservatively excluded as set out in the VCS Program document *VCS Methodology Requirements*, in which case the project shall not be subject to the WRC requirements.

Non-Permanence Risk

3.2.9 Projects shall prepare a non-permanence risk report in accordance with the VCS Program document *AFOLU Non-Permanence Risk Tool* at both validation and verification. In the case of projects that are not validated and verified simultaneously, having their initial risk assessments validated at the time of VCS project validation will assist VCU buyers and sellers by providing a more accurate early indication of the number of VCUs projects are expected to generate. The non-permanence risk report shall be prepared using the *VCS Non-Permanence Risk Report Template*, which may be included as an annex to the project description or monitoring report, as applicable, or provided as a stand-alone document.

---

[4] Brown, S., M. Hall, K. Andrasko, F. Ruiz, W. Marzoli, G. Guerrero, O. Masera, A. Dushku, B. DeJong, and J. Cornell, 2007. Baselines for land-use change in the tropics: application to avoided deforestation projects. Mitigation and Adaptation Strategies for Global Change, 12 (6):1001-1026.

3.2.10 Projects with tree harvesting shall demonstrate that the permanence of their carbon stock is maintained and shall put in place management systems to ensure the carbon against which VCUs are issued is not lost during a final cut with no subsequent replanting or regeneration.

3.2.11 WRC projects shall demonstrate that the permanence of their soil carbon stock will be maintained. The maximum quantity of GHG emission reductions that may be claimed by the project is limited to the difference between project and baseline scenario after a 100-year time frame, as further described in the VCS Program document *VCS Methodology Requirements*.

3.2.12 Buffer credits shall be deposited in the AFOLU pooled buffer account based upon the non-permanence risk report assessed by the validation/verification body(s). Buffer credits are not VCUs and cannot be traded. The full rules and procedures with respect to the deposit of buffer credits are set out in the VCS Program document *Registration and Issuance Process*.

3.2.13 Projects shall perform the non-permanence risk analysis at every verification event because the non-permanence risk rating may change. Projects that demonstrate their longevity, sustainability and ability to mitigate risks are eligible for release of buffer credits from the AFOLU pooled buffer account. The full rules and procedures with respect to the release of buffer credits are set out in the VCS Program document *Registration and Issuance Process*.

3.2.14 Assessment of non-permanence risk analyses may be conducted by the same validation/verification body that is conducting validation or verification of the project and at the same time as the validation or verification of the project, as applicable. The rules and requirements for the process of assessment by validation/verification body(s) are set out in Section 4 below.

3.2.15 Where an event occurs that is likely to qualify as a loss event (see the VCS Program document *Program Definitions* for definition of loss event), the project proponent shall notify Verra within 30 days of discovering the likely loss event. Where VCUs have been previously issued, a loss event report shall be prepared and submitted to the Verra registry, as follows:

1) The loss event report shall be prepared using the *VCS Loss Event Report Template*. It shall include a conservative estimate of the loss of previously verified emission reductions and removals due to losses in carbon stocks from the project, based on monitoring of the full area affected by the loss event.
2) The loss event report shall be accompanied by a loss event representation signed by the project proponent and representing that the loss estimate is true and accurate in all material respects. The template for the loss event representation is available on the Verra website.
3) The loss event report shall be submitted to the Verra registry within two years of the date of discovery of the loss event. Where a loss event report is not submitted within two years of the date of discovery of the loss event, the project shall no longer be eligible to issue VCUs.

4) The Verra registry shall put buffer credits from the AFOLU pooled buffer account on hold, in an amount equivalent to the estimated loss stated in the loss event report.

3.2.16 At the verification event subsequent to the loss event, the monitoring report shall restate the loss from the loss event and calculate the net GHG benefit for the monitoring period in accordance with the requirements set out in the methodology applied. In addition, the following applies:

1) Where the net GHG benefit of the project, compared to the baseline, for the monitoring period is negative, taking into account project emissions, removals and leakage, a reversal has occurred (see the VCS Program document *Program Definitions* for definition of reversal) and buffer credits equivalent to the reversal shall be cancelled from the AFOLU pooled buffer account, as follows:

a) Where the total reversal is less than the number of credits put on hold after the submission of the loss event report, Verra shall cancel buffer credits equivalent to the reversal. Any remaining buffer credits shall be released from their hold status (though remain in the AFOLU pooled buffer account).

b) Where the reversal is greater than stated by the loss event report, the full amount of buffer credits put on hold with respect to the submission of the loss event report shall be cancelled, and additional buffer credits from the AFOLU pooled buffer account shall be cancelled to fully account for the reversal.

2) Where the net GHG benefit for the monitoring period is positive, taking into account project emissions, removals and leakage (i.e., all losses have been made up over the monitoring period), a reversal has not occurred and buffer credits put on hold after the submission of the loss event report shall be released from their hold status (but shall remain in the AFOLU pooled buffer account).

3.2.17 At a verification event, where a reversal has occurred, the following applies:

1) Where the reversal is a catastrophic reversal (see the VCS Program document *Program Definitions* for the definition of catastrophic reversal), the following applies:

a) The baseline may be reassessed, including any relevant changes to baseline carbon stocks and, where reassessed, shall be validated at the time of the verification event subsequent to the reversal. Note that allowing baseline revisions after catastrophic reversal supersedes any methodological requirements for a fixed baseline.

b) The same geographic boundary shall be maintained. The entire project area, including areas degraded or disturbed by the catastrophic event, shall continue to be a part of project monitoring. GHG credits may not be claimed from any increased rate of sequestration from natural regeneration after a catastrophic reversal until the loss from catastrophic reversals is recovered. At the subsequent VCU issuance, GHG credits from the project equal to the additional number of buffer credits cancelled after the reversal from the AFOLU pooled buffer account on behalf of the project (i.e., above what has been previously contributed by the project) shall be deposited in the AFOLU pooled buffer account. For example, if the project previously contributed 100 buffer credits and 150 credits were cancelled from the AFOLU pooled buffer account after a reversal, the project would deposit an additional 50 buffer credits (to replenish the pool at large) in addition to the amount required by the risk analysis at the current verification event. Buffer credits deposited to replenish the pool after a reversal (50 in the example above) shall never be eligible for release back to the project, as set out in Section 3.2.12. In addition, buffer credits shall be deposited in the AFOLU pooled buffer account based upon the non-permanence risk analysis determined in accordance with the VCS Program document *AFOLU Non-Permanence Risk Tool*, as assessed by the validation/verification body(s).

2) Where the reversal is a non-catastrophic reversal (e.g., due to poor management, removal of a portion of the project area from participation in the project or over-harvesting), the following applies:

   a) No further VCUs shall be issued to the project until the deficit is remedied. The deficit is equivalent to the full amount of the reversal, including GHG emissions from losses to project and baseline carbon stocks.

   b) The same geographic boundary shall be maintained. The entire project area, including areas degraded or disturbed by the non-catastrophic event, shall continue to be a part of project monitoring. Projects may not claim GHG credits from any increased rate of sequestration from natural regeneration after a reversal until the loss from catastrophic reversals is recovered.

   Note – Notwithstanding the rules set out in (b) above, where a portion of the project area is removed from participation in the project, it is not expected that the project proponent maintain the same geographic boundary of the project, nor is it expected that the area that is removed from the project continue to be monitored.

3.2.18 As set out in the VCS Program document *Registration and Issuance Process*, where projects fail to submit a verification report within five or ten years from the previous verification event, a percentage of buffer credits is put on hold under the conservative assumption that the carbon benefits represented by buffer credits held in the AFOLU pooled buffer account may have been reversed or lost in the field. Where projects fail to submit a verification report within 15 years from the previous verification event, buffer credits are cancelled under the same assumption. The full rules and requirements with respect to the cancellation and holding of buffer credits are set out in the VCS Program document *Registration and Issuance Process*.

3.2.19 The remaining balance of buffer credits is cancelled at the end of the project crediting period.

Long-term Average GHG Benefit

3.2.20 ARR and IFM projects with harvesting activities shall not be issued GHG credits above the long-term average GHG benefit maintained by the project.

3.2.21 Where ARR or IFM projects include harvesting, the loss of carbon due to harvesting shall be included in the quantification of project emissions. The maximum number of GHG credits available to projects shall not exceed the long-term average GHG benefit. The GHG benefit of a project is the difference between the project scenario and the baseline scenario of carbon stocks stored in the selected carbon pools and adjusted for any project emissions of N_2O, CH_4 and fossil-derived CO_2, and leakage emissions. The long-term average GHG benefit shall be calculated using the following procedure:

1) Establish the period over which the long-term average GHG benefit shall be calculated, noting the following:

   a) For ARR or IFM projects undertaking even-aged management, the time period over which the long-term GHG benefit is calculated shall include at minimum one full harvest/cutting cycle, including the last harvest/cut in the cycle. For example, where a project crediting period is 40 years and has a harvest cycle of 12 years, the long-term average GHG benefit will be determined for a period of 48 years.

   b) For ARR projects under conservation easements with no intention to harvest after the project crediting period, or for selectively-cut IFM projects, the time period over which the long-term average is calculated shall be the length of the project crediting period.

2) Determine the expected total GHG benefit of the project for each year of the established time period. For each year, the total GHG benefit is the to-date GHG emission reductions or removals from the project scenario minus baseline scenario.

3) Sum the total GHG benefit of each year over the established time period.

4) Calculate the average GHG benefit of the project over the established time period.

5) Use the following equation to calculate the long-term average GHG benefit:

$$LA = \frac{\sum_{t=0}^{n} PE_t - BE_t}{n}$$

Where:

LA = The long-term average GHG benefit

PE_t = The total to-date GHG emission reductions and removals generated in the project scenario (tCO_2e). Project scenario emission reductions and removals shall also consider project emissions of CO_2, N_2O, CH_4 and leakage.

BE_t = The total to-date GHG emission reductions and removals projected for the baseline scenario (tCO_2e)

t = Year

n = Total number of years in the established time period

6) A project may claim GHG credits during each verification event until the long-term average GHG benefit is reached. Once the total number of GHG credits issued has reached this average, the project can no longer issue further GHG credits. The long-term average GHG benefit shall be calculated at each verification event, meaning the long-term average GHG benefit may change over time based on monitored data. For an example of determining the long-term average GHG benefit, see the Verra website.

   Buffer credits are withheld only when GHG credits are issued. the number of buffer credits to withhold is based on the change in carbon stocks only (not the net GHG benefit), as such the buffer credits will be based on the long-term average change in carbon stock. Use the following equation to calculate the long-term average change in carbon stock.

   Where:

$$LC = \frac{\sum_{t=0}^{n} PC_t - BC_t}{n}$$

LC = The long-term average change in carbon stock

PC_t = The total to-date carbon stock in the project scenario (tCO_2e)

BC_t = The total to-date carbon stock projected for the baseline scenario (tCO_2e)

t = Year

n = Total number of years in the established time period

Note – The VCS Program guidance document AFOLU Guidance: Example for Calculating the Long-Term Average Carbon Stock for ARR Projects with Harvesting*, available on the Verra website, provides examples for calculating the long-term average carbon stock for a variety of ARR project scenarios with harvesting. The same examples can be applied to IFM projects with harvesting.*

3.3 ODS-Specific Matters

Concept

ODS projects may encounter unique circumstances related to project implementation, avoidance of perverse incentives and other matters. This section sets out high-level requirements related to such ODS-specific matters. Note that additional ODS-specific requirements are also set out throughout this document.

Requirements

Eligible ODS

3.3.1 ODS residing in stockpiles or ODS recovered directly from any of the products set out in Section 3.3.2 are eligible. The following ODS controlled by the Montreal Protocol for which the IPCC publishes a global warming potential (100-year time horizon) are eligible:

1) Annex A, Group I
2) Annex B, Group I
3) Annex C, Group I

3.3.2 The destruction of ODS recovered from the following products are eligible:

1) Refrigeration equipment, systems or appliances;
2) Air conditioning equipment, systems or appliances;
3) Fire suppression equipment or systems; and
4) Thermal insulation foams.

3.3.3 The destruction of ODS recovered from pre-polymers, aerosol products or other products is not eligible.

ODS Origin

3.3.4 Where ODS is recovered from products that have been imported specifically for their disassembly (i.e., the products have not been collected in the host country), the following shall apply:

1) The products shall not originate from any country in which any law, statute or other regulatory framework requires the recovery and destruction of the relevant ODS from such products.
2) The project proponent shall provide documentary evidence, such as shipping manifests, bills of lading and evidence of collection of the products in the originating country, to demonstrate the origin of such products.

3.3.5 Documentary evidence shall be provided to verify the origin of all ODS destroyed by the project. Evidence may include, inter alia, shipping manifests, bills of lading, other commercial documentation, and addresses of households, commercial premises and other evidence of collection of the products. Such evidence shall be appropriate to the nature and scale of the project.

Destruction Technology

3.3.6 The project shall use a destruction technology that meets the screening criteria for destruction technologies set out in the *UNEP April 2002 Report of the Technology and Economic Assessment Panel (TEAP), Volume 3b, Report of the Task Force on Destruction Technologies*[5], as may be updated from time to time. The report sets out, inter alia, requirements for Destruction and Removal Efficiency (DRE).

3.3.7 For concentrated sources (e.g., refrigerants), projects shall use a destruction technology with a minimum verified DRE of 99.99 percent.

3.3.8 For dilute sources (i.e., foams), projects shall use a destruction technology with a minimum verified DRE of 95 percent. In addition, a minimum Recovery and Destruction Efficiency (RDE) of 85 percent shall be achieved. RDE describes the proportion of blowing agent (ODS) remaining in the foam immediately prior to decommissioning that is recovered in the overall end-of-life management step, including ultimate destruction. For a full specification of RDE, see the *UNEP May 2005 Report of the Technology and Economic Assessment Panel, Volume 3, Report of the Task Force on Foam End-of-Life Issues*.[6]

Note – The May 2005 TEAP report *provides a theoretical model for calculating RDE and methodology elements will need to specify a practical approach for determining RDE, such as those provided in* RAL GZ 728 (Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment, 2007)*, the* WEEE Forum standard (Requirements for the Collection, Transportation, Storage, Handling and Treatment of Household Cooling and Freezing Appliances containing CFC, HCFC or HFC, 2007) *or another appropriate approach.*

3.4 Project Documentation

Concept

In order to complete the project validation process, project proponents shall prepare a project description, which describes the project's GHG emission reduction or removal activities. In order to complete the project verification process, project proponents shall prepare a monitoring report, which describes the data and information related to the monitoring of GHG emission reductions or removals.

[5] UNEP, 2002, UNEP April 2002 Report of the Technology and Economic Assessment Panel, Volume 3b, Report of the Task Force on Destruction Technologies. (http://ozone.unep.org/teap/Reports/Other_Task_Force/TEAP02V3b.pdf)
[6] UNEP, 2005, UNEP May 2005 Report of the Technology and Economic Assessment Panel, Volume 3, Report of the Task Force on Foam End-of-Life Issues. (http://ozone.unep.org/teap/Reports/TEAP_Reports/TEAP-May-2005-Vol-2-Forms-End-of-Life.pdf)

Requirements

Project Description

3.4.1 The project proponent shall use the *VCS Project Description Template*, an approved combined project description template available on the Verra website or an approved GHG program project description template where the project is registered under an approved GHG program, as appropriate. The project proponent shall adhere to all instructional text within the template.

3.4.2 All information in the project description shall be presumed to be available for public review, though commercially sensitive information may be protected, as set out in the VCS Program document *Registration and Issuance Process*, where it can be demonstrated that such information is commercially sensitive. The validation/verification body shall check that any information designated by the project proponent as commercially sensitive meets the VCS Program definition of commercially sensitive information. Information in the project description related to the determination of the baseline scenario, demonstration of additionality, and estimation and monitoring of GHG emission reductions and removals shall not be considered to be commercially sensitive and shall be provided in the public versions of the project description.

Monitoring Report

3.4.3 The project proponent shall use the *VCS Monitoring Report Template* or an approved combined monitoring report template available on the Verra website, as appropriate, and adhere to all instructional text within the template.

3.4.4 The monitoring period of the monitoring report shall be a distinct time period that does not overlap with previous monitoring periods. Projects shall not be eligible for crediting of GHG emission reductions generated in previous monitoring periods. In addition, monitoring periods shall be contiguous with no time gaps between monitoring periods.

3.4.5 Where a monitoring report and associated verification report divide a monitoring period into vintages, separate VCU issuance records in accordance with vintage periods may be issued, as set out in the VCS Program document *Registration and Issuance Process*.

3.5 Project Design

Concept

The VCS Program allows for different approaches to project design. Projects may be designed as a single installation of an activity. Projects may also be designed to include more than one project activity, such as an AFOLU project that includes REDD and ALM components. In addition, projects may be designed to include more than one project activity instance, such as a clean cookstove project that distributes cookstoves to a number of different communities. Finally, projects may be designed as grouped projects, which are projects structured to allow the expansion of a project activity subsequent to project validation.

Note – Project activity and project activity instance both have the specific meanings that are set out in the VCS Program document Program Definitions*.*

Requirements

Multiple Project Activities

3.5.1 Projects may include multiple project activities where the methodology applied to the project allows more than one project activity and/or where projects apply more than one methodology.

3.5.2 Where more than one methodology has been applied to a project with multiple project activities, the following applies:

1) Each project activity shall be specified separately in the project description, referencing the relevant methodology.

2) All criteria and procedures set out in the applied methodologies in relation to applicability conditions, demonstration of additionality, determination of baseline scenario and GHG emission reduction and removal quantification shall be applied separately to each project activity, noting the following:

   a) A single set of criteria and procedures for the demonstration of additionality may be applied where the applied methodologies reference the same additionality tool and/or procedures, and where separate demonstration of additionality for each project activity is not practicable.

      For example, separate demonstration of additionality may not be practicable in project activities that are implemented at a single facility and therefore represent a single investment. The onus is upon the project proponent to demonstrate to the validation/verification body that separate demonstration of additionality is not practicable, failing which separate demonstration of additionality shall be provided. Where a methodology specifies requirements for demonstrating additionality in addition to those specified in the referenced additionality tool and/or procedures, such requirements shall be adhered to.

   b) The criteria and procedures for identifying the baseline scenario may be combined where the relevant methodologies or the referenced additionality tool and/or procedures specify criteria and procedures for combining baseline scenarios.

3) The criteria and procedures relating to all other aspects of the methodologies may be combined.

4) Where AFOLU projects are required to undertake non-permanence risk assessment and buffer withholding determination, this shall be done separately for each project activity.

Note – Where a single methodology is applicable to more than one project activity and where the methodology does not provide clear procedures for the application of more than one project activity, the above requirements shall be adhered to.

3.5.3 AFOLU projects that include multiple project activities shall comply with the respective project requirements of each included AFOLU category.

For example, projects that combine agroforestry or enrichment planting with community forestry in a single project, where farmers integrate these activities within a single landscape, shall follow an ARR methodology for planting activities and an IFM methodology for community forestry activities (except where the activities have been combined in a single methodology). Similarly, projects that integrate avoided grassland and shrubland conversion and improved grazing practices shall follow an ACoGS methodology for grassland or shrubland protection activities and an ALM methodology for improved grazing practices (except where both activities have been combined into a single methodology). Avoided conversion projects in landscapes that contain both forest and non-forest shall follow a REDD methodology for forested lands and an ACoGS methodology for non-forested lands. For each activity covered by a different methodology, the geographic extent of the area to which the methodology is applied shall be clearly delineated.

Multiple Instances of Project Activities

3.5.4 Inclusion of further project activity instances subsequent to initial validation of a non-grouped project is not permitted (see Sections 3.5.8 – 3.5.16 for information on grouped projects).

3.5.5 The baseline determination and additionality demonstration for all project activity instances shall be combined (e.g., multiple wind turbines shall be assessed in combination rather than individually).

3.5.6 Where a project includes multiple project activity instances from multiple project activities, the project activity instances from each project activity shall be assessed in accordance with Sections 3.5.1 – 3.5.3.

3.5.7 Non-grouped projects with multiple project activity instances shall not exceed any capacity limits to which a project activity is subject.

Grouped Projects

Baseline Scenario and Additionality

3.5.8 Grouped projects shall have one or more clearly defined geographic areas within which project activity instances may be developed. Such geographic areas shall be defined using geodetic polygons as set out in Section 3.10 below.

3.5.9 Determination of baseline scenario and demonstration of additionality are based upon the initial project activity instances. The initial project activity instances are those that are included in the project description at validation and shall include all project activity instances currently implemented on the issue date of the project description. The initial project activity instances may also include any planned instances of the project activity that have been planned and developed to a sufficient level of detail to enable their assessment at validation. Geographic areas with no initial project activity instances shall not be included in the project unless it can be demonstrated that such areas are subject to the same (or at least as conservative) baseline scenario and rationale for the demonstration of additionality as a geographic area that does include initial project activity instances.

3.5.10 As with non-grouped projects, grouped projects may incorporate multiple project activities (see Section 3.5.1 – 3.5.3 for more information on multiple project activities). Where a grouped project includes multiple project activities, the project description shall designate which project activities may occur in each geographic area.

3.5.11 The baseline scenario for a project activity shall be determined for each designated geographic area, in accordance with the methodology applied to the project. Where a single baseline scenario cannot be determined for a project activity over the entirety of a geographic area, the geographic area shall be redefined or divided such that a single baseline scenario can be determined for the revised geographic area or areas.

3.5.12 The additionality of the initial project activity instances shall be demonstrated for each designated geographic area, in accordance with the methodology applied to the project. Where the additionality of the initial project activity instances within a particular geographic area cannot be demonstrated for the entirety of that geographic area, the geographic area shall be redefined or divided such that the additionality of the instances occurring in the revised geographic area or areas can be demonstrated.

3.5.13 Where factors relevant to the determination of the baseline scenario or demonstration of additionality require assessment across a given area, the area shall be, at a minimum, the grouped project geographic area. Examples of such factors include, inter alia, common practice; laws, statutes, regulatory frameworks or policies relevant to demonstration of regulatory surplus; determination of regional grid emission factors; and historical deforestation and degradation rates.

Capacity Limits

3.5.14 Where a capacity limit applies to a project activity included in the project, no project activity instance shall exceed such limit. Further, no single cluster of project activity instances shall exceed the capacity limit, determined as follows:

1) Each project activity instance that exceeds one percent of the capacity limit shall be identified.
2) Such instances shall be divided into clusters, whereby each cluster is comprised of any system of instances such that each instance is within one kilometer of at least one other instance in the cluster. Instances that are not within one kilometer of any other instance shall not be assigned to clusters.

3) None of the clusters shall exceed the capacity limit and no further project activity instances shall be added to the project that would cause any of the clusters to exceed the capacity limit.

Eligibility Criteria

3.5.15 Grouped projects shall include one or more sets of eligibility criteria for the inclusion of new project activity instances. At least one set of eligibility criteria for the inclusion of new project activity instances shall be provided for each combination of project activity and geographic area specified in the project description. A set of eligibility criteria shall ensure that new project activity instances:

1) Meet the applicability conditions set out in the methodology applied to the project.
2) Use the technologies or measures specified in the project description.
3) Apply the technologies or measures in the same manner as specified in the project description.
4) Are subject to the baseline scenario determined in the project description for the specified project activity and geographic area.
5) Have characteristics with respect to additionality that are consistent with the initial instances for the specified project activity and geographic area. For example, the new project activity instances have financial, technical and/or other parameters (such as the size/scale of the instances) consistent with the initial instances, or face the same investment, technological and/or other barriers as the initial instances.

Note – Where grouped projects include multiple baseline scenarios or demonstrations of additionality, such projects will require at least one set of eligibility criteria for each combination of baseline scenario and demonstration of additionality specified in the project description.

Inclusion of New Project Activity Instances

3.5.16 Grouped projects provide for the inclusion of new project activity instances subsequent to the initial validation of the project. New project activity instances shall:

1) Occur within one of the designated geographic areas specified in the project description.
2) Comply with at least one complete set of eligibility criteria for the inclusion of new project activity instances. Partial compliance with multiple sets of eligibility criteria is insufficient.
3) Be included in the monitoring report with sufficient technical, financial, geographic and other relevant information to demonstrate compliance with the applicable set of eligibility criteria and enable sampling by the validation/verification body.

4) Be validated at the time of verification against the applicable set of eligibility criteria.

5) Have evidence of project ownership, in respect of each project activity instance, held by the project proponent from the respective start date of each project activity instance (i.e., the date upon which the project activity instance began reducing or removing GHG emissions).

6) Have a start date that is the same as or later than the grouped project start date.

7) Be eligible for crediting from the start date of the instance through to the end of the project crediting period (only). Note that where a new project activity instance starts in a previous verification period, no credit may be claimed for GHG emission reductions or removals generated during a previous verification period (as set out in Section 3.4.4) and new instances are eligible for crediting from the start of the next verification period.

Where inclusion of a new project activity instance necessitates the addition of a new project proponent to the project, such instances shall be included in the grouped project within two years of the project activity instance start date or, where the project activity is an AFOLU activity, within five years of the project activity instance start date. The procedure for adding new project proponents is set out in the VCS Program document *Registration and Issuance Process*.

AFOLU Projects

3.5.17 AFOLU non-permanence risk analyses, where required, shall be assessed for each geographic area specified in the project description (for requirements related to geographic areas of grouped projects see the VCS Standard). Where risks are relevant to only a portion of each geographic area, the geographic area shall be further divided such that a single total risk rating can be determined for each geographic area. Where a project is divided into more than one geographic area for the purpose of risk analysis, the project's monitoring and verification reports shall list the total risk rating for each area and the corresponding net change in the project's carbon stocks in the same area, and the risk rating for each area applies only to the GHG emissions reductions generated by project activity instances within the area.

3.5.18 Activity-shifting, market leakage and ecological leakage assessments, where required, shall be undertaken as set out in Section 3.14.5 – 3.14.15, and the methodology applied, on the initial group of instances of each project activity and reassessed where new instances of the project activity are included in the project.

Project Description for Grouped Projects

3.5.19 A grouped project shall be described in a single project description, which shall contain the following (in addition to the content required for non-grouped projects):

1) A delineation of the geographic area(s) within which all project activity instances shall occur. Such area(s) shall be defined by geodetic polygons as set out in Section 3.10 below.

2) One or more determinations of the baseline for the project activity in accordance with the requirements of the methodology applied to the project.

3) One or more demonstrations of additionality for the project activity in accordance with the requirements of the methodology applied to the project.

4) One or more sets of eligibility criteria for the inclusion of new project activity instances at subsequent verification events.

5) A description of the central GHG information system and controls associated with the project and its monitoring.

Note – Where the project includes more than one project activity, the above requirements shall be addressed separately for each project activity, except for the delineation of geographic areas and the description of the central GHG information system and controls, which shall be addressed for the project as a whole.

3.6 Ownership

Concept

Project and jurisdictional proponents shall demonstrate that they have the legal right to control and operate project or program activities.

Requirements

3.6.1 The project description shall be accompanied by one or more of the following types of evidence establishing project ownership accorded to the project proponent(s), or program ownership accorded to the jurisdictional proponent(s), as the case may be (see the VCS Program document *Program Definitions* for definitions of project ownership and program ownership). To aid the readability of this section, the term project ownership is used below, but should be substituted by the term program ownership, as appropriate:

1) Project ownership arising or granted under statute, regulation or decree by a competent authority.

2) Project ownership arising under law.

3) Project ownership arising by virtue of a statutory, property or contractual right in the plant, equipment or process that generates GHG emission reductions and/or removals (where the project proponent has not been divested of such project ownership).

4) Project ownership arising by virtue of a statutory, property or contractual right in the land, vegetation or conservational or management process that generates GHG emission reductions and/or removals (where the project proponent has not been divested of such project ownership).

5) An enforceable and irrevocable agreement with the holder of the statutory, property or contractual right in the plant, equipment or process that generates GHG emission reductions and/or removals which vests project ownership in the project proponent.

6) An enforceable and irrevocable agreement with the holder of the statutory, property or contractual right in the land, vegetation or conservational or management process that generates GHG emission reductions or removals which vests project ownership in the project proponent.

7) Project ownership arising from the implementation[7] or enforcement of laws, statutes or regulatory frameworks that require activities be undertaken or incentivize activities that generate GHG emission reductions or removals.

3.7 Project Start Date

Concept

The project start date of a non-AFOLU project is the date on which the project began generating GHG emission reductions or removals. The project start date of an AFOLU project is the date on which activities that led to the generation of GHG emission reductions or removals are implemented (e.g., preparing land for seeding, planting, changing agricultural or forestry practices, rewetting, restoring hydrological functions, or implementing management or protection plans). Projects shall complete validation within specific timeframes from the project start date.

Requirements

Non-AFOLU Projects

3.7.1 Non-AFOLU projects shall complete validation within two years of the project start date. Additional time is granted for non-AFOLU projects to complete validation where they are applying a new VCS methodology. Specifically, projects using a new VCS methodology and completing validation within two years of the approval of the methodology by Verra may complete validation within four years of the project start date.

3.7.2 Note that new VCS methodology in this context refers to both newly issued VCS methodologies and newly issued VCS revisions to approved GHG program methodologies. The grace period does not apply in relation to any subsequent versions of such new methodologies and new methodology revisions that may be issued.

AFOLU Projects

3.7.3 AFOLU projects shall complete validation within five years of the project start date.

[7] Implemented in the context of this paragraph means enacted or introduced, consistent with use of the term under the CDM rules on so-called Type E+ and Type E- policies.

ODS Projects

3.7.4 ODS projects shall comply with at least one of the following in relation to project start date:

1) The project start date shall not be before the Montreal Protocol production phase-out deadline (except for critical/essential uses) for the relevant ODS as it applies to the host country and/or any country from which ODS destroyed by the project is imported (as applicable); or

2) The project start date shall not be before the date the host country and/or any country from which ODS destroyed by the project is imported (as applicable) implements the production phase-out, or consumption phase-out where such country does not produce the relevant ODS, of the relevant ODS (critical/essential uses exempted). Such phase-outs shall be implemented in combination with an import ban on the relevant ODS (critical/essential uses exempted). This project start date requirement accounts for countries that phase-out the relevant ODS in advance of their Montreal Protocol production phase-out deadline.

Note – The project can destroy ODS that has not been phased out under either of the two options in above (e.g., if one ODS has contaminated another), but it shall receive no credit for the destruction of such ODS. Note also that the relevant production phase-out deadlines are those of the individual substances and not the substance groups.

Note – The relevant production phase-out deadlines are those of the individual substances and not the substance groups.

3.7.5 Where the project imports ODS, it shall provide documentary evidence, such as shipping manifests and bills of lading, to demonstrate that the ODS originates from a country meeting with the above.

Standardized Methods

3.7.6 Notwithstanding the requirements set out in Sections 3.7.1 – 3.7.5 above, projects applying a standardized method for determining additionality shall initiate the project pipeline listing process set out in the VCS Program document *Registration and Issuance Process* within the project validation timelines set out above. Validation may be completed any time thereafter.

For example, a non-AFOLU project applying a standardized method for determining additionality shall initiate the project pipeline listing process within two years of the project start date, and may complete validation any time thereafter.

Projects Registered with Other GHG Programs

3.7.7 For projects registered under an approved GHG program which are seeking registration with the VCS Program, further specification with respect to the validation deadline is set out in Sections 3.19.5 and 3.19.6.

3.8 Project Crediting Period

Concept

The project crediting period is the time period for which GHG emission reductions or removals generated by the project are eligible for issuance as VCUs. Project crediting periods shall be renewed periodically in order to ensure that changes to a project's baseline scenario and regulatory surplus are taken into consideration throughout the lifetime of the project.

Requirements

Project Crediting Period Length

Non-AFOLU Projects

3.8.1 For non-AFOLU projects, the project crediting period shall be either seven years, twice renewable for a total of 21 years, or ten years fixed.

AFOLU Projects

3.8.2 For ALM projects focusing exclusively on reducing N_2O, CH_4 and/or fossil-derived CO_2 emissions, the project crediting period shall be either seven years, twice renewable for a total of 21 years, or ten years fixed.

3.8.3 For all other AFOLU projects other than such ALM projects described above, the project crediting period shall be a minimum of 20 years up to a maximum of 100 years, which may be renewed at most four times with a total project crediting period not to exceed 100 years.

3.8.4 AFOLU projects shall have a credible and robust plan for managing and implementing the project over the project crediting period.

3.8.5 For ARR or IFM extension of rotation age or low-productive to high-productive projects with harvesting, the length of the project crediting period shall be set to include at least one complete harvest/cutting cycle. In the case of selectively cut IFM projects, where trees are individually selected for harvest, the harvest/cutting cycle is the allowable re-entry period into the harvest area as determined by legal and regulatory requirements, and/or common practice.

3.8.6 The earliest project crediting period start date for AFOLU projects shall be 1 January 2002.

Projects Registered under Other GHG Programs

3.8.7 Projects registered under other GHG programs are not eligible for VCU issuance beyond the end of the total project crediting period under those programs. For example, a CDM project with a seven year twice renewable project crediting period is not eligible for VCU issuance beyond the end of those 21 years. Where projects have been registered under more than one other GHG program, they are not eligible for VCU issuance after the date that is the earliest end date of all applicable project crediting periods.

Note – Since the total project crediting period under the Joint Implementation (JI) program is not defined ex-ante, the total project crediting period shall be deemed as 21 years for non-AFOLU JI projects and as 60 years for AFOLU JI projects[8].

Renewal of Project Crediting Period

3.8.8 Where projects fail to renew the project crediting period, the project crediting period shall end and the project shall be ineligible for further crediting.

3.8.9 The following shall apply with respect to the renewal of the project crediting period under the VCS Program:

1) A full reassessment of additionality is not required when renewing the project crediting period. However, regulatory surplus shall be demonstrated in accordance with the requirements set out in the VCS Program rules and the project description shall be updated accordingly.
2) The validity of the original baseline scenario shall be demonstrated, or where invalid a new baseline scenario shall be determined, when renewing the project crediting period, as follows:
    a) The validity of the original baseline scenario shall be assessed. Such assessment shall include an evaluation of the impact of new relevant national and/or sectoral policies and circumstances on the validity of the baseline scenario.
    b) Where it is determined that the original baseline scenario is still valid, the GHG emissions associated with the original baseline scenario shall be reassessed using the latest version of the *CDM Tool to assess the validity of the original/current baseline and to update the baseline at the renewal of a crediting period*.
    c) Where it is determined that the original baseline scenario is no longer valid, the current baseline scenario shall be established in accordance with the VCS Program rules.
    d) The project description, containing updated information with respect to the baseline, the estimated GHG emission reductions or removals and the monitoring plan, shall be submitted for validation. Such updates shall be based upon the latest approved version of the methodology or its replacement. Where the project does not meet the requirements of the latest approved version of the methodology or its replacement, the project proponent shall select another applicable approved methodology (which may be a new methodology or methodology revision it has had approved via the methodology approval process), or shall apply a methodology deviation (where a methodology deviation is appropriate). Failing this, the project shall not be eligible for renewal of its project crediting period.

[8] Consistent with the UNFCCC's other project-based mechanism, CDM.

3) The updated project description shall be validated in accordance with the VCS Program rules. In addition, the project shall be validated against the (current) scope of the VCS. Such validation report shall be issued after the end of the (previous) project crediting period but within two years after the end of the (previous) project crediting period.

Additional time is granted for projects to complete such validation where they are switching to a new VCS methodology (*new VCS methodology* in this context has the same meaning as set out in Section 3.7.1) when renewing the project crediting period. Specifically, projects switching to a new VCS methodology and completing such validation within one year of the approval of the methodology by Verra may complete such validation within three years of the end of the (previous) project crediting period.

3.9 Project Scale

Concept

Projects are categorized by size according to their estimated average annual GHG emission reductions or removals. Materiality thresholds differ for projects of different sizes.

Requirements

3.9.1 Project size categorizations are as follows:

1) *Projects*: Less than or equal to 300,000 tonnes of CO_2e per year.
2) *Large projects*: Greater than 300,000 tonnes of CO_2e per year.

3.9.2 Materiality requirements for validation and verification differ according to project size, as set out in Section 4.1.8 below.

3.9.3 Where applying a methodology with scale and/or capacity limits, it shall be demonstrated that the project is not a fragmented part of a larger project or activity that would otherwise exceed such limits. The project shall be considered a fragmented part of a larger project if within one kilometer of the project boundary there exists another project where:

1) The project proponents for both projects are the same.
2) The sectoral scope and project activity for both projects are the same.
3) The other project has been registered under the VCS Program or another GHG program within the previous two years.

3.10 Project Location

Concept

The project location shall be provided in order to accurately describe project characteristics and to demonstrate a project's conformance with other requirements, such as project ownership and regulatory compliance.

Requirements

General

3.10.1 Project location shall be specified in the project description as follows:

1) Project location for non-AFOLU projects shall be specified by a single geodetic coordinate.
2) Where there are multiple project activity instances (see Sections 3.5.4 – 3.5.7 for more information on multiple project activities), project location shall be specified according to the following:
    a) Where it is reasonable to do so, a geodetic coordinate shall be provided for each instance and provided in a KML file; or
    b) Where there are a large number project activity instances (e.g., cookstoves or energy efficient light bulbs), at least one geodetic coordinate shall be provided, together with sufficient additional geographic information (with respect to the location of the instances) to enable sampling by the validation/verification body.
3) Project location for grouped projects shall be specified using geodetic polygons to delineate the project's geographic area or areas (see Section 3.5.8 for further information on geographic areas for grouped projects) and provided in a KML file.

AFOLU Projects

3.10.2 The project location for AFOLU projects shall be specified in the project description in terms of its project area. The spatial extent of the project shall be clearly specified to facilitate accurate monitoring, reporting and verification of GHG emission reductions and removals and to demonstrate that the project meets the eligibility criteria of the relevant project category. The description of the project location shall include the following information:

1) Name of the project area (e.g., compartment number, allotment number and local name).
2) Maps of the project area.
3) Geodetic polygons that delineate the geographic area of each AFOLU project activity, provided in a KML file.
4) Total size of the project area.
5) Details of ownership.

Where the project area is comprised of multiple polygons (parcels), the project location details of each polygon/parcel shall be included in the project description.

3.10.3 The project proponent shall demonstrate control over the entire project area with documentary evidence establishing project ownership, noting the following:

1) For non-grouped projects, the entire project area shall be under the control of the project proponent at the time of validation, or shall come to be under the control of the project proponent by the first verification event.

2) Where the project proponent does not yet have control over the entire area at validation, the entire project area (that shall be specified in accordance with Section 3.10.2) is to be validated as if it were under control and the project is ready to be implemented.

3) Where less than 80 percent of the total proposed area of the project is under current control at validation, the following applies:

   a) It shall be demonstrated that the result of the additionality test is applicable to the project area at the time of validation and to the entire project area to come under control in the future.

   b) The monitoring plan shall be designed such that it is flexible enough to deal with changes in the size of the project.

   c) The project shall be verified within five years of validation. At verification, the size of the project becomes fixed.

   d) Where the area fixed at verification is smaller than intended at validation, areas that at verification have not come under control of the project shall be considered in the leakage management, mitigation and accounting. This requires the selection, at validation, of a methodology with appropriate leakage methods that may be used in the event the entire area does not come under control of the project.

3.10.4 WRC projects shall demonstrate that:

1) There is no hydrological connectivity to adjacent (non-project) areas; or

2) It is not possible for hydrologically connected areas to have a negative impact on the hydrology within the project area that could cause a significant increase in GHG emissions; or

3) Where projects are hydrologically connected to adjacent areas that may have a negative impact on the hydrology within the project area, projects shall demonstrate that such impacts will not result in a significant increase in GHG emissions, as follows:

   a) Peatland projects shall establish a buffer zone to ensure that potential negative impacts to the hydrology in the project area, such as causing the water table in the project area to drop or otherwise negatively impacting the hydrology, are mitigated. The buffer zone may be inside or outside the geographic boundary of the project area.

Where it is outside of the project area, the buffer zone shall be adjacent to the project geographic boundary and binding water management agreements with land holders in the buffer zone shall be in place by the time of the first verification. The size and shape of the buffer zone shall be sufficient to avoid such negative impacts on the project area, which may be demonstrated through peer reviewed literature or expert judgment.

b) All other wetland projects shall establish a buffer zone as set out in Section 3.10.4(3)(a) above, or implement project activities or establish a mitigation plan to ensure that impacts to the hydrology (e.g., interrupted water or sediment supply) do not result in a significant increase in GHG emissions. Emphasis shall be placed on hydrological connectivity that is immediately adjacent to the project area. Coastal wetlands shall consider hydrological connectivity originating from adjacent lands and shall follow the applied methodology with respect to oceanic impacts.

Where a project activity to mitigate impacts from hydrological connectivity causes an increase in GHG emissions in the project area or buffer zone, such emissions shall be included in GHG accounting where above *de minimis.*

3.11 Project Boundary

Concept

The project boundary includes the GHG sources, sinks and reservoirs that are relevant to the project and baseline scenarios. The relevant GHG sources, sinks and reservoirs that shall be included or excluded, or are optional, are set out in the methodology(s) applied by the project.

Requirements

3.11.1 The project boundary shall be described (using diagrams, as required) and GHG sources, sinks and reservoirs shall be identified and assessed in accordance with the methodology applied to the project. The project shall justify not selecting any relevant GHG source, sink and reservoir.

3.12 Baseline Scenario

Concept

The baseline scenario represents the activities and GHG emissions that would occur in the absence of the project activity. The baseline scenario shall be accurately determined so that an accurate comparison can be made between the GHG emissions that would have occurred under the baseline scenario and the GHG emission reductions and/or removals that were achieved by project activities.

Requirements

3.12.1 The baseline scenario for the project shall be determined in accordance with the requirements set out in the methodology applied to the project, and the choice of baseline scenario shall be justified.

3.12.2 Equivalence in type and level of activity of products or services provided by the project and the baseline scenario shall be demonstrated and, where appropriate, any significant differences between the project and the baseline scenario shall be explained.

3.12.3 In developing the baseline scenario, assumptions, values and procedures shall be selected that help ensure that net GHG emission reductions and removals are not overestimated.

3.13 Additionality

Concept

A project activity is additional if it can be demonstrated that the activity results in emission reductions or removals that are in excess of what would be achieved under a “business as usual” scenario and the activity would not have occurred in the absence of the incentive provided by the carbon markets. Additionality is an important characteristic of GHG credits, including VCUs, because it indicates that they represent a net environmental benefit and a real reduction of GHG emissions, and can thus be used to offset emissions.

Requirements

3.13.1 Additionality shall be demonstrated and assessed in accordance with the requirements set out in the methodology applied to the project, noting the following exceptions:

1) Where a VCS module using an activity method (see the *VCS Methodology Requirements* for further information on activity methods) is applicable to the project, additionality may be demonstrated using the module in substitution of the additionality requirements set out in the methodology.

   For example, if a module uses an activity method (i.e., positive list) to deem a project activity additional, the project proponent does not have to follow the additionality requirements in the methodology applied to the project and may instead demonstrate additionality by demonstrating that it meets the applicability conditions and any other criteria of the activity method.

   Note that only modules may be used in this way. Where a methodology contains an activity method for additionality, the additionality procedures may not be applied in conjunction with a different methodology.

2) Where the applied methodology was developed under an approved GHG program and uses an activity method or other simplified procedure for demonstrating additionality, the project proponent shall demonstrate to the validation/verification body that the simplified procedure is appropriate to apply to the project considering the project characteristics, including the context in which the project activity takes place. Failing this demonstration, the project proponent shall not use the simplified procedure for demonstrating additionality, and shall instead use an appropriate additionality assessment method in substitution.

For example, where a project is developed in the United States and applies a CDM methodology which uses a simplified procedure for demonstrating additionality, the project proponent shall demonstrate to the validation/verification body that the simplified procedure is appropriate to apply given that the simplified procedure was originally developed for application in a developing country context.

ODS Projects

3.13.2 The project shall not be mandated by any law, statute or other regulatory framework applying in the host country that was implemented on or before 11 November 2001, or the compliance rate of any such law, statute or other regulatory framework during (part of) the project crediting period shall be below 50 percent.

3.14 Quantification of GHG Emission Reductions and Removals

Concept

GHG emission reductions and removals achieved by projects are the basis for the volume of VCUs that can be issued. GHG emissions reductions and removals shall be quantified in accordance with the applied methodology(s).

Requirements

3.14.1 GHG emission and/or removals shall be estimated for each GHG source, sink and/or reservoir relevant for the project (including leakage) and the baseline scenarios.

3.14.2 The net GHG emission reductions and removals generated by the project shall be quantified.

3.14.3 Metric tonnes shall be used as the unit of measure and the quantity of each type of GHG shall be converted to tonnes of CO_2e.

3.14.4 The six Kyoto Protocol greenhouse gases and ozone-depleting substances shall be converted using 100-year global warming potentials derived from the IPCC's *Fourth Assessment Report*.

AFOLU Projects

3.14.5 The potential for leakage shall be identified for AFOLU projects, and projects are encouraged to include leakage management zones as part of the overall project design. Leakage management zones can minimize the displacement of land use activities to areas outside the project area by maintaining the production of goods and services, such as agricultural products, within areas under the control of the project proponent or by addressing the socio-economic factors that drive land use change. Activities to mitigate ecological leakage in WRC projects may include the establishment of a leakage management zone inside the project boundary.

3.14.6 Activities to mitigate leakage and sustainably reduce deforestation and/or forest or wetland degradation are encouraged and may include the establishment of agricultural intensification practices on non-wetlands, lengthened fallow periods, agroforestry and fast-growing woodlots on degraded land, forest under-story farming, ecotourism and other sustainable livelihood activities, sustainable production of non-timber forest products, and/or sustainable aquaculture. Leakage mitigation activities may be supplemented by providing economic opportunities for local communities that encourage forest or wetland protection, such as employment as protected-area guards, training in sustainable forest use or assisting communities in securing markets for sustainable forest products, such as rattan, vanilla, cacao, coffee and natural medicines, or wetland products, such as rattan, fish and shellfish.

3.14.7 Where projects are required to account for leakage, such leakage evaluation shall be documented in the appropriate section of the project description and/or monitoring report, as applicable.

3.14.8 Market leakage assessments shall occur per the requirements set out in the applied methodology(s) at validation and verification.

3.14.9 Notwithstanding the requirement set out in Section 3.14.8 above, IFM projects may apply the appropriate market leakage discount factor identified in Table 2 to the net change in carbon stock associated with the activity that reduces timber harvest to determine market leakage.

Table 2: Market Leakage Discount Factors

Project Action	Leakage Risk	Market Leakage Discount Factor
IFM activity with no effect or minimal effect on total timber harvest volumes (e.g., RIL with less than 25% reduction)	None	0%
IFM activity that leads to a shift in harvests across time periods but minimal change in total timber harvest over time (e.g., ERA with rotation extension of 5-10 years)	Low	10%
IFM activity that substantially reduces harvest levels permanently (e.g., RIL activity that reduces timber harvest across the project area, or project that halts logging by at least 25%)	Moderate to High	Conditional upon where timber harvest is likely to be shifted, as follows: • Where the ratio of merchantable biomass to total biomass is higher within the area to which harvesting is displaced compared to the project area, 20% • Where the ratio of merchantable biomass to total biomass is similar within the area to which harvesting is displaced compared to the project area, 40% • Where the ratio of merchantable biomass to total biomass is lower within the area to which harvesting is displaced compared to the project area, 70% • Where the leakage is out of country, 0%

3.14.10 Leakage occurring outside the host country (international leakage) does not need to be quantified.

3.14.11 Projects shall not account for positive leakage (i.e., where GHG emissions decrease or removals increase outside the project area due to project activities).

3.14.12 Where the applied methodology(s) does not set out a method to determine whether leakage is *de minimis*, projects may use the process set out in the VCS Program document *VCS Methodology Requirements* or the CDM A/R methodological *Tool for testing significance of GHG Emissions in A/R CDM Project Activities.*

3.14.13 Projects may apply optional default leakage deductions at validation under the following circumstances:

1) Where the applied methodology requires the quantification of activity-shifting leakage, projects may apply the optional default activity-shifting leakage deduction of 15 percent to the gross GHG emission reductions and/or removals.

2) Where the applied methodology requires the quantification of market leakage and where a) timber is a significant[9] commodity that is driving deforestation and/or degradation in the baseline scenario and b) the project country is not a leading producer or exporter of forest products as defined by the United Nations Food and Agriculture Organization (FAO)[10], projects may apply the optional default market leakage deduction of 10 percent to the gross GHG emission reductions and/or removals.

3.14.14 Projects shall monitor and calculate leakage, per the applied methodology, for all ex-post accounting (i.e., at each verification), and leakage shall be deducted from the total GHG emission reductions and/or removals of the project. Any leakage shall be subtracted from the number of GHG emission reductions and removals eligible to be issued as VCUs.

3.14.15 The number of GHG credits issued to projects is determined by subtracting out the buffer credits from the net GHG emission reductions or removals (including leakage) associated with the project. The buffer credits are calculated by multiplying the non-permanence risk rating (as determined by the *AFOLU Non-Permanence Risk Tool*) times the change in carbon stocks only. The full rules and procedures with respect to assignment of buffer credits are set out in the VCS Program document *Registration and Issuance Process*.

3.15 Monitoring

Concept

The impacts of project activities on relevant emission sources, sinks and reservoirs shall be monitored in order to determine the net GHG benefit. Projects shall be monitored in accordance with the applied methodology(s).

---

[9] Defined as contributing to 20 percent or more of baseline emissions.

[10] The FAO releases annual listings of countries that are Major Producers of Forest Products (http://www.fao.org/forestry/statistics/80938@180723/en/) and Major Exporters of Forest Products (http://www.fao.org/forestry/statistics/80938@180724/en/).

Requirements

Data and Parameters

3.15.1 Data and parameters used for the quantification of GHG emission reductions and/or removals shall be provided in accordance with the methodology.

3.15.2 Quality management procedures to manage data and information shall be applied and established. Where applicable, procedures to account for uncertainty in data and parameters shall be applied in accordance with the requirements set out in the methodology.

Monitoring Plan

3.15.3 The project proponent shall establish a GHG information system for obtaining, recording, compiling and analyzing data and information important for quantifying and reporting GHG emissions and/or removals relevant for the project (including leakage) and baseline scenario.

3.15.4 A monitoring plan for the project that includes roles and responsibilities shall be established.

3.15.5 Where measurement and monitoring equipment is used, the project proponent shall ensure the equipment is calibrated according to the equipment's specifications and/or relevant national or international standards.

3.16 Safeguards

Concept

Project activities shall not negatively impact the natural environment or local communities. Project proponents shall identify and address any negative environmental and socio-economic impacts of project activities, and shall engage with local stakeholders during the project development and implementation processes.

Requirements

General

No Net Harm

3.16.1 The project proponent shall identify potential negative environmental and socio-economic impacts, and shall take steps to mitigate them. Additional certification standards may be applied to demonstrate social and environmental benefits beyond GHG emission reductions or removals.

Note that VCUs may be labeled with additional standards and certifications on the Verra registry where both the VCS Program and another standard are applied. The Verra website provides the list of standards that are accepted as VCU labels and the procedure for attaining such VCU labels.

Local Stakeholder Consultation

3.16.2 The project proponent shall conduct a local stakeholder consultation prior to validation as a way to inform the design of the project and maximize participation from stakeholders. Such consultations allow stakeholders to evaluate impacts, raise concerns about potential negative impacts and provide input on the project design.

3.16.3 The project proponent shall establish mechanisms for ongoing communication with local stakeholders to allow stakeholders to raise concerns about potential negative impacts during project implementation.

3.16.4 The project proponent shall take due account of all and any input received during the local stakeholder consultation and through ongoing communications, which means it will need to either update the project design or justify why updates are not appropriate. The project proponent shall demonstrate to the validation/verification body what action it has taken in respect of the local stakeholder consultation as part of validation, and in respect of ongoing communications as part of each subsequent verification.

Public Comment Period

3.16.5 All projects are subject to a 30-day public comment period. The date on which the project is listed on the project pipeline marks the beginning of the project's 30-day public comment period (see the VCS Program document *Registration and Issuance Process* for more information on the VCS project pipeline).

3.16.6 Projects shall remain on the project pipeline for the entirety of their 30-day public comment period.

3.16.7 Any comments shall be submitted to Verra at secretariat@verra.org and respondents shall provide their name, organization, country and email address. At the end of the public comment period, Verra provides all and any comments received to the project proponent.

3.16.8 The project proponent shall take due account of any and all comments received during the consultation, which means it will need to either update the project design or demonstrate the insignificance or irrelevance of the comment. It shall demonstrate to the validation/verification body what action it has taken.

AFOLU Projects

3.16.9 Where AFOLU project activities do not impact local stakeholders, projects are not required to meet the requirements set out in Sections 3.16.11– 3.16.18 below. The project proponent shall provide evidence that project activities do not impact local stakeholders at validation and each verification.

3.16.10 Where AFOLU projects complete a validation or verification to the Climate, Community & Biodiversity (CCB) Program at the same time as a VCS Program validation or verification, they are not required to conduct a separate demonstration of compliance with the requirements set out in this Section 3.16.

Note – Where an AFOLU project has previously certified to the Climate, Community & Biodiversity (CCB) Program, but is completing a VCS Program verification without also completing a CCB Program verification for the same verification period, the project proponent shall demonstrate compliance with the requirements set out in Sections 3.16.11 – 3.16.18 below.

Local Stakeholder Identification and Background

3.16.11 The project proponent shall conduct a thorough assessment of the local stakeholders that will be impacted by the project. The project description shall include information on local stakeholders at the start of the project, including:

1) The process(es) used to identify local stakeholders likely impacted by the project and a list of such stakeholders;
2) Identification of any legal or customary tenure/access rights to territories and resources, including collective and/or conflicting rights, held by local stakeholders;
3) A description of the social, economic and cultural diversity within local stakeholder groups and the differences and interactions between the stakeholder groups;
4) Any significant changes in the makeup of local stakeholders over time;
5) The expected changes in well-being and other stakeholder characteristics under the baseline scenario, including changes to ecosystem services identified as important to local stakeholders;
6) The location of communities, local stakeholders and areas outside the project area that are predicted to be impacted by the project; and
7) The location of territories and resources which local stakeholders own or to which they have customary access.

Risks to Local Stakeholders

3.16.12 The project proponent shall identify likely natural and human-induced risks to local stakeholder well-being expected during the project lifetime and outline measures needed to mitigate these risks.

3.16.13 The project proponent shall identify the risks for local stakeholders to participate in the project, including project design and consultation. Risks should include trade-offs with food security, land loss, loss of yields and climate change adaptation. The project shall be designed and implemented to avoid trade-offs and manage the identified risks to local stakeholders.

3.16.14 The project proponent or any other entity involved in project design or implementation shall not be involved in any form of discrimination or sexual harassment.

3.16.15 The management teams involved in the project shall have expertise and prior experience implementing land management and carbon projects with community engagement at the project scale. Where relevant experience is lacking, the project proponent shall either demonstrate how they have partnered with other organizations to support the project or have a recruitment strategy to fill the identified gaps.

Respect for Local Stakeholder Resources

3.16.16 The project proponent shall avoid negative impacts of project implementation and mitigate impacts when unavoidable, including the following:

1) The project proponent shall recognize, respect and support local stakeholders' property rights and where feasible, take measures to help secure rights. The project shall not encroach on private, stakeholder or government property or relocate people off their lands without consent. The project may affect property rights if free, prior and informed consent is obtained from those concerned and a transparent agreement is reached that includes provisions for just and fair compensation. In the event there are any ongoing or unresolved conflicts over property rights, usage or resources, the project shall undertake no activity that could exacerbate the conflict or influence the outcome of an unresolved dispute.
2) To reduce damage to the ecosystems on which the local stakeholders rely:
    a) The project shall not introduce any invasive species or allow an invasive species to thrive through project implementation.
    b) The project shall justify the use of non-native species over native species, explaining the possible adverse effects of non-native species.
    c) The project shall justify the use of fertilizers, chemical pesticides, biological control agents and other inputs used by the project and their possible adverse effects.

Communication and Consultation

3.16.17 The project proponent shall take all appropriate measures to communicate and consult with local stakeholders in an ongoing process for the life of the project. The project proponent shall communicate:

1) The project design and implementation, including the results of monitoring.
2) The risks, costs and benefits the project may bring to local stakeholders.
3) All relevant laws and regulations covering workers' rights in the host country.
4) The process of VCS Program validation and verification and the validation/verification body's site visit.

3.16.18 The project proponent shall develop a grievance redress procedure to address disputes with local stakeholders that may arise during project planning and implementation, including with regard to benefit sharing. The procedure shall include processes for receiving, hearing, responding and attempting to resolve grievances within a reasonable time period, taking into account culturally-appropriate conflict resolution methods. The procedure and documentation of disputes resolved through the procedure shall be made publicly available. The procedure shall have three stages:

1) The project proponent shall attempt to amicably resolve all grievances and provide a written response to the grievances in a manner that is culturally appropriate.

2) Any grievances that are not resolved by amicable negotiations shall be referred to mediation by a neutral third party.

3) Any grievances that are not resolved through mediation shall be referred either to a) arbitration, to the extent allowed by the laws of the relevant jurisdiction or b) competent courts in the relevant jurisdiction, without prejudice to a party's ability to submit the grievance to a competent supranational adjudicatory body, if any.

3.16.19 All communication and consultation shall be performed in a culturally appropriate manner, including language and gender sensitivity, directly with local stakeholders or their legitimate representatives when appropriate. The results of implementation shall be provided in a timely manner and consultation shall be performed prior to design decisions or implementation to allow stakeholders adequate time to respond to the proposed design or action.

3.17 Methodology Deviations

Concept

Projects may deviate from the procedures set out in methodologies in certain cases, where alternative methods may be more efficient for project-specific circumstances, and where the deviation will achieve the same level of accuracy or is more conservative than what is set out in the methodology.

Requirements

3.17.1 Deviations from the applied methodology are permitted where they represent a deviation from the criteria and procedures relating to monitoring or measurement set out in the methodology (i.e., deviations are permitted where they relate to data and parameters available at validation, data and parameters monitored, or the monitoring plan).

3.17.2 Methodology deviations shall not negatively impact the conservativeness of the quantification of GHG emission reductions or removals, except where they result in increased accuracy of such quantification. Deviations relating to any other part of the methodology shall not be permitted.

3.17.3 Methodology deviations shall be permitted at validation or verification and their consequences shall be reported in the validation or verification report, as applicable, and all subsequent verification reports. Methodology deviations are not considered to be precedent setting.

3.18 Project Description Deviations

Concept

Projects may deviate from the validated project description in certain cases in order to accommodate changing circumstances post-validation. Such deviations shall be described and assessed by a validation/verification body during the next project verification.

Requirements

3.18.1 Deviations from the project description are permitted at verification.

3.18.2 The procedures for documenting a project description deviation depend on whether the deviation impacts the applicability of the methodology, additionality or the appropriateness of the baseline scenario. Interpretation of whether the deviation impacts any of these shall be determined consistent with the *CDM Guidelines on assessment of different types of changes from the project activity as described in the registered PDD,* mutatis mutandis. The procedures are as follows:

1) Where the deviation impacts the applicability of the methodology, additionality or the appropriateness of the baseline scenario, the deviation shall be described and justified in a revised version of the project description. This shall include a description of when the changes occurred, the reasons for the changes and how the changes impact the applicability of the methodology, additionality and/or the appropriateness of the baseline scenario.

   An example of such a deviation is a change in project capacity where a different baseline scenario would be more plausible, the applied methodology would no longer be applicable, or there would be a significant impact on the investment analysis used by the project to demonstrate additionality. Other examples include changes to the project that might have similar impacts such as the addition of new carbon pools or new types of project activities.

2) Where the deviation does not impact the applicability of the methodology, additionality or the appropriateness of the baseline scenario, and the project remains in compliance with the applied methodology, the deviation shall be described and justified in the monitoring report. This shall include a description of when the changes occurred and the reasons for the changes. The deviation shall also be described in all subsequent monitoring reports.

   Examples of such deviations include changes in the procedures for measurement and monitoring, or project design changes that do not have an impact on the applicability of the methodology, additionality or the appropriateness of the baseline scenario.

Note that project proponents may apply project description deviations for the purpose of switching to the latest version of the methodology, or switching to a different methodology. For example, a project proponent may want to switch to the latest version of a methodology where such version includes additional types of carbon pools or project activities.

3.18.3 The deviation shall be assessed by a validation/verification body and the process, findings and conclusions shall be reported in the verification report. The assessment shall determine whether the deviation is appropriately described and justified, and whether the project remains in compliance with the VCS Program rules. The deviation shall also be reported on in all subsequent verification reports. Project description deviations are not considered to be precedent-setting.

3.18.4 The validation/verification body assessing the project description deviation shall be accredited for the validation, recognizing that assessment of project description deviations is a validation activity, as further set out in the VCS Program Guide.

3.19 Participation under Other GHG Programs

Concept

Projects may be registered under both the VCS Program and either an approved GHG program or a GHG program that is not an approved GHG program.

Requirements

General

3.19.1 Project proponents shall not claim credit for the same GHG emission reduction or removal under the VCS Program and another GHG program. Projects issuing GHG credits under both the VCS Program and another GHG program shall also comply with the rules and requirements set out in the VCS Program document *Registration and Issuance Process*.

3.19.2 Projects registered under other GHG programs are not eligible for VCU issuance beyond the end of the total project crediting period under those programs (see Section 3.8.7 for further information).

3.19.3 For projects registered under the CDM as a program of activities (PoA), the following applies:

1) Each component project activity (CPA) shall be registered with the VCS Program as a separate project accompanied by its associated program of activities design document.

2) Each such project shall be validated in accordance with Section 3.19.5(1) below.

3) The project start date for such projects is the date on which the first activity under the program of activities began reducing or removing GHG emissions.

4) Validation shall be completed within the relevant project start date deadline, as set out in Section 3.19(in this case, validation refers to validation of the first CPA under the associated PoA).

AFOLU Projects

3.19.4 In addition to the above, AFOLU projects registered under both the VCS Program and another GHG program shall comply with the following:

1) All and any (VCS) monitoring and verification reports shall state the total amount of credits (GHG credits and, where applicable, buffer credits) issued under the other GHG program.

2) The project shall prepare a non-permanence risk report in accordance with the VCS Program document *AFOLU Non-Permanence Risk Tool* and a validation/verification body shall undertake a full validation of same in accordance with the VCS Program rules. The non-permanence risk analysis shall be based upon the project as a whole, though the buffer withholding shall apply to the net change in carbon stocks for which credits are sought under the VCS Program.

3) Where temporary GHG credits (e.g., tCERs or lCERs) have been issued to the project, VCUs may be issued to the project only in accordance with the rules and requirements set out in the VCS Program document *Registration and Issuance Process*.

4) Where a loss event or a reversal occurs, the project shall comply with the rules for reporting a loss event and holding/cancelling credits set out in Section 3.2.15 and the VCS Program document *Registration and Issuance Process*. Such reporting, holding and cancelling shall apply to the proportion of credits (GHG credits and buffer credits) granted to date under the VCS Program.

   For example, if 50 percent of the total credits (GHG credits and, where applicable, buffer credits) related to the project have been issued under the VCS Program and a loss event results in a reversal of GHG emission reductions or removals achieved, buffer credits would be cancelled to cover 50 percent of the reversal. An example calculation is available on the Verra website.

Approved GHG Programs

3.19.5 The following applies with respect to projects registered under an approved GHG program which are seeking registration with the VCS Program:

1) For projects registered under the CDM, the cover page and sections 1.1, 1.2, 1.3, 1.5, 1.6, 1.7, 1.8, 1.9, 1.10, 1.12, 1.13, 1.14, 1.15.1, 1.16, 1.17 and 2.6 of the *VCS Project Description Template* shall be completed. A validation/verification body shall undertake a validation of same, which shall be accompanied by a validation representation, to provide a gap validation for the project's compliance with the VCS Program rules.

2) For projects registered under the JI program, a new *VCS Project Description Template* shall be completed (applying a methodology eligible under the VCS Program). A validation/verification body shall undertake a full validation of same in accordance with the VCS Program rules. The validation report shall be accompanied by a validation representation.

3) For projects registered under the Climate Action Reserve, the cover page and sections 1.1, 1.2, 1.3, 1.5, 1.6, 1.7, 1.8, 1.9, 1.10, 1.12, 1.13, 1.15.1, 1.16, 1.17, 2.1, 2.2, 2.3, 2.4 and 3.6 of the *VCS Project Description Template* shall be completed. A validation/verification body shall undertake a validation of same, which shall be accompanied by a validation representation, to provide a gap validation for the project's compliance with VCS Program rules.

4) The approved GHG program validation (or verification, where the approved GHG program does not have a validation step) or VCS validation shall be completed within the relevant validation deadline as set out in Section 3.7. Validation (or verification) is deemed to have been completed when the validation (or verification) report that is submitted to the relevant program to request registration has been issued.

Other GHG Programs

3.19.6 Projects registered under a GHG program that is not an approved GHG program may also register with the VCS Program where a validation or verification report has been issued under such program (by an entity approved under the program to issue such reports). For such projects, the following applies:

1) The project start date shall be on or after 19 November 2007.

2) A new *VCS Project Description Template* shall be completed (using a methodology eligible under the VCS Program) and a validation/verification body shall undertake a full validation of same in accordance with the VCS Program rules. The validation report shall be accompanied by a validation representation.

3) The validation or verification that is submitted to request registration under the other GHG program shall be completed within the relevant validation deadline set out in Section 3.7. Validation or verification is deemed to have been completed when the validation or verification report that is submitted to the other GHG program to request registration has been issued.

Projects Rejected by Other GHG Programs

3.19.7 Projects rejected by other GHG programs due to procedural or eligibility requirements can be considered under the VCS Program, but the following conditions shall be met:

1) The project description (where the other GHG program has rejected the project before VCS validation) or monitoring report (where the other GHG program has rejected the project after VCS validation) shall clearly state all GHG programs to which the project has applied

for registration and the reason(s) for rejection. Such information shall not be deemed as commercially sensitive information.

2) The validation/verification body shall be provided with the rejection document(s), including any additional explanations.

3) The project shall be validated against the VCS Program rules. For projects where the other GHG program has rejected the project after VCS validation, this means a complete revalidation of the project against the VCS Program rules.

3.20 Other Forms of Credit

Concept

In order to maintain atmospheric integrity, GHG emission reductions/removals that are issued as VCUs cannot also be issued as other types of GHG credits or claimed as other forms of environmental credit. Project proponents shall demonstrate that project emission reductions or removals are not also used under emission trading programs, other mechanisms that include GHG allowance trading, or as other forms of environmental credit.

Requirements

Emission Trading Programs and Other Binding Limits

3.20.1 Where projects reduce GHG emissions from activities that are included in an emissions trading program or any other mechanism that includes GHG allowance trading, evidence shall be provided that the GHG emission reductions or removals generated by the project have not and will not be otherwise counted or used under the program or mechanism. Such evidence may include:

1) A letter from the program operator, designated national authority or other relevant regulatory authority that emissions allowances (or other GHG credits used in the program) equivalent to the reductions or removals generated by the project have been cancelled from the program or national cap, as applicable.

2) Evidence of the purchase and cancellation of GHG allowances equivalent to the GHG emissions reductions or removals generated by the project related to the program or national cap.

3) Evidence from the program operator, designated national authority or other relevant regulatory authority stating that the specific GHG emission reductions or removals generated by the project or type of project are not within the scope of the program or national cap.

Other Forms of Environmental Credit

3.20.2 Projects may generate other forms of GHG-related environmental credits, such as renewable energy certificates (RECs), though GHG emission reductions and removals presented for VCU issuance shall not also be recognized as another form of GHG-related environmental credit. The requirements set out in Sections 3.20.2 and 3.20.3 below assist Verra in confirming that this requirement has been met at the point of the issuance request (i.e., Verra uses the information disclosed in the project documents to perform its checks).

Therefore, project proponents interested in issuing (sequentially) both VCUs and another GHG-related environmental credit should consider which periods of time they wish to issue one credit or the other. Project proponents should also investigate whether such other GHG-related environmental credits can be cancelled from the relevant program, in case such credits have already been issued for periods where the project proponent wishes to issue VCUs. Note that additional requirements regarding evidence that no double issuance has occurred are set out in the VCS Program document *Registration and Issuance Process*.

3.20.3 Where projects have sought or received another form of GHG-related environmental credit, the following information shall be provided to the validation/verification body:

1) Name and contact information of the relevant environmental credit program.
2) Details of the project as registered under the environmental credit program (e.g., project title and identification number as listed under the program).
3) Monitoring periods for which GHG-related environmental credits were sought or received under the environmental credit program.
4) Details of all GHG-related environmental credits sought or received under the environmental credit program (e.g., volumes and serial numbers).

3.20.4 Where projects are eligible to participate under one or more programs to create another form of GHG-related environmental credit, but are not currently doing so, a list of such programs shall be provided to the validation/verification body.

Note – The requirements set out in Section 3.20.3 above and this Section 3.20.4 do not apply to non-GHG related environmental credits, such as water or biodiversity credits.

3.21 Records and Information

Concept

The project proponent shall make relevant information available to the validation/verification body during validation and each verification and retain documents and records related to the project for future reference.

Requirements

Records Relating to the Project

3.21.1 The project proponent shall ensure that all documents and records are kept in a secure and retrievable manner for at least two years after the end of the project crediting period.

Information for the Validation/Verification Body

3.21.2 For validation, the project proponent shall make available to the validation/verification body the project description, evidence of project ownership and any requested supporting information and data needed to support statements and data in the project description and evidence of project ownership.

3.21.3 For verification, the project proponent shall make available to the validation/verification body the project description, validation report, monitoring report applicable to the monitoring period and any requested supporting information and data needed to evidence statements and data in the monitoring report.

4 VALIDATION AND VERIFICATION REQUIREMENTS

This section sets out the rules and requirements for validation and verification of projects under the VCS Program. Validation/verification bodies must assess projects' compliance with VCS Program rules and requirements and the applied methodology(s) in accordance with the sections below. Validation/verification bodies must be approved under the VCS Program, and meet the eligibility criteria set out in the *VCS Program Guide*.

4.1 Introduction and General Requirements

Concept

Validation is the independent assessment of the project by a validation/verification body that determines whether the project complies with the VCS Program rules. Verification is the periodic ex-post independent assessment by a validation/verification body of the GHG emission reductions and removals that have occurred as a result of the project during the monitoring period, conducted in accordance with the VCS Program rules.

Requirements

General

4.1.1 Validation and verification is a risk-based process and shall be carried out in conformance with *ISO 14064-3:2006* and *ISO 14065:2013*. Additional requirements with respect to validation and verification are set out in this Section 4 and shall be adhered to.

4.1.2 The validation/verification body shall select samples of data and information to be validated or verified to provide a reasonable level of assurance and to meet the materiality requirements of the specific project.

4.1.3 The project shall be validated and GHG emission reductions or removals verified by a validation/verification body that meets with the eligibility requirements set out in the *VCS Program Guide*.

4.1.4 Validation and verification of the project may be undertaken by the same validation/verification body, noting the rules on rotation of validation/verification bodies set out in Section 4.1.20 below. Validation may occur before the first verification or at the same time as the first verification.

4.1.5 The project shall be listed on the project pipeline before the opening meeting between the validation/verification body and the project proponent (such opening meeting representing the beginning of the validation process). The validation/verification body is responsible for checking that the project is listed on the project pipeline and shall not conduct the opening meeting or otherwise begin validation until such time as the project is listed.

4.1.6 Where the project applies a methodology from an approved GHG program that does not have an independent validation step, the VCS Program rules still require validation of the project.

4.1.7 Validation/verification bodies are expected to follow the guidance provided in the *VCS Validation and Verification Manual* when validating or verifying projects and conducting methodology assessments under the VCS Program.

Validation and Verification Process

4.1.8 In addition to the requirements set out in *ISO 14064-3:2006*, the following shall apply:

1) The level of assurance shall be reasonable, with respect to material errors, omissions and misrepresentations, for both validation and verification.
2) The criteria for validation shall be the *VCS Version 4*, or approved GHG program where the validation is performed under an approved GHG program (as in cases of participation under the VCS Program and an approved GHG program). The criteria for verification shall be the *VCS Version 4* (regardless of the VCS version or GHG program under which the project was validated). This means the validation or verification shall ensure conformance of the project with the VCS Program rules, or rules and requirements of the approved GHG program, as applicable.
3) The objective of validation or verification shall be in conformance with the VCS Program rules and the methodology applied to the project.
4) The threshold for materiality with respect to the aggregate of errors, omissions and misrepresentations relative to the total reported GHG emission reductions and/or removals shall be five percent for projects and one percent for large projects.

4.1.9 Where the project does not fully comply with the methodology, the validation/verification body shall determine whether this represents a methodology deviation or a methodology revision (in accordance with the specifications for each), and the case shall be handled accordingly.

4.1.10 Where the project applies a revision to an approved GHG program methodology and the version of the (underlying) methodology referenced by the methodology revision is no longer current, the validation/verification body shall determine whether material changes have occurred to the underlying methodology that affect the integrity of the methodology revision. Where such material changes have occurred, the project shall not be approved.

4.1.11 Where the project does not meet the criteria for validation or verification, the validation/verification body shall produce a negative validation conclusion and provide the validation or verification report and project description, or monitoring report, to Verra. The project shall be ineligible for registration until such time as corrective action is taken and the (same) validation/verification body has provided a positive validation or verification.

Competence

4.1.12 The validation/verification body and validation and verification team shall meet the competence requirements set out in *ISO 14065:2013*, mutatis mutandis.

Validation and Verification Reporting

4.1.13 The validation report describes the validation process, any findings raised during validation and their resolutions, and the conclusions reached by the validation/verification body. The validation/verification body shall use the *VCS Validation Report Template,* an approved combined validation report template available on the Verra website, or an approved GHG program validation report template where the project is registered under an approved GHG program, as appropriate, and adhere to all instructional text within the template. The validation report shall be accompanied by a validation representation, which shall be prepared using the *VCS Validation Deed of Representation Template*.

4.1.14 The verification report describes the verification process, any findings raised during verification and their resolutions, and the conclusions reached by the validation/verification body. The validation/verification body shall use the *VCS Verification Report Template* or an approved combined verification report template available on the Verra website, and adhere to all instructional text within the template. The verification report shall be accompanied by a verification representation, which shall be prepared using the *VCS Verification Deed of Representation Template*.

4.1.15 Where a monitoring report and associated verification report divide a verification period into vintages, separate VCU issuance records in accordance with vintage periods may be issued, as set out in the VCS Program document *Registration and Issuance Process*.

Validation and Verification Statement

4.1.16 The validation report and the verification report shall contain a validation statement and a verification statement, respectively.

4.1.17 Validation and verification statements shall:

1) Describe the level of assurance of the validation or verification.
2) Describe the objectives, scope and criteria of the validation or verification.
3) Describe whether the data and information supporting the GHG assertion were hypothetical, projected and/or historical in nature.

4) Include the validation/verification body's conclusion on the GHG assertion, including any qualifications or limitations.

5) For AFOLU projects, state the version number of the non-permanence risk report or market leakage evaluation documentation upon which the statement is based.

4.1.18 The verification statement shall state the volume of GHG emission reductions or removals generated during the monitoring period that have been verified. For AFOLU projects, the verification statement shall also include the non-permanence risk rating, leakage emissions and number of GHG emission reductions or removals eligible to be issued as VCUs.

Records of Validation and Verification

4.1.19 The validation/verification body shall keep all documents and records in a secure and retrievable manner for at least two years after the end of the project crediting period, even where they do not conduct verification for the whole project crediting period.

Rotation of Validation/Verification Bodies

4.1.20 Rotation of validation/verification bodies is required in respect of validation and verification, as follows:

1) Validation (including project crediting period renewal validation) and the first verification of a project (in a given project crediting period) may be undertaken by the same validation/verification body. However, the subsequent verification shall be undertaken by a different validation/verification body. For example, if validation and verification were undertaken at the same time, the subsequent verification would have to be undertaken by a different validation/verification body. If validation were undertaken first (i.e., separately), the first verification could be undertaken by the same validation/verification body, but the subsequent verification would have to be undertaken by a different validation/verification body.

Note – The gap validation of a project registered under an approved GHG program may be disregarded when assessing adherence to these requirements.

2) A validation/verification body may not verify more than six consecutive years of a project's GHG emission reductions or removals. The validation/verification body may undertake further verification for the project only when at least three years of the project's GHG emission reductions or removals have been verified by a different validation/verification body. Additionally, where a validation/verification body verifies the final six consecutive years of a project crediting period, the project crediting period renewal validation shall be undertaken by a different validation/verification body. Notwithstanding these rules, where AFOLU projects have verification periods longer than six years, a validation/verification body is permitted to verify more than six consecutive years of a project's GHG emission reductions or removals, and the subsequent verification shall be undertaken by a different validation/verification body.

Note – Validations and verifications performed under other GHG programs shall be counted when assessing adherence to these requirements.

Validation and Verification Requirements for Grouped Projects

4.1.21 Validation and verification of grouped projects shall assess conformance of the project with the requirements for grouped projects set out in the VCS Program rules.

4.1.22 New project activity instances shall be validated, based on the information reported in the monitoring report, against the applicable set of eligibility criteria. The validation/verification body shall specify which instances meet the eligibility criteria for inclusion in the project. Such validation may be reported in the verification report or a separate validation report.

4.1.23 Where, due to the number of project activity instances, it is unreasonable to undertake an individual assessment of each initial or new instance, the validation/verification body shall document and explain the sampling methods employed for the validation of such instances. Such sampling methods shall be statistically sound. The number of instances included in the project, eligible for monitoring and generation of VCUs shall be proportional to the percentage of sampled instances found to be in compliance by the validation/verification body.

4.1.24 The verification report for grouped projects shall document and explain the sampling methods employed by the validation/verification body for the verification of GHG emission reductions or removals generated by the project. Such methods shall be statistically sound. Any subsequent changes to the sampling method(s) required as a result of the verification findings shall be documented.

Non-Permanence Risk Analysis and Market Leakage Evaluations for AFOLU Projects

4.1.25 Non-Permanence risk analysis and market leakage evaluations shall be assessed by the validation/verification body in accordance with the VCS Program rules.

4.1.26 The validation/verification body shall assess the risk analysis carried out by the project proponent in accordance with the VCS Program document A*FOLU Non-Permanence Risk Tool*. The project proponent shall respond to all and any of the validation/verification body's findings. As a result of any such findings, the project proponent shall amend the documentation as necessary and update the risk rating accordingly.

APPENDIX 1 ELIGIBLE AFOLU PROJECT CATEGORIES

This appendix defines the types of activities that are included within each AFOLU project category, and is intended to aid project proponents in determining which type of methodology may be applicable to their AFOLU project activity(s). As set out in Section 3.2 above, AFOLU projects must apply a methodology eligible under the VCS Program.

Additional information about the eligible activities and specific GHG sources, sinks and reservoirs that must be included in methodologies developed under the VCS Program for each eligible AFOLU project category is available in the VCS Program document *VCS Methodology Requirements*.

Afforestation, Reforestation and Revegetation (ARR)

A1.1 Eligible ARR activities are those that increase carbon sequestration and/or reduce GHG emissions by establishing, increasing or restoring vegetative cover (forest or non-forest) through the planting, sowing or human-assisted natural regeneration of woody vegetation. Eligible ARR projects may include timber harvesting in their management plan. The project area shall not be cleared of native ecosystems within the 10 year period prior to the project start date, as set out in Section 3.2.4.

Note – Activities which improve forest management practices such as enrichment planting and liberation thinning are categorized as IFM project activities.

Agricultural Land Management (ALM)

A1.2 Eligible ALM activities are those that reduce net GHG emissions on croplands and grasslands by increasing carbon stocks in soils and woody biomass and/or decreasing CO_2, N_2O and/or CH_4 emissions from soils. The project area shall not be cleared of native ecosystems within the 10-year period prior to the project start date. Eligible ALM activities include:

1) Improved Cropland Management (ICM): This category includes practices that demonstrably reduce net GHG emissions of cropland systems by increasing soil carbon stocks, reducing soil N_2O emissions, and/or reducing CH_4 emissions.

2) Improved Grassland Management (IGM): This category includes practices that demonstrably reduce net GHG emissions of grassland ecosystems by increasing soil carbon stocks, reducing N_2O emissions and/or reducing CH_4 emissions.

3) Cropland and Grassland Land-use Conversions (CGLC): This category includes practices that convert cropland to grassland or grassland to cropland and reduce net GHG emissions by increasing carbon stocks, reducing N_2O emissions, and/or reducing CH_4 emissions.

Note – Project activities relating to manure management are eligible under sectoral scope 15 (livestock, enteric fermentation, and manure management), not sectoral scope 14 (AFOLU).

Improved Forest Management (IFM)

A1.3 Eligible IFM activities are those that increase carbon sequestration and/or reduce GHG emissions on forest lands managed for wood products such as sawtimber, pulpwood and fuelwood by increasing biomass carbon stocks through improving forest management practices. The baseline and project scenarios for the project area shall qualify as forests remaining as forests, such as set out in the *IPCC 2006 Guidelines on National GHG Inventories*, and the project area shall be designated, sanctioned or approved for wood product management by a national or local regulatory body (e.g., as logging concessions or plantations).

A1.4 Various sanctioned forest management activities may be changed to increase carbon stocks and/or reduce emissions, but only a subset of these activities make a measurable difference to the long-term increase in net GHG emissions compared to the baseline scenario. Eligible IFM activities include:

1) Reduced Impact Logging (RIL): This category includes practices that reduce net GHG emissions by switching from conventional logging to RIL during timber harvesting.
2) Logged to Protected Forest (LtPF): This category includes practices that reduce net GHG emissions by converting logged forests to protected forests. By eliminating harvesting for timber, biomass carbon stocks are protected and can increase as the forest re-grows and/or continues to grow. Harvesting of trees to advance conservation purposes (e.g., the removal of diseased trees) may continue in the project scenario.
3) Extended Rotation Age / Cutting Cycle (ERA): This category includes practices that reduce net GHG emissions of evenly aged managed forests by extending the rotation age or cutting cycle and increasing carbon stocks.
4) Low-Productive to High-Productive Forest (LtHP): This category includes practices that increase carbon sequestration by converting low-productivity forests to high-productivity forests. Note - Activities that reduce GHG emissions from unsanctioned forest degradation (e.g., illegal logging) are considered REDD activities. Projects focusing solely on the reduction of forest fires are not eligible under IFM. Activities that degrade wetlands to increase forest production are not eligible.

Reduced Emissions from Deforestation and Degradation (REDD)

A1.5 Eligible REDD activities are those that reduce net GHG emissions by reducing deforestation and/or degradation of forests. Deforestation is the direct, human-induced conversion of forest land to non-forest land. Degradation is the persistent reduction of canopy cover and/or carbon stocks in a forest due to human activities such as animal grazing, fuelwood extraction, timber removal or other such activities, but which does not result in the conversion of forest to non-forest land (which would be classified as deforestation), and qualifies as *forests remaining as forests*, such as set out under the *IPCC 2003 Good Practice Guidance*. The project area shall meet an internationally accepted definition of forest, such as those based on UNFCCC host-country thresholds or FAO definitions, and shall qualify as forest for a minimum of 10 years before the project start date. The definition of forest may include mature forests, secondary forests, and degraded forests. Under the VCS Program, secondary forests are considered to be forests that have been cleared and have recovered naturally and that are at least 10-years-old and meet the lower bound of the forest threshold parameters at the start of the project. Forested wetlands, such as floodplain forests, peatland forests and mangrove forests, are also eligible provided they meet the forest definition requirements mentioned above.

A1.6 Activities covered under the REDD project category are those that are designed to stop planned (designated and sanctioned) deforestation or unplanned (unsanctioned) deforestation and/or degradation. Avoided planned degradation is classified as IFM.

A1.7 Activities that stop unsanctioned deforestation and/or illegal degradation (such as removal of fuelwood or timber extracted by non-concessionaires) on lands that are legally sanctioned for timber production are eligible as REDD activities. However, activities that reduce or stop logging only, followed by protection, on forest lands legally designated or sanctioned for forestry activities are included within IFM. Projects that include both avoided unplanned deforestation and/or degradation as well as stopping sanctioned logging activities, shall follow the REDD guidelines for the unplanned deforestation and/or degradation and the IFM guidelines for the sanctioned logging activities, and shall follow the requirements set out in Section 3.5.2.

A1.8 Eligible REDD activities include:

1) Avoiding Planned Deforestation and/or Degradation (APDD): This category includes activities that reduce net GHG emissions by stopping or reducing deforestation or degradation on forest lands that are legally authorized and documented for conversion.

2) Avoiding Unplanned Deforestation and/or Degradation (AUDD): This category includes activities that reduce net GHG emissions by stopping deforestation and/or degradation of degraded to mature forests that would have occurred in any forest configuration.

Avoided Conversion of Grasslands and Shrublands (ACoGS)

A1.9 Eligible ACoGS activities are those that reduce net GHG emissions by reducing the conversion of grassland and shrubland ecosystems to other land uses with lower carbon densities. Eligible avoided conversion activities include avoiding, at a minimum, the removal/replacement of vegetation and may also include avoiding soil disturbance.

A1.10 The project area shall be native grasslands (including savanna) and/or shrublands (including chaparral). Non-forested wetlands, including peatlands, are not eligible under ACoGS and are covered under other AFOLU project categories.

A1.11 Activities covered under the ACoGS project category are those that are designed to stop planned (designated and sanctioned) conversion or unplanned (unsanctioned) conversion on public or private lands. This category type only includes avoided conversion of non-forested lands, noting that other management activities on non-forested land may qualify under ALM or ARR project categories.

A1.12 Eligible ACoGS activities include:

1) Avoiding Planned Conversion (APC): This category includes activities that reduce net GHG emissions by stopping conversion of grasslands or shrublands that are legally authorized and documented for conversion.

2) Avoiding Unplanned Conversion (AUC): This category includes activities that reduce net GHG emissions by stopping unplanned conversion of grasslands or shrublands.

Wetlands Restoration and Conservation (WRC)

A1.13 Eligible WRC activities are those that increase net GHG removals by restoring wetland ecosystems or that reduce GHG emissions by rewetting or avoiding the degradation of wetlands. The project area shall meet an internationally accepted definition of wetland, such as from the IPCC, Ramsar Convention on Wetlands, those established by law or national policy, or those with broad agreement in the peer-reviewed scientific literature for specific countries or types of wetlands. Common wetland types include peatland, salt marsh, tidal freshwater marsh, mangroves, wet floodplain forests, prairie potholes and seagrass meadows. WRC activities may be combined with other AFOLU project categories, as further explained in Section 59.

A1.14 A peatland is an area with a layer of naturally accumulated organic material (peat) at the surface (excluding the plant layer). Common peatland types include peat swamp forest, mire, bog, fen, moor, muskeg and pocosin. Rewetting of drained peatland and the conservation of undrained or partially drained peatland are sub-categories of restoring wetland ecosystems and conservation of intact wetlands, respectively[11].

A1.15 Activities that generate net reductions of GHG emissions from wetlands are eligible as WRC projects or combined category projects (such as REDD on peatland). Activities that actively lower the water table depth in wetlands are not eligible. Eligible WRC activities include:

1) Restoring Wetland Ecosystems (RWE): This category includes activities that reduce GHG emissions or increase carbon sequestration in a degraded wetland through restoration activities. Such activities include enhancing, creating and/or managing hydrological conditions, sediment supply, salinity characteristics, water quality and/or native plant communities. For the purpose of these requirements, restoration activities are those that

[11] These categories existed as rewetting drained peatlands (RDP) and conservation of undrained and partially drained peatlands (CUPP) in the *AFOLU Requirements* v3.2.

result in the reestablishment of ecological processes, functions, and biotic and/or abiotic linkages that lead to persistent, resilient systems integrated within the landscape.

2) Conservation of Intact Wetlands (CIW): This category includes activities that reduce GHG emissions by avoiding degradation and/or the conversion of wetlands that are intact or partially altered while still maintaining their natural functions, including hydrological conditions, sediment supply, salinity characteristics, water quality and/or native plant communities.

   Wetland degradation or conversion can be planned (designated and sanctioned) or unplanned (unsanctioned). Planned and unplanned degradation or conversion of wetlands can therefore encompass a wide variety of activities such as those listed under REDD while adding a wetland component. Activities covered under the CIW project category are those that are designed to stop or reduce planned or unplanned degradation or conversion in the project area to other land uses. The following CIW activities are eligible:

   a) Avoiding Planned Wetland Degradation (APWD): This activity reduces GHG emissions by avoiding degradation of wetlands, or further degradation in partially drained wetlands that are legally authorized and documented for conversion.

   b) Avoiding Unplanned Wetland Degradation (AUWD): This activity reduces GHG emissions by avoiding unplanned degradation of wetlands, or by avoiding further degradation in partially degraded wetlands.

Note – Activities where drainage is continued or maintained are not eligible. This includes, for example, projects that require the maintenance of drainage channels to maintain the pre-project drainage level on a partially drained peatland (e.g., where periodic deepening may be needed to counteract peat subsidence). Projects that allow selective harvesting that results in a lowering of the water table depth (e.g., by extracting timber using drainage canals) or affects the ability of vegetation to act as a major hydrological regulation device (e.g., extracting trees which support the peat body) are also not eligible. Project activities may include selective harvesting where harvesting does not lower the water table, for example by extracting timber using wooden rails instead of drainage canals.

A1.16 Activities that generate net GHG emission reductions by combining other AFOLU project activities with wetlands restoration or conservation activities are eligible as WRC combined projects. RWE may be implemented without further conversion of land use or it may be combined with ARR, ALM, IFM, REDD or ACoGS activities, referred to as ARR+RWE, ALM+RWE, IFM+RWE, REDD+RWE or ACoGS+RWE, respectively. CIW may be implemented on non-forest land or combined with IFM, REDD or ACoGS activities, referred to as IFM+CIW, REDD+CIW or ACoGS+CIW, respectively.

Table 3 illustrates the types of WRC activities that may be combined with other AFOLU project categories. The table identifies the applicable AFOLU requirements that shall be followed for combined category projects, based on the condition of the wetland in the baseline scenario, the land use in the baseline scenario and the project activity.

Table 3: Eligible WRC Combined Category Projects

Baseline Scenario		Project Activity	Applicable Guidance
Condition	Land Use		
Degraded wetland (including, drained, impounded, and with interrupted sediment supply)	Non-forest (including aquacultures, grasslands and shrublands)	Restoration of wetlands*	RWE
		Restoration of wetlands* and revegetation or conversion to forest	ARR+RWE
		Restoration of wetlands* and conversion to wetland agriculture (including paludiculture)	ALM+RWE
		Restoration of wetlands* and avoided conversion of grasslands or shrublands	ACoGS+RWE
	Forest	Restoration of wetlands*	RWE
	Forest with deforestation/ degradation	Restoration of wetlands* and avoided deforestation/degradation	REDD+RWE
	Forest managed for wood products	Restoration of wetlands* and improved forest management	IFM+RWE
Non-wetland or open water	Non-forest	Creation of wetland conditions and afforestation, reforestation or revegetation	ARR+RWE
	Open water or impounded wetland	Creation or restoration of conditions for vegetation development and afforestation, reforestation or revegetation	ARR+RWE
Intact wetland	Non-forest (including grasslands and shrublands)	Avoided drainage and/or interrupted sediment supply	CIW
		Avoided conversion to open water or impounded wetland (including excavation to create fish ponds)	CIW
		Avoided drainage and/or interrupted sediment supply and avoided conversion of grasslands and Shrublands	ACoGS+CIW
	Forest	Avoided drainage and/or interrupted sediment supply	CIW

		Avoided conversion to open water or impounded wetland	CIW
	Forest with deforestation/ degradation	Avoided drainage and/or interrupted sediment supply and avoided deforestation/degradation	REDD+CIW
		Avoided conversion to open water or impounded wetland and avoided deforestation/degradation	REDD+CIW
	Forest managed for wood products	Avoided drainage and/or interrupted sediment supply and improved forest management	IFM+CIW

* *Restoration of wetlands* includes all the activities set out in Section A1.15.

A1.17 Combined category projects shall use the relevant WRC requirements and the respective AFOLU project category requirements for quantifying GHG emissions/removals, unless the former may be deemed *de minimis* or conservatively excluded.

APPENDIX 2 DOCUMENT HISTORY

Version	Date	Comment
v4.0	Released: 19 Sep 2019 Updated: 9 Mar 2020	Initial version released under *VCS Version 4*, with immediate effect except for the following: For project activities that were eligible under *VCS Version 3*, but are now excluded from the scope of the VCS Program (Section 2.1): **Updated on 9 March 2020** to revise the effective dates for projects registered with an approved GHG Program. New text is shown in red and deleted text is shown in strikethrough, below. 1) Registered VCS projects and projects that request registration with the VCS Program on or before 31 December 2019 remain eligible under the VCS Program for the entirety of their crediting periods. 2) Grouped projects registered under the VCS Program shall be prohibited from adding new project activity instances of the newly excluded project types on or after 1 January 2020; verification reports dated on or after 1 January 2020 shall not be accepted where they include the validation of such new project activity instances. 3) Projects registered under an approved GHG program shall only be eligible to complete a gap validation and/or transfer to the VCS Program where the project has applied for registration with the VCS Program ~~approved GHG program~~ on or before 9 March 2020 ~~31 December 2019~~, unless evidence of contracting for a VCS gap validation prior to 9 March 2020 is provided. 4) GHG credits issued under an approved GHG program shall only be eligible to be converted into VCUs where a conversion request has been submitted ~~the project has applied for registration with the approved GHG program~~ on or before 9 March 2020 ~~31 December 2019~~, unless evidence of contracting for a CER conversion prior to 9 March 2020 is provided, in which case the conversion must take place on or before 9 April 2020. For projects subject to new crediting period requirements under *VCS Version 4* (i.e., non-AFOLU projects and ALM projects focusing exclusively on reducing N_2O, CH_4 and/or fossil-derived CO_2 emissions) (Section 3.8): 1) Registered projects and projects that complete validation on or before 19 March 2020 remain eligible to apply the crediting period requirements under *VCS Version 3.* 2) Projects applying a new VCS methodology (i.e., a methodology for which a concept note was submitted to Verra on or before 31 December 2018) shall be granted additional time to apply the crediting period requirements under VCS Version 3. Specifically, projects using a new VCS methodology and completing validation within two years of the approval of the methodology may apply the crediting requirements as set out under *VCS Version 3*.

v4.0

ABOUT VERRA

Verra supports climate action and sustainable development through the development and management of standards, tools and programs that credibly, transparently and robustly assess environmental and social impacts, and drive funding for sustaining and scaling up these benefits. As a mission-driven, non-profit (NGO) organization, Verra works in any arena where we see a need for clear standards, a role for market-driven mechanisms and an opportunity to achieve environmental and social good.

Verra manages a number of global standards frameworks designed to drive finance towards activities that mitigate climate change and promote sustainable development, including the Verified Carbon Standard (VCS) Program and its Jurisdictional and Nested REDD+ framework (JNR), the Verra California Offset Project Registry (OPR), the Climate, Community & Biodiversity (CCB) Standards and the Sustainable Development Verified Impact Standard (SD VISta). Verra is also developing new standards frameworks, including LandScale, which will promote and measure sustainability outcomes across landscapes. Finally, Verra is one of the implementing partners of the Initiative for Climate Action Transparency (ICAT), which helps countries assess the impacts of their climate actions and supports greater transparency, effectiveness, trust and ambition in climate policies worldwide.

CONTENTS

1 INTRODUCTION

This document provides the requirements for methodologies developed under the VCS Program. The purpose of this document is to assist methodology developers and validation/verification bodies in developing and assessing methodologies.

Where external documents are referenced, such as the *IPCC 2006 Guidelines for National GHG Inventories*, and such documents are updated, the most recent version of the document shall be used.

This document will be updated from time-to-time and readers shall ensure that they are using the most current version of the document.

2 GENERAL REQUIREMENTS

This section sets out the general rules and requirements for all methodologies under the VCS Program. Specific requirements for agriculture, forestry and other land use (AFOLU) and ozone depleting substances (ODS) methodologies are set out throughout this Section 2 (and Section 3) below, as these methodology types may encounter unique circumstances related to project implementation, monitoring and other matters, which must be addressed.

In order to become an approved methodology under the VCS Program, methodologies shall demonstrate how they meet the rules and requirements set out below. Methodologies shall be assessed per the process set out in the VCS Program document *Methodology Approval Process*.

2.1 Methodology Development

Concept

Establishing consistent and standardized criteria for development and assessment of methodologies is critical to ensuring their integrity. Accordingly, certain high-level requirements shall be met by all methodologies, as set out below.

Requirements

2.1.1 Methodologies shall comply with the requirements set out in this document and any other applicable requirements set out in the VCS Program rules, and be approved via the methodology approval process (as set out in the VCS Methodology Approval Process).

2.1.2 New methodologies shall not be developed where an existing methodology could reasonably be revised (i.e., developed as a methodology revision) to meet the objective of the proposed methodology.

2.1.3 Methodology elements shall be guided by the principles set out in the VCS Program document *VCS Standard*. They shall clearly state the assumptions, parameters and procedures that have significant uncertainty, and describe how such uncertainty shall be addressed.

2.1.4 Methodologies shall be informed by a comparative assessment of the project and its alternatives in order to identify the baseline scenario. Such an analysis shall include, at a minimum, a comparative assessment of the implementation barriers and net benefits faced by the project and its alternatives.

2.2 Methodology Structure

Concept

The VCS Program allows for different methodology structures, including modular approaches, and different approaches for demonstrating additionality and/or determining the crediting baseline.

Requirements

General

2.2.1 Methodologies may employ a modular approach in which a framework document provides the structure of the methodology and separate modules and/or tools are used to perform specific methodological tasks. Such methodologies shall use the *VCS Methodology Template* for the framework document and the *VCS Module Template* for the modules and tools. The framework document shall clearly state how the modules and/or tools are to be used within the context of the methodology.

Additionality and Crediting Baseline Approaches

2.2.2 Methodologies shall use a standardized method (i.e., performance method or activity method) or a project method to determine additionality and/or the crediting baseline, and shall state which type of method is used for each.

1) A project method is a methodological approach that uses a project-specific approach for the determination of additionality and/or crediting baseline.
2) Standardized methods are further described in Section 2.3.1 and additional guidance is available in VCS document *Guidance for Standardized Methods*. This guidance document provides additional information to aid the interpretation of the VCS Program rules on standardized methods and should be read before developing or assessing such methods. Although the guidance document does not form part of the VCS Program rules, interpretation of the rules shall be consistent with the guidance document.

2.2.3 Methodologies may use any combination of project, performance or activity methods for determining additionality and the crediting baseline. However, methodologies shall provide only one method (i.e., a project method or performance method) for determining the crediting baseline (i.e., methodologies shall not provide the option of using either a project method or a performance method for the crediting baseline).

2.3 Standardized Methods

Concept

Standardized methods are methodological approaches that standardize the determination of additionality and/or the crediting baseline for a given class of project activity, with the objective of streamlining the development and assessment process for individual projects. The VCS Program allows for the use of two types of standardized methods: performance methods, which establish performance benchmarks for the demonstration of additionality and/or the crediting baseline, and activity methods, which pre-determine additionality for given classes of project activities using a positive list.

Requirements

2.3.1 Additionality and/or the crediting baseline are determined for the class of project activity, and qualifying conditions and criteria are set out in the methodology. Individual projects need only meet the conditions and apply the pre-defined criteria set out in the standardized method, obviating the need for each project to determine additionality and/or the crediting baseline via project-specific approaches and analyses.

The VCS Program defines two types of standardized methods:

1) Performance methods: These methods establish performance benchmark metrics for determining additionality and/or the crediting baseline. Projects that meet or exceed a pre-determined level of the metric may be deemed as additional and a pre-determined level of the metric may serve as the crediting baseline.
2) Activity methods: These methods pre-determine additionality for given classes of project activities using a positive list. Projects that implement activities on the positive list are automatically deemed as additional and do not otherwise need to demonstrate additionality. One of three options (namely activity penetration, financial feasibility or revenue streams) is used to qualify the project activity for the positive list, as set out in Section 3.5.9.

Note – There is some overlap between performance and activity methods with respect to concepts, objectives and outcomes, and methodologies may use any combination of methods (performance, activity and project) for determining additionality and the crediting baseline as set out in Section 2.2.2. However, both performance and activity methods are sufficiently distinct, and this document sets out the rules and requirements for each method separately.

2.3.2 Methodologies shall include sufficient information and evidence to allow the reader to reach the same assessment conclusion on the appropriateness and rigor of the standardized method reached by the two validation/verification bodies in the methodology approval process, noting that the confidentiality of proprietary data may be protected as set out in Section 3.4.6(5). To aid the readability and clarity of methodologies, such information and evidence may be included in appendices to methodology documents rather than in the body of the documents themselves. Following their initial approval, methodologies are subject to periodic re-assessment, as set out in the VCS Program document *Methodology Approval Process*.

Performance Methods

2.3.3 All new performance methods shall be prepared using the *VCS Methodology Template*. A performance method is an integral part of a methodology and therefore it cannot be developed and approved as a separate module that is then applied by projects in conjunction with other methodologies.

2.3.4 Methodologies may use a performance method for determining additionality only, for determining additionality and the crediting baseline, or for determining the crediting baseline only. The level of the performance benchmark metric for determining additionality and for the crediting baseline may be the same, or each may be different. Where they are different, the level for determining additionality shall be more stringent than the level of the crediting baseline.

2.3.5 Where a methodology uses a performance method for determining both additionality and the crediting baseline, the methodology shall list all methodologies that use a project method for determining the crediting baseline that are applicable to similar project activities and are approved under the VCS Program or an approved GHG program. The purpose of this requirement is to facilitate the transition to standardized methods, as further set out in the VCS Program document *VCS Standard*.

2.3.6 The performance benchmark metric shall be specified in terms of tonnes of CO_2e per unit of output (i.e., GHG emissions per unit of product or service), tonnes of CO_2e per unit of input (e.g., GHG emissions per unit of input per unit of land area) or as a sequestration metric (e.g., carbon stock per unit of land area), as appropriate to the project activity applicable under the methodology. This may represent tonnes of CO_2e reduced or tonnes of CO_2e sequestered. An input metric shall only be used where an output metric is not practicable (e.g., the corresponding output metric is subject to influences outside the control of the project proponent) and leakage shall be addressed. The unit shall be unambiguously defined to allow a consistent comparison of project performance with the performance benchmark. The *GHG Protocol for Project Accounting,* Chapter 7 (WRI-WBCSD) provides some examples of products and services that may serve as candidates for performance benchmark metrics. Note that proxies for the performance benchmark metric may be used for determining additionality, as set out in Section 3.5.7.

2.3.7 It is recognized that an overly stringent level for the performance benchmark metric used for additionality may exclude additional projects (false negatives) while an overly lenient level may allow in non-additional projects (false positives). Similarly, an overly stringent level of the performance benchmark metric used for the crediting baseline may result in too little incentive for project proponents while an overly lenient level may allow the crediting of non-additional GHG emission reductions and removals. In order to address these considerations, the following shall apply with respect to setting the level(s) of the performance benchmark metric:

1) Methodologies shall provide a description and analysis of the current distribution of performance within the sector as such performance relates to the applicability of the methodology or each performance benchmark (see Section 3.2.5 for further information on applicability of methodologies and performance benchmarks). Methodologies shall also provide an overview of the technologies and/or measures available for improving performance within the sector, though an exhaustive list is not required recognizing that performance methods may be somewhat agnostic with respect to the technologies and/or measures implemented by projects.
2) Methodologies shall discuss and evaluate the trade-off between false negatives and false positives and shall describe objectively and transparently the evidence used (including reference to primary and secondary data sources), experts consulted, assumptions made, and analysis (including numerical analysis) and process undertaken in determining the selected level(s) of the performance benchmark metric (noting that expert consultation is a key part of this process, as set out below). The selected level(s) shall not systematically overestimate GHG emission reductions or removals.
3) The process of determining the level(s) of the performance benchmark metric shall include and be informed by an expert consultation process, undertaken by the methodology developer as follows:
    a) The objective of the expert consultation shall be to engage and solicit input from technical experts on the appropriateness of the proposed level(s) of the performance benchmark metric to ensuring environmental integrity and provision of sufficient financial incentive to potential projects. Technical experts are persons who have specific knowledge or expertise relevant to the methodology and performance benchmark metric.
    b) The methodology developer shall ensure that a representative group of experts participates in the consultation, including, but not limited to, representation from industry, environmental non-governmental organizations, and government or other regulatory bodies. Where a diverse range of views can be expected with regard to the appropriate level of the performance benchmark metric, experts representing the range of views shall participate in the consultation. Participation by experts shall be pro-actively sought and facilitated. Consultation that does not involve a representative group of experts shall be deemed insufficient.
    c) Experts shall be provided, under appropriate confidentiality agreements (as necessary), with sufficient background and technical information about the methodology and its context to allow meaningful participation in the consultation. The consultation process shall use meetings, conference calls and other appropriate methods to allow all experts to provide comments and exchange views in an open, fair and transparent manner.
    d) A report on the expert consultation process and outcome shall be prepared and submitted to Verra when a methodology is submitted under the methodology approval process. This may be included as an annex to the methodology, to be removed from

any final approved version of the methodology. The report shall provide a summary of expert views, and shall demonstrate how the above requirements have been met and how expert views were taken due account of (i.e., how expert views have affected the final level(s) of the performance benchmark metric in the draft methodology).

Note that expert consultation only needs to be undertaken by the methodology developer with respect to the level of the performance benchmark metric, since the methodology is also subject to public stakeholder consultation as part of the VCS Program methodology approval process.

2.3.8 Where there is heterogeneity of performance (measured in terms of the performance benchmark metric) that may be practicably achieved by individual projects, multiple benchmarks or correction factors may be required. Multiple benchmarks or correction factors shall be established under the following circumstances:

1) The project activity includes technologies and/or measures which may be implemented at both greenfield and brownfield sites and the performance (measured in terms of the performance benchmark metric) that may be practicably achieved at each is substantially different.
2) The methodology encompasses both larger and smaller scale project activities and the performance (measured in terms of the performance benchmark metric) that may be practicably achieved in each case is substantially different.
3) Any other circumstances related to the baseline scenario or project activity, such as plant age, raw material quality and climatic circumstances, that lead to heterogeneity of performance (measured in terms of the performance benchmark metric) that may be practicably achieved by individual projects.

Activity Methods

2.3.9 Activity methods shall be prepared using the *VCS Module Template*, or, where a new methodology is being developed, may be written directly into the methodology (i.e., a positive list may be prepared and approved as a standalone additionality test that may be used in conjunction with applicable methodologies, or may be prepared as a direct part of a new methodology, in which case it may not be used in conjunction with other methodologies). To aid the readability of this document, it is assumed that the activity method is being written directly into the methodology, so readers should take references to methodology to mean methodology or module, as appropriate.

2.3.10 Activity methods shall set out, using the specification of the project activity under the applicability conditions, a positive list of project activities that are deemed as additional under the activity method (see Section 3.2 for further information on providing specification of project activities). All such project activities are deemed as additional under the activity method.

2.4 Uncertainty

Concept

Uncertainty is a characteristic of a measurement or sample that describes the dispersion of values that could reasonably be attributed to the measured value. Certain measurements and sampled data will have inherent uncertainty. Where relevant, methodologies shall set out procedures for projects to estimate uncertainty and apply confidence deductions to account for uncertainty, according to recognized statistical approaches.

Requirements

2.4.1 Where applicable, methodology elements shall provide a means to estimate a 90 or 95 percent confidence interval. Where a methodology applies a 90 percent confidence interval and the width of the confidence interval exceeds 20 percent of the estimated value or where a methodology applies a 95 percent confidence interval and the width of the confidence interval exceeds 30 percent of the estimated value, an appropriate confidence deduction shall be applied.

2.4.2 Methods used for estimating uncertainty shall be based on recognized statistical approaches such as those described in the *IPCC Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories*. Confidence deductions shall be applied using conservative factors such as those specified in the CDM Meth Panel *guidance on addressing uncertainty in its Thirty Second Meeting Report, Annex 14*.

2.5 Models, Default Factors and Proxies

Concept

Methodologies may use models, default factors and/or proxies to streamline monitoring or measurement processes. Where methodologies use models, default factors and/or proxies, they shall follow the requirements set out below in order to ensure the integrity of the model, default factor(s) and proxy(s) used.

Requirements

2.5.1 Where methodologies mandate the use of specific models to simulate processes that generate GHG emissions (i.e., the project proponent is not permitted to use other models), the following applies, given the note below:

1) Models shall be publicly available, though not necessarily free of charge, from a reputable and recognized source (e.g., the model developer's website, IPCC or government agency).

2) Model parameters shall be determined based upon studies by appropriately qualified experts that identify the parameters as important drivers of the model output variable(s).

3) Models shall have been appropriately reviewed and tested (e.g., ground-truthed using empirical data or results compared against results of similar models) by a recognized, competent organization, or an appropriate peer review group.

4) All plausible sources of model uncertainty, such as structural uncertainty or parameter uncertainty, shall be assessed using recognized statistical approaches such as those described in *2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 1, Chapter 3*.

5) Models shall have comprehensive and appropriate requirements for estimating uncertainty in keeping with IPCC or other appropriate guidance, and the model shall be calibrated by parameters such as geographic location and local climate data.

6) Models shall apply conservative factors to discount for model uncertainty (in accordance with the requirements set out in Section 2.1.3), and shall use conservative assumptions and parameters that are likely to underestimate, rather than overestimate, the GHG emission reductions or removals.

Note – The criteria set out in (2)-(6) above are targeted at more complex models. For simple models, certain of these criteria may not be appropriate, or necessary to the integrity of the methodology. Such criteria may be disregarded, though the onus is upon the methodology developer to demonstrate that they are not appropriate or necessary.

2.5.2 Where methodologies use default factors and standards to ascertain GHG emission data and any supporting data for establishing baseline scenarios and demonstrating additionality, the following applies:

1) Where the methodology uses third party default factors and/or standards, such default factors and standards shall meet with the requirements for data set out in Section 3.4.6, *mutatis mutandis*.

2) Where the methodology itself establishes a default factor, the following applies:

   a) The data used to establish the default factor shall comply with the requirements for data set out in Section 3.4.6, *mutatis mutandis*.

   b) The methodology shall describe in detail the study or other method used to establish the default factor.

   c) The methodology developer shall identify default factors which may become out of date (i.e., those default factors that do not represent physical constants or otherwise would not be expected to change significantly over time). Such default factors are subject to periodic re-assessment, as set out in the VCS Program document *Methodology Approval Process*.

3) Where methodologies allow project proponents to establish a project-specific factor, the methodology shall provide a procedure for establishing such factors.

Note – Methodologies may use deemed savings factors which, as set out in the definition of deemed savings factor, are a specific type of default factor.

2.5.3 Where proxies are used, it shall be demonstrated that they are strongly correlated with the value of interest and that they can serve as an equivalent or better method (e.g., in terms of reliability, consistency or practicality) to determine the value of interest than direct measurement of the value itself.

2.6 AFOLU Methodologies

Concept

AFOLU projects may encounter unique circumstances related to project implementation, monitoring and other matters. Methodologies applicable to AFOLU projects shall meet additional requirements in order to address these circumstances. This section sets out high-level methodological requirements related to such AFOLU-specific matters. Note that additional AFOLU-specific requirements are also set out throughout this document.

Requirements

2.6.1 There are currently six AFOLU project categories under the VCS Program, as further described in Appendix 1 Eligible AFOLU Project Categories. Proposed AFOLU methodologies shall fall within one or more of these AFOLU project categories.

2.6.2 Where a methodology combines AFOLU project categories, the methodology shall adhere to all sets of requirements pertaining to each and every project category covered, either separating activities, or where activities cannot be separated, taking a conservative approach to each requirement.

2.6.3 Biofuel crop production activities are eligible as a project activity only to the extent that they generate measurable long-term increases in aboveground, belowground, and/or soil carbon stocks or substantially reduce soil carbon losses. Biofuel crop production on undrained or rewetted wetlands shall follow the wetlands restoration and conservation (WRC) requirements. Although a number of biofuel crops require drainage, some forms of biomass production on wetlands (e.g., paludicultures on peatland) are compatible with rewetting and may even lead to organic matter accumulation. This activity is feasible, for example, with crops that grow on wet peatlands and that do not consume the peat body, such as alder, papyrus and willow. Biofuel crop production activities on drained wetlands or on wetlands cleared of, or converted from, native ecosystems are not eligible.

2.7 ODS Methodologies

Concept

ODS projects may encounter unique circumstances related to project implementation, avoidance of perverse incentives and other matters. Methodologies applicable to ODS projects shall meet additional requirements in order to address these circumstances. This section sets out high-level methodological requirements related to such ODS-specific matters. Note that additional ODS-specific requirements are also set out throughout this document.

Requirements

2.7.1 Methodology elements for ODS destruction projects are categorized under sectoral scope 11, fugitive emissions from production and consumption of halocarbons and sulphur hexafluoride.

2.7.2 ODS projects are eligible for immediate crediting of future avoided emissions and methodology elements may use such a crediting model.

Note – Crediting shall still be in relation to the baseline scenario. In many cases, methodology elements will credit projects for all of the ODS destroyed by the project (minus any project emissions and leakage). However, it is possible that projects could destroy ODS from existing stockpiles and only a portion of the ODS would have been emitted under the baseline scenario. For example, if the baseline scenario includes use of the ODS to service existing equipment and a certain proportion of such ODS would be recovered and destroyed at the end of that equipment's life (whether voluntarily or due to regulation), then the volume of credits granted to the project shall reflect this.

2.8 Methodology Revisions

Concept

VCS methodologies and approved GHG program methodologies may be revised under the VCS Program. Additionally, standardized methods must be re-evaluated periodically to ensure that they are still valid, and necessary updates to a standardized method may require revision to the underlying methodology.

Requirements

General

2.8.1 Methodology revisions are appropriate where a project activity is broadly similar to the project activities eligible under an existing methodology and such project activity can be included through reasonable changes to that methodology. Methodology revisions are also appropriate where an existing methodology can be materially improved. Materially improving a methodology involves comparing the existing and proposed methodologies so as to show that the changes will deliver material improvements that will result in greater accuracy of measurement of GHG emissions reductions or removals, improved conservatism and/or reduced transaction costs.

2.8.2 Methodology revisions shall be prepared using the *VCS Methodology Template* and shall be managed via the methodology approval process. They may be prepared and submitted to the methodology approval process by the developer of the original methodology or any other entity.

2.8.3 The VCS Program distinguishes between revisions to VCS methodologies and revisions to approved GHG program methodologies. The requirements for the development and assessment of each are set out in the VCS Program document *Methodology Approval Process*.

Standardized Methods

2.8.4 Standardized methods approved under the VCS Program shall be periodically reviewed and may require revision, as set out in the VCS Program document *Methodology Approval Process*.

2.8.5 Where an activity method uses the activity penetration option and the level of activity penetration has risen (since initial approval) to exceed the five-percent threshold level, the activity method may not be revised to use the financial feasibility or revenue streams options.

3 METHODOLOGY COMPONENTS

This section sets out the rules and requirements for each component of VCS methodologies.

In order to be approved under the VCS Program, methodologies shall be assessed per the process set out in the VCS Program document *Methodology Approval Process*.

3.1 Definitions

Concept

Methodologies may set out defined terms in addition to those already included in the VCS *Program Definitions* to help users understand the context of the methodology and improve its readability.

Requirements

3.1.1 Definitions shall be written in a clear and concise manner.

3.1.2 Defined terms shall be used within the methodology and methodologies shall not define terms that are already included in the VCS *Program Definitions*.

3.2 Applicability Conditions

Concept

Applicability conditions define the project activities which are eligible to apply a given methodology. These may include conditions such as geographic applicability, technology type, historical land use and any other conditions under which the methodology is or is not applicable.

Requirements

General

3.2.1 Methodologies shall use applicability conditions to specify the project activities to which it applies and shall establish criteria that describe the conditions under which the methodology can (and cannot, if appropriate) be applied. Any applicability conditions set out in tools or modules used by the methodology shall also apply.

Standardized Methods

3.2.2 Precise specification of the project activity is required to provide a carefully targeted standardized method with an appropriate level of aggregation with respect to the project activity. The applicability conditions shall be specified accordingly and shall cause to be excluded from the methodology, to the extent practicable, those classes of project activities that it can be reasonably assumed will be implemented without the intervention created by the carbon market. For example, a methodology may exclude facilities larger than a specific size or capacity, constructed before a given date or that have regular access to lower cost fuels than most facilities. Methodologies shall demonstrate how the applicability conditions achieve such objective with respect to free-riders.

Performance Methods

3.2.3 The applicability conditions shall limit the applicability of the methodology to project activities whose performance can be described in terms of the performance benchmark metric set out in the methodology.

3.2.4 Where a methodology uses a performance method for determining additionality, the applicability conditions shall ensure that the project implements technologies and/or measures that cause substantial performance improvement relative to the crediting baseline and what is achievable within the sector, and the methodology shall explicitly specify such technologies and/or measures (or examples thereof). Note that the implementation date of such technologies and/or measures is the project start date and the VCS Program rules with respect to project start date apply (i.e., implementation will need to have occurred within timeframes permitted under the VCS Program rules on project start date). Activities that have not implemented any such technologies and/or measures, or that have implemented them on a date that is earlier than that permitted under the VCS rules on project start date, shall be excluded from the methodology.

3.2.5 The applicability conditions shall establish the scope of validity of the methodology, and where multiple benchmarks are established, each performance benchmark, including the geographic scope. In establishing the scope of validity of the methodology or each performance benchmark, the methodology shall clearly demonstrate that there is similarity across the sub-areas of the geographic scope in factors such as socio-economic conditions, climatic conditions, energy prices, raw material availability and electricity grid emission factors, as such factors relate to the baseline scenario and additionality, noting that variation is permitted where correction factors address such variation as set out in Section 2.3.8.

It may be necessary to stratify and establish multiple performance benchmarks, or to limit the applicability of the methodology, to comply with this requirement.

3.2.6 The applicability of a methodology or a performance benchmark shall be limited to the geographic area for which data are available, or it shall be demonstrated that data from one geographic area are representative of another or that it is conservative to apply data from one geographic area to another. Representativeness shall be determined in terms of the similarity of the geographic areas considering such factors as those set out in Section 3.2.5 above. Likewise, it shall be determined that it is conservative to apply data from one geographic area by considering the same factors. In determining whether two areas are sufficiently similar, or that it is conservative, to allow data to apply from one area to another, only factors related to the baseline scenario and additionality need to be considered.

Activity Methods

3.2.7 The applicability conditions specify the project activity and they shall therefore serve as the specification of the positive list (i.e., all project activities that satisfy the applicability conditions are deemed as additional).

3.2.8 Methodologies shall clearly specify the project activity in terms of a technology or measure and its context of application. A technology or measure encompasses the plant, equipment, process, management and conservation measure or other practice that directly or indirectly generates GHG emission reductions and/or removals. The context of application refers to the conditions or circumstances under which such technology or measure may be implemented.

3.2.9 The applicability conditions shall establish the scope of validity of the methodology, including the geographic scope. In establishing the scope of validity of the methodology, the methodology shall clearly demonstrate that there is similarity across the sub-areas of the geographic scope in factors such as socio-economic conditions, climatic conditions, energy prices, raw material availability and electricity grid emission factors; as such factors relate to the baseline scenario and additionality, it may be necessary to limit the applicability of the methodology to comply with this requirement.

3.2.10 Where the activity method is set out as a separate module (i.e., is not an integrated part of a methodology), the activity method may be applied to any methodology eligible under the VCS Program that permits the project activity specified in the module (see the VCS Program document *VCS Standard* for further details).

3.3 Project Boundary

Concept

The project boundary includes the GHG sources, sinks and reservoirs that are controlled by the project proponent, are related to the project or are affected by project activities. Methodologies shall describe the project boundary and the GHG sources, sinks and reservoirs included in or excluded from the project boundary.

Requirements

General

3.3.1 Methodologies shall establish criteria and procedures for describing the project boundary and identifying and assessing GHG sources, sinks and reservoirs relevant to the project and baseline scenarios. Justification for GHG sources, sinks and reservoirs included or excluded shall be provided.

3.3.2 In identifying GHG sources, sinks and reservoirs relevant to the project, methodologies shall set out criteria and procedures for identifying and assessing GHG sources, sinks and reservoirs that are controlled by the project proponent, related to the project or affected by the project (i.e., leakage).

3.3.3 In identifying GHG sources, sinks and reservoirs relevant to the baseline scenario, methodologies shall:

1) Set out criteria and procedures used for identifying the GHG sources, sinks and reservoirs relevant for the project.
2) Where necessary, explain and apply additional criteria for identifying relevant baseline GHG sources, sinks and reservoirs.
3) Compare the GHG sources, sinks and reservoirs identified for the project with those identified in the baseline scenario, to ensure equivalency and consistency.

AFOLU Methodologies

3.3.4 The relevant carbon pools for AFOLU project categories are aboveground tree biomass (or aboveground woody biomass, including shrubs, in ARR, ALM and ACoGS projects), aboveground non-tree biomass (aboveground non-woody biomass in ARR and ALM projects), belowground biomass, litter, dead wood, soil (including peat) and wood products. Methodologies shall include the relevant carbon pools set out in Table 1 below.

Table 1: Carbon Pools to be considered in Methodologies

		Above-ground tree* biomass	Above-ground non-tree* biomass	Below-ground biomass	Litter	Dead wood	Soil	Wood products
ARR		Y	S	S	S	S	S	O
ALM		S	N	O	N	N	Y	O
IFM	Reduced Impact Logging (RIL) with no or minimal (<25%) effect on total timber extracted	Y	N	O	N	Y	N	N
	Reduced Impact Logging (RIL) with at least 25% reduction in timber extracted	Y	N	O	N	Y	N	Y
	Logged to Protected Forest (LtPF)	Y	N	O	N	Y	N	Y
	Extended Rotation Age (ERA)	Y	N	O	N	O	N	O
	Low-productive to High-productive Forests (LtHP)	Y	N	O	N	O	O	O
REDD	Planned or unplanned deforestation/degradation (APD or AUDD) with annual crop as the land cover in the baseline scenario	Y	O	O	N	O	O	S
	Planned or unplanned deforestation/degradation (APD or AUDD) with pasture grass as the land cover in the baseline scenario	Y	O	O	N	O	N	S
	Planned or unplanned deforestation/degradation (APD or AUDD) with perennial tree crop[1] as the land cover in the baseline scenario	Y	Y	O	N	O	N	S

[1] Common perennial crops include oil palm, bananas, other fruit trees, spice trees, tea shrubs, and the like, which may or may not meet the definition of a tree used within a host country.

ACoGS	Planned or unplanned conversion	O	O	O	O	O	O	N
WRC		Y	O	O	N	O	Y	O

Y: Carbon pool shall be included in the project boundary.

S: Carbon pool shall be included where project activities may significantly reduce the pool, and may be included where baseline activities may significantly reduce the pool, as set out in Sections 3.3.10 to 3.3.28. The methodology shall justify the exclusion or inclusion of the pool in the project boundary.

N: Carbon pool does not have to be included, because it is not subject to significant changes or potential changes are transient in nature. The pool may be included in the project boundary because of positive impacts to reducing or removing emissions. Where the carbon pool is included in the project boundary, methodologies shall establish criteria and procedures to set out when a project proponent may include the pool.

O: Carbon pool is optional and may be excluded from the project boundary. Where the pool is included in the methodology, the methodology shall establish criteria and procedures to set out when a project proponent shall or may include the pool.

* For ARR, ALM and ACoGS projects, in place of "Aboveground tree" and "Aboveground non-tree", these two carbon pool categories should be read as "Aboveground woody" and "Aboveground non-woody" respectively.

3.3.5 Additional guidance and further requirements with respect to specific carbon pools and GHG sources are set out below in Sections 3.3.10 to 3.3.28.

3.3.6 Specific carbon pools and GHG sources, including carbon pools and GHG sources that cause project and leakage emissions, may be deemed *de minimis* and do not have to be accounted for if together the omitted decrease in carbon stocks (in carbon pools) or increase in GHG emissions (from GHG sources) amounts to less than five percent of the total GHG benefit generated by the project. The methodology shall establish the criteria and procedures by which a pool or GHG source may be determined to be *de minimis*.

For example, peer reviewed literature or the CDM A/R methodological tool *Tool for testing significance of GHG emissions in A/R CDM project activities* may be used to determine whether decreases in carbon pools and increases in GHG emissions are *de minimis*.

Further, the following GHG sources may be deemed *de minimis* and need not be accounted for:

1) ARR, IFM and REDD: N_2O emissions from project activities that apply nitrogen containing soil amendments and N_2O emissions caused by microbial decomposition of plant materials that fix nitrogen. ALM projects that apply nitrogen fertilizer and/or manure or plant nitrogen fixing species shall account for N_2O emissions.

2) ARR, IFM, REDD, ACoGS and WRC: GHG emissions from the removal or burning of herbaceous vegetation and collection of non-renewable wood sources for fencing of the project area.

3) ARR, IFM, REDD, ACoGS and WRC: Fossil fuel combustion from transport and machinery use in project activities. Where machinery use for selective harvesting activities may be significant in IFM project activities as compared to the baseline or where machinery use for earth moving activities may be significant in WRC project activities as compared to the baseline, emissions shall be accounted for if above *de minimis*, in accordance with this Section 3.3.6. Fossil fuel combustion from transport and machinery use in rewetting of drained peatland and conservation of peatland project activities need not be accounted for.

3.3.7 Specific carbon pools and GHG sources do not have to be accounted for if their exclusion leads to conservative estimates of the total GHG emission reductions or removals generated. The methodology shall establish criteria and procedures by which a project proponent may determine a carbon pool or GHG source to be conservatively excluded. Such conservative exclusion may be determined by using tools from an approved GHG program, such as the CDM A/R methodological tool *Procedure to determine when accounting of the soil organic carbon pool may be conservatively neglected in CDM A/R project activities*, or by using peer-reviewed literature.

3.3.8 Reductions of N_2O and/or CH_4 emissions are eligible for crediting if in the baseline scenario the project area would have been subject to livestock grazing, rice cultivation, burning and/or nitrogen fertilization.

3.3.9 Reductions of CH_4 emissions are eligible for crediting if fire would have been used to clear the land in the baseline scenario.

Afforestation, Reforestation and Revegetation (ARR)

3.3.10 Where a methodology is applicable to projects that may reduce the aboveground non-woody biomass, belowground biomass, litter, dead wood or soil pools above *de minimis* (as set out in Section 3.3.6), the relevant carbon pool shall be included in the project boundary.

Agricultural Land Management (ALM)

3.3.11 Where a methodology is applicable to projects with livestock grazing in the project or baseline scenario, CH_4 emissions from enteric fermentation and CH_4 and N_2O emissions from manure shall be included in the project boundary.

3.3.12 Where land-use conversion requires intensive energy inputs or infrastructure development, such as the establishment of irrigation or drainage systems, the methodology shall include the GHG emissions associated with the conversion process in the project boundary.

3.3.13 Where energy-conserving practices reduce emissions of CO_2, such as adopting no-till practices to reduce fuel use, the methodology may include these GHG emissions reductions in the project boundary.

3.3.14 Where activities convert drained, farmed organic soils to perennial non-woody vegetation and reduce or eliminate drainage to reduce CO_2 and N_2O emissions from organic soils, such activities may increase CH_4 emissions. Methodologies applicable to such activities shall include CH_4 emissions in the project boundary.

Improved Forest Management (IFM)

3.3.15 IFM methodologies applicable to activities that reduce harvested timber shall account for the GHG emissions associated with changes in the wood products pool to avoid overestimating project net GHG benefits. The quantity of live biomass going into wood products shall be quantified where above *de minimis* (as set out in Section 3.3.6).

3.3.16 For IFM activities, changes in soil carbon are likely to be *de minimis* for forests on mineral upland soils, though they could be considerably above *de minimis* for forests growing in wetland areas such as peatland forests or mangroves. Although it may be conservative to omit the soil carbon pool for such projects, additional GHG credits may be available if the soil carbon pool is included. Therefore, the pool may be included in the project boundary.

3.3.17 RIL and LtPF methodologies shall include the dead wood carbon pool in the project and baseline scenario. Both of these activities reduce the amount of timber extracted per unit area, which, in turn, may reduce the dead wood pool in the project scenario.

3.3.18 Accounting for the dead wood carbon pool in ERA methodologies is complex because GHG emissions will depend on how post-harvest slash is treated. Slash may either be piled and burned on site, as typically happens in fire prone areas, or left on site to decompose. Extending a harvest rotation or cutting cycle would result in larger trees at harvest, which would increase the amount of dead wood produced at each harvest, but not necessarily the total amount of dead wood produced over time. Because the dead wood pool may increase above the *de minimis* in the baseline or project scenario, this carbon pool is deemed optional.

Reduced Emissions from Deforestation and Degradation (REDD)

3.3.19 Where timber removal is associated with deforestation and/or degradation in the baseline scenario, the wood product pool shall be included in the project boundary because significant quantities of carbon can be stored in wood products instead of entering the atmosphere during deforestation. The quantity of live biomass going into wood products shall be quantified if above *de minimis* (as set out in Section 3.3.6) or may be conservatively excluded (as set out in Section 3.3.7).

3.3.20 Where the baseline scenario is the conversion of forest to annual crops, additional GHG credits may be available if the soil carbon pool is included because decreases in soil carbon stocks in the baseline scenario can be significant.

Avoided Conversion of Grasslands and Shrublands (ACoGS)

3.3.21 Grasslands and shrublands are highly variable in their above- and belowground biomass, so the relevant carbon pools will vary. Non-forest land commonly generates negligible amounts of wood products, hence the pool is not required for ACoGS. All other pools are optional for ACoGS activities, because none of the carbon pools are expected to decrease with the project activity. Soil carbon is likely to be the carbon pool that generates the most GHG emission reductions in ACoGS projects. In addition, in non-forested ecosystems, the belowground biomass pool is often several times larger than the aboveground biomass pools[2]. Methodologies shall set out the carbon pools that shall or may be included in the project boundary.

3.3.22 Grazing is a common practice in many grassland and some shrubland ecosystems. As such, livestock grazing does not preclude ACoGS project eligibility, and grazing may continue on project areas. Projects that incorporate improved grazing practices shall follow the Improved Grassland Management requirements for such activities in the ALM category. Such activities may provide GHG benefits in addition to those achieved by avoiding conversion under this ACoGS category. Where livestock grazing may be present in the project scenario, methodologies shall set out criteria and procedures to account for CH_4 emissions from enteric fermentation and CH_4 and N_2O emissions from manure. Where grazing occurs in both the baseline and project scenarios, net changes in CH_4 and N_2O associated with grazing may be deemed *de minimis* and excluded in accordance with Sections 3.3.6 and 3.3.7.

3.3.23 Where the baseline scenario may include conversion to cropland, methodologies may include CH_4 and N_2O emissions from fertilizer application (manure or synthetic) in the baseline and project scenarios.

3.3.24 Where the baseline scenario may include the conversion of vegetation to perennial crops, such as where oil palm or short-rotation woody crops would be planted, the aboveground woody and non-woody biomass pools shall be included.

Wetlands Restoration and Conservation (WRC)

3.3.25 Methodologies that allow for combined category projects shall apply the relevant WRC requirements for the soil carbon pool and the respective non-WRC AFOLU project category requirements for the other pools, unless the former may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7)

3.3.26 Methodologies shall include CH_4 emissions in the project boundary (for example, transient peaks of CH_4 that may arise after rewetting peatland). The methodology shall establish the criteria and procedures by which the CH_4 source may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7)

---

[2] Mokany, K., R. J. Raison, and A. S. Prokushkin. 2006. Critical analysis of root: shoot ratios in terrestrial biomes. Global Change Biology 12:84-96.

3.3.27 N_2O emissions shall be included in the project boundary for RWE activities. The methodology shall establish the criteria and procedures by which the N_2O source may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

3.3.28 For project activities implemented on coastal wetlands, methodologies shall establish criteria and procedures for establishing the geographic boundary that considers projections of expected relative sea level rise. The procedures shall account for the potential effect of sea level rise on the lateral movement of wetlands during the project crediting period and the potential that the wetlands will migrate beyond the project boundary.

3.4 Baseline Scenario

Concept

The baseline scenario represents the activities and GHG emissions that would occur in the absence of the project activity. The baseline scenario must be accurately determined so that an accurate comparison can be made between the GHG emissions that would have occurred under the baseline scenario and the GHG emission reductions and/or removals that were achieved by project activities.

Requirements

General

3.4.1 Methodologies using a project method shall establish criteria and procedures for identifying alternative baseline scenarios and determining the most plausible scenario, taking into account the following:

1) The identified GHG sources, sinks and reservoirs.
2) Existing and alternative project types, activities and technologies providing equivalent type and level of activity of products or services to the project.
3) Data availability, reliability and limitations.
4) Other relevant information concerning present or future conditions, such as legislative, technical, economic, socio-cultural, environmental, geographic, site-specific and temporal assumptions or projections.

3.4.2 Methodologies using a standardized method for determining the crediting baseline shall describe (taking into account the factors set out Section 3.4.1 above), as far as is possible, the technologies or measures that represent the most plausible baseline scenario or the aggregated baseline scenario (see Section 3.4.4 for further information on aggregate baseline scenarios), though it is recognized that it may not be possible to specify precisely all technologies or measures given that the baseline may represent a variety of different technologies and measures.

Standardized Methods

3.4.3 Standardized methods shall be developed with the objective of predicting, as accurately as is practicable, the most plausible baseline scenario or aggregated baseline scenario. Notwithstanding this principle, it is recognized that standardized methods cannot perfectly capture the precise baseline behavior for all proposed projects eligible under a standardized method.

Performance Methods

3.4.4 Methodologies shall identify alternative baseline scenarios and determine either the most plausible baseline scenario or an aggregate baseline scenario for the project activity. Aggregate baseline scenarios shall be determined by combining likely scenarios on a probabilistic (i.e., likelihood) basis.

3.4.5 Performance benchmarks shall be established based upon available technologies and/or current practices, and trends, within the sector. Where the analysis of trends shows a clear trend of improvement in the baseline scenario over time, the performance benchmark shall take account of the trend. This means that where the performance benchmark does not use a dataset that is updated at least annually, an autonomous improvement factor shall be used that provides a performance benchmark that tightens annually. Notwithstanding this requirement, methodologies may allow projects to use the level of the performance benchmark metric available at project validation for the duration of their project crediting periods (see also Section 3.4.7 below). Where the analysis of trends shows a trend of increasing GHG emissions or decreasing GHG removals in the baseline scenario over time, the performance benchmark shall not consider such trend.

3.4.6 Appropriate data sources for developing performance methods include economic and engineering analyses and models, peer-reviewed scientific literature, case studies, empirical data, and common practice data. The data and dataset derived from such data sources shall meet the requirements below. The CDM *Guidelines for quality assurance and quality control of data used in the establishment of standardized baselines* also provides useful related guidance.

1) Data collected directly from primary sources shall comply with relevant and appropriate standards, where available, for data collection and analysis, and be audited at an appropriate frequency by an appropriately qualified, independent organization.

2) Data collected from secondary sources shall be available from a recognized, credible source and must be reviewed for publication by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.

3) Data shall be from a time period that accurately reflects available technologies and/or current practice, and trends, within the sector. Selection of the appropriate temporal range shall be determined based on the guidance provided in the *GHG Protocol for Project Accounting*, Chapter 7 (WRI-WBCSD).

4) Where sampling is applied in data collection, the requirements set out in Section 2.1.3 shall be adhered to. The methodology developer shall demonstrate that sampling results provide an unbiased and reliable estimate of the true mean value (i.e., the sampling does not systematically underestimate or overestimate the true mean value).

5) Data shall be publicly available or made publicly available. Proprietary data (e.g., data pertaining to individual facilities) may be aggregated, and therefore not made publicly available, where there are demonstrable confidentiality considerations. However, sufficient data shall be publicly available to provide transparency and credibility to the dataset.

6) All data shall be made available, under appropriate confidentiality agreements as necessary, to Verra and each of the validation/verification bodies assessing the proposed performance benchmark methodology, to allow them to reproduce the determination of the performance benchmark. Data shall be presented in a manner that enables them to independently assess the presented data.

7) Data shall be appropriate to the methodology's geographic scope and the project activities applicable under it.

8) All reasonable efforts shall be undertaken to collect sufficient data and the use of expert judgment as a substitute for data shall only be permitted where it can be demonstrated that there is a paucity of data. Expert judgment may be applied in interpreting data. Where expert judgment is used, good practice methods for eliciting expert judgment shall be used (e.g., *IPCC 2006 Guidelines for National GHG Inventories*).

9) Where data must be maintained in a central repository on an on-going basis (e.g., in a database that holds sector data for use by project proponents in establishing specific performance benchmarks for their projects), there shall be clear and robust custody arrangements for the data and defined roles and responsibilities with respect to the central repository.

Where such data requirements set out above cannot be met, a performance method shall not be applied except as set out in Section 3.2.5.

3.4.7 The dataset may be documented and contained within the methodology, or may be maintained in a separate repository that is referenced by the methodology. Datasets documented and contained within methodologies are static datasets, where all projects use the level of the performance benchmark metric specified in the methodology (noting that autonomous improvement factors may be used, as set out in Section 3.4.5 above). The following applies with respect to datasets maintained in a separate repository:

1) The dataset may be static or dynamic (i.e., may or may not be periodically updated).

2) The methodology shall establish criteria and procedures for use of the dataset and for establishing specific performance benchmarks for individual projects.

3) The methodology may specify that projects use the level of the performance benchmark metric available at project validation for the duration of their project crediting periods, or

may specify that projects use an updated level of the performance benchmark metric at each verification event. The frequency that data is updated within the dataset shall be determined by the methodology developer.

4) It shall be demonstrated that procedures are in place to maintain the dataset in accordance with the applicable requirements set out for data and datasets in Section 3.4.6 above.

Activity Methods

3.4.8 There are no specific requirements for activity methods, noting that methodologies using an activity method may use a project or performance method for determining the crediting baseline, as set out in Section 2.2.2.

AFOLU Methodologies

3.4.9 The determination and establishment of a baseline scenario shall follow an internationally accepted GHG inventory protocol, such as the *IPCC 2006 Guidelines for National GHG Inventories*.

Agricultural Land Management (ALM)

3.4.10 The criteria and procedures for establishing the baseline scenario shall require the project proponent to take into account current and previous management activities. The quantification of the baseline scenario may be determined from measured inventory estimates and/or activity-based estimation methods, such as those found in the *IPCC 2006 Guidelines for National GHG Inventories*.

Improved Forest Management (IFM)

3.4.11 Methodologies that establish criteria and procedures for establishing the baseline scenario using a project method, rather than a performance method shall require the following:

1) Documented evidence of the project proponent’s operating history, such as five or more years of management records, to provide evidence of normal historical practices. Management records may include, *inter alia*, data on timber cruise volumes, length of roads and skid trails, inventory levels, and harvest levels within the project area. Where the project proponent or implementing partner is a new owner or management entity and does not have a history of management practices within the project area, procedures shall be established to identify the most plausible baseline scenario based upon the most likely owner or operator, noting the following:

   a) For RIL and LtPF projects, where the project proponent takes over ownership or management of a property specifically to implement the project, the baseline scenario shall represent the most likely management plan of the most likely owner or operator (i.e., be based on the projected management plans of the previous property owners and/or operators or the management plans of the most likely operator).

b) In all other cases, the baseline scenario shall reflect the local common practices and legal requirements. However, if the common practice is unsustainable and unsustainable practices are inconsistent with the mission or the historical management practices of the new owner or management entity, then a sustainable baseline is the minimum that can be adopted.

2) Adherence to the legal requirements for forest management and land use in the area unless verifiable evidence is provided demonstrating that common practice in the area does not adhere to such requirements.

3) Baseline environmental management practices shall not be set below (i.e., be less environmentally robust than) those commonly considered a minimum standard among similar landowners in the area. For example, where common practice exceeds minimum legal practice, the baseline cannot be the minimum legal requirement and the baseline scenario shall, at a minimum, be based on common practice.

Reduced Emissions from Deforestation and Degradation (REDD)

3.4.12 The baseline for REDD projects is comprised of a land-use and land-cover (LU/LC) change component and a carbon stock change component. These components may be addressed separately in a methodology as their scale of analysis may differ.

3.4.13 For inclusion of the non-CO_2 gases, methodologies shall require projects to provide evidence to demonstrate that the practice for which the project plans to claim credit is not common practice in the area. The guidance in the *IPCC 2003 Good Practice Guidelines for LULUCF* and the *IPCC 2006 Guidelines for National GHG Inventories* may be used to estimate such GHG emissions.

3.4.14 Determination and establishment of the LU/LC change component of the baseline is handled differently for the two eligible REDD activity types, as follows:

1) APD: The criteria and procedures for establishing the baseline scenario shall require the project proponent to provide verifiable evidence to demonstrate, based on government plans (for publicly owned and managed land), community plans (for publicly owned and community-managed land), concessionary plans (for publicly owned and concession-holder managed) or landowner plans (for privately owned land), that the project area was intended to be cleared. The baseline scenario shall take into account the following:

a) Where it is common practice in the area for timber to be removed before clearing, wood products shall be included in the baseline scenario.

b) Where the agent of deforestation is not the landowner (e.g., in situations where the project proponent successfully outcompeted other agents to acquire a government concession or privately-owned lands) and the project can identify the most-likely agent of deforestation, the baseline scenario shall be determined based on the activities of the most-likely agent who would have acquired control of and cleared the project area.

c) Where the agent of deforestation is not the landowner and cannot be specifically identified, the criteria and procedures for establishing the baseline scenario may be determined based on the most-likely-class of deforestation agents and the intent to deforest. This may be demonstrated through a historical analysis of similar deforestation within the region by the identified most-likely class of deforestation agents. The most-likely-class of deforestation agents are the entities (e.g., individuals, companies or associations) classified based on common characteristics and rates of deforestation that would have been likely to undertake deforestation activities and post-deforestation land-use practices in the project area. The annual rate of forest conversion shall be based on the recent historical practice of the most-likely class (i.e., how much forest is typically cleared each year by similar baseline activities) and projection of the rate of their deforestation activities in the area.

2) AUDD: The criteria and procedures for establishing the baseline scenario shall require the project proponent to take into account deforestation/degradation that would have occurred in the project area during the project crediting period. The baseline scenario shall take into account the following:

a) Methodologies shall set out criteria and procedures to identify where deforestation would likely occur using spatial analysis and projections (except for certain mosaic configurations as set out in Section 3.4.14(2)(c)). Such analysis shall be based on historical factors over at least the previous 10 years that explain past patterns and can be used to make future projections of deforestation.

b) In the frontier configuration, most of the forest area to be protected will have low rates of historical deforestation and/or degradation because most of the project area was not accessible in the past to the agents of deforestation/degradation expected to encroach during the project crediting period. Where the expansion of the deforestation frontier into the project area is linked to the development of infrastructure (e.g., roads) that does not yet exist, clear evidence shall be provided to demonstrate that such infrastructure would have been developed in the baseline scenario. Evidence may include permits, maps showing construction plans, construction contracts or open tenders, an approved budget and/or evidence that construction has started.

c) The criteria and procedures for establishing the baseline scenario in the frontier and mosaic configurations shall take into account such factors as historical deforestation and/or degradation rates and require the project proponent to develop a baseline by determining and analyzing a reference area (which need not be contiguous to the project area), that shall be similar to the project area in terms of drivers and agents of deforestation and/or degradation, landscape configuration, and socio-economic and cultural conditions, noting the following.

i) Where, in the mosaic configuration, no patch of forest in project areas exceeds 1,000 ha and the forest patches are surrounded by anthropogenically cleared land, or where it can be demonstrated that 25 percent or more of the perimeter of the project area is within 120 meters of land that has been anthropogenically deforested within the 10 years prior to the project start date, spatial projections to determine where in the project area deforestation is likely to occur are not required. Though not required, such spatial projections may be applied, in accordance with the methodology. Analysis of historical deforestation rates that explain past deforestation in the reference area is required and shall be applied conservatively to the project area.

Avoided Conversion of Grasslands and Shrublands (ACoGS)

3.4.15 The baseline for ACoGS projects is comprised of a land-use and land-cover (LU/LC) change component, a carbon stock change component and a non-CO_2 GHG component where applicable. These components may be addressed with separate analyses in a methodology because the appropriate scale of analysis may differ for each component.

3.4.16 Determination and establishment of the LU/LC change component of the baseline is handled differently for the two eligible ACoGS activity types, as follows:

1) APC: The criteria and procedures for establishing the baseline scenario shall require the project proponent to provide verifiable evidence to demonstrate, based on government plans (for publicly owned and managed land), community plans (for publicly owned and community-managed land), concessionaire plans (for publicly owned and concession holder managed) or landowner plans (for privately owned land), that the project area was intended to be converted. Documentation of the ability to increase net present value of land through conversion is required, including government subsidies or funding that promotes conversion. Further documentation of landowner plans for conversion may include government approval of conversion or a purchase offer from an entity dedicated to conversion. The baseline scenario shall account for spatial heterogeneity in the project area. Where certain areas are unlikely to be converted, these areas shall be excluded from the baseline scenario. The baseline scenario shall take into account the following:

   a) Where the agent of conversion is not the landowner (e.g., in situations where the project proponent successfully outcompeted other agents to acquire a government concession or privately-owned lands) and the project can identify the most-likely agent of conversion, the baseline scenario shall be determined based on historical and current conversion activities of the most-likely agent who would have acquired control of and converted the project area.

   b) Where the agent of conversion is not the landowner and cannot be specifically identified, the criteria and procedures for establishing the baseline scenario shall be determined based on the most-likely-class of conversion agents and their intent to convert, which shall be demonstrated through a history of similar conversion within the region by the identified most-likely class. The most-likely-class of conversion agents are the entities (e.g., individuals, companies or associations) classified based on common characteristics and rates of conversion that would have been likely to undertake conversion activities and post-conversion land-use practices in the project area. The annual rate of land conversion shall be based on the recent historical practice of the most-likely class (i.e., how much land is typically converted each year by similar baseline activities) and projection of the rate of their conversion activities in the area. The timeframe used to quantify recent historical practice shall be justified by the project proponent as being of long enough duration to average over typical market fluctuations, commonly between 5-15 years. This rate of conversion shall only be extrapolated to lands that were identified as susceptible to conversion in the baseline scenario.

2) AUC: The criteria and procedures for establishing the baseline scenario shall require the project proponent to take into account conversion that would have occurred in the project area during the project crediting period. The baseline scenario shall account for spatial heterogeneity within the project area. Where certain areas are unlikely to be converted, these areas shall be excluded from the baseline scenario. This analysis shall take into account the patch size at which land conversion typically occurs (e.g., areas unsuitable for crops may still be plowed if they are a small part of a larger suitable parcel. Alternatively, even suitable areas may be unlikely to be plowed if they are a small part of a larger unsuitable area). The baseline scenario shall take into account the following:

   a) Methodologies shall set out criteria and procedures to identify where land conversion would likely occur using spatial analysis and projections. Such analysis shall be based on historical factors over at least the previous 10 years that explain past patterns and can be used to make future projections of land conversion.

   b) In cases where future land conversion rates are predicted to exceed historical rates in the project area, evidence documenting the factors contributing to increased conversion must be presented. Where the expansion of the conversion frontier into the project area is linked to the development of infrastructure (e.g., roads) that does not yet exist, clear evidence shall be provided to demonstrate that such infrastructure would have been developed in the baseline scenario. Evidence may include permits, an approved budget or executed construction contracts.

   c) The criteria and procedures for establishing the baseline scenario shall take into account such factors as historical conversion rates and require the project proponent to develop a baseline by determining and analyzing a reference area (which need not be contiguous to the project area), that shall be similar to the project area in terms of drivers and agents of land conversion, landscape configuration, and socio-economic and cultural conditions.

Wetland Restoration and Conservation (WRC)

3.4.17 The criteria and procedures for establishing the RWE baseline scenario shall take into account the following:

1) The current and historic hydrological characteristics of the watershed or coastal plain, and the drainage system in which the project occurs.
2) The long-term average climate variables influencing water table depths and the timing and quantity of water flow. The long-term average climate variables shall be determined using data from climate stations that are representative of the project area and shall include at least 20 years of data.
3) Planned water management activities (such as dam construction).

3.4.18 The criteria and procedures for establishing the RWE baseline scenario shall also consider the relevant non-human induced rewetting brought about by any of the following:

1) Collapsing dikes or ditches that would have naturally failed over time without their continued maintenance.
2) Progressive subsidence of deltas or peatlands leading to a rise in relative water table depths, thus reducing CO_2 emissions but possibly increasing CH_4 emissions in freshwater systems.
3) Non-human induced elevation of non-vegetated wetlands to build vegetated wetlands. Deltaic systems with high sediment load from rivers often do this naturally, and this should be counted as part of the baseline.

3.4.19 The criteria and procedures for establishing the CIW baseline scenario are handled differently for each of the eligible CIW activities, as follows:

1) AUWD: The criteria and procedures for establishing the baseline scenario shall require the project proponent to reference a period of at least 10 years for modeling a spatial trend in conversion, taking into account the long-term average climate variables, and the observed conversion practices (e.g., drainage including canal width, depth, length and maintenance). The long-term average climate variable shall be determined using data from climate stations that are representative of the project area and shall include at least 20 years of data.
2) APWD: The criteria and procedures for establishing the baseline scenario shall require the project proponent to provide verifiable evidence to demonstrate that, based on government plans (for publicly owned and managed wetland), community plans (for publicly owned and community-managed wetland), concessionary plans (for publicly owned and concession holder managed) or landowner plans (for privately owned wetland), the project area was intended to be drained or otherwise converted. The annual rate and depth of drainage or rate of other conversion shall be based on the common practice in the area—that is, how much wetland is typically drained or converted each year by similar baseline activities.

3.4.20 The criteria and procedures for identifying fire in the baseline scenario shall demonstrate with fire maps and historical databases on fires that the project area is now and in the future would be under risk of anthropogenic fires. The procedure for identifying fire in the baseline scenario shall also consider any relevant current and planned land use conditions that may affect the occurrence of fire in order to establish the most plausible scenario for fire in the baseline.

3.4.21 Many land use activities on wetlands (e.g., aquaculture and agriculture) involve the exposure of wetland soils to aerobic decomposition through piling, dredging (expansion of existing channels) or channelization (cutting through wetland plains). Where relevant, the criteria and procedures for identifying WRC baseline scenarios shall account for such processes as they expose disturbed carbon stocks to aerobic decomposition thus increasing the rate of organic matter decomposition and GHG emissions that may continue for years from the stockpiles. Methodologies shall include credible methods for quantifying and forecasting GHG emissions from such degradation.

3.4.22 Where relevant, the criteria and procedures for identifying WRC baseline scenarios shall take account of hydrological processes that lead to increased carbon burial and GHG reductions within the project area. Such processes include changes in the landscape form (i.e., construction of levees to constrain flow and flooding patterns or dams to hold water) and changes in land surface (i.e., forest clearing, and ditching or paving leading to intensified run-off).

3.4.23 Where relevant, the criteria and procedures for identifying WRC baseline scenarios shall take account of processes within the project area that reduce sediment supply associated with changes in the landscape (e.g., construction of upstream dams or stabilization of eroding feeder cliffs along the coast). The supply of sediment varies over time and the time-averaged delivery of sediment shall be considered.

3.4.24 Where relevant, methodologies shall establish criteria and procedures for identifying wetland erosion and/or migration resulting from sea level rise in the baseline scenario on the basis of wetland maps, historical trend data, future projection of sea level rise and how changes in management would impact carbon stocks.

3.4.25 Where relevant, the criteria and procedures for establishing the baseline scenario shall require the project proponent to take into account current and historic management activities outside the project area that have significantly impacted or may significantly impact the project area, including the following:

1) Disruption to or improvement of natural sediment delivery, as this will alter the rate and magnitude of coastal wetlands response to sea level rise.

2) Upstream dam construction, as this will alter water and sediment delivery, as well as salinity in coastal lowlands.

3) Construction of infrastructure inland of coastal wetlands, as this will impair wetland capacity to migrate landwards with sea level rise.

4) Construction of coastal infrastructure, as this can impair sediment movement along shorelines causing wetland loss and increasing risk of carbon emissions with sea level rise.

3.4.26 Methodologies that allow for combined category projects shall require the use of the relevant WRC requirements and the respective non-WRC AFOLU project category requirements for the determination and establishment of the baseline scenario.

ODS Methodologies

3.4.27 Where the destruction of the ODS by the project is mandated by law, statute or other regulatory framework applied in the host country, the baseline shall be the gradually increasing compliance with such law, statute or other regulatory framework, and the baseline emissions shall be calculated as follows:

$$BE_{y,a} = BE_y * (1 - CR_y)$$

Where:

$BE_{y,a}$ = The baseline emissions to be used for the calculation of GHG emission reductions in year y.

BE_y = The baseline emissions in year y.

CR_y = The host country level compliance rate of the law, statute or other regulatory framework in the year y. Calculation of the compliance rate shall exclude other projects implemented under GHG programs. If the compliance rate exceeds 50%, the project shall receive no further credit.

3.5 Additionality

Concept

A project activity is additional if it can be demonstrated that the activity results in emission reductions or removals that are in excess of what would be achieved under a "business-as-usual" scenario and the activity would not have occurred in the absence of the incentive provided by the carbon markets. Additionality is an important characteristic of GHG credits, including VCUs, because it indicates that they represent a net environmental benefit and a real reduction of GHG emissions, and can thus be used to offset emissions. Methodologies shall set out a procedure for demonstrating additionality using a project method or a standardized method (i.e., performance method or activity method).

Requirements

General

3.5.1 Methodologies shall establish a procedure for the demonstration and assessment of additionality based upon the requirements set out below.

The steps which shall be included in methodologies for each method of demonstrating additionality (i.e., project methods, performance methods and activity methods) are set out below.

3.5.2 Methodologies shall use a project method, performance method and/or activity method to determine additionality. The high level specifications and procedural steps for each approach are set out in Sections 3.5.3 to 3.5.9 below. New methodologies developed under the VCS Program shall meet this requirement by doing one of the following:

1) Referencing and requiring the use of an appropriate additionality tool that has been approved under the VCS Program or an approved GHG program;

2) Developing a full and detailed procedure for demonstrating and assessing additionality directly within the methodology; or

3) Developing a full and detailed procedure for demonstrating and assessing additionality in a separate tool, which shall be approved via the methodology approval process, and referencing and requiring the use of such new tool in the methodology.

Note – Reference in a methodology to the VCS Program requirements on additionality is insufficient. The VCS Program requirements are high level requirements and do not represent a full and detailed procedure for the demonstration of additionality. The only exception to this is with respect to regulatory surplus (i.e., methodologies may directly reference the VCS Program requirements on regulatory surplus and do not need to further develop a procedure for demonstrating and assessing regulatory surplus).

Project Method

3.5.3 <u>Step 1: Regulatory Surplus</u>

The project shall not be mandated by any law, statute or other regulatory framework, or for UNFCCC non-Annex I countries, any systematically enforced law, statute or other regulatory framework. For UNFCCC non-Annex I countries, laws, statutes, regulatory frameworks or policies implemented[3] since 11 November 2001 that give comparative advantage to less emissions-intensive technologies or activities relative to more emissions-intensive technologies or activities need not be taken into account. For all countries, laws, statutes, regulatory frameworks or policies implemented since 11 December 1997 that give comparative

[3] Implemented in the context of this paragraph means enacted or introduced, consistent with use of the term under the CDM rules on so-called Type E+ and Type E- policies.

advantage to more emissions-intensive technologies or activities relative to less emissions-intensive technologies or activities shall not be taken into account.

3.5.4 Step 2: Implementation Barriers

The project shall face one or more distinct barrier(s) compared with barriers faced by alternatives to the project:

1) Investment barrier: Project faces capital or investment return constraints that can be overcome by the additional revenues associated with the sale of GHG credits.
2) Technological barriers: Project faces technology-related barriers to its implementation.
3) Institutional barriers: Project faces financial (other than identified in investment barrier above), organizational, cultural or social barriers that the VCU revenue stream can help overcome.

3.5.5 Step 3: Common Practice

The project shall not be common practice, determined as follows:

1) Project type shall not be common practice in sector/region, compared with projects that have received no carbon finance.
2) Where it is common practice, the project proponent shall identify barriers faced compared with existing projects.
3) Demonstration that the project is not common practice shall be based on guidance provided in *The GHG Protocol for Project Accounting*, Chapter 7 (WRI-WBCSD).

Standardized Methods

Performance Methods

3.5.6 Step 1: Regulatory Surplus

The project activity shall meet with the requirements on regulatory surplus set out under the project method in Section 3.5.3.

3.5.7 Step 2: Performance Benchmark

The GHG emissions generated (or carbon sequestered) per unit of output, unit of input or sequestration metric by the project shall be below (or above, for sequestration) the prescribed performance benchmark metric or proxy for such metric (see Section 2.3.6 for specification of the metric). Proxy metrics or conditions may be specified where it can be demonstrated that they are strongly correlated with the performance benchmark metric and that they can serve as an equivalent or better method (e.g., in terms of reliability, consistency or practicality) to determine whether performance is achieved to a level at least equivalent to that of the performance benchmark metric.

GHG emissions generated (or carbon sequestered) may be above (or below, for sequestration) the prescribed performance benchmark metric or proxy for such metric for a given verification period, though the project shall not be granted credit for such verification periods.

Activity Methods

3.5.8 Step 1: Regulatory Surplus

The project activity shall meet with the requirements on regulatory surplus set out under the project method in Section 3.5.3.

3.5.9 Step 2: Positive List

The methodology shall apply one or more of the following three options:

1) Option A: Activity Penetration

The methodology shall demonstrate that the project activity has achieved a low level of penetration relative to its maximum adoption potential, as follows:

a) The methodology shall demonstrate that the project activity has achieved a low level of penetration relative to its maximum adoption potential, determined using the following equation:

$$AP_y = OA_y / MAP_y$$

Where:

AP_y = Activity penetration of the project activity in year y (percentage)

OA_y = Observed adoption of the project activity in year y (e.g., total number of instances installed at a given date in year y, or amount of energy supplied in year y)

MAP_y = Maximum adoption potential of the project activity in year y (e.g., total number of instances that potentially could have been installed at a given date in year y, or the amount of energy that potentially could have been supplied in year y)

The maximum adoption potential is the total adoption of a project activity that could currently be achieved given current resource availability, technological capability, level of service, implementation potential, total demand, market access and other relevant factors within the methodology's applicable geographically defined market. Maximum adoption potential does not consider market price, cost of adoption, consumer education, cultural or behavioral barriers, and laws, statutes, regulatory frameworks or policies.

Maximum adoption potential is constrained by numerous factors each imposing their own limitations on the total adoption of a project activity. The following list provides further specification with respect to factors that do, and do not, need to be considered in determining maximum adoption potential:

i) Resource availability is the limitation imposed by the supply of raw materials or energy resources to the activity.

ii) Technological capability is the limitation imposed by the technical efficiency of the project activity.

iii) Level of service is the limitation imposed by the technical reliability or quality of the service provided by the project activity relative to its alternatives.

iv) Implementation potential is the limitation imposed by the availability of appropriate locations for implementing the project activity.

v) Total demand is the limitation imposed by demand for the product or service provided by, or associated with, the project activity and all relevant alternative sources of the product or service.

vi) Market access is the limitation imposed by current infrastructure and the degree to which the outputs of project activity can be practically supplied to the market.

vii) Market price is the limitation imposed by the current price achievable for outputs from the project activity. Cost of adoption is the limitation imposed by the cost of switching to the project activity from an alternative activity. Consumer education is the public knowledge or awareness of the activity and its benefits. Behavioral or cultural barriers are limitations resulting from social or cultural inertia with respect to the adoption of the project activity.

Data used in determining the level of activity penetration shall meet the requirements for data set out for performance benchmarks in Section 3.4.6, *mutatis mutandis*.

b) The level of penetration of the project activity shall be no higher than five percent.

c) Where the project activity has been commercially available in any area of the applicable geographic scope for less than three years (i.e., it uses a new technology or measure), it shall be demonstrated that the project activity faces barriers to its uptake. Such barriers shall be demonstrated in accordance with Step 3 (barrier analysis) of the latest version of the CDM *Tool for the demonstration and assessment of additionality.*

2) Option B: Financial Feasibility

The methodology shall demonstrate that the project activity is less financially or economically attractive than the alternatives to the project activity using the procedures for investment analysis set out in the CDM *Tool for the demonstration and assessment of additionality*. This requires that Steps 1, 2 and 4 of such tool are followed. The analysis shall be conducted for the class of project activities to which the methodology is applicable, and the following also applies:

a) Sub-step 1a. *Other realistic and credible alternative scenarios* shall be taken to mean the full range of alternatives to the class of project activity that are found and are operational in the applicable geographic scope.

b) Sub-step 1b. Where the methodology is applicable to more than one country, the mandatory applicable legal and regulatory requirements of all countries shall be examined.

c) Sub-step 2b and Sub-step 2c. The following applies:

   i) The full range of circumstances which can influence the project activity shall be considered, and either average circumstances or the circumstances that lead to the most cost effective outcome shall be assumed (e.g., if the observed wind resource in the geographic scope of the methodology leads to plant load factors for wind turbines of between 25 and 30 percent, an average of these figures can be used, or 30 percent may be assumed).

   ii) Likewise, the full range of cost and/or revenue estimates for the project activity shall be considered, and either average estimates or the estimates that lead to the most cost effective outcome shall be assumed.

   iii) The full range of circumstances related to the baseline alternatives shall be considered, and either average circumstances or the circumstances that lead to the most cost effective outcome shall be assumed. Only observed or realistic circumstances shall be included (e.g., in a country where cement plants are all located close to harbors or large rivers with a view to easy access to transport, it would not be realistic to assume cement plants would be located in remote areas without easy access to transport).

   iv) Likewise, the full range of cost and/or revenue estimates for the baseline alternatives shall be considered, and either average estimates or estimates pertaining to the most likely baseline alternative shall be assumed. Where estimates pertaining to the most likely baseline alternative are used, it shall be substantiated that such baseline alternative is the most likely among the alternatives.

d) Sub-step 2b, Option III. Company internal benchmarks may not be used.

e) Sub-step 2d. Where average circumstances or estimates have been used in Sub-step 2b and/or Sub-step 2c (i.e., calculations have been based upon a range of circumstances or estimates, see above), a sensitivity analysis shall be undertaken. The objective of the sensitivity analysis is to test whether the conclusion regarding the financial/economic attractiveness of the class of project activity is robust to reasonable variations in the critical assumptions, and where it does not demonstrate conclusively that the (entire class of) project activity is additional, the project activity shall not qualify for the positive list under this Option B. Where the most cost effective, and therefore most conservative, circumstances or estimates have been used, a sensitivity analysis is not required.

f) Step 2 (General). Where there are multiple circumstances and estimates that must be aggregated in order to calculate output figures, the method of aggregation shall account for the correlations between each circumstance and estimate.

g) Step 4 (Common practice analysis). It shall be demonstrated that the project activity is not common practice using the full procedures for common practice analysis set out in the CDM *Tool for the demonstration and assessment of additionality*.

3) Option C: Revenue Streams

The methodology shall demonstrate that the project activity does not have any significant sources of revenue other than revenue from the sale of GHG credits, as follows:

a) The project activity's gross annual revenue (including cost savings) excluding from the sale of GHG credits shall not exceed five percent of capital expenditure (see the VCS Program document *Program Definitions* for definition of capital expenditure). All capital expenditures incurred during the project crediting period shall be accounted for and where the project activity involves capital expenditure subsequent to year zero, an appropriate discount rate shall be applied.

b) It shall be demonstrated that the project activity is not common practice using the full procedures for common practice analysis set out in the CDM *Tool for the demonstration and assessment of additionality*.

3.6 Baseline and Project Emissions/Removals

Concept

Baseline emissions, and project emissions and/or removals, must be accurately quantified in order to determine net emission reductions and removals achieved by projects. Methodologies shall therefore set out procedures to quantify these emissions and/or removals.

Requirements

General

3.6.1 Methodologies shall establish criteria and procedures for quantifying GHG emissions and/or removals, and/or carbon stocks, for all selected GHG sources, sinks and/or reservoirs identified in the project boundary.

AFOLU Methodologies

3.6.2 *The IPCC 2006 Guidelines for National GHG Inventories* or the *IPCC 2003 Good Practice Guidance for Land Use, Land-Use Change and Forestry* shall be used as guidance for quantifying increases or decreases in carbon stocks and GHG emissions. The IPCC Guidelines shall also be followed in terms of quality assurance/quality control (QA/QC) and uncertainty analysis.

3.6.3 The *IPCC 2006 Guidelines for National GHG Inventories* may be referenced to establish procedures for quantifying GHG emissions/removals associated with the following carbon pools including:

1) Litter;
2) Dead wood;
3) Soil (methodologies may follow the IPCC guidelines for the inclusion of soil carbon, including the guidelines that are in sections not related to forest lands); and
4) Belowground biomass (estimated using species-dependent root-to-shoot ratios, the Mokany et al.[4] ratios and equations, or the Cairns equations).

3.6.4 Where carbon would have been lost in the baseline scenario due to land use conversion or disturbance, GHG emissions from soil carbon, belowground biomass, wood products and dead wood carbon pools generally occur over a period of time following the event. It shall not be assumed that all GHG emissions from these carbon pools in the project categories specified below occur instantaneously or within a short period of time.

Methodologies shall set out criteria and procedures to reliably establish the pattern of carbon loss over time using empirical evidence, such as studies that use primary data or locally calibrated models, or methodologies shall apply an appropriate decay model (such as a linear or exponential decay function) that is scientifically sound, based on empirical evidence and not likely to overestimate early carbon losses.

Where appropriate, belowground biomass, soil carbon and dead wood decay models shall be calibrated. Where models are calibrated using measurement plots or data from research plots, sound and reliable measurement methods shall be applied as set out in Section 3.9.5.

Where the following carbon pools are included in the project boundary, methodologies may opt to comply with the requirement to establish a pattern of carbon loss over time by incorporating the respective procedures below:

1) Belowground biomass pool for IFM LtPF and REDD. The pattern of carbon loss shall be modeled based upon a 10-year linear decay function.

---

[4] Mokany, K., Raison, R. J., and Prokushkin, A. S. 2006. *Critical analysis of root:shoot ratios in terrestrial biomes*. Global Change Biology 12: 84-96

2) Dead wood pool in IFM and REDD. The pattern of carbon loss shall be modeled using a 10-year linear decay function.

3) Soil carbon pool in all AFOLU project categories. The pattern of carbon loss shall be modeled based upon a 20-year linear decay function, taking into account the depth of affected soil layers and the total portion of the pool that would have been lost.

4) Wood products pool in IFM and REDD. The pattern of carbon loss shall be modeled as follows:

   a) For short-term wood products and wood waste that would decay within 3 years, all carbon shall be assumed to be lost immediately.

   b) For medium-term wood products that are retired between 3 and 100 years, a 20-year linear decay function shall be applied.

   c) For long-term wood products that are considered permanent (i.e., carbon is stored for 100 years or more), it may be assumed no carbon is released.

Note – Where applying the wood products procedure set out above, it is not required to separately account for the portion of wood products in landfills and the decay rate for such products, due to the current lack of established, reliable data and methods. Such products shall apply the rates for short-, medium-, or long-term wood products, as appropriate.

3.6.5 Where activity-based methods are used for determining baseline soil carbon stocks, estimates shall be conservatively determined relative to the computed maximum carbon stocks that occurred in the designated project area within the previous 10 years. For example, if carbon stocks in the project area were 100 tonnes C/ha in 2002 and declined to 90 tonnes C/ha by 2007 after intensive tillage, the minimum baseline carbon stock for a project established in 2008 would be 100 tonnes C/ha.

Afforestation, Reforestation and Revegetation (ARR)

3.6.6 Where ARR or IFM projects include harvesting, the loss of carbon due to harvesting shall be included in the quantification of project emissions. The maximum number of GHG credits available to projects shall not exceed the long-term average GHG benefit. The GHG benefit of a project is the difference between the project scenario and the baseline scenario of carbon stocks stored in the selected carbon pools and adjusted for any project emissions of N_2O, CH_4 and fossil-derived CO_2, and leakage emissions. The long-term average GHG benefit shall be calculated using the following procedure:

1) Establish the period over which the long-term average GHG benefit shall be calculated, noting the following:

   a) For ARR or IFM projects undertaking even-aged management, the time period over which the long-term GHG benefit is calculated shall include at minimum one full harvest/cutting cycle, including the last harvest/cut in the cycle. For example, where a project crediting period is 40 years and has a harvest cycle of 12 years, the long-term average GHG benefit will be determined for a period of 48 years.

b) For ARR projects under conservation easements with no intention to harvest after the project crediting period, or for selectively-cut IFM projects, the time period over which the long-term average is calculated shall be the length of the project crediting period.

2) Determine the expected total GHG benefit of the project for each year of the established time period. For each year, the total GHG benefit is the to-date GHG emission reductions or removals from the project scenario minus baseline scenario.

3) Sum the total GHG benefit of each year over the established time period.

4) Calculate the average GHG benefit of the project over the established time period.

5) Use the following equation to calculate the long-term average GHG benefit:

$$LA = \frac{\sum_{t=0}^{n} PE_t - BE_t}{n}$$

Where:

LA	=	The long-term average GHG benefit
PE_t	=	The total to-date GHG emission reductions and removals generated in the project scenario (tCO_2e). Project scenario emission reductions and removals shall also consider project emissions of CO_2, N_2O, CH_4 and leakage.
BE_t	=	The total to-date GHG emission reductions and removals projected for the baseline scenario (tCO_2e)
t	=	Year
n	=	Total number of years in the established time period

6) A project may claim GHG credits during each verification event until the long-term average GHG benefit is reached. Once the total number of GHG credits issued has reached this average, the project can no longer issue further GHG credits. The long-term average GHG benefit shall be calculated at each verification event, meaning the long-term average GHG benefit may change over time based on monitored data. For an example of determining the long-term average GHG benefit, see the Verra website.

Buffer credits are withheld only when GHG credits are issued. As set out in Section 3.8.5, the number of buffer credits to withhold is based on the change in carbon stocks only (not the net GHG benefit), as such the buffer credits will be based on the long-term average change in carbon stock. Use the following equation to calculate the long-term average change in carbon stock.

$$LC = \frac{\sum_{t=0}^{n} PC_t - BC_t}{n}$$

Where:

LC = The long-term average change in carbon stock

PC_t = The total to-date carbon stock in the project scenario (tCO_2e)

BC_t = The total to-date carbon stock projected for the baseline scenario (tCO_2e)

t = Year

n = Total number of years in the established time period

Note – VCS guidance document AFOLU Guidance: Example for Calculating the Long-Term Average Carbon Stock for ARR Projects with Harvesting*, available on the Verra website, provides examples for calculating the long-term average carbon stock for a variety of ARR project scenarios with harvesting. The same examples can be applied to IFM projects with harvesting.*

Agricultural Land Management (ALM)

3.6.7 Methodologies that target soil carbon stock increases shall quantify, where significant, concomitant increases in N_2O, CH_4 and fossil-derived CO_2. Similarly, methodologies targeting N_2O emission reductions shall establish the criteria and procedures by which the changes in soil carbon stocks may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

3.6.8 Procedures to quantify GHG emissions/removals from cropland and grassland soil management projects may include activity-based model estimates, direct measurement approaches, or a combination of both.

3.6.9 Procedures to measure soil carbon stocks shall be based on established and reliable sampling methods, with sufficient sampling density to determine statistically significant changes at a 95 percent confidence level. Uncertainty related to sampling shall be addressed as set out in Section 2.4, above.

3.6.10 Procedures to estimate soil carbon stock shall use soil carbon stock change factors that are based on measurements of soil carbon stocks to the full depth of affected soil layers (usually 30 cm), accounting for differences in bulk density as well as organic carbon concentrations.

3.6.11 Procedures to quantify N_2O and CH_4 emissions factors shall be based on scientifically defensible measurements of sufficient frequency and duration to determine emissions for a full annual cycle. Minimum baseline estimates for N_2O and CH_4 emissions shall be based on documented management records averaged over the five-year period prior to the project start date. Documented management records may include fertilizer purchase records, manure production estimates and/or livestock data. For new management entities or where such records are unavailable, minimum baseline estimates may be based on a conservative estimate of common practice in the region.

Improved Forest Management (IFM)

3.6.12 Procedures for quantifying GHG emissions/removals in selected carbon pools may reference the *IPCC 2006 Guidelines for National GHG Inventories* section on forests remaining as forests.

3.6.13 Procedures for quantifying GHG emissions/removals in wood products may reference Skog et al. 2004[5] or other sources published in scientific peer-reviewed literature.

3.6.14 Where biomass is burned as part of the slash removal after harvesting, or nitrogen fertilizer is used, methodologies may reference *IPCC 2006 Guidelines for National GHG Inventories* for the quantification of such GHG emissions.

3.6.15 Where IFM projects include harvesting, the loss of carbon due to harvesting shall be included in the quantification of project emissions. The maximum number of GHG credits available to projects shall not exceed the long-term average GHG benefit, as set out in Section 3.6.6.

Reduced Emissions from Deforestation and Degradation (REDD)

3.6.16 Procedures for quantifying GHG emissions/removals in all selected carbon pools may reference *IPCC 2006 Guidelines for National GHG Inventories* sections on conversion of forest to non-forest (for deforestation) and forests remaining as forest (for degradation).

3.6.17 Procedures for quantifying GHG emissions/removals in long-lived wood products (e.g., wood products lasting longer than five years) may reference published scientific peer-reviewed literature (such as Skog et al. 2004).

3.6.18 Where harvesting is allowed in the project scenario (e.g., the project activity reduces deforestation but selective harvesting is allowed), the methodology shall include criteria and procedures to quantify GHG emissions/removals from such harvesting. The methodology shall also include criteria and procedures by which the change in carbon stocks from such harvesting may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

Avoided Conversion of Grasslands and Shrublands (ACoGS)

3.6.19 Procedures for quantifying N_2O emissions from the use of synthetic fertilizers may reference the CDM A/R methodological tool for the *Estimation of direct and indirect (e.g., leaching and runoff) nitrous oxide emission from nitrogen fertilization*.

3.6.20 Procedures for quantifying GHG emissions/removals in all selected carbon pools may reference *IPCC 2006 Guidelines for National GHG Inventories*. Baseline scenarios may include annual estimates of changes in each carbon pool over the entire project period. Differences in shorter and longer term effects may be accounted for by distinguishing phases of effects. For example, effects of conversion on biomass may occur entirely in year one, whereas effects on soil carbon shall take into account the timing of such effects that may occur over many years, as set out in

---

[5] Skog, K.E., K. Pingoud, J. E. Smith. 2004. A method countries can use to estimate changes in carbon stored in harvested wood products and the uncertainty of such estimates. Environmental Management 33 (suppl 1): S65-S73

Section 3.6.4.

3.6.21 Under the default assumption that management does not change in the project scenario and carbon pools are at steady state, the project scenario shall ensure the maintenance (or increase) of existing carbon pools. Where methodologies include criteria and procedures to account for increases in carbon pools on lands where conversion is avoided, evidence shall be provided that such increases may occur. Where changes in management are the basis for increases in carbon pools, ALM accounting rules shall be followed. Where revegetation or restoration is the basis for increases in carbon pools under the project scenario, projects shall follow ARR or ALM requirements for quantifying GHG emissions/removals, depending on whether the project activities involve woody biomass.

3.6.22 GHG emissions associated with conversion and post-conversion land management practices that are avoided shall be estimated based on expected land management practices. Baseline estimates for N_2O and CH_4 emissions shall be based on documented management practices used on lands similar to the project area, or that represent average local or regional land management practices. Preference shall be given to data that are more specific to the project area (e.g., site specific data, where available, are preferable to state or province level data). Documentation of land management practices may include, for example, fertilizer purchase or application records, manure production estimates and/or livestock data.

3.6.23 Quantifying GHG emissions and/or removals from avoided conversion requires estimates of changes in carbon pools that would have occurred if the land protected by the project had been converted. Although the direct measurement of carbon pools on protected lands can provide an estimate of initial carbon stocks for the baseline scenario, subsequent years under the baseline scenario require estimates of the effects of conversion that are extrapolated from lands similar to the project area but which have already undergone conversion. Estimates of expected changes in carbon stocks following conversion may be based on activity-based model estimates, direct measurement (including direct measurements reported in the scientific literature), or a combination of both.

3.6.24 Direct measurements needed for estimating the baseline shall be taken on lands similar to the project area that have already undergone conversion to the same land use as the one(s) being avoided in the project area, rather than direct measurements on the project area itself. Similar lands refers to lands with similar vegetation, climate, topography and soils, and therefore with similar expected responses to conversion. Such extrapolation from similar lands necessarily introduces uncertainty, which shall be accounted for by using methods that allow for calculating a confidence interval as set out in Section 2.4.1 above. Uncertainty from baseline modeling shall be combined with other sources of uncertainty using valid statistical approaches (e.g., as set out in Chapter 5.2 of the *IPCC Good Practice Guidance for LULUCF*).

3.6.25 Estimation of carbon stock change and/or soil emission factors shall be based on data from replicated field experiments whose management treatments have a duration of at least five years (preferably longer), for climate and soil conditions and management activities representative of the project conditions, using established, reliable measurement methods. Stock change factors for soil carbon or woody biomass carbon that are based on experiments shall not be projected over a longer period than the length of the study. Complex, dynamic models that have been validated for conditions representative of the project area are also acceptable. Models shall be parameterized to reflect the range of soil, climate, land use and management conditions in the project area.

Wetland Restoration and Conservation (WRC)

3.6.26 The following applies with respect to the criteria and procedures for quantifying GHG emissions/removals in the baseline scenario:

1) For WRC activities on peatland the peat depletion time (PDT) shall be included in the quantification of GHG emissions and removals in the baseline scenario, and for non-peat wetlands, the soil organic carbon depletion time (SDT) shall be included in the quantification of GHG emissions and removals in the baseline scenario, noting the following:

    a) PDT is the time it would have taken for the peat to be completely lost due to oxidation or other losses, or for the peat depth to reach a level where no further oxidation or other losses occur. No GHG emission reductions may be claimed for a given area of peatland for longer than the PDT. The procedure for determining the PDT shall conservatively consider peat depth and oxidation rate within the project boundary and may be estimated based on the relationship between water table depth, subsidence (e.g., using peat loss and water table depth relationships established in scientific literature), and peat depth in the project area. The PDT is considered part of the baseline and thus shall be reassessed with the baseline in accordance with the requirements set out in the VCS Program document *VCS Standard.*

    b) SDT is the time it would have taken for the soil organic carbon to be lost due to oxidation or to reach a steady stock where no further losses occur. No GHG emissions reductions may be claimed for a given area of wetland for longer than the SDT. The procedure for determining the SDT shall conservatively consider soil organic carbon content and oxidation rate within the project boundary and may be estimated based on the relationship between water table depth and soil organic carbon content in the project area. Where wetland soils are subject to sedimentation or erosion, the procedure for determining the SDT shall conservatively account for the associated gain or loss of soil organic carbon. This assessment is not mandatory in cases where soil organic carbon content on average may be deemed *de minimis* as set out in Section 3.3.6.

2) Any applicable and justifiable proxies, as established in scientific literature, for GHG emissions projected throughout the project crediting period shall be estimated.

3) Net baseline GHG emissions during the project crediting period, including emissions associated with the estimated water table depths, salinity or another justifiable proxy for GHG emissions, plus emissions from other activities such as biomass loss or fires, as well as carbon sequestration, where applicable, shall be estimated.

3.6.27 Baseline emissions shall be estimated conservatively and consider that the water table depth in the project area may rise during the project crediting period due to any or all of the causes identified in alternative baseline scenarios as set out in Section 3.4.18.

3.6.28 The procedure for quantifying CO_2 emissions for the baseline and project emissions may be estimated through hydrological modeling or the modeling of proxies for GHG emissions in place of direct on-site gas flux measurements. The procedure may include estimation through well-documented relationships between CO_2 emissions and other variables such as vegetation types, water table depth, salinity or subsidence, or remote sensing techniques that adequately assess and monitor soil moisture. Because of the dominant relationship between water table depth and CO_2 emissions, drainage depth can be used as a proxy for CO_2 emissions in the absence of emissions data.[6] Where relevant, the micro-topography of the project area (e.g., the proportion of hummocks and hollows and vegetation patterns in peatlands) shall be considered. Net GHG emissions reductions shall be calculated using the same methods that are used for the baseline estimates, but using monitored data.

3.6.29 Where relevant, the fate of transported organic matter as a result of sedimentation, erosion and oxidation shall be assessed conservatively based on peer-reviewed literature and considering the following:

1) It is conservative to not account for the loss of sediment from the project area in the baseline scenario.

2) It is conservative to not account for further sedimentation in the project area in the project scenario. Where soil carbon is included in the project boundary, sedimentation shall be accounted for so that carbon sequestration resulting from the growth of vegetation can be estimated separately from carbon accumulated in sedimentation. In the absence of the project activity, such high carbon silt would be washed out to sea and would not have been oxidized and emitted in the baseline, and in such cases carbon accumulated in sedimentation is not eligible for crediting.

3.6.30 With respect to the soil carbon pool, the maximum quantity of GHG emission reductions that may be claimed by the project shall not exceed the net GHG benefit generated by the project 100 years after its start date. This limit is established because in wetlands remaining partially

[6] Couwenberg, J, Dommain, R, Joosten, H. 2010. Greenhouse gas fluxes from tropical peatlands in south-east Asia. Global Change Biology 16: 1715-1732.

drained or not fully rewetted, or where drainage continues, the soil carbon will continue to erode and/or oxidize leading to GHG emissions and eventually depletion of the soil carbon. To determine this long-term net GHG benefit, methodologies shall establish criteria and procedures to estimate the remaining soil carbon stock adjusted for any project emissions and leakage emissions in both the baseline and project scenarios for 100 years, taking into account uncertainties in modeling and using verifiable assumptions. Projects unable to establish and demonstrate a significant difference in the net GHG benefit between the baseline and project for at least 100 years are not eligible.

3.6.31 Emissions of CH_4 from drained or saline wetlands may be excluded in the baseline scenario where it may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

3.6.32 As WRC activities are likely to influence CH_4 emissions, methodologies shall establish procedures to estimate such emissions, and shall establish the criteria and procedures by which the source may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7). Where relevant, the micro-topography of the project area (i.e., the proportion of hummocks and hollows and vegetation patterns) shall be considered.

3.6.33 Methodologies that combine project categories shall use the relevant WRC requirements and the respective AFOLU project category requirements for quantifying GHG emissions/removals, unless the former may be deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

3.6.34 RWE projects on peatland that include an activity designed specifically to reduce incidence and severity of fires shall deduct the amount of peat assumed to burn when estimating peat depletion times. Where peat depletion times are estimated based only on oxidation rates due to drainage, the outcome would be a longer period than when first subtracting the amount of peat that is considered to burn in the baseline.

3.6.35 Methodologies for RWE projects on peatland explicitly addressing anthropogenic peatland fires occurring in drained peatlands shall establish procedures for determining or conservatively estimating the baseline emissions from peatland fire occurring in the project area using defensible data (such as fire maps, historical databases on fires, and where appropriate, combined with temperature and precipitation data). Methods for estimating GHG emissions from fire may be based on the *IPCC 2006 Guidelines for National GHG Inventories*, or other methods based on scientific, peer-reviewed literature.

3.6.36 Where relevant, methodologies shall establish procedures to account for any changes in carbon sequestration or GHG emission reductions resulting from lateral movement of wetlands due to sea level rise, or coastal squeeze associated with any structures that prevent wetland landward migration and cause soil erosion.

3.7 Leakage

Concept

Leakage is the net change of anthropogenic GHG emissions that occurs outside the project boundary and is attributable to project activities. Methodologies shall establish procedures to quantify leakage, where the potential for leakage is identified, as projects may otherwise overestimate their net emission reductions and/or removals.

Requirements

General

3.7.1 The methodology shall establish criteria and procedures for quantifying leakage.

AFOLU Methodologies

3.7.2 The methodology shall establish procedures to quantify all significant sources of leakage. Leakage is defined as any increase in GHG emissions that occurs outside the project boundary (but within the same country), and is measurable and attributable to the project activities. All leakage shall be accounted for, in accordance with this Section 3.7. The three types of leakage are:

1) Market leakage occurs when projects significantly reduce the production of a commodity causing a change in the supply and market demand equilibrium that results in a shift of production elsewhere to make up for the lost supply.

2) Activity-shifting leakage occurs when the actual agent of deforestation and/or forest or wetland degradation moves to an area outside of the project boundary and continues its deforestation or degradation activities elsewhere.

3) Ecological leakage occurs in WRC projects where a project activity causes changes in GHG emissions or fluxes of GHG emissions from ecosystems that are hydrologically connected to the project area.

3.7.3 Leakage that is determined, in accordance with Section 3.3.6, to be below *de minimis* (i.e., insignificant) does not need to be included in the GHG emissions accounting. The significance of leakage may also be determined using the CDM A/R methodological tool *Tool for testing significance of GHG Emissions in A/R CDM Project Activities*.

3.7.4 GHG emissions from leakage may be determined either directly from monitoring, or indirectly when leakage is difficult to monitor directly but where scientific knowledge provides credible estimates of likely impacts. The GHG credit calculation table provided below in Section 3.8 includes an example of indirect leakage accounting.

3.7.5 The methodology shall require projects to account for market leakage where the production of a commodity (e.g., timber, aquacultural products or agricultural products) is significantly affected by the project. The significance of timber production is determined as set out in

Section 3.3.6 above or as set out in Section 3.7.15 below.

3.7.6 Leakage occurring outside the host country (international leakage) does not need to be quantified.

3.7.7 Where leakage mitigation measures include tree planting, aquacultural intensification, agricultural intensification, fertilization, fodder production, other measures to enhance cropland and/or grazing land areas, leakage management zones or a combination of these, then any significant increase in GHG emissions associated with these activities shall be accounted for, unless deemed *de minimis* (as set out in Section 3.3.6) or can be conservatively excluded (as set out in Section 3.3.7).

3.7.8 Methodologies shall not allow for projects to account for positive leakage (i.e., where GHG emissions decrease or removals increase outside the project area due to project activities).

Afforestation/Reforestation/Revegetation (ARR)

3.7.9 Activity-shifting leakage in ARR projects can result from, inter alia, the shifting of grazing animals, shifting of households or communities, shifting of aquacultural or agricultural activities or shifting of fuelwood collection (from non-tree sources). Leakage emissions may also result from transportation and machinery use. The requirements for assessing and managing leakage in ARR projects are similar to those for CDM afforestation/reforestation project activities, and methodologies may require or allow projects to apply CDM tools for estimating leakage, such as the *Tool for calculation of GHG emissions due to leakage from increased use of non-renewable woody biomass attributable to an A/R CDM project activity*.

3.7.10 Where deforestation increases outside the project area due to leakage from project activities, methodologies shall set out criteria and procedures for projects to assess and quantify the effects of this deforestation on all carbon pools, unless determined to be *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7).

Agricultural Land Management (ALM)

3.7.11 ALM projects setting aside land for conservation shall quantify activity-shifting leakage emissions associated with the displacement of pre-project activities, unless deemed *de minimis* (as set out in Section 3.3.6) or conservatively excluded (as set out in Section 3.3.7). Guidance on accounting for leakage associated with shifting of pre-project activities due to land conversions from agriculture to grassland is functionally similar to conversion of land to forest vegetation under ARR (see Section 3.3.6 and 3.3.7).

3.7.12 Market leakage in ALM projects involving cropland or grassland management activities is likely to be negligible because the land in the project scenario remains maintained for commodity production, and therefore does not need to be included in the GHG emissions accounting, unless determined to be above *de minimis* in accordance with Section 3.3.6.

3.7.13 Where livestock are displaced to outside the project area, methodologies shall set out criteria and procedures for projects to quantify such activity-shifting leakage to capture potential reductions in carbon stocks and potential increases in livestock-derived CH_4 and N_2O emissions from outside the project area.

Improved Forest Management (IFM)

3.7.14 Leakage in IFM projects can result from activities shifting within the project proponent's operations. Methodologies shall set out criteria and procedures for projects to demonstrate that there is no leakage to areas that are outside the project area but within the project proponent's operations, such as areas where the project proponent has ownership of, management of, or legally sanctioned rights to use forest land within the country. Methodologies shall set out criteria and procedures for projects to demonstrate that the management plans and/or land-use designations of all other lands operated by the project proponent (which shall be identified by location) have not materially changed as a result of the project activity (e.g., harvest rates have not been increased or land has not been cleared that would otherwise have been set aside). Where the project proponent is an entity with a conservation mission, it may be demonstrated that there have been no material changes to other lands managed or owned by the project proponent by providing documented evidence that it is against the policy of the organization to change the land use of other owned and/or managed lands including evidence that such policy has historically been followed.

3.7.15 Leakage in IFM projects is predominantly attributable to market leakage (market effects). Methodologies shall set out criteria and procedures to quantify market leakage by either of the following:

1) Applying the appropriate market leakage discount factor identified in Table 2 to the net change in carbon stock associated with the activity that reduces timber harvest.

2) Directly accounting for market leakage associated with the project activity. Where directly accounting for leakage, market leakage shall be accounted for at the country-scale applied to the same general forest type as the project (i.e., forests containing the same or substitutable commercial species as the forest in the project area) and shall be based on methods for quantifying leakage from scientific peer-reviewed journal sources.[7]

[7] The following three papers may be helpful in assessing market leakage:

- Murray, B.C., B.A. McCarl, and H. Lee. 2004. Estimating Leakage from Forest Carbon Sequestration Programs. Land Economics 80(1):109-124. (http://ideas.repec.org/p/uwo/uwowop/20043.html)
- Murray, B.C., B.L. Sohngen, et al. 2005. EPA-R-05-006. Greenhouse Gas Mitigation Potential in U.S. Forestry and Agriculture. Washington, D.C: U.S. Environmental Protection Agency, Office of Atmospheric Programs. (www.epa.gov/sequestration/pdf/greenhousegas2005.pdf)
- Sohngen, B. and S. Brown. 2004. Measuring Leakage from Carbon Projects in Open Economies: A Stop Timber Harvesting Project as a Case Study, Canadian Journal of Forest Research. 34: 829-839 (http://www.winrock.org/ecosystems/files/Sohngen_Brown_2004.pdf)

Table 2: Market Leakage Discount Factors

Project Action	Leakage Risk	Market Leakage Discount Factor
IFM activity with no effect or minimal effect on total timber harvest volumes (e.g., RIL with less than 25% reduction)	None	0%
IFM activity that leads to a shift in harvests across time periods but minimal change in total timber harvest over time (e.g., ERA with rotation extension of 5-10 years)	Low	10%
IFM activity that substantially reduces harvest levels permanently (e.g., RIL activity that reduces timber harvest across the project area, or project that halts logging by at least 25%)	Moderate to High	Conditional upon where timber harvest is likely to be shifted, as follows: • Where the ratio of merchantable biomass to total biomass is higher within the area to which harvesting is displaced compared to the project area, 20% • Where the ratio of merchantable biomass to total biomass is similar within the area to which harvesting is displaced compared to the project area, 40% • Where the ratio of merchantable biomass to total biomass is lower within the area to which harvesting is displaced compared to the project area, 70% • Where the leakage is out of country, 0%

Reduced Emissions from Deforestation and Degradation (REDD)

3.7.16 Methodologies shall set out criteria and procedures to assess and manage leakage for the two eligible REDD project types as follows:

1) APD: Leakage shall be quantified by directly monitoring the activities of the deforestation agent identified in the baseline scenario. The deforestation agent can be an entity that has ownership of, management of, or legally sanctioned rights to use, multiple parcels of forest land within the country or can be the most-likely-class of deforestation agent. Such forest land could be used to make up for the generation of goods and/or services lost through implementation of the REDD project, therefore leading to reductions in carbon stocks or increases in GHG emissions outside the project boundary. Leakage shall be accounted for

as follows:

a) Where the specific deforestation agent can be identified, leakage need not be considered where it can be demonstrated that the management plans and/or land-use designations of the deforestation agent's other lands (which shall be identified by location) have not materially changed as a result of the project (e.g., the deforestation agent has not designated new lands as timber concessions, increased harvest rates in lands already managed for timber, cleared intact forests for agricultural production or increased fertilizer use to enhance agricultural yields). Where management plans and/or land-use designations of the deforestation agent's other lands have materially changed, leakage shall be quantified by directly monitoring the activities of the deforestation agent.

b) Where the specific deforestation agent cannot be identified, leakage shall be quantified based upon the difference between historic and with-project rates of deforestation by the identified most-likely-class of deforestation agent within the region. Alternatively, where such agents are driven by the demand for market commodities, the project may directly account for market leakage associated with the specific project activity. Where directly accounting for leakage, market leakage shall be accounted for at the country-scale, taking into account the supply and demand elasticities for the commodity affected, and shall be based on methods for quantifying leakage from scientific peer-reviewed journal sources, as described above in Section 3.7.15.

2) AUDD: The potential for leakage shall be identified and the project shall address (and describe in the project description) the socio-economic factors that drive deforestation and/or degradation. Leakage shall be calculated by monitoring forested areas surrounding the project and other forested areas within the country susceptible to leakage from project activities.

3.7.17 Where the project baseline includes illegal logging activities that supply regional, national and/or global timber markets, domestic market leakage shall be quantified using the market leakage discount factors for IFM projects set out in Sections 3.7.14 and 3.7.15. The market leakage effects associated with stopping illegal logging need not be considered where GHG emissions are not included in the baseline and GHG credits from stopping such activities are not claimed.

Avoided Conversion of Grasslands and Shrublands (ACoGS)

3.7.18 Leakage in ACoGS projects can result from activities shifting within the project proponent's operations. It shall be demonstrated that there is no leakage to areas that are outside the project area but within the project proponent's operations, such as areas where the project proponent has ownership of, management of, or legally sanctioned rights to use land within the country. It shall be demonstrated that the management plans and/or land-use designations of all other lands operated by the project proponent (which shall be identified by location) have not materially changed as a result of the project activity (e.g., land has not been cleared that would otherwise have been set aside).

Where the project proponent is an entity with a conservation mission, it may be demonstrated that there have been no material changes to other lands managed or owned by the project proponent by providing documented evidence that it is against the policy of the organization to change the land use of other owned and/or managed lands including evidence that such policy has historically been followed.

3.7.19 Methodologies shall set out criteria and procedures to assess and manage leakage for the two eligible ACoGS project types as follows:

1) APC: Leakage shall be quantified by directly monitoring the activities of the conversion agent identified in the baseline scenario. The conversion agent can be an entity that has ownership of, management of, or legally sanctioned rights to use, multiple parcels of land within the country or can be the most-likely-class of conversion agent. Such land could be used to make up for the generation of goods and/or services lost through implementation of the ACoGS project, therefore leading to reductions in carbon stocks or increases in GHG emissions outside the project boundary. Leakage shall be accounted for as follows:

    a) Where the specific conversion agent can be identified, leakage need not be considered where it can be demonstrated that the management plans and/or land-use designations of the conversion agent's other lands (which shall be identified by location) have not materially changed as a result of the project (e.g., land has not been cleared that would otherwise have been set aside). Where management plans and/or land-use designations of the conversion agent's other lands have materially changed, leakage shall be quantified by directly monitoring the activities of the conversion agent.

    b) Where the specific conversion agent cannot be identified, leakage shall be quantified based upon the difference between historic and with-project rates of conversion by the identified most-likely-class of conversion agent within the region. Alternatively, where such agents are driven by the demand for market commodities, the project may directly account for market leakage associated with the specific project activity. Where directly accounting for leakage, market leakage shall be accounted for at the country-scale, taking into account the supply and demand elasticities for the commodity affected, and shall be based on methods for quantifying leakage from scientific peer-reviewed journal sources, as described above in Section 3.7.15.

2) AUC: The potential for leakage shall be identified and the project shall address (and describe in the project description) the socio-economic factors that drive conversion. Leakage shall be calculated by monitoring areas surrounding the project and areas within the country susceptible to leakage from project activities.

Wetland Restoration and Conservation (WRC)

3.7.20 RWE projects involving rewetting of forested wetlands are likely to reduce the productivity of the forest or make harvesting more difficult, which could lead to fewer forest products and thus result in leakage (i.e., GHG emissions from logging and drainage elsewhere). Where the project results in activity shifting of forest products, the applicable requirements for leakage in IFM or REDD project activities shall be followed, accounting for both activity-shifting and/or market leakage. Where the project results in the shifting of drainage activities or other activities that would lower the water table, the expected GHG emissions from a lower water table shall also be accounted for. RWE projects on peatland shall assume that the PDT of leakage activities occurs over the length of the project crediting period if the PDT is longer than the project crediting period.

3.7.21 Rewetting in the project area may lead to higher water table depths in some areas beyond the project boundary, and consequently leading to lower water table depths in downstream areas further beyond the project boundary (e.g., in the case of project activities that reverse subsidence), or cause transportation of organic matter to areas beyond the project boundary. In such cases, the project proponent shall be required to demonstrate that such changes in water table depths or export caused by the project do not lead to increases in GHG emissions outside the project area, or the affected areas shall be identified and the resulting leakage shall be quantified and accounted for.

3.7.22 Methodologies shall set out criteria and procedures to assess and manage leakage for CIW, REDD+CIW and IFM+CIW projects as follows, noting that for combined category projects, the IFM or REDD leakage requirements also apply:

1) APWD: Activity-shifting leakage shall be quantified by directly monitoring the activities of the land conversion agent (e.g., deforestation agent or agent causing other forms of wetland degradation) identified in the baseline scenario. The land conversion agent can be an entity that has ownership of, management of, or legally sanctioned rights to use multiple parcels of wetland within the country, or can be the most-likely-class of land conversion agent. These other wetlands could be used to make up for the generation of goods and/or services lost through implementation of the WRC project, therefore leading to reductions in carbon stocks or increases in GHG emissions outside the project boundary. Leakage shall be accounted for as follows:

   a) Where the specific land conversion agent can be identified, leakage need not be considered where it can be demonstrated that the management plans and/or land-use designations of the land conversion agent's other lands (which shall be identified by location) have not materially changed as a result of the project (e.g., a deforestation agent has not designated new lands as timber concessions, increased harvest rates in lands already managed for timber, cleared intact forests for agricultural production or increased fertilizer use to enhance agricultural yields). Where management plans and/or land-use designations of the land conversion agent's other lands have materially changed, leakage shall be quantified by directly monitoring the activities of the land conversion agent.

b) Where the specific land conversion agent cannot be identified, leakage shall be quantified based upon the difference between historic and with-project rates of wetland degradation by the identified most-likely-class of land conversion agent within the region.

2) AUWD: The potential for leakage shall be identified and the project shall address the socio-economic factors that drive wetland degradation. Leakage shall be calculated by monitoring wetland areas surrounding the project and other wetland areas within the country susceptible to leakage from project activities.

3.7.23 Wetland restoration methodologies including fire reduction activities shall follow the requirements for accounting for fire under REDD, where land use changes are identified as the cause (or one of the causes) of anthropogenic fires in the project region.

ODS Methodologies

3.7.24 Methodologies shall establish criteria and procedures to quantify and account for GHG emissions associated with any substitute substances that can be assumed to be used to provide the service previously provided by the ODS destroyed by the project.

For example, where a project destroys ODS that under the baseline would have been recovered and reused, the project shall account for the GHG emissions associated with substitute substances, since the market demand that was being serviced by the ODS can be assumed to be supplied from alternative sources. Conversely, where a project destroys ODS that under the baseline would have leaked or been released to the atmosphere, the ODS was not meeting any market demand and accounting for GHG emissions associated with substitute substances is not applicable. Such quantification and accounting shall be done using one of the following options:

1) Identify the actual type and quantity of substitute substances used to provide the service previously provided by the ODS destroyed by the project, calculate or monitor the GHG emissions associated with such substances that arise during the project crediting period, and deduct such GHG emissions from the GHG emission reductions;

2) Identify the actual type and quantity of substitute substances used to provide the service previously provided by the ODS destroyed by the project, assume 100 percent of such substances leak or are released to the atmosphere during the project crediting period, and deduct such GHG emissions from the GHG emission reductions;

3) Identify, based on conservative assumptions using appropriate data, the type and quantity of substitute substances used to provide the service previously provided by the ODS destroyed by the project, assume 100 percent of such substances leak or are released to the atmosphere during the project crediting period, and deduct such GHG emissions from the GHG emission reductions claimed by the project; or

4) The project shall not claim GHG emission reductions for the ODS destroyed by the project that under the baseline would have been recovered and reused.

3.8 Quantification of GHG Emission Reductions and Removals

Concept

Net GHG emission reductions and removals achieved by projects are the basis for the volume of VCUs that can be issued. Methodologies shall establish criteria and procedures for quantifying net GHG emission reductions and removals.

Requirements

General

3.8.1 Methodologies shall establish criteria and procedures for quantifying GHG emissions and/or removals, and/or carbon stocks, for the selected GHG sources, sinks and/or reservoirs, separately for the project (including leakage) and baseline scenarios.

3.8.2 Methodologies shall establish criteria and procedures for quantifying net GHG emission reductions and removals generated by the project, which shall be quantified as the difference between the GHG emissions and/or removals, and/or as the difference between carbon stocks, from GHG sources, sinks and reservoirs relevant for the project and those relevant for the baseline scenario. The GHG emissions and/or removals in the project scenario shall be adjusted for emissions resulting from project activities and leakage. Where appropriate, net GHG emission reductions and removals, and net change in carbon stocks, shall be quantified separately for the project and the baseline scenarios for each relevant GHG and its corresponding GHG sources, sinks and/or reservoirs.

Standardized Methods

Performance Methods

3.8.3 In any given verification period, a methodology may result in the project's GHG emission reductions or removals being quantified as negative. This is permitted and the project shall be granted no credit in such periods.

AFOLU Methodologies

3.8.4 AFOLU methodologies shall establish procedures for quantifying the net change in carbon stocks, so that the number of buffer credits withheld in the AFOLU pooled buffer account and market leakage emissions may be quantified for the project.

3.8.5 AFOLU methodologies shall include procedures to determine the number of GHG credits issued to projects, which is determined by subtracting out the buffer credits from the net GHG emission reductions or removals (including leakage) associated with the project. The buffer credits are calculated by multiplying the non-permanence risk rating (as determined by the

AFOLU Non-Permanence Risk Tool) times the change in carbon stocks only. The full rules and procedures with respect to assignment of buffer credits are set out in the VCS Program document *Registration and Issuance Process*. This calculation process is illustrated in the example below.

3.8.6 To illustrate the calculation of buffer credits, the following example is provided:

At the first verification event, the example project in Table 3 below has generated a change in carbon stocks in the project scenario compared to the baseline scenario of 1000 tonnes. It also reduced GHG emissions by 60 tonnes by avoiding machinery use as compared to the baseline, resulting in a total change in GHG emissions from baseline to project scenario of 1060 tonnes. The project displaced some pre-project activities and resulted in leakage totalling 280 tonnes, including a reduction in carbon stocks outside the project boundary and associated emissions (note that carbon stock losses caused by leakage are considered permanent). Such leakage is subtracted from the change in GHG emissions of the project, resulting in 780 GHG emission reductions or removals (net GHG benefit). The project is assessed to have a 20 percent non-permanence risk rating, which is multiplied by the change in carbon stocks only (not the net GHG benefit). This results in a buffer withholding of 200 credits, with 580 GHG credits issued as VCUs.

Table 3: Example GHG credit calculation

Project Compared to Baseline	tCO_2e	Comment
Change in carbon stocks	1000	Reversal risk
Change in non-stock related GHG emissions (e.g., from decrease in machinery use)	60	No reversal risk
Total change in GHG emissions for project vs. baseline	1060	= 1000 + 60
Leakage		
Change in carbon stocks outside the project area (e.g., 20% market leakage, as determined in Table 2)	-200	= 1000 × 0.2 (considered permanent)
Change in GHG emissions	-80	No reversal risk
Total leakage	-280	= -200 - 80
Total GHG Credits Generated		
GHG emission reductions and removals generated (net GHG benefit)	780	= 1060 − 280

Buffer credits (determined as a percentage of net change carbon stocks*)	200	= 1000 × 20%
GHG credits issued (VCUs)	580	= 780 - 200

* Where the net change in carbon stocks is not a whole number, round the calculated VCU and buffer credit volumes down to the nearest whole number. Where the net change in carbon stocks is a whole number, round the calculated buffer volume up, and the VCU volume down, to the nearest whole number.

3.9 Monitoring

Concept

Methodologies shall describe the data and parameters available at validation (i.e., those that are fixed for the duration of the project crediting period) and data and parameters monitored (i.e., those that must be monitored during the project crediting period for each verification). Additionally, methodologies shall describe the criteria and procedures for obtaining, recording, compiling and analyzing monitored data and parameters.

Requirements

General

3.9.1 The methodology shall describe the data and parameters to be reported, including sources of data and units of measurement.

3.9.2 When highly uncertain data and information are relied upon, conservative values shall be selected that ensure that the quantification does not lead to an overestimation of net GHG emission reductions or removals.

3.9.3 Metric tonnes shall be used as the unit of measure and the quantity of each type of GHG shall be converted to tonnes of CO_2e consistent with the requirements set out in the VCS Program document *VCS Standard*.

3.9.4 The methodology shall establish criteria and procedures for monitoring, which shall cover the following:

1) Purpose of monitoring.
2) Monitoring procedures, including estimation, modeling, measurement or calculation approaches.
3) Procedures for managing data quality.
4) Monitoring frequency and measurement procedures.

AFOLU Methodologies

3.9.5 Where measurement plots or data from research plots are used to calibrate belowground biomass, soil carbon and dead wood decay models (as described above in Section 3.6.4), sound and reliable methods for monitoring changes in carbon stocks, including representative location of samplings sites and sufficient frequency and duration of sampling shall be applied. In addition, plots used to calibrate soil carbon models shall be measured considering appropriate sampling depths, bulk density and the estimated impact of any significant erosion (or plots with significant erosion shall be avoided). Data used to calibrate belowground biomass and dead wood models shall consider an estimation of oven-dry wood density and the state of decomposition.

ODS Methodologies

3.9.6 The methodology shall establish procedures for monitoring the chemical composition and quantity of the ODS destroyed by the project.

3.9.7 Where projects destroying ODS contained in products or mixed with other substances are eligible under the methodology, the methodology shall establish procedures for monitoring the mass of ODS contained in such products or other substances. This shall be achieved using a mass balance analysis and/or other approach (based on conservative assumptions), as appropriate to the nature and scale of the project.

APPENDIX 1 ELIGIBLE AFOLU PROJECT CATEGORIES

As set out in Section 2.6 above, there are currently six AFOLU project categories under the VCS Program, as further described below. Proposed AFOLU methodologies shall fall within one or more of these AFOLU project categories and shall meet with the criteria and requirements set out below.

Afforestation, Reforestation and Revegetation (ARR)

A1.1 Eligible ARR activities are those that increase carbon sequestration and/or reduce GHG emissions by establishing, increasing or restoring vegetative cover (forest or non-forest) through the planting, sowing or human-assisted natural regeneration of woody vegetation. Eligible ARR projects may include timber harvesting in their management plan. The project area shall not be cleared of native ecosystems within the 10-year period prior to the project start date, as set out in the VCS Program document *VCS Standard*.

Note – Activities that improve forest management practices, such as enrichment planting and liberation thinning, are categorized as IFM project activities.

Agricultural Land Management (ALM)

A1.2 Eligible ALM activities are those that reduce net GHG emissions on croplands and grasslands by increasing carbon stocks in soils and woody biomass and/or decreasing CO_2, N_2O and/or CH_4 emissions from soils. The project area shall not be cleared of native ecosystems within the 10-year period prior to the project start date. Eligible ALM activities include:

1) Improved Cropland Management (ICM): This category includes practices that demonstrably reduce net GHG emissions of cropland systems by increasing soil carbon stocks, reducing soil N_2O emissions, and/or reducing CH_4 emissions, noting the following:

    a) Soil carbon stocks can be increased by practices that increase residue inputs to soils and/or reduce soil carbon mineralization rates. Such practices include, but are not limited to, the adoption of no-till, elimination of bare fallows, use of cover crops, creation of field buffers (e.g., windbreaks or riparian buffers), use of improved vegetated fallows, conversion from annual to perennial crops and introduction of agroforestry practices on cropland. Where perennial woody species are introduced as part of cropland management (e.g., field buffers and agroforestry), carbon sequestration in perennial woody biomass may be included as part of the ALM project.

    b) Soil N_2O emissions can be reduced by improving nitrogen fertilizer management practices to reduce the amount of nitrogen added as fertilizer or manure to targeted crops. Examples of practices that improve efficiency while reducing total nitrogen additions include improved application timing (e.g., split application), improved formulations (e.g., slow release fertilizers or nitrification inhibitors) and improved placement of nitrogen.

c) Soil CH_4 emissions can be reduced through practices such as improved water management in flooded croplands (in particular flooded rice cultivation), through improved management of crop residues and organic amendments and through the use of rice cultivars with lower potential for CH_4 production and transport.

2) Improved Grassland Management (IGM): This category includes practices that demonstrably reduce net GHG emissions of grassland ecosystems by increasing soil carbon stocks, reducing N_2O emissions and/or reducing CH_4 emissions, noting the following:

a) Soil carbon stocks can be increased by practices that increase belowground inputs or decrease the rate of decomposition. Such practices include increasing forage productivity (e.g., through improved fertility and water management), introducing species with deeper roots and/or more root growth and reducing degradation from overgrazing.

b) Soil N_2O emissions can be reduced by improving nitrogen fertilizer management practices on grasslands as set out in Section A1.2(1)(b), above.

c) N_2O and CH_4 emissions associated with burning can be reduced by reducing the frequency and/or intensity of fire.

d) N_2O and CH_4 emissions associated with grazing animals can be reduced through practices such as improving livestock genetics, improving the feed quality (e.g., by introducing new forage species or by feed supplementation) and/or by reducing stocking rates.

3) Cropland and Grassland Land-use Conversions (CGLC): This category includes practices that convert cropland to grassland or grassland to cropland and reduce net GHG emissions by increasing carbon stocks, reducing N_2O emissions, and/or reducing CH_4 emissions, noting the following:

a) The conversion of cropland to perennial grasses can increase soil carbon by increasing belowground carbon inputs and eliminating and/or reducing soil disturbance. Decreases in nitrogen fertilizer and manure applications resulting from a conversion to grassland may also reduce N_2O emissions.

b) Conversion of drained, farmed organic or wetland soils to perennial non-woody vegetation, where there is substantial reduction or elimination of drainage, is an eligible practice but shall follow both the WRC and ALM requirements.

c) Grassland conversions to cropland production (e.g., introducing orchard crops or agroforestry practices on degraded pastures) may increase soil and biomass carbon stocks. Only conversions where the crop in the project activity does not qualify as forest are included under ALM. Land conversions of cropland or grassland to forest vegetation are considered ARR activities. Projects that convert grasslands shall demonstrate that they do not have a negative impact on local ecosystems as set out in the VCS Program document *VCS Standard*.

Note – Project activities relating to manure management are eligible under sectoral scope 15 (livestock, enteric fermentation, and manure management), not sectoral scope 14 (AFOLU).

Improved Forest Management (IFM)

A1.3 Eligible IFM activities are those that increase carbon sequestration and/or reduce GHG emissions on forest lands managed for wood products such as sawtimber, pulpwood and fuelwood by increasing biomass carbon stocks through improving forest management practices. The baseline and project scenarios for the project area shall qualify as *forests remaining as forests*, such as set out in the *IPCC 2006 Guidelines on National GHG Inventories*, and the project area shall be designated, sanctioned or approved for wood product management by a national or local regulatory body (e.g., as logging concessions or plantations).

A1.4 Various sanctioned forest management activities may be changed to increase carbon stocks and/or reduce emissions, but only a subset of these activities make a measurable difference to the long-term increase in net GHG emissions compared to the baseline scenario. Eligible IFM activities include:

1) Reduced Impact Logging (RIL): This category includes practices that reduce net GHG emissions by switching from conventional logging to RIL during timber harvesting. Carbon stocks can be increased by:

    a) Reducing damage to other trees (e.g., by implementing directional felling or vine cutting);

    b) Improving the selection of trees for harvesting based on inventoried knowledge concerning tree location, size and quality;

    c) Improving planning of log landing decks, skid trails and roads (e.g., in peatland forests this could include avoiding the use of canals, which drain the peat and increase GHG emissions, to extract the logs); and/or

    d) Reducing the size of logging roads, skid trails and log landing decks.

2) Logged to Protected Forest (LtPF): This category includes practices that reduce net GHG emissions by converting logged forests to protected forests. By eliminating harvesting for timber, biomass carbon stocks are protected and can increase as the forest re-grows and/or continues to grow. Harvesting of trees to advance conservation purposes (e.g., the removal of diseased trees) may continue in the project scenario. LtPF activities include:

    a) Protecting currently logged or degraded forests from further logging.

    b) Protecting unlogged forests that would otherwise be logged.

3) Extended Rotation Age/Cutting Cycle (ERA): This category includes practices that reduce net GHG emissions of evenly aged managed forests by extending the rotation age or cutting cycle and increasing carbon stocks. Because trees are typically harvested at an economically optimal rotation age before they are fully mature, extending the age at which the trees are cut increases the average carbon stock on the land. There is no fixed period of years over which the extension should occur, but generally the longer the period, on the order of 5 to 20 years, the more the average carbon stock increases. ERA activities may also include extending the cutting cycle or harvest schedule in uneven-aged forest management that may have similar effects as extending rotation age in even-aged forest management. Though such activities may have a limited carbon benefit, where methodologies are able to establish criteria and procedures for the credible monitoring of such activities, they are eligible. Examples of extending cutting cycles are:
   a) Increasing the minimum diameter limit of cutting thresholds.
   b) Extending the re-entry period for selective harvesting.
4) Low-Productive to High-Productive Forest (LtHP): This category includes practices that increase carbon sequestration by converting low-productivity forests to high-productivity forests. Carbon stocks can be increased by improving the stocking density of low-productivity forests, noting the following:
   a) Low-productivity forests usually satisfy one of the following conditions:
      i) They qualify as forest as defined by the host country for its UNFCCC national inventory accounting, but contain minimal to no timber of commercial value.
      ii) They are in a state of arrested succession, where regeneration is inhibited for extended periods of time, following either a catastrophic natural event to which the forest is maladapted thus causing massive mortality, or ongoing human-induced disturbance, for example uncharacteristically severe fire or widespread flooding, animal grazing, or burning.
      iii) They have a very slow growth rate or low crown cover.
   b) Improving the stocking density of low-productivity forests can be achieved through the following activities:
      i) Introducing other tree species with higher growth rates.
      ii) Adopting enrichment planting to increase the density of trees.
      iii) Adopting other forest management techniques to increase carbon stocks (e.g., fertilization or liming).

Note – Activities that reduce GHG emissions from unsanctioned forest degradation (e.g., illegal logging) are considered REDD activities. Projects focusing solely on the reduction of forest fires are not eligible under IFM. Activities that degrade wetlands to increase forest production are not eligible.

Reduced Emissions from Deforestation and Degradation (REDD)

A1.5 Eligible REDD activities are those that reduce net GHG emissions by reducing deforestation and/or degradation of forests. Deforestation is the direct, human-induced conversion of forest land to non-forest land. Degradation is the persistent reduction of canopy cover and/or carbon stocks in a forest due to human activities such as animal grazing, fuelwood extraction, timber removal or other such activities, but which does not result in the conversion of forest to non-forest land (which would be classified as deforestation), and qualifies as *forests remaining as forests*, such as set out under the *IPCC 2003 Good Practice Guidance*. The project area shall meet an internationally accepted definition of forest, such as those based on UNFCCC host-country thresholds or FAO definitions, and shall qualify as forest for a minimum of 10 years before the project start date. The definition of forest may include mature forests, secondary forests, and degraded forests. Under the VCS Program, secondary forests are considered to be forests that have been cleared and have recovered naturally and that are at least 10-years-old and meet the lower bound of the forest threshold parameters at the start of the project. Forested wetlands, such as floodplain forests, peatland forests and mangrove forests, are also eligible provided they meet the forest definition requirements mentioned above.

A1.6 Avoiding deforestation and/or degradation can affect GHG emissions and removals in a number of ways. The main effect is on carbon emissions that are reduced by preventing the conversion of forest lands with high carbon stocks to non-forest lands with lower carbon stocks. Where the forest is young or degraded, stopping its further degradation and deforestation also allows for additional sequestration of carbon on the land as the forest re-grows (with or without assisted regeneration). Avoiding conversion of forests to cropland or pasture can reduce emissions of N_2O and CH_4 that are associated with biomass burning used to clear the land, fertilizer use and other agricultural practices that would have occurred if the forests had been converted.

A1.7 Activities covered under the REDD project category are those that are designed to stop planned (designated and sanctioned) deforestation or unplanned (unsanctioned) deforestation and/or degradation. Avoided planned degradation is classified as IFM.

A1.8 Activities that stop unsanctioned deforestation and/or illegal degradation (such as removal of fuelwood or timber extracted by non-concessionaires) on lands that are legally sanctioned for timber production are eligible as REDD activities. However, activities that reduce or stop logging only, followed by protection, on forest lands legally designated or sanctioned for forestry activities are included within IFM. Projects that include both avoided unplanned deforestation and/or degradation as well as stopping sanctioned logging activities, shall follow the REDD guidelines for the unplanned deforestation and/or degradation and the IFM guidelines for the sanctioned logging activities, and shall follow the requirements set out in the VCS Program document *VCS Standard*.

A1.9 Eligible REDD activities include:

1) Avoiding Planned Deforestation and/or Degradation (APDD): This category includes activities that reduce net GHG emissions by stopping or reducing deforestation or degradation on forest lands that are legally authorized and documented for conversion, noting the following:

    a) This practice can occur in degraded to mature forests.

    b) Planned deforestation can encompass a wide variety of activities where forest land is converted to non-forest land, including inter alia:

        i) National resettlement programs from non-forested to forested regions.

        ii) National land plans to reduce the forest estate and convert it to industrial-scale production of commodities such as soybeans, pulpwood and oil palm, where the converted land would not qualify as forest land.

        iii) Plans to convert community-owned forests to other non-forest uses.

        iv) Planned forest conversion for urban, rural and infrastructure development.

    c) Planned degradation includes activities where a forest system would have been cleared and replaced by a different forest system with a lower carbon stock and where the recovery of timber was not the primary objective of the initial forest clearance. For example, national land plans to reduce the forest estate and convert it to industrial-scale production of commodities such as pulpwood and oil palm, where the converted land would still meet the country definition of forest land, are considered planned degradation.

    d) Avoided planned deforestation and degradation can include decisions by individual land owners, governments, or community groups, whose land is legally zoned for agriculture, not to convert their forest(s) to crop production or biofuel plantations. For example, a community may determine that GHG credits from forest protection are more valuable than the potential revenue from crop or commodity production. Similarly, an owner of land zoned for conversion to agriculture or urban development may choose to protect forested lands by partnering with a conservation organization, either in a joint management agreement or an outright sale.

    e) Avoiding planned degradation in a managed forest (e.g., legally sanctioned timber extraction) is an eligible activity under IFM.

Note – Activities that only reduce or avoid logging, followed by protection, on forest lands legally designated or sanctioned for forest products are eligible as IFM activities.

2) Avoiding Unplanned Deforestation and/or Degradation (AUDD): This category includes activities that reduce net GHG emissions by stopping deforestation and/or degradation of degraded to mature forests that would have occurred in any forest configuration, noting the following:

a) Unplanned deforestation and/or degradation can occur as a result of socio-economic forces that promote alternative uses of forest land and the inability of institutions to control these activities. Poor law enforcement and lack of property rights can result in piecemeal conversion of forest land. Unplanned deforestation and/or degradation activities can include, inter alia, subsistence farming or illegal logging occurring on both public lands legally designated for timber production and on public or communal lands that are poorly managed or otherwise degraded.

b) Methodologies may be designed for frontier and/or mosaic configurations, which are described as follows:

   i) The frontier deforestation and/or degradation pattern can result from the expansion of roads and other infrastructure into forest lands. Roads and other infrastructure can improve forest access and lead to increased encroachment by human populations, such as subsistence farming and fuelwood gathering on previously inaccessible forest lands.

   ii) The mosaic deforestation and/or degradation pattern can result when human populations and associated agricultural activities and infrastructure are spread out across the forest landscape. In a mosaic configuration most areas of the forest landscape are accessible to human populations.

   Mosaic deforestation and/or degradation typically occur: where population pressure and local land use practices produce a patchwork of cleared lands, degraded forests, secondary forests of various ages, and mature forests; where the forests are accessible; and where the agents of deforestation and/or degradation are present within the region containing the area to be protected.

Avoided Conversion of Grasslands and Shrublands (ACoGS)

A1.10 Eligible ACoGS activities are those that reduce net GHG emissions by reducing the conversion of grassland and shrubland ecosystems to other land uses with lower carbon densities. Eligible avoided conversion activities include avoiding, at a minimum, the removal/replacement of vegetation and may also include avoiding soil disturbance. There is no specific requirement with respect to the post-conversion land use that would have occurred in the baseline scenario.

A1.11 The project area shall be native grasslands (including savanna) and/or shrublands (including chaparral). Non-forested wetlands, including peatlands, are not eligible under ACoGS and are covered under other AFOLU project categories.

A1.12 Avoiding conversion of ecosystems can affect GHG emissions in a number of ways. Avoiding the conversion of grasslands and shrublands to cropland can reduce emissions from both soil and biomass carbon pools, with the bulk of avoided emissions likely coming from the soil carbon pool. Avoiding conversion to cropland can also reduce emissions of N_2O that are associated with fertilizer use and other agricultural practices that would have occurred following conversion. Avoiding conversion of shrublands or savanna to agriculture or development uses can reduce GHG emissions associated with the activities of clearing aboveground woody biomass.

A1.13 Activities covered under the ACoGS project category are those that are designed to stop planned (designated and sanctioned) conversion or unplanned (unsanctioned) conversion on public or private lands. This category type only includes avoided conversion of non-forested lands, noting that other management activities on non-forested land may qualify under ALM or ARR project categories.

A1.14 For both avoided planned conversion and avoided unplanned conversion, spatially explicit analysis is required to demonstrate that lands included in the project area are economically and physically suitable for the type of conversion being avoided. For example, where protecting lands from conversion to cropland, areas that are too steep, rocky, infertile for crops, or otherwise not viable for agricultural use, shall be considered unsuitable for conversion. The spatial analysis shall take into account local land use practices that may include the conversion of marginally suitable lands due to subsidies or population pressures. Unsuitable lands shall be excluded from baseline conversion scenarios.

A1.15 Eligible ACoGS activities include:

1) Avoiding Planned Conversion (APC): This category includes activities that reduce net GHG emissions by stopping conversion of grasslands or shrublands that are legally authorized and documented for conversion.

   Planned conversion may include decisions by individual land owners or community groups, whose land is legally zoned for agriculture or other development, not to convert their land(s). Similarly, an owner of land zoned for conversion to agriculture or development may choose to protect lands by partnering with an NGO or conservation organization either in a joint management agreement, conservation easement, or outright sale or lease.

2) Avoiding Unplanned Conversion (AUC): This category includes activities that reduce net GHG emissions by stopping unplanned conversion of grasslands or shrublands.

   Unplanned conversion can occur as a result of socio-economic forces that promote alternative uses of native grasslands or shrublands and the inability of institutions to control these activities. Poor law enforcement and weak or lacking property rights can result in piecemeal land conversion. Unplanned conversion activities may include, inter alia, subsistence agriculture, unsanctioned commercial agriculture and collection of biomass fuel where such collection would result in land conversion.

Wetlands Restoration and Conservation (WRC)

A1.16 Eligible WRC activities are those that increase net GHG removals by restoring wetland ecosystems or that reduce GHG emissions by rewetting or avoiding the degradation of wetlands. The project area shall meet an internationally accepted definition of wetland, such as from the IPCC, Ramsar Convention on Wetlands, those established by law or national policy, or those with broad agreement in the peer-reviewed scientific literature for specific countries or types of wetlands. Common wetland types include peatland, salt marsh, tidal freshwater marsh, mangroves, wet floodplain forests, prairie potholes and seagrass meadows. WRC activities may be combined with other AFOLU project categories, as further explained in Section A1.20.

A1.17 Avoiding the degradation or conversion of a wetland can reduce GHG emissions by preventing the release of carbon stored in wetland soils and vegetation. Many wetlands rely on a natural supply of sediments to support soil formation. Sediment supply may be interrupted by a physical alteration to the landscape, such as a river diversion, canal construction or isolation of wetlands behind man-made structures (e.g., road or rail embankments, levees or dams).

Restoring wetland ecosystems_reduces and/or removes GHG emissions by creating the necessary physical, biological or chemical conditions that enhance carbon sequestration. Activities that affect the hydrology of the project area are only eligible where changes in hydrology result in the accumulation or maintenance of soil carbon stock.

A1.18 A peatland is an area with a layer of naturally accumulated organic material (peat) at the surface (excluding the plant layer). Peat originates due to water saturation, and peat soils are either saturated with water for long periods or have been artificially drained. Common peatland types include peat swamp forest, mire, bog, fen, moor, muskeg and pocosin. Rewetting of drained peatland and the conservation of undrained or partially drained peatland are sub-categories of restoring wetland ecosystems and conservation of intact wetlands, respectively. These activities reduce GHG emissions by rewetting or avoiding the drainage of peatland. There are specific requirements regarding reductions of GHG emissions from fire (as set out in Sections 3.4.21, 3.6.25, 3.6.33, 3.6.34 and A1.19).

A1.19 Activities that generate net reductions of GHG emissions from wetlands are eligible as WRC projects or combined category projects (such as REDD on peatland). Activities that actively lower the water table depth in wetlands are not eligible. Eligible WRC activities include:

1) <u>Restoring Wetland Ecosystems (RWE)</u>: This category includes activities that reduce GHG emissions or increase carbon sequestration in a degraded wetland through restoration activities. Such activities include enhancing, creating and/or managing hydrological conditions, sediment supply, salinity characteristics, water quality and/or native plant communities. For the purpose of these requirements, restoration activities are those that result in the reestablishment of ecological processes, functions, and biotic and/or abiotic linkages that lead to persistent, resilient systems integrated within the landscape, noting the following:

a) Restoration or management of water table depth (e.g., the rewetting of peatlands, the reintroduction of river flows to floodplains, or the reintroduction of tidal flows to coastal wetlands) implies long-term and measurable changes in water table depth that sequester carbon and/or reduce emissions. Methodologies shall establish the appropriate change in water table depth (such as raising, lowering or restoring hydrological function) that is expected for eligible project activities, considering the following baseline scenario conditions:

   i) Drained wetlands have a water table depth that is lower than the natural average annual water table depth due to accelerated water loss or decreased water supply resulting from human activities and/or construction, either on- and/or off-site. Baseline activities include purposeful draining through pumping, ditching, stream channelization, levee construction, and purposeful decreases in water supply through dams and water diversions. Examples of this include selectively logged peatland swamp forests in Southeast Asia impacted by logging canals or wetlands with water tables lowered for agriculture.

      Activities shall raise the average annual water table depth in a drained wetland by partially or entirely reversing the existing drained state. Rewetting does not require the restoration of the average annual water table depth to the level of the soil or peat surface. However, RWE projects shall raise the water table depth close to the surface in order to be eligible to generate GHG credits. A clear relationship between GHG emissions and water table depth in wetlands, including peatlands[8] has been established in scientific literature with most changes in emissions occurring with water table depths close to the surface. This relationship is most dramatic on highly-organic soils (e.g., peatland). On such sites, activities that establish a higher water table depth compared to the baseline scenario can be eligible where they measurably decrease the rate of soil subsidence due to oxidation to decrease or cease within the project crediting period, and where the permanence requirements set out in Section 3.6.28 can be satisfied.

   ii) Impounded wetlands have a water table that has been artificially raised, intentionally or unintentionally, as a result of impaired natural drainage behind a constructed feature and can result in CH_4 emissions. Examples of impounded wetlands include flooded areas behind artificial barriers to natural drainage (such as road or rail embankments or levees), flooded areas for the purpose of subsidence reversal, man-made reservoirs and fish and shrimp ponds.

      Activities that restore hydrological function to an impounded wetland or lower the water table depth shall restore hydrological flow, considering the dynamics of the

[8] For a literature review see Couwenberg, J, Dommain, R, Joosten, H. 2010. *Greenhouse gas fluxes from tropical peatlands in south-east Asia*. Global Change Biology 16: 1715-1732.

system and the hydrological connectivity necessary to maintain carbon stock and GHG fluxes.

iii) Open water is an area continuously flooded or subject to natural periods of flooding, without in-situ vegetation contributing to soil carbon accumulation. Wetlands convert to open water in response to impaired sediment supply, sea level rise and/or impaired water quality.

Activities that restore hydrological function to an open water wetland shall restore the hydrological flow, considering the dynamics of the system and the hydrological connectivity necessary to maintain carbon stock and GHG fluxes.

b) RWE projects may generate GHG credits from the reduction of GHG emissions associated with avoiding peat fires on drained or partially drained peatlands. Fire-related activities on peatlands that exclude rewetting as part of the project are not eligible, because fire reduction activities on drained peatland are unlikely to be effective over the long term without rewetting.

Note – Activities that increase net GHG removals through carbon sequestration by restoring soil carbon sequestration conditions (e.g., peat-forming conditions) are eligible under RWE. The restoration of conditions that favor soil carbon sequestration requires high water table depths over the long term and the presence of vegetation that produces soil carbon. Carbon sequestration rates resulting from rewetting and restoring drained non-tidal wetlands tend to be low on a unit-per-land area basis compared to GHG emissions reduced by avoiding soil carbon oxidation. Soil carbon sequestration restoration is therefore considered to have a relatively small contribution to GHG mitigation from non-tidal RWE projects. Soil carbon sequestration in tidal wetlands can be relatively rapid compared to non-tidal wetlands and will typically be expected to contribute significantly to the GHG mitigation effectiveness of RWE projects. Methodologies for forecasting soil carbon sequestration in tidal wetlands may be proposed, noting that they shall separate the sequestration of carbon as a result of project activities from the deposit of carbon rich soil into the project area as a result of sedimentation, (as set out in Section 3.6.29).

2) <u>Conservation of Intact Wetlands (CIW)</u>: This category includes activities that reduce GHG emissions by avoiding degradation and/or the conversion of wetlands that are intact or partially altered while still maintaining their natural functions, including hydrological conditions, sediment supply, salinity characteristics, water quality and/or native plant communities.

Wetland degradation or conversion can be planned (designated and sanctioned) or unplanned (unsanctioned). Planned and unplanned degradation or conversion of wetlands can therefore encompass a wide variety of activities such as those listed under REDD while adding a wetland component. Activities covered under the CIW project category are those that are designed to stop or reduce planned or unplanned degradation or conversion in the project area to other land uses. The following CIW activities are eligible:

a) <u>Avoiding Planned Wetland Degradation (APWD)</u>: This activity reduces GHG emissions by avoiding degradation of wetlands, or further degradation in partially drained wetlands that are legally authorized and documented for conversion.

b) Avoiding Unplanned Wetland Degradation (AUWD): This activity reduces GHG emissions by avoiding unplanned degradation of wetlands, or by avoiding further degradation in partially degraded wetlands. Unplanned wetland degradation can occur as a result of socio-economic forces that promote alternative uses of wetlands and the inability of institutions to control these activities. Poor law enforcement and weak or lack of property rights can result in piecemeal wetland conversion. Unplanned conversion activities may include, inter alia, subsistence farming, illegal logging, unsanctioned commercial agriculture and collection of biomass fuel where such collection would result in land conversion subsistence agriculture.

Note – Activities where drainage is continued or maintained are not eligible. This includes, for example, projects that require the maintenance of drainage channels to maintain the pre-project drainage level on a partially drained peatland (e.g., where periodic deepening may be needed to counteract peat subsidence). Projects that allow selective harvesting that results in a lowering of the water table depth (e.g., by extracting timber using drainage canals) or affects the ability of vegetation to act as a major hydrological regulation device (e.g., extracting trees which support the peat body) are also not eligible. Project activities may include selective harvesting where harvesting does not lower the water table, for example by extracting timber using wooden rails instead of drainage canals.

Note – WRC activities that are unable to establish and demonstrate a significant difference in the net GHG benefit between the baseline and project scenarios for at least 100 years are not eligible, as set out in Section 3.6.30.

A1.20 Activities that generate net GHG emission reductions by combining other AFOLU project activities with wetlands restoration or conservation activities are eligible as WRC combined projects. RWE may be implemented without further conversion of land use or it may be combined with ARR, ALM, IFM, REDD or ACoGS activities, referred to as ARR+RWE, ALM+RWE, IFM+RWE, REDD+RWE or ACoGS+RWE, respectively. CIW may be implemented on non-forest land or combined with IFM, REDD or ACoGS activities, referred to as IFM+CIW, REDD+CIW or ACoGS+CIW, respectively.

Table 4 illustrates the types of WRC activities that may be combined with other AFOLU project categories. The table identifies the applicable AFOLU requirements that shall be followed for combined category projects, based on the condition of the wetland in the baseline scenario, the land use in the baseline scenario and the project activity.

Table 4: Eligible WRC Combined Category Projects

Baseline Scenario		Project Activity	Applicable Guidance
Condition	Land Use		
Degraded wetland (including, drained, impounded, and with interrupted sediment supply)	Non-forest (including aquacultures, grasslands and shrublands)	Restoration of wetlands*	RWE
		Restoration of wetlands* and revegetation or conversion to forest	ARR+RWE
		Restoration of wetlands* and conversion to wetland agriculture (including paludiculture)	ALM+RWE
		Restoration of wetlands* and avoided conversion of grasslands or shrublands	ACoGS+RWE
	Forest	Restoration of wetlands*	RWE
	Forest with deforestation/ degradation	Restoration of wetlands* and avoided deforestation/degradation	REDD+RWE
	Forest managed for wood products	Restoration of wetlands* and improved forest management	IFM+RWE
Non-wetland or open water	Non-forest	Creation of wetland conditions and afforestation, reforestation or revegetation	ARR+RWE
	Open water or impounded wetland	Creation or restoration of conditions for vegetation development and afforestation, reforestation or revegetation	ARR+RWE
Intact wetland	Non-forest (including grasslands and shrublands)	Avoided drainage and/or interrupted sediment supply	CIW
		Avoided conversion to open water or impounded wetland (including excavation to create fish ponds)	CIW
		Avoided drainage and/or interrupted sediment supply and avoided conversion of grasslands and shrublands	ACoGS+CIW
	Forest	Avoided drainage and/or interrupted sediment supply	CIW
		Avoided conversion to open water or impounded wetland	CIW
	Forest with deforestation/ degradation	Avoided drainage and/or interrupted sediment supply and avoided deforestation/degradation	REDD+CIW
		Avoided conversion to open water or impounded wetland and avoided	REDD+CIW

		deforestation/degradation	
	Forest managed for wood products	Avoided drainage and/or interrupted sediment supply and improved forest management	IFM+CIW

* *Restoration of wetlands* includes all the activities set out in Section A1.19(1).

The eligible WRC combined categories are further elaborated below:

1) ARR on Wetland (ARR+RWE): RWE may be implemented in combination with ARR, for example by planting a native or adapted tree or shrub species on peatland or in mangroves. While existing oxidation in drained conditions is accounted for in the baseline, ARR activities on peatland shall not enhance peat oxidation, therefore this activity requires at least some degree of rewetting. ARR+RWE on already drained peatland without full rewetting is permitted in cases where the biomass carbon stock increases more than the peat carbon stock decreases by oxidation over a period of centuries.[9]

   Note – ARR activities that involve nitrogen fertilization, active peatland drainage or lowering of the water table depth, such as draining in order to harvest, are not eligible project activities, as they are likely to enhance net GHG emissions. Activities involving selective logging, combined with artificial drainage and/or construction of channels to extract the timber are not eligible as these may result in decomposition and subsidence of the peat which could be accompanied by an increase in CO2 emissions or additional GHG fluxes.

2) ALM on Wetland (ALM+RWE): This is an eligible activity if the water table depth of an agricultural wetland is raised to a level that can still support agriculture. The following ALM+RWE practices qualify as eligible activities:

   a) Rewetting a wetland combined with adapted wet agriculture that includes the cultivation of biomass on undrained or rewetted wetland. The wetland shall be sufficiently wet so as to avoid long-term net soil organic carbon losses as set out in Section 3.6.28.

   b) Improved grassland management activities that reduce overgrazing, high-intensity use and gully erosion for reducing peat erosion on sloping peatlands. In many steppe and mountain regions with dry climates, and also in cold or humid regions ("blanket bogs"), peatlands are the most productive and attractive, or the only available, lands for grazing. Overgrazing on sloping peatlands, frequently leads to vegetation damage and peat soil degradation.

[9] For more information on the relationship between biomass carbon stock increases and peat carbon stock decreases, see Laine, J. & Minkkinen, K. 1996. *Forest drainage and the greenhouse effect*. In: Vasander, H. (Ed.) Peatlands in Finland. Finnish Peatland Society, Helsinki, pp 159-164.

c) Improved cropland and grassland management activities that reduce wind erosion on peatlands that are devegetated or sparsely vegetated due to overgrazing, soil degradation or crop production.

Note – ALM activities that involve regular tillage and/or nitrogen fertilization on wetland soil or that actively lower the water table depth in wetlands are not eligible project activities.

3) IFM, REDD and ACoGS on Wetland (IFM+RWE, IFM+CIW, REDD+RWE, REDD+CIW, ACoGS+RWE and ACoGS+CIW): RWE and CIW may be implemented in combination with IFM, REDD and ACoGS project activities. Such activities reduce GHG emissions by increasing, or avoiding the loss of, forest, shrubland or grassland carbon stocks, and avoiding the drainage required to undertake such baseline activities, noting the following:

a) IFM, REDD and ACoGS project activities on wetlands shall not increase drainage. With respect to the forest biomass component, the requirements provided for IFM, REDD or ACoGS apply.

b) For IFM+CIW projects on peatland that include harvesting activities in the project scenario, selective harvesting shall not significantly affect the hydrology of the peat layer and cause peat decomposition. Where the peat layer in the baseline scenario is partially drained, the effect of harvesting on top soil hydrology is likely to be much less significant. CIW projects that have clear-cut or patch-cut harvesting activities are not eligible.

c) For IFM+RWE projects, activities that avoid fire of a peat layer are eligible for crediting. IFM activities focusing solely on the reduction of forest fires are not eligible under AFOLU, as set out in Section A1.4.

A1.21 Many seagrass meadows sit upon significant stocks of soil carbon. Degradation of seagrass meadows likely increases the vulnerability of carbon stocks to disturbance and recirculation. Increases in CO_2 in the water column from decomposition of seagrass bed carbon stocks will lead to an increased CO_2 flux to the atmosphere, although the flux to the atmosphere could be reduced by dissolution of the carbonate soils underlying some seagrass meadows or by the export of CO_2-enriched waters to deeper waters below the mixing depth. Methodologies shall include credible methods for quantifying and forecasting GHG emissions to the atmosphere associated with seagrass degradation.

A1.22 Peat may be used as fuel, soil improver or horticultural substrate. Due to the existence of extensive local, regional and global markets, projects that avoid peat mining are likely to suffer significant (and potentially 100 percent) leakage emissions and therefore are not eligible. Project activities that serve the demand side and avoid peat mining by providing alternatives for peat as fuel or substrate, are outside the scope of AFOLU but may qualify under another sectoral scope.

v4.0

ABOUT VERRA

Verra supports climate action and sustainable development through the development and management of standards, tools and programs that credibly, transparently and robustly assess environmental and social impacts, and drive funding for sustaining and scaling up these benefits. As a mission-driven, non-profit (NGO) organization, Verra works in any arena where we see a need for clear standards, a role for market-driven mechanisms and an opportunity to achieve environmental and social good.

Verra manages a number of global standards frameworks designed to drive finance towards activities that mitigate climate change and promote sustainable development, including the Verified Carbon Standard (VCS) Program and its Jurisdictional and Nested REDD+ framework (JNR), the Verra California Offset Project Registry (OPR), the Climate, Community & Biodiversity (CCB) Standards and the Sustainable Development Verified Impact Standard (SD VISta). Verra is also developing new standards frameworks, including LandScale, which will promote and measure sustainability outcomes across landscapes. Finally, Verra is one of the implementing partners of the Initiative for Climate Action Transparency (ICAT), which helps countries assess the impacts of their climate actions and supports greater transparency, effectiveness, trust and ambition in climate policies worldwide.

1 INTRODUCTION

This document provides the definitions for terms used in the VCS Program documents. In addition, the definitions set out in *ISO 14064-2:2006*, *ISO 14064-3:2006* and *ISO 14065:2016* shall apply to the VCS Program. Note that defined terms in the VCS Program documents, in common with ISO convention, are used without capital first letters. Section 3 lists acronyms used in the VCS Program documents. This document will be updated from time-to-time and readers shall ensure that they are using the most current version of the document.

2 DEFINITIONS

Aboveground Biomass

Living biomass above the soil, including the stem, stump, branches, bark, seeds and foliage

Agroforestry

An ecologically-based natural resource management system in which trees are integrated in farmland and rangeland

Agro-ecological zones

Geographic areas based on similar characteristics such as combinations of soil, landform and climatic conditions

Accession Representation

- The deed issued by the project proponent, and an acceding entity, made in respect of an acceding entity joining a project as project proponent, and which is prepared using the *VCS Deed of Accession in Respect of Registration Deed of Representation Template*; or
- The deed issued by the jurisdictional proponent, and an acceding entity, made in respect of an acceding entity joining a jurisdictional baseline or program as jurisdictional proponent, and which is prepared using the *VCS Deed of Accession in Respect of JNR Baseline Registration Deed of Representation Template* or the *VCS Deed of Accession in Respect of JNR Program Registration Deed of Representation Template*, respectively

Activity Method

A methodological approach that determines additionality for a given class of project activity in accordance with the VCS Program rules

Afforestation

The direct human-induced conversion of land that has not been forested for a period of at least 50 years to forested land through planting, seeding and/or the human-induced promotion of natural seed sources

Afforestation, Reforestation and Revegetation (ARR)

Activities that increase carbon stocks in woody biomass (and in some cases soils) by establishing, increasing and/or restoring vegetative cover through planting, sowing and/or the human-assisted natural regeneration of woody vegetation

Agriculture, Forestry and Other Land Use (AFOLU)

The sectoral scope that covers GHG emissions and emission reductions and/or removals from project or program activities in the agriculture, forestry, and other land use/land use change sectors and for which the VCS Program has established rules and requirements with respect to specific project categories

Agricultural Land Management (ALM)

Activities that increase carbon stocks in soils and woody biomass and/or decrease CO_2, N_2O and/or CH_4 emissions from soils on croplands and/or grasslands

AFOLU Expert

A person with expertise and experience in AFOLU methodologies, tools, modules and/or projects, and who is approved by Verra for methodology element assessments within a given AFOLU project category

AFOLU Pooled Buffer Account

The account in the Verra registry containing non-tradable AFOLU buffer credits for covering the risk of unforeseen losses in carbon stocks across the AFOLU project portfolio

Approved GHG Program

A GHG program that has been approved by the Verra Board, through a gap analysis, as a VCS Program approved GHG program

Authorized Representative

An entity authorized by the project or jurisdictional proponent to communicate with and provide instructions to the Verra registry on its behalf, with such authorization granted through a communications agreement signed by both/all parties and submitted to the Verra registry

Belowground Biomass

Living biomass of live roots, sometimes excluding fine roots of less than 2 mm diameter because these often cannot be distinguished empirically from soil organic matter or litter

Cancellation

The permanent removal of a VCU from circulation in the Verra registry system for purposes other than retirement (e.g., converting VCUs into another form of GHG credit, compensating for excess VCU issuance)

Capacity Limit

A limitation on any quantity in relation to the project imposed by a methodology applied to the project, the GHG program under which the methodology applied to the project was developed or the GHG program under which the project was developed

Capital Expenditure

The costs to the project activity of acquiring new assets or improving existing assets that are utilized for the duration of the project crediting period

Carbon Pools

A reservoir of carbon that has the potential to accumulate (or lose) carbon over time, which for AFOLU projects or programs encompasses aboveground biomass, belowground biomass, litter, dead wood, soil and wood products

Carbon Stock

The quantity of carbon held within a pool, measured in tonnes of CO_2

Catastrophic Reversal

A type of reversal caused by disasters such as hurricanes, earthquakes, flooding, drought, fires, tornados or winter storms, or man-made events over which the project proponent has no control such as acts of terrorism or war

Commercially Sensitive Information

See “Sensitive Information”

Communications Agreement

The agreement by which the project or jurisdictional proponent authorizes a third party to communicate with and provide instructions to the Verra registry on its behalf, the form and scope of which shall be determined solely by the Verra registry and the signatories to the agreement

Crediting Period

The time period for which GHG emission reductions or removals generated by the project are eligible for issuance as VCUs, the rules with respect to the length of such time period and the renewal of the project crediting period being set out in the *VCS Standard*. Also referred to as “Project Crediting Period”; or

The time period for which GHG emission reductions or removals generated by the jurisdictional REDD+ program are eligible for issuance as VCUs, the rules with respect to the length of such time period and the renewal of the program crediting period being set out in the VCS Program document *JNR Requirements.* Also referred to as “Program Crediting Period”.

Cropland

Arable and tillage land and agro-forestry systems where vegetation falls below the threshold used for the forest land category

Dead Wood

Non-living woody biomass not contained in the litter, either standing, lying on the ground or in the soil. Dead wood includes wood lying on the surface, dead roots, and stumps larger than or equal to 10 cm in diameter or any other diameter used by the host country for its UNFCCC national inventory accounting

Deemed Savings Factor

A type of default factor used to estimate the GHG emission reductions or removals associated with a unit of activity implemented by the project, such as a project activity instance

Default Factor

A parameter value that is specified in a methodology with the intention of standardizing the calculation of net GHG emission reductions and/or removals and providing greater consistency of calculations across projects

Deforestation

The direct human-induced conversion of forest land to non-forest land

Degradation

The persistent reduction of canopy cover and/or carbon stocks in a forest due to human activities such as animal grazing, fuelwood extraction, timber removal or other such activities, but that does not result in the conversion of forest to non-forest land, and falls under the *IPCC 2003 Good Practice Guidance* land category of *forest remaining forest*

Drained Peatland

A peatland having a lower than natural average annual water level due to accelerated water loss or decreased water supply resulting from human activities and constructions, both on- and off-site

Double Counting

The scenario under which a singular GHG emission reduction or removal is monetized separately by two different entities or where a GHG emission reduction or removal is sold to multiple buyers

Free-rider

An activity that is undertaken without requiring any intervention from the carbon market but that nonetheless receives credit for the GHG emission reductions or removals that it generates

Forest

Land with woody vegetation that meets an internationally accepted definition (e.g., UNFCCC, FAO or IPCC) of what constitutes a forest, which includes threshold parameters, such as minimum forest area, tree height and level of crown cover, and may include mature, secondary, degraded and wetland forests

Emission Trading Program

A voluntary or regulatory program that allows for trading in GHG credits or allowances

GHG Program

A formal or organized program, system or arrangement for the recognition of activities leading to GHG emission reductions or removals, and/or the crediting or issuance of instruments representing, or acknowledging, GHG emission reductions or removals

Grassland

Areas dominated by grasses with a density of trees too low to meet an internationally accepted definition of forest, including savannas (i.e., grasslands with scattered trees). Grasslands also include managed rangeland and pastureland that is not considered cropland where the primary land use is grazing, and which may also include grass-dominated systems managed for conservation or recreational purposes

Grouped Project

A project to which additional instances of the project activity, which meet pre-established eligibility criteria, may be added subsequent to project validation

Implementing Partner

The individual or organization operating the project or program activity (or activities) in partnership with the project or jurisdictional proponent, respectively

Improved Forest Management (IFM)

Activities that change forest management practices and increase carbon stock on forest lands managed for wood products such as saw timber, pulpwood and fuelwood

Internal Allocation Mechanism

The mechanism for the distribution of GHG credits and/or other benefits, established by the jurisdictional proponent as part of the jurisdictional REDD+ program

Issuance Representation

- The unilateral representation issued by the project proponent at each VCU issuance request, made in respect of the GHG emission reductions and/or removals generated by the project, and which is prepared using the *VCS Issuance Deed of Representation Template*; or
- The unilateral representation issued by the jurisdictional proponent at each VCU issuance request, made in respect of the GHG emission reductions and/or removals generated by the jurisdictional

program, and which is prepared using the *VCS JNR Program Issuance Deed of Representation Template*

Jurisdiction

The administrative unit such as a nation, state, province, region, department or district, or an eco-region or other defined area, specified in the jurisdictional program description

Jurisdictional and Nested REDD+ (JNR)

The approach under the VCS Program by which reduced emissions from deforestation, reduced emissions from degradation and removals from carbon stock enhancements can be credited at the jurisdictional and/or nested project levels

Jurisdictional Approval Authority

The government agency, department or organization that has control of and responsibility for reviewing and giving approval, or the no-objection letter, to lower-level jurisdictional REDD+ programs and/or projects, and that may or may not be the same entity as the jurisdictional proponent

Jurisdictional Baseline Period

The time period for which the baseline for a jurisdictional REDD+ program is valid

JNR Program Description (Program Description)

The document that describes the jurisdictional baseline and/or program GHG emission reductions or removals and that uses the *VCS JNR Baseline Description Template* (for jurisdictions registering only a jurisdictional baseline) or the *VCS JNR Program Description Template* (for jurisdictional REDD+ programs), respectively

Jurisdictional Proponent

The government agency, department or organization that has overall control and responsibility for the jurisdictional REDD+ program, or a government agency, department or organization that together with others, each of which is also a jurisdictional proponent, has overall control of or responsibility for the jurisdictional REDD+ program. The entity(s) that can demonstrate program ownership in respect of the jurisdictional REDD+ program.

JNR Expert

A person with expertise and experience in jurisdictional baselines and/or REDD+ programs who is approved by Verra for participation on expert panels for the validation/verification of jurisdictional REDD+ programs

Jurisdictional REDD+ Program and Jurisdictional Program

See “Program”

Jurisdictional Pooled Buffer Account

The account in the Verra registry containing non-tradable jurisdictional and nested REDD+ buffer credits for covering the risk of unforeseen losses in carbon stocks across the jurisdictional REDD+ program and REDD+ project portfolio

Land-Based Accounting

A method of GHG accounting in which all land in an entire geographic area or jurisdiction is included in the accounting through categorization of land-use types and a sampling or modeling approach sufficient to capture carbon stocks and changes in carbon stocks, irrespective of activity

Large Project

A project that generates 300,000 tonnes CO_2e or more of GHG emissions reductions or removals per year

Large-Scale Commercial Deforestation

An area of deforestation that exceeds 1,000 ha, cleared in a single monitoring period (or, between two points of remotely sensed historical data), that has a single post-deforestation land use (e.g., commercial agriculture or timber plantation), not including areas covered by the footprint of large infrastructure (such as a dam) or those affected by natural disturbances (i.e., due to geologic or weather-related events)

Leakage

Net changes of anthropogenic emissions by GHG sources that occur outside the project or program boundary, but are attributable to the project or program

Listing Representation

- The unilateral representation issued by the project proponent at the time of the project pipeline listing request, made in respect of the project, and which is prepared using the *VCS Listing Representation Template*; or

- The unilateral representation issued by the jurisdictional proponent at the time of the jurisdictional baseline or program listing request, made in respect of the jurisdictional baseline or program, and which is prepared using the *VCS JNR Baseline Listing Deed of Representation Template* or the *VCS JNR Program Listing Deed of Representation Template*, respectively

Litter

Non-living biomass, with a size less than a minimum threshold diameter (e.g., 10 cm) chosen by the host country for its UNFCCC national inventory accounting, lying dead, in various states of decomposition above the mineral or organic soil, including litter, fumic and humic layers. Live fine roots (of less than the threshold diameter for belowground biomass) are included in litter where they cannot be distinguished from it empirically.

Loss Event

- In an AFOLU project, any event that results in a loss of more than five percent of previously verified emission reductions and removals due to losses in carbon stocks in pools included in the project boundary that is not planned for in the project description (e.g., harvesting as set out in management plans and described in the project description is not a loss event). Examples include catastrophic events (see definition of catastrophic reversal) as well as human-induced losses such as those caused by poor management, tillage, over-harvesting or encroachment by outside actors (e.g., illegal logging or fuelwood collection); or

- In a jurisdictional program, any event that results in a loss of more than five percent of previously verified emission reductions and removals due to losses in carbon stocks in pools included in the program boundary that is not planned for in the program description (e.g., harvesting as set out in management plans and described in the program description is not a loss event). Examples include harvesting beyond levels predicted in the baseline, construction of roads or other infrastructure not included in the baseline, or significant natural disturbances .

Loss Event Report

The document that describes and records a loss event using the *Loss Event Report Template*

Loss Event Representation

- The unilateral representation issued by the project proponent, prepared using the *VCS Loss Event Deed of Representation Template* and made in respect of the carbon stock loss estimate in a loss event report; or

- The unilateral representation issued by the jurisdictional proponent, prepared using the *VCS JNR Program Loss Event Deed of Representation Template* and made in respect of the carbon stock loss estimate in a loss event report

Market Leakage Evaluation

The evaluation by the project or jurisdictional proponent of the project's or program's market leakage impacts and discount factor, documented in the project description, program description or monitoring report, as applicable

Materiality

The concept applied to determine if errors, omissions and misstatements in information could affect the GHG assertion and influence decisions resulting from it

Methodology

A specific set of criteria and procedures, which apply to specific project activities, for identifying the project boundary, determining the baseline scenario, demonstrating additionality, quantifying net GHG emission reductions and/or removals, and specifying the monitoring procedures

Methodology Approval Process

The process by which new methodology elements are approved under the VCS Program

Methodology Deviation

A deviation from the criteria and procedures for monitoring or measurement set out in a methodology applied to the project

Methodology Element

A methodology, methodology revision, module or tool (including additionality tools, performance benchmarks and technology benchmarks)

Methodology Element Developer

An entity that develops a methodology element

Methodology Revision

A revision to the criteria and procedures of an existing methodology

Model

A formula or set of formulae that uses parameters and input values to establish the value of one or more output variables

Module

A component of a methodology that can be applied to perform a specific methodological task

Monitoring Report

- The document that records data to allow the assessment of the GHG emission reductions or removals generated by the project during a given time period in accordance with the monitoring plan set out in the project description, and which is prepared using the *VCS Monitoring Report Template* or an approved combined monitoring report template available on the Verra website; *or*
- The document that records data to allow the assessment of the GHG emission reductions or removals generated by the program during a given time period in accordance with the monitoring plan set out in the jurisdictional program description, and which is prepared using the *VCS JNR Monitoring Report Template* available on the Verra website

Natural Disturbance

Non-anthropogenic events or non-anthropogenic circumstances that cause significant emissions from forests and are beyond the control of, and not materially influenced by, a project or jurisdictional proponent, such as wildfires, insect and disease infestations, extreme weather events and/or geological disturbances. Harvesting and prescribed burning are not considered natural disturbance.

Native Ecosystem

A landscape composed of indigenous vegetation not established by planting and/or seeding

Nested Project

A registered REDD+ project, that is not currently subject to a grandparenting period, and that is located within a jurisdiction covered by a registered jurisdictional REDD+ program

Nested Subnational Jurisdiction

A subnational jurisdiction that is located within a national jurisdiction covered by a jurisdictional REDD+ program that is also registered under the VCS Program

No-Objection Letter

A written letter or other written communication from the jurisdictional approval authority of the higher-level jurisdiction stating that it does not object to a specific (lower-level) jurisdictional REDD+ program element or project being submitted for registration under the VCS Program

Non-Project Areas

Forest areas (or areas converted to forest or otherwise revegetated) within a jurisdiction, but outside project boundaries or nested subnational jurisdiction boundaries, that are included in the accounting of GHG emissions and emission reductions and/or removals (e.g., areas where GHG emission reductions and/or removals are generated through the implementation of government policies and programs, rather than by projects or activities implemented within nested subnational jurisdictions)

Non-Permanence Risk Analysis

- The assessment of the risk of a potential loss in carbon stock in the project over a period of 100 years, prepared by the project proponent using the *VCS Non-Permanence Risk Report Template*; or

- The assessment of the risk of a potential loss in carbon stock in the jurisdictional program over a period of 100 years, prepared by the jurisdictional proponent using the *VCS JNR Non-Permanence Risk Report Template*

Official Translation

A translation by a member of a member body of the International Federation of Translators

Partial Release Representation

- The deed issued by the project proponents and the Verra registry, made in respect of a project proponent leaving a project, and which is prepared using the *VCS Deed of Partial Release in Respect of Registration Deed of Representation Template*; or

- The deed issued by the jurisdictional proponent and the Verra registry, made in respect of a jurisdictional proponent leaving a jurisdictional baseline or jurisdictional program, and which is prepared using the *VCS Deed of Partial Release in Respect of JNR Baseline Registration Deed of Representation Template* or the *VCS Deed of Partial Release in Respect of JNR Program Registration Deed of Representation Template*, respectively

Peatland

An area with a layer of naturally accumulated organic material (peat) that meets an internationally accepted threshold (e.g., host-country, FAO or IPCC) for the depth of the peat layer and the percentage of organic material composition. Peat originates because of water saturation. Peat soil is either saturated with water for long periods or is artificially drained. Common names for peatland include mire, bog, fen, moor, muskeg, pocosin and peat swamp (forest).

Performance Benchmark

A benchmark against which the performance of individual projects is assessed for the purpose of determining additionality and/or the crediting baseline

Performance Benchmark Metric

The indicator, specified in terms of tonnes of CO_2e per unit of output, tonnes of CO_2e per unit of input or as a sequestration metric, used to define the performance benchmark

Performance Method

A methodological approach that establishes a performance benchmark to determine additionality and/or the crediting baseline in accordance with the VCS Program rules

Program

The program established by a national or subnational jurisdictional proponent that establishes and operationalizes rules and requirements to enable accounting and crediting of REDD+ policies and measures and/or nested projects, implemented as GHG mitigation activities, and described in the jurisdictional program description. Also referred to as "Jurisdictional REDD+ Program" or "Jurisdictional Program".

Program Activity

The specific set of REDD+ policies and measures, specified by the jurisdictional REDD+ program, that alter the conditions identified in the baseline scenario and which result in GHG emission reductions or removals

Program Crediting Period

See "Crediting Period"

Program Ownership

The legal right to control and operate the program activities. Distinct from proof of right.

Program Start Date

See "Start Date"

Program Sensitive Information

See "Sensitive Information Project". The project activity or activities implemented as a GHG project and described in the project description.

Project Activity

The specific set of technologies, measures and/or outcomes, specified in a methodology applied to the project, that alter the conditions identified in the baseline scenario and which result in GHG emission reductions or removals

Project Activity Instance (Instance)

A particular set of implemented technologies and/or measures that constitute the minimum unit of activity necessary to comply with the criteria and procedures applicable to the project activity under the methodology applied to the project

Project Crediting Period

See "Crediting Period"

Project Crediting Period Start Date

The date on which the first monitoring period commences

Project Description

The document that describes the project's GHG emission reduction or removal activities and that uses either the *VCS Project Description Template*, an approved combined project description template available on the Verra website or the project description template specified by the relevant approved GHG program

Project Description Deviation

A deviation from the project design, procedures and other specifications set out in the project description

Project Documents

The documents required to register the project and/or issue VCUs, as set out in the VCS Program document *Registration and Issuance Process*

Project Method

A methodological approach that uses a project-specific approach for the determination of additionality and/or the crediting baseline in accordance with the VCS Program rules

Project Ownership

The legal right to control and operate the project activities. Distinct from proof of right.

Project Pipeline

The list of projects on the Verra registry, which are either *under development* or *under validation*

Project Proponent

The individual or organization that has overall control and responsibility for the project, or an individual or organization that together with others, each of which is also a project proponent, has overall control or responsibility for the project. The entity(s) that can demonstrate project ownership in respect of the project.

Project Proponent Representation

A unilateral deed of representation issued by the project proponent(s) and/or individuals or organizations accorded certain rights in respect of a project

Project Start Date

See "Start Date"

Proof of Right

The document(s) demonstrating the entity's right to all and any GHG emission reductions or removals generated by the project or program during the crediting period or verification period, as the case may be. Distinct from project ownership and program ownership.

Proxy

A parameter that is monitored or measured to determine the value of a strongly correlated parameter that is not monitored or measured

Reduced Emissions from Deforestation and Degradation (REDD)

Activities that reduce GHG emissions by slowing or stopping conversion of forests to non-forest land and/or reduce the degradation of forest land where forest biomass is lost

REDD+

Activities that reduce GHG emissions from deforestation and/or degradation by slowing or stopping conversion of forests to non-forest land and/or reducing the degradation of forest land where forest biomass is lost; and/or activities that enhance carbon stocks through improved forest management and/or afforestation, reforestation or revegetation

Registration Representation

- The unilateral representation issued by the project proponent at the time of the project registration request, made in respect of the project, and which is prepared using the *VCS Registration Deed of Representation Template*; or

- The unilateral representation issued by the jurisdictional proponent at the time of the program registration request, made in respect of the jurisdictional baseline or program, and which is prepared using the *VCS JNR Baseline Registration Deed of Representation Template* or the *JNR Program Registration Deed of Representation Template*, respectively

Reforestation

The direct human-induced conversion of non-forested land to forested land through planting, seeding and/or the human-induced promotion of natural seed sources on land that was once forested but has been converted to non-forested land

Remote Sensing (RS)

The use of an instrument, such as a radar device or camera, to scan the earth from a distance in order to collect data (e.g., for forest inventory or monitoring)

Retirement

The permanent removal of a VCU from circulation in the Verra registry system which represents an offset of one metric tonne of CO_2 equivalent

Revegetation

A direct human-induced activity to increase carbon stocks of woody biomass on sites through the establishment of vegetation that covers a minimum area of 0.05 hectares and does not meet the definitions of afforestation and reforestation

Reversal

A situation where the net GHG benefit, taking into account project or program emissions, removals and leakage, in any monitoring period is negative. The amount of a reversal is calculated as the difference between the current total to-date net GHG benefit of the project or program, compared to the total to-date net GHG benefit of the project or program at the previous verification event.

Rewetting

The elevation of the average annual water table in drained peatland by partially or entirely reversing the existing drained state

Sensitive Information

- Trade secrets, financial, commercial, scientific, technical or other information whose disclosure could reasonably be expected to result in a material financial loss or gain, prejudice the outcome of contractual or other negotiations or otherwise damage or enrich the person or entity to which the information relates. Also referred to as "Commercially Sensitive Information"; or
- Internal policy decisions, classified, financial, commercial, scientific, technical or other information whose public disclosure could reasonably be expected to undermine or negatively affect the development and/or implementation of a program, or damage national security. Also referred to as "Program Sensitive Information".

Shrubland

Areas dominated by shrubs, with a density of trees too low to meet an internationally accepted definition of forest, including chaparral, scrubland, heathland and thickets

Soil organic carbon

Organic carbon in mineral and organic soils (including peat) to a specified depth chosen by the host country for its UNFCCC national inventory accounting and applied consistently through the crediting period. Live fine roots (of less than the threshold diameter limit for belowground biomass) are included with soil organic matter where they cannot be distinguished from it empirically. In organic soils, soil organic carbon encompasses the entire depth of the organic layer (i.e., up to the depth of the mineral substrate). In the case of peatland, this depth can be several meters.

Standardized Method

A methodological approach that standardizes elements of additionality and/or the crediting baseline, for a given class of project activity, via a performance method or activity method

Standardized Methods Expert

A person with expertise and experience in standardized approaches to baselines and additionality, and who is approved by Verra for assessments of methodology elements that use standardized methods

Start Date

- The date on which the project began generating GHG emission reductions or removals. Also referred to as "Project Start Date"; or
- The date on which the jurisdictional REDD+ program began generating GHG emission reductions or removals. Also referred to as "Program Start Date"

Subnational Jurisdiction

An administrative- or other sub-unit within a country, such as a state, province, region, department, district, or an eco-region or other defined area, specified in the jurisdictional program description

Tool

A type of module that provides a procedure for performing a specific analysis

Uncertainty

Uncertainty is a parameter associated with the result of measurement that characterizes the dispersion of the values that could be reasonably attributed to the measured amount

Validation Report

The written report of validation prepared by the validation/verification body in accordance with the VCS Program rules

Validation Representation

- The deed issued by the validation/verification body, referencing the validation report to which it relates, containing a unilateral representation that it has validated the project's compliance with the applicable VCS Program rules, and which is prepared using the *VCS Validation Deed of Representation Template*; or
- The deed issued by the validation/verification body, referencing the validation report to which it relates, containing a unilateral representation that it has validated the jurisdictional baseline's or program's compliance with the applicable VCS Program rules, and which is prepared using the *VCS JNR Baseline Validation Deed of Representation Template* or the *VCS JNR Program Validation Deed of Representation Template*, respectively

Validation/Verification Body (VVB)

An organization approved by Verra to act as a validation/verification body in respect of providing validation and/or verification services in accordance with the VCS Program rules

VCS Program

The GHG program operated by Verra which establishes rules and requirements that operationalize the *VCS Standard* to enable the validation of GHG projects and programs, and the verification of GHG emission reductions and removals

VCS Program Rules

The rules and requirements set out in the *VCS Program Guide*, the *VCS Standard* and the other VCS Program documents; such rules and requirements may be updated from time–to-time

VCU Conversion Representation

The unilateral representation issued by the project proponent, prepared using the applicable VCS Program template and made in respect of cancellation of GHG credits under another GHG program and/or conversion of GHG credits issued under an approved GHG program into VCUs

VCU Issuance Levy

The fee charged by Verra at the time of VCU issuance to cover the administration costs of the VCS Program

Verification Period

The time period specified in a verification report during which the GHG emission reductions or removals were generated and have been verified by a validation/verification body

Verification Report

The written report of the verification prepared by the validation/verification body in accordance with the VCS Program rules

Verification Representation

- The deed issued by the validation/verification body, referencing the verification report to which it relates, containing a unilateral representation that it has verified the relevant GHG emission reductions or removals in accordance with the applicable VCS Program rules, and which is prepared using the *VCS Verification Deed of Representation Template*; or
- The deed issued by the validation/verification body, referencing the verification report to which it relates, containing a unilateral representation that it has verified the relevant GHG emission reductions or removals in accordance with the applicable VCS Program rules, and which is prepared using the *VCS JNR Program Verification Deed of Representation Template*

Verified Carbon Unit (VCU)

A unit issued by and held in the Verra registry representing the right of an accountholder in whose account the unit is recorded to claim the achievement of a GHG emission reduction or removal in an amount of one (1) metric tonne of CO_2 equivalent that has been verified by a validation/verification body in accordance with the VCS Program rules. Recordation of a VCU in the account of the holder at the Verra registry is prima facie evidence of that holder's entitlement to that VCU.

Verra Registry

The platform that records all projects and programs (listed and registered) and VCUs issued under the VCS Program. Provides public access to all project, program and VCU information, including retirement and tracking of the AFOLU and jurisdictional pooled buffer accounts, and provides project and jurisdictional proponents with the ability to list and register projects and programs, and issue, hold and retire VCUs.

Verra Website

The Verra website: www.verra.org

Vintage

The set of GHG emission reductions or removals generated by a project or program during a single vintage period

Vintage Period

The time period for which a particular set of GHG emission reductions or removals generated by the project or program are verified, which may be any subset of a verification period

Wetland

Land that is inundated or saturated by water for all or part of the year (e.g., peatland), at such frequency and duration that under natural conditions they support organisms adapted to poorly aerated and/or saturated soil. Wetlands (including peatlands) cut across the different AFOLU categories. Project activities may be specific to wetlands or may be combined with other AFOLU activities.

Wood products

Products derived from wood harvested from a forest, including fuelwood and logs and the products derived from them such as sawn timber, plywood, wood pulp and paper

VM0001

Infra-red Automatic Refrigerant Leak Detection Efficiency Project Methodology

Version 1.1

17 March 2017

Sectoral Scope 11

I. SOURCE, DEFINITIONS AND APPLICABILITY

Sources

This methodology is based on the project activity "HFC Refrigerant Carbon Credit Project", whose baseline and monitoring methodology and project design document were prepared by CN Business Network in consultation with its Environmental Advisory Board.

This methodology also draws upon the latest approved versions of the following tools:

- The CDM "tool for the demonstration and assessment of additionality"
- WRI/WBCSD's "The GHG Protocol for Project Accounting"

Both tools lay out useful guidance regarding the investment and barriers analysis referenced in this VCS methodology; the GHG Protocol is also germane to the common practice assessment. For more information regarding the CDM tools please refer to http://cdm.unfccc.int/goto/MPappmeth.
For more information on the WRI/WBCSD tool, please refer to http://www.ghgprotocol.org/files/ghg_project_protocol.pdf.

Selected approach from paragraph 48 of the CDM modalities and procedures

The project will be assessed based upon the following approach:

1. Using "Existing actual or historical emissions, as applicable"

Definitions: Please provide definitions of key terms that are used in this proposed new methodology

2. For the purpose of this methodology, the following definitions apply:

- **Infrared (IR) real time automatic leak detection system**: Refrigerant leak detection system that monitors refrigerant at regular intervals throughout the day using infrared technology and communicates readings back to a central monitoring center on a real time basis.
- **DX refrigeration equipment**: Direct Expansion (DX) refrigeration equipment that uses a two-phase fluid directly in an evaporator to absorb heat through an expansion and evaporation process.
- **HVAC system**: An air conditioning system that provides comfort heating and cooling to a room, area or entire building.
- **Seasonal top-offs and draw-downs**: The adjustment of the refrigerant charge quantity of a system to compensate for the additional refrigerant needed for condenser flooding in winter to maintain head pressure and the removal of refrigerant in the summer to prevent overfilling of the system receiver.
- **EPA GreenChill program**: An EPA program open to supermarket chains, refrigerant producers and supermarket refrigeration manufacturers whose goal is to reduce supermarket refrigeration leak rates through the collaborative effort of its members.
- **HFC**: Hydrofluorocarbon, a greenhouse gas covered under Kyoto Protocol
- **HCFC**: Hydrochlorofluorocarbon, a greenhouse gas not covered under Kyoto Protocol but under consideration by the VCS as a qualifying credit.

Applicability conditions/Eligibility Criteria

3. This methodology applies to project activities that install infra-red, real-time leak detection systems on US retail DX refrigeration equipment systems in order to reduce leaks of HFC refrigerants. A parallel methodology has been prepared which will include HCFC refrigerants pending VCS board determination regarding the parameters for their eligibility.

4. The methodology is applicable under the following conditions:

   - Applies to the installation of infra-red (IR), real-time automatic leak detection/management systems installed in commercial refrigeration systems in US supermarkets provided the IR equipment is new or has been sourced from within the project boundary as the underlying refrigeration equipment is replaced or decommissioned
   - When installed onto DX refrigeration systems, so that there is no change in underlying refrigeration system technologies
   - Including any associated HVAC systems in these same locations which are managed using the same IR systems
   - Focused exclusively upon HFC leakage rates (since these are the Kyoto gases) (with a contingency to expand to HCFC's pending any VCS policy review as outlined in the second accompanying methodology)
   - Within the United States
   - Focused, in the US, only on refrigeration systems containing less than 2000 lbs[1] refrigerant charge
   - Supported by data systems for leak reporting/management which are used for ozone depleting substance (ODS) compliance purposes

NOTE: If projects seek to qualify located outside of the US, the VCS double approval process will be required to establish whether the conservative baseline cap (in the US provided by EPA's Green Chill program leak rates) can be provided on a credible basis by appropriate entities in those locations.

NOTE: If a country's designated agency is unable to provide the conservative cap baseline cap, then the methodology will still stand without including this potential conservative cap baseline process since the additionality of a project, based upon its historical baseline, can still be adequately assessed, on a retrofit basis, using the CDM and WRI tools reference.

II. BASELINE METHODOLOGY PROCEDURE

Project boundary

5. The physical boundary is the set of retail stores in which the infra-red, real-time leak (IR) detection systems have been installed and HFC refrigerants are used. When HVAC systems in these stores are supported by these same IR detection systems, then the physical boundary includes these HVAC systems also.

6. The greenhouse gases included are HFC's, which are increasingly used as refrigerants in retail refrigeration systems. [A parallel methodology has been developed to potentially also include HCFC's pending VCS board confirmation of their status and eligibility criteria.]

7. The methodology covers following categories of HFC emissions reductions from the equipment within the project boundary:
   - HFC emissions during DX refrigeration equipment operations and/or repairs/maintenance
   - HFC emissions during seasonal "top offs" and "draw downs"

---

[1] Quantities are indicated in the imperial units (lb) since the scope of this methodology is currently the US: however, if the methodology is extended to other regions, SI-units should be used and adapted accordingly.

Table 1: Emissions sources included in or excluded from the project boundary

Source		Gas	Included?	Justification / Explanation
Baseline	Emissions from Retail Refrigeration Equipment	HFC	Yes	Project activity is prevention of HFC leaks to atmosphere
		HCFC	Pending	Separate methodology considers project activity which would include prevention of HCFC leaks to atmosphere, pending VCS board decision regarding inclusion of ODS's and relevant eligibility criteria. This methodology does not include HCFCs.
		Other: CO_2 CH_4	No	IR systems do not impact energy efficiency of underlying DX systems; rather, more timely maintenance of refrigerant levels enables refrigeration equipment to run more efficiently and thus positive CO_2 gains are conservatively set to zero.
	Upstream/ Downstream	HFC	No	Project activity produces positive gains upstream, which are conservatively set at zero. Project activity has no impact or influence on separate end of life decisions regarding refrigerant disposal as equipment is decommissioned: separate credit methodologies exist for these actions taken in this realm
		HCFC	No	Ibid
		Others	No	Ibid
Project activity	Emissions from Retail Refrigeration Equipment	HFC	Yes	Project activity is prevention of HFC leaks to atmosphere
		HCFC	Pending	Separate methodology considers project activity which would include prevention of HCFC leaks to atmosphere, pending VCS board decision regarding inclusion of ODS's and relevant eligibility criteria. This methodology does not include HCFCs.
		Other: CO_2 CH_4	No	IR systems do not impact energy efficiency of underlying systems; rather, more timely maintenance of refrigerant levels enables refrigeration equipment to run more efficiently and thus positive CO_2 gains are conservatively set to zero. Electricity required to run IR systems is de minimis (91kwh/year vs 3-4m kwh/year for each store of which 1.5-2m kwh/year for refrigerant equipment/HVAC systems: less than 0.01%)
	Upstream/ Downstream	HFC	Yes	Project activity produces positive gains upstream, which are conservatively set at zero. Project activity has no impact or influence on separate end of life decisions regarding refrigerant disposal as equipment is decommissioned: separate credit methodologies exist for these actions taken in this realm
		HCFC	Pending	Ibid
		Other: CO_2 CH_4	No	Ibid

Procedure for the Selection of the Most Plausible Baseline Scenario

8. Since IR detection systems are retrofitted on top of existing refrigeration management systems, the baseline scenario shall be determined by analyzing the following potential alternatives
   - Implementing the project activity without carbon financing; and
   - Continuation of the present practice without IR detection systems, which shall be described in the PDD.

9. Although retrofit projects do not require any further conservative measure to ensure that credits are not granted for reductions from levels considered to be unacceptably high, this methodology will ideally also include the consideration of a conservative cap baseline. Thus this further conservative cap baseline option will be founded upon the following:
   - Best practice leak rates as demonstrated by a national voluntary leak reduction program supported by a credible agency or organization whose average reported leak rates (at some agreed level of performance) and eligibility as a conservative cap baseline has been separately approved by VCS validators, through a double approval process, as reasonable
     - In the US, this alternative baseline will be provided by EPA Green Chill program's reported leak rates for their supermarket members, as estimated to represent the 50% percentile of industry performance based on their memberships' reported leak rates and share of industry stores (see 20 below)

10. Assessment of National Policy/regulations on HFCs
    - List national or regional policies/regulation to evaluate whether they a) place a fixed limit on cumulative basis for the total HFC emissions within a given year's operations; b) transfer ownership of all resulting HFC reductions to other entities to meet their separate compliance obligations (e.g. such as would arise in upstream cap/trade requirements); c) stipulate the installation of IR leak detection systems as the only option to fulfill retail operations' compliance purposes.
    - If such policies exist, assess the enforcement of the policies.
    - If above-mentioned policies/regulation exist and are enforced, then the project activity without carbon financing is the baseline scenario and thus the project does not qualify for credits.

    This regulatory assessment should be undertaken again when the project comes forward for re-validation at the end of the first and second crediting period (see article 25).

11. This methodology is applicable only if the baseline scenario includes the continuation of the present practice.

12. NOTE: Consistent with the GHG Protocol for Project Accounting, a review of the barriers faced by the two baseline alternatives – continuation of current practice and adoption of the IR project -- is undertaken in the Additionality section below. In a retrofit project, continuation of the present practice typically faces no barriers and thus constitutes the baseline. This methodology is only applicable if, in the barriers analysis below, the continuation of present practice faces no barriers and the IR project without carbon financing can demonstrate, as in the additionality section below, that it faces barriers to implementation.

13. NOTE for US: If EPA Green Chill program is unable in a given year to provide the alternative baseline cap information, then the methodology will still stand without including this potential conservative cap baseline since the additionality of the project, based upon its historical baseline, can still be adequately assessed, on a retrofit basis, using the CDM and WRI tools referenced.

Additionality: Please describe the procedure for demonstrating additionality

14. The additionality of the project activity shall be demonstrated and assessed using the latest version of "Tool for the demonstration and assessment of additionality" agreed by the CDM Executive Board, which is available on the UNFCCC CDM web site. (See Sources).

Proponents will use the required referenced CDM tool, and it is required that the investment analysis be performed: this will require applying the investment benchmark (2b Option III) analysis since this is a retrofit project (which precludes 2b Option II) and there are refrigerant cost savings which arise, alongside the carbon reductions(which precludes 2b Option I).

Using the CDM tool, if a further barriers analysis is required, the investment barriers as outlined in the CDM tool may be augmented with demonstration of other barriers from WRI/WBCSD (e.g. Table 8.1, see sources).

Baseline emissions

15. The baseline emissions will be determined using the yearly average leak rate arising from the total HFC and HCFCs emitted during the baseline period, whether emitted during operations, repair or maintenance of the equipment within the project boundary, and incurred in locations where HFCs are in use. The baseline period will be either:
    a) a period of three years prior to the installation of the IR equipment (year (x))
    b) a three year consecutive period including the IR installation year (x) which can extend at most three years subsequent to such installation if data records for emission rates are not accessible for a)

16. The historical baseline is anchored upon emissions rates for both HFC's and HCFC's since this is more conservative: while HFC's are gradually substituting for HCFC's, HCFC leak rates are lower than those for HFC's as confirmed by both EPA and leading companies. Thus, to adopt a baseline based only on HFC leak rates would potentially inflate credits. Since both refrigerants perform functionally comparable service, taking the blended leak rates for all refrigerants as the historical baseline for HFC credits reflects both historical emission rates for any given location while remaining conservative.

17. The data inputs will be based upon those which the company uses for its ODS/refrigerant compliance purposes. The baseline data shall therefore be based on such corporate records for the relevant project locations including the equipments' refrigerant charges and leaks/use data (based upon the leak records and/or purchase records for replacement refrigerant as reflected in the compliance systems) according to the steps described below.

18. Since this is a retrofit project and the installed base of stores in which IR systems are present may be increasing year on year, this historical baseline will need to be recalculated for each year (y) in which project credits are to be estimated based on the set of stores' equipment which has IR systems installed by year y, the year in which credits are currently to be calculated. This ensures that the historical baseline is taken from the same set of systems against which the new total IR systems have been retrofitted and against which the leak rates for year y will be estimated. Thus the baseline emissions will be given by a baseline leak rate tailored to year y: BLRy

19. The baseline emissions of HFC's are estimated using the following approach and equations:

For the year x, when the first IR systems are installed: the historical baseline would be calculated based on totals for <u>*all*</u> refrigerants in use (HCFC and HFCs), using totals for both leaks and charges across all the refrigeration systems in stores where IR systems have been installed and HFC's are in use by year y, the year in which the carbon credits are to be calculated, as:

$$BLRy = [Lx / Cx + Lx\text{-}1 / Cx\text{-}1 + Lx\text{-}2/ Cx\text{-}2\ ] / 3$$

Where:
BLRy = Baseline leak rate from stores which have IR systems installed by year *y* and which have HFC's in use by year y (%)
Lx = Total leaks from HFC and HCFC refrigerants in year x (lb) from equipment in stores which a) have the IR systems installed by year y and b) provided that HFC's are in use in this store by year y
Cx = Total Charge for HFC and HCFC refrigerants in year x (lb) from equipment in stores which a)

have the IR systems installed by year y and b) provided that HFC's are in use in this store by year y
Note: C_x will be measured consistent with the requirements for EPA ODS reporting.

Note: as confirmed in the data tables below (see 27), the total leaks and total charge volumes are estimated from the database systems used for ODS management purposes which measure the amounts of refrigerants used to refill the refrigeration equipment each time a leak occurs, reflecting the amount of refrigerant leaked. Each entry will describe the number of pounds of refrigerant installed into the equipment at the time of a leak – thus providing the data inputs which summarized over a year give totals for Lx. These same datasystems also document the refrigerant charges for each piece of equipment in the stores. Thus, again, adding these refrigerant charges for each piece of relevant equipment will give the totals for Cx.

Note: L_x includes adjustments for seasonal "top offs" and "draw downs" if practiced. These are seasonal increases and decreases in the refrigerant charge levels to adjust for seasonal temperature changes in the environment. "Top offs" will be considered a "leak" (thus an addition to emissions); "draw downs" will be considered the opposite and thus a credit to the leakage tally.

If historical leak rate information prior to IR installation is not available, a more conservative alternative historical baseline can be created using emission rates from the year x when IRs are first installed through the subsequent two years:
That is:
BLRy = [Lx / Cx + Lx+1 / Cx+1 + Lx+2/ Cx+2] / 3

Alternative Baseline Cap:

This alternative baseline cap is introduced only to provide a further measure of conservatism:

20. In parallel, an alternative baseline cap will be calculated using the leak rate information from the credible agency approved under "Applicable Eligibility Conditions". In the US, this will be the EPA Green Chill program leak rates, which EPA will provide annually to reflect, based on its members' annually reported leak rates, its estimate for the 50th percentile performance leak rate for the industry.

EPA will establish this EPA BLR_y leak rate by:

1. Estimating its members' share of total industry emissions, based on their Green Chill members' total number stores divided by the EPA's estimate of the industry's total number of stores
2. If Green Chill members' share of industry is less than 50%, the EPA BLR_y will be the lowest performing leak rate (that is the highest leak rate) from among their members' averages (provided this is not more than the EPA's estimate for the US industry average leak rate of 25% whereupon the EPA BLR_y will be considered EPA's estimate for the industry average, which is 25% in 2007).
3. If Green Chill members' share of industry is more than 50%, the EPA BLR_y will be the leak rate achieved by the supermarket member which, on a ranked basis from highest performing to lowest performing (that is lowest leak rate to highest leak rate) represents the 50[2] percentile of stores.
4. A supermarket's industry capacity will be calculated as its number of stores divided by the industry's total number of stores (consistent with #1 above)

Supermarket "i"	LR_i	IC_i	Sumi = 0 through i (ICi)
(anonymous)	Avg leak rate For Supermarket i	% Industry capacity	Cumulative Capacity
Supermarket A	7%	3%	3%
Supermarket B	9%	15%	18%

[2] Example: 50th Percentile Leak Rate Estimate at 17%

Supermarket C	11%	4%	22%
Supermarket D	13%	12%	34%
Supermarket E	15%	8%	42%
Supermarket F	17%	10%	52%
Supermarket G	19%	5%	57%
Supermarket H	21%	3%	60%

Thus EPA BLR_y is given by:

<u>If sum over all GC members for ICi <50%, then:</u>

If EPA Green Chill program has members whose total share of industry capacity has not yet reached 50% of the industry, then:

EPA BLR_y = minimum (LR_i=L_i/C_i, 25%)
Where supermarket i has the highest leak rate of the GC members and thus:
Sumi = 0 through i (ICi) is the highest for the group; and
sumi = 0 through i (ICi) < 50%
And
ICi = Si / EPA ST
And 25% is the EPA stated average for leak rates in the supermarket sector

<u>If sum over all GC members for ICi >50%, then:</u>

If EPA Green Chill program has members whose total share of industry capacity has now reached more than 50% of the industry, then:

EPA BLR_y = minimum (LR_i=L_i/C_i, 25%)
Where, for supermarket i, the sumi = 0 through i (ICi-1) <50% and sumi = 0 through i (ICi) > 50% And
ICi = Si / EPA ST
And 25% is the EPA stated average leak rate for the supermarket sector.

Where:
EPA BLRy = Baseline leak rate for HFC's and HCFC's for the Green Chill member company estimated to represent the 50th percentile performance leak rate for the industry in year x (%)
LRi = Average leak rate reported to EPA Green Chill by the supermarket "i" (across its HFC and HCFC refrigerants) in year x (%) whose performance sits at this 50th percentile
Li = Total leaks from HFC and HCFC refrigerants in year x (lb) from supermarket "i" as reported to EPA Green Chill
Ci = Total Charge for HFC and HCFC refrigerants in year x (lb) reported by supermarket "i" to EPA Green Chill
ICi = Share of industry capacity represented by supermarket i in year x Si = Number of stores operated by supermarket i
EPA ST = Total number US supermarket stores as determined by EPA Green Chill Program

NOTE: If the EPA BLR_y data does not exist for year x for a project seeking validation, because year x precedes 2007, then the first year of EPA Green Chill program available data shall be used as the conservative cap baseline. The EPA 50th percentile leak rate is determined to be 25% for 2007. This approach is conservative, given the gradual improvements which will take place over time in the conservative cap baseline at the 50th percentile leak rate level.

NOTE: If EPA's BLR_y data is not available in a given year, then the prior year's estimates will be used. If the EPA Green Chill program ceases to exist or cannot provide further data, then the alternative baseline will not be considered as part of this methodology.

Final Baseline Selection:

21. If the historical project baseline (BLRy) is greater than the alternative baseline cap, (EPA BLRy,) then the alternative baseline cap shall be the baseline. This approach is included in order to ensure that a supermarket chain who's historical emissions rate was particularly large would not be awarded credits for reductions from a baseline that, although historically accurate, could arguably be considered inflated. Using the EPA BLRy also ensures that, unless the historical baselines are already more conservative, a baseline is selected that will reflect any gradual improvements in the leak rate efficiencies for the Green Chill member companies and thus the industry.

Thus, if BLRy > EPA alternative baseline selected (EPA BLRy), then the Final BLRy would the lower of these options

This is given by:
Final BLRy = @ min (BLRy, EPA BLRy)

Where:
Final BLRy = Baseline leak rate to be adopted for the project for use by year y (%)
BLRy = Baseline leak rate for the supermarket submitting the project, arising from stores which have IR systems installed by year *y* and which have HFC's in use by year y (%)
EPA BLRy = Baseline leak rate for HFC's and HCFC's for the Green Chill member company estimated to represent the 50^{th} percentile performance leak rate for the industry in year x (%)

Note: the project's emission reductions will then be calculated by comparing the final baseline leak rate to the later year's leak rate to derive the total pounds of refrigerant avoided in year y (by applying the difference in leak rates to the refrigerant change in situ in year y). The composition of refrigerants used by year y may have changed from year x. So the average global warming potential of the released gases in year y will then be applied to these pounds reduced in year y since the global warming reduction reflects the reduced usage of the gas combinations used during that particular year y This thus ensures that the credits granted in year y reflects the reduction efficiencies in pounds of refrigerant emitted in year y compared to year x (since the refrigerant types are interchangeable) but using GWP intensities that reflect the refrigerant usage from the particular crediting year y.

Project emissions

22. Project emissions will be determined using the average leak rate arising from the total HFC emitted during year y, the year in which credits are sought, whether emitted during operations, repair or maintenance of the equipment within the project boundary.

The project emissions from HFC's are estimated using the following approach and equations:

PLRy = [Ly / Cy]

Where:
PLRy = Project leak rate from equipment which has both HFC's and IR systems installed by year *y* (%) Ly = Total leaks from HFC refrigerants in year y (lb) from this same set of equipment
Cy = Total Charge in year y for HFC refrigerants (lb) within this same set of equipment
Note: Ly includes adjustments for HFC top offs and draw downs if practiced

Again, the project's emission reductions will be calculated by comparing the final baseline leak rate to the project year y's leak rate to derive the total pounds of refrigerant avoided in year y (by applying the difference in leak rates to the refrigerant change in situ in year y). The weighted average global warming potential of the released gases in year y will then be applied to these pounds reduced in year y since the global warming benefits reflects the reduced usage of the gases used during that particular year.

Leakage

23. There is no requirement for the project to consider leakage as it is not likely to occur for the following reasons:

a. Any refrigerant savings achieved in the supermarket location due to lower leak rates will result in smaller refrigerant purchases. Thus any upstream leaks during manufacture or transportation of the refrigerant (which are estimated to be a relatively low percentage of the total supply chain leaks from refrigerant use) will also be saved. This constitutes "positive leakage": efficiencies during supermarket use will achieve further leak reductions upstream. These are conservatively set at zero in this methodology and thus there is no further project requirement to consider leakage.

b. Any "top up" or "draw down" changes in refrigerant use for the relevant periods is already captured under L_y and L_x

c. The IR systems do not control, influence or impact the release of refrigerants as equipment is decommissioned. Separate credit methodologies already exist to address whether beyond business as usual GHG reductions are gained through completely separate and distinct actions which are not related to IR system installations. Without any influence, this methodology must assume that the refrigeration equipment's original charges are handled on a business as usual basis during decommissioning. Incorporating their future decommissioning choices also risks double counting reductions with other project methodologies which VCS is developing and already exist under CCX and CDM.

d. The methodology does not apply to used IR equipment sourced from outside the project boundary (since in this case emissions could rise in the external location while credits were counted within the project). Note: IR equipment already installed within the project boundary DX equipment can be removed (e.g. if DX equipment is being decommissions) and the IR equipment used again (e.g. if new DX equipment is purchased) since these changes all take place within the project boundary.

Emission reductions

24. Emission reductions are calculated as

follows: LRRy =Final BLRy - PLRy

Where:
LRRy = Leak rate reduction for project in year *y* (%)
PLRy = Project leak rate from equipment which has both HFC's and IR systems installed by year *y*
(%) Final BLRy = Final baseline leak rate (as defined above as the lower of the historical leak rate
BLR_y (from equipment which has IR systems installed by year *y* (%)) and the EPA Baseline Cap (%))

ERy = LLRy * Cy * GWPHFC-y

Where:
ERy = Emissions reduction in year y (tCO2e/yr)
LRRy = Leak rate reduction for project in year
y (%)
Cy = Total Charge for HFC refrigerants in year y (lb) within this same set of equipment
GWPHFC-y = Weighted average global warming potential of HFC's installed/used in year y (tCO2e/lbHFC)

And, to be clear, GWPHFC-y is calculated by:

GWPHFC-y = sum over all HFC types T [LHFC-T-y * GWPHFC-T-y] / sum (over T) LHFC-

T-y Where:
LHFC-T-y = Total leaks from HFC refrigerant Type T in year y (lb) from this same set of equipment
GWPHFC-T-y = Weighted average global warming potential of HFC's Type T installed/used in year y (tCO2e/lbHFC)

Elaborating on this calculation, again for clarity, this is estimated as:
GWPHFC-y =
[sum HFC leaks (lbs) from HFC #1 * GWP #1 + sum HFC leaks from HFC #2 * GWP #2 + etc + sum HFC leaks (lbs) from HFC#m * GWP#m]
Divided by:
[Total HFC leaks (lbs) (across # 1 through m) from systems with IR installed by year y]

Changes required for methodology implementation in 2nd and 3rd crediting periods

25. No changes are required for consideration of the methodology in future crediting periods. It should be noted that the project developer will need to check on national and regional policies at the renewal of each crediting period, in case these have changed paying particular attention to those already outlined above. In case the project, or part of the project activity, has become part of the baseline due to changes in policies, the project developer will have to redefine the baseline as appropriate or potentially withdraw the project from consideration for a new VCS project period.

Data and parameters not monitored

26. In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

Data / parameter:	1 GWPHFC-T-y / GWP of HFC type T
Data unit:	t CO2e/lb HFC
Description:	Global warming potential of HFC used in year y
Source of data:	GWP values must be derived from sources specified by the VCS rules
Measurement procedures (if any):	
Any comment:	

Data / parameter:	2 GWPHCFC-T-y / GWP of HCFC type T
Data unit:	t CO2e/lb HCFC
Description:	Global warming potential of HCFC Type T used in year y
Source of data:	GWP values must be derived from sources specified by the VCS rules
Measurement procedures (if any):	
Any comment:	y

Data / parameter:	3 EPA Alternative Baseline Leak Rate EPA BLRy
Data unit:	%
Description:	Baseline leak rate coverage HFC's and HCFC's for the Green Chill member company estimated to represent the 50th percentile performance leak rate for the industry in year x (%)
Source of data:	EPA Green Chill Program Director
Measurement procedures (if any):	For the US: EPA will report these results to the VCS or other designated agency on a yearly basis
Any comment:	Use EPA BLRy cited for year x unless project initiated prior to 2007 whereupon EPA BLR2007 will be used If the EPA Green Chill program ceases to exist or cannot provide further data, then the alternative baseline will not be considered as part of this methodology.

III. MONITORING METHODOLOGY

27. All data collected as part of monitoring should be archived electronically and be kept at least for 2 years after the end of the last crediting period. 100% of the data should be monitored if not indicated otherwise in the tables below. All measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

28. As an overview, the monitoring and verification/validation (M&V) system will require:

- Leak management data to be drawn from companies' compliance records for ODS refrigerants under Montreal Protocol
    - Thus the data management systems upon which a project's core leak/charge data draws will already be in place and used for complementary regulatory purposes.
    - If the project draws upon HFC reductions, (when the refrigerant is not an ODS), the HFC leaks must be using the same process and compliance systems that apply to ODS refrigerants in order for this data to have the integrity needed.
- Review of the further calculations performed in order to establish cumulative annual leak rates for systems and relevant averages (historical leak rates and current year leak rates) which will typically be conducted separately from compliance records
    - Including the review of seasonal invoices or data logs for "top up" "draw down" changes in refrigerants if these are not automatically included in the compliance real time data systems.
- Comparison of a companies' historical baseline leak rates (BLRy) to the EPA Green Chill conservative cap baseline (EPA BLRy) in order to pick the more conservative baseline and not award credits to those whose historical performance would be outside sensible industry average or better practice norms.
- Review of calculations of the average weighted GWP based on the volume of refrigerants used by the supermarket in the crediting year, allocating GWP savings across HFC404A, HFC507 and other HFC's on an accurate pro-rata annual basis as established by the methodology

NOTE: While the IR systems has a real time, electronic LDMS system in order to provide timely alerts and communications, this methodology does not assume that the monitoring and verification systems are necessarily electronically based. Similarly, although some companies have chosen to use third party agencies (e.g. contractors such as Verisae, Parasense), there is not requirement in this methodology that the data management be performed by such entities. The project's third party

VCS verifier is sufficient to establish the integrity of the data systems applied to the project crediting purposes. However, consistent with conflict of interest concerns, the company's third party service agency which provides real time leak rate monitoring services cannot simultaneously serve as the third party carbon credit verifier for VCS carbon crediting purposes.

29. Thus, for clarity's sake only, the verification actions would focus upon:

1. Ensuring that the charge and leak data are consistent with the logs in the companies' compliance record
    a. Measurement units: weight
2. Assessing whether top up/draw down procedures are used for seasonal variations and, if so, ensuring that these refrigerant changes are part of the cumulative leak rate data base (even if they are not part of the compliance records)
3. Reviewing the calculations for the cumulative annual leak rates for the relevant systems to ensure these are accurately assessed
4. Reviewing the calculations for the historical leak rate baseline and current year leak rates across the relevant systems to ensure they meet the Methodology specifications
5. Comparing the historical leak rate to the EPA alternative baseline cap in order to ensure that the more conservative one is selected
6. Accurate estimates of the average GWP for the refrigerants used in each year (since this is updated annually to reflect any changes in the composition of refrigerants used) consistent with the methodology. The lbs of refrigerants used is again taken from the same data log in #1 and 3

30. All the calculations are outlined in the Methodology. The monitoring frequencies and measurement procedures from which the refrigerant leaks are tracked will have been established by the underlying compliance requirements for ODS and will be considered sufficient. In the US, this will typically mean that refrigerant leaks will be aggregated on a monthly basis while refrigerant charges will be updated annually, drawing again on the underlying ODS compliance databases. Similarly, the measurement and monitoring equipment in the IR systems will be calibrated according to current good practice consistent with such compliance requirements.

Data and parameters monitored

Data / parameter:	Lx
Data unit:	Lbs
Description:	Total leaks from HFC and HCFC refrigerants in year x (lb) from all DX equipment in stores which a) have the IR systems installed by year y and b) in which HFC's are in use by year y
Source of data:	Refrigerant compliance logs for relevant stores/equipment
Measurement procedures (if any):	The total leaks volumes are derived from the database systems used for ODS management purposes. These measure the amounts of refrigerants used to refill the refrigeration equipment each time a leak occurs during year x, reflecting the amount of refrigerant leaked. Thus each entry will describe the number of pounds of refrigerant installed into the equipment at the time of a leak during year x – thus providing the data inputs which summarized over year x give the total leak volumes for Lx.
Monitoring frequency:	Lx is annually updated if the IR systems are installed in new stores each year. Leaks are typically reported in compliance logs as new refrigerant is installed in the equipment. Compliance logs report these as monthly totals from which annual totals can be calculated.

QA/QC procedures:	Check for consistency between project data logs and compliance logs
Any comment:	Ensure that any seasonal "top up" or "draw down" additions/removals are included/netted out in Lx even if these are not incorporated into compliance logs

Data / parameter:	Cx
Data unit:	Lbs
Description:	Total Charge for HFC and HCFC refrigerants in year x (lb) from all DX equipment in stores which a) have the IR systems installed by year y and b) in which HFC's are in use by year y
Source of data:	Refrigerant compliance logs for relevant stores/equipment
Measurement procedures (if any):	These same ODS management datasystems also document the refrigerant charges for each piece of equipment in the stores. Thus, again, adding these refrigerant charges for each piece of relevant equipment as itemized for year x will give the totals for Cx.
Monitoring frequency:	Cx is annually updated if the IR systems are installed in new stores each year to include the total HFC + HCFC capacity charges for the new stores
QA/QC procedures:	Check for consistency between project data logs and compliance logs
Any comment:	Note that charge capacities for HFCs may have changed over baseline period because these refrigerants are gradually replacing HCFC's, whose charge levels could be declining. Since Cx can fractionally change if IR systems are installed in new stores, annual monitoring of data/compliance logs in year y for total HFC and HFCF charge amounts in baseline years is required to take into accounts stores where new IR systems have been installed by year y. Note: Cx will be measured consistent with the requirements for EPA ODS reporting.

Data / parameter:	Ly
Data unit:	Lbs
Description:	Total leaks from HFC refrigerants in year y from equipment which has HFC's installed by year y and which also has IR systems installed by year y
Source of data:	Refrigerant compliance logs for relevant stores/equipment
Measurement procedures (if any):	The total leaks volumes are derived from the database systems used for ODS management purposes. These measure the amounts of refrigerants used to refill the refrigeration equipment each time a leak occurs during year y, reflecting the amounts leaked. Thus each entry will describe the number of pounds of refrigerant installed into the equipment at the time of a leak during year y – thus providing the data inputs which summarized over year y give the total leak volumes for Ly.
Monitoring frequency:	Assessed once for year y. Leaks typically totalled on a monthly basis in compliance logs.
QA/QC procedures:	Check for consistency between project data logs and compliance logs

Any comment:	Ensure that any seasonal "top up" or "draw down" additions/removals are included/netted out in Ly even if these are not incorporated into compliance logs

Data / parameter:	Cy
Data unit:	Lbs
Description:	Total charge in year y for equipment which has HFC installed as refrigerant by year y and which also has IR systems installed by year y
Source of data:	Refrigerant compliance logs for relevant stores/equipment
Measurement procedures (if any):	These same ODS management datasystems also document the refrigerant charges for each piece of equipment in the stores. Thus, again, adding these refrigerant charges for each piece of relevant equipment as itemized for year y will give the totals for Cy.
Monitoring frequency:	Assessed once for year y.
QA/QC procedures:	Check for consistency between project data logs and compliance logs
Any comment:	Note that charge capacities for HFCs will likely be rising over time as these refrigerants are installed across more equipment in a given store, replacing HCFC's. Thus annual monitoring of data/compliance logs in year y for total HFC charge amounts is required since they will likely not equal C_X.

Data / parameter:	LHFC-T-y
Data unit:	Lbs
Description:	Total leaks from HFC refrigerant Type T (only) in year y (lb) from equipment which has HFC's installed by year y and which also has IR systems installed by year y
Source of data:	Refrigerant compliance logs for relevant stores/equipment
Measurement procedures (if any):	As above for Lx and Ly for relevant HFC leaks by individual type.
Monitoring frequency:	Assessed once for year y. Leaks typically totalled on a monthly basis in compliance logs.
QA/QC procedures:	Check for consistency between project data logs and compliance logs
Any comment:	Ensure that any seasonal "top up" or "draw down" additions/removals are included/netted out in LHFC-T-y even if these are not incorporated into compliance logs

Version	Date of Issue	Comment
1.0	16 Feb 2010	Initial version, developed by CN Business Network
1.1	17 Mar 2017	Clarified that GWP values must be derived from sources specified by the VCS rules (GWP parameter tables listed below paragraph 26)

NEW COGENERATION FACITILITES SUPPLYING LESS CARBON INTENSIVE ELECTRICITY TO GRID AND STEAM AND/OR HOT WATER TO ONE OR MORE GRID CUSTOMERS

SOURCE

This Methodology is based on elements of the following CDM methodologies:

- AM0029 V 02 " Baseline Methodology for Grid Connected Electricity Generation Plants Using Natural Gas";
- AM0048 "New Cogeneration facilities supplying electricity and/or steam to multiple customers and displacing grid/off grid electricity generation with more carbon intensive fuels".

This methodology also refers to the latest approved version of the following tools:

- Methodological "Tool for the demonstration and assessment of additionality";
- Methodological "Tool to calculate the emissions factor of an electricity system";
- Methodological "Combined tool to identify the baseline scenario and demonstrate additionality";
- Methodological "Tool to calculate baseline, project and/or leakage emissions from electricity consumption".

DEFINITIONS

Waste Heat A by-product thermal energy from machines or process equipment for which no useful application is found in the absence of project activity and which is demonstrated to be unused in other activities

Project Customer An industrial and/or commercial and/or residential entity receiving electricity, steam and/or hot water from the project facility. This may include the power grid, in the case of electricity and the steam and/or hot water generating facility or the entity that draws steam and/or hot water off a steam and/or hot water grid. Clusters of smaller residential or commercial customers can be considered as a single project customer.

Project Facility Combined heat and power generation facility developed as a project activity to supply electricity to the power grid and steam and/or hot water to grid/off-grid to any industrial, commercial and/or residential entities.

APPLICABILITY

- The project activity is the construction and operation of a new gas fired cogeneration plant which is connected to the electrical grid and where all the electricity produced other than that required to operate the cogeneration facility is exported to the grid;

- The geographical/physical boundaries of the baseline power grid can be clearly identified and information is publicly available to establish the grid emissions factor;

- Natural gas is sufficiently available in the region or country, for example future natural gas power capacity additions of similar size to that of the project activity are not constrained by the use of natural gas in the project activity;

- This methodology is only applicable to cases in which the steam and/or hot water that is to be displaced by the project activity is either produced for export to a steam/hot water grid or is drawn from a steam/hot water grid. It shall not be applied to situations in which it would lead to the displacement of steam and/or hot water that is generated at a project customer's installations to meet its heating/process requirements;

- Where the project activity results in the substitution of imported steam and/or hot water, the project proponent shall provide evidence to prove that the thermal energy which is displaced is that which the project customer(s) would have otherwise imported from the grid and not that which is self-generated, assuming that such option exists for the project customer(s);

- The methodology is applicable only to project customers that do not cogenerate electricity, steam and/or hot water in the baseline scenario;

- Only applicable to project customers that ensure that the equipment displaced by the project activity will not be sold for other purposes;

IDENTIFICATION OF THE BASELINE SCENARIO AND DEMONSTRATION OF ADDITIONALITY

STEP 1. Identification of realistic and credible alternative baseline scenarios that are consistent with current laws and regulations

Substep 1a. Define realistic and credible alternatives to the project activity.

Project proponents shall identify realistic and credible alternative(s) available to both the project developer and project customer(s) that enable electricity, steam and/or hot water:

- to be produced in similar quantities as by the project activity;
- to deliver similar services;
- to be provided at the same grade, quality or properties as those provided by the proposed VCS project activity .

In other words, they shall identify possible baseline scenario alternatives that enable:

- electricity to be generated and sold to the grid, for base or peak load service;
- steam at a required pressure and temperature to be generated, delivered and sold to one or more project customers;
- hot water to be generated at the required temperature and sold to one or more project customers.

The proposed VCS project activity constitutes an alternative means for both the project developer and the project customers to produce electricity and thermal energy (when the project customer is a District Heating Plant that produces steam and/or hot water) or to source or buy it from (when the project customer is a thermal energy end user connected to a District heating steam/hot water grid). Hence, project developer and project customers, be it through the actions they take or do not take, define what the most plausible baseline scenario would most likely be in the absence of the project activity. In the case of power generation, the baseline scenario is shaped by the actions taken or not by the project developer and other market players that sell power to the grid.

Hence, in establishing what the most likely baseline scenario is, baseline alternative scenarios shall be identified for both the project developer and the project customer(s). Technologies or practices that have been implemented previously or are currently being introduced in the relevant country and that constitute alternatives for an independent utility producer shall be considered as part of this exercise. Those technologies or practices that do not meet this condition, shall not be considered a baseline scenario alternative, because they would be a “first of their kind”.

Baseline alternative scenarios for the project participants are therefore related to the technology and circumstances but also to the investor’s line of business or activity.

It shall be noted that for the purpose of this methodology, actions taken by project customers which are energy end users (i.e. purchase thermal energy to use it for heating/ process needs as opposed to selling it on to project customers who in turn resell it to their own customers) and result in a reduction in the end user demand of energy in the form of steam and/or hot water are not considered to be alternatives to the project activity. This is because such actions do not constitute a similar product/service: the provision of electricity, steam and hot water, which in the case of the project activity is carried out in a less carbon intensive manner than that which would have otherwise occurred. i.e. from the utilization of waste heat to generate steam and/or hot water.

Energy efficiency measures that enable the production, transmission and distribution of thermal energy to the end users with a lesser amount of GHG generation which may be implemented in the future, during the crediting period however are considered for the purpose of calculating the baseline emissions, but not as part of the process for the selection of the most plausible baseline scenario, because they do not constitute alternative means to providing the same services as those provided by the project activity. Similarly, improvements in energy efficiency undertaken by the project customer(s) may lead to an increase or decrease in the efficiency with which each unit of thermal energy is produced, depending on the operating point on the boiler's efficiency – load curve. The baseline emissions calculations given in section (5) of this methodology take this into consideration.

Procedure for the identification of Baseline Scenario Alternatives to the project activity

The project proponent shall clearly indicate the amount of electricity, steam and/or hot water which the proposed project activity would generate, indicating whether the electricity which is planned to be generated is peak/base load power, as well as the conditions of the steam and hot water to be produced.

This establishes a common technical basis upon which to identify the baseline scenario alternatives.

Electricity, steam and or hot water in similar amounts, service type and quality may be delivered in a separate manner (e.g. a gas turbine generator set and steam and hot water boilers) or in an integrated manner (e.g. a Combined Heat and Power Plant).

Therefore, possible baseline scenario alternatives for the project participants (project developer and project customer(s) with regards to the production/provision of electricity, steam and hot water, may include, either a combination of different options to generate each of the utilities independently from one another (non-integrated options) or through combined heat and power systems, which provide all three of such utilities (integrated options):

Step A. Non integrated baseline scenario alternatives for the production of electricity, steam and hot water

A.1 Electricity production

The project activity involves the construction and operation of an energy plant that produces several utilities, one of which is electricity which is exported to the grid.

In assessing what baseline scenario alternatives exist for electricity generation it shall be noted that these need not consist solely of power plants of the same capacity, load factor and operational characteristics (i.e. several smaller plants or the share of a larger plant may be a reasonable alternative to this portion of the project activity). However all the options considered must be capable of delivering a similar service (e.g. peak vs. base load power).

The proponents shall include those power generation options that are available to them. In this sense, project proponents shall ensure that all relevant power plant technologies that have been recently constructed or are under construction or are being planned are considered when building the list of baseline scenario alternatives.

Alternatives for electricity generation include, amongst others, but are not limited to the following:

- grid connect power plants;
- new steam turbine power plants;
- new gas turbines power plants;
- new IC engine power plants.

The project proponents shall establish which of the identified baseline scenario alternatives can be considered credible and realistic alternatives

A.2 Thermal energy (Steam and/or hot water):

Baseline scenario alternatives that enable the production of the same quantity and grade of steam and/or hot water as the proposed project activity for export (if the project customer is a centralized district heating plant) or importing (where a project customer draws steam and/or hot water from a district heating grid) may include but are not limited to the following:

- continued generation of steam and/or hot water for export purposes to a district steam and or hot water grid, by a district heating plant;

- continued use of the existing sources of imported steam and or imported hot water by a project customer connected to the steam and/or hot water grid;

- waste heat derived steam and or hot water from waste heat sources available at the project customer's facility;

- the installation of standalone steam and or hot water generation equipment;

- the installation of steam and or hot water generation equipment for export into a district heating grid or supplying to a specific customer.

The outcome of step A will be the realistic baseline scenario alternatives for the combined production of electricity, steam and/or hot water from separate sources subject to the conditions given in Substep 1(a).

Step B. Integrated generation baseline scenario alternatives for the production electricity, steam and/or hot water (cogeneration of electricity, steam and/or hot water)

Integrated forms of generating the above mentioned utilities shall be considered, as they constitute alternatives to the production of electricity, steam and/or hot water. As indicated above, only those options that meet technical requirements and are available to the project participants established in Substep 1a shall be considered as possible baselines alternatives.

Combined heat and power baseline scenario alternatives may include:

1. Steam turbine CHP plant
    - CHP with back-pressure turbine
    - CHP with extraction / condensing turbine

2. CHP with gas turbine

3. Internal combustion (IC) reciprocating engine generator with waste heat recovery

4. Combined-cycle HP plant

The outcome of Step B will be realistic baseline alternatives for the co production of electricity, steam and/or hot water from an integrated energy facility subject to the conditions indicated in Substep 1 (a)

Outcome of Sub Step 1a: After having applied the above procedure realistic and credible alternatives baseline scenario that remain may include:

From Step A:

- One or more combinations of forms of generating electricity and thermal energy using independent technologies, and/or;

- Electricity from the grid and thermal energy from a district heating plant (continuation of existing practice).

From Step B

- One or more options of combined heat and power generation, including the VCS project activity without VER's.

Substep 1.b: Consistency with mandatory laws and regulations:

Ensure that the baseline scenario alternatives identified above comply with mandatory laws and regulations. This assessment shall be carried as described in the "Tool for Demonstration and Assessment of Additionality"

Outcome of Step 1b: Identified realistic and credible alternative scenario(s) to the project activity that are in compliance with mandatory legislation and regulations taking into account the enforcement in the region or country and VCS decisions on national and/or sectoral policies and regulations.

STEP 2. Determination of additionality and the most plausible baseline scenario

The most plausible baseline scenario shall be the one that includes the most likely means of producing electricity, steam and hot water in the absence of the proposed VCS project activity. It is the result of the combination of the most likely baseline scenarios for both the project developer and the project customer(s).

After having applied the procedure given in Step 1, three (3) realistic baseline scenario alternative categories will have been identified. The definition of the most plausible baseline scenario shall be assessed from both the project developer and project customer(s) perspectives. The project proponent may demonstrate this by applying investment or barrier analysis as deemed appropriate.

Step 2.1: Assessment and demonstration of additionality

The project proponent shall demonstrate that the proposed project activity is not an attractive option for the project developer to undertake unless the project activity can be registered under the VCS.

Project proponent shall demonstrate additionality by applying either one or two of the following options:

Option 1: Investment analysis

Option 2: Barrier analysis

Project proponents may also elect to complete both options. The above options refer to Steps 2 and 3 of the "Tool for demonstration and assessment of additionality".

Additionality shall be demonstrated using the latest version of the "Tool for demonstration and assessment of additionality". Project participants can use either investment analysis or barrier analysis step. They may, if they wish so, use both the investment and barrier analysis steps.

OPTION 1. INVESTMENT ANALYSIS

Project proponents shall apply the latest version of the "Tool for demonstration and assessment of additionality" i.e., shall determine whether the proposed project activity is not:

(a) The most economical or financially attractive, or;

(b) Not economically attractive.

The indicator to be applied shall be either IRR, or the unit cost of producing electricity, thermal energy for steam and hot water.

The selection of the benchmark IRR shall be carried out according to the latest version of the "Tool for demonstration and assessment of additionality".

Where the unit cost of energy is the chosen indicator, the benchmark to be applied to the steam and/or hot water will depend on whether the project customer is:

a) A centralized steam and/or hot water generating facility purchasing steam and/or hot water from the project facility, in which case the benchmark is the unit purchase price or tariff of the thermal energy offered by the district heating plant to the project developer;

b) An importer of steam and or hot water from the grid, in which case the benchmark shall be the unit cost of thermal energy paid by the project customer which imports steam and or hot water from the grid.

In providing any benchmarks, the DOE shall be presented with supporting evidence, such as energy purchase agreements (in cases where the project customer is the central steam and or hot water generating facility), actual energy invoices or contracts (in the case of a project customer that imports thermal energy from the grid) where it is indicated in a transparent manner what the benchmark value is.

Calculation of the indicator

IRR

If IRR is chosen as the indicator then, the IRR calculation shall be applied to assess the additionality of the project activity following the guidance given in the latest version of the “Tool for demonstration and assessment of additionality”.

Unit cost of energy

Where unit cost of energy us the chosen indicator, the unit cost of electricity, steam and or heat to be provided by the project activity shall be calculated taking into account the investment, operation and maintenance costs, and the revenues excluding carbon but possibly including other sources of revenue as mentioned in the “Tool for Demonstration and Assessment of Additionality” and compared with that of the baseline scenario alternatives which provide those utilities. The approach used in such calculations shall be presented in a transparent manner in accordance with the “Tool for Demonstration and Assessment of Additionality”, in a way that shall enable the DOE to assess their appropriateness and reproduce the results presented by the project proponents. The calculations used to determine such indicators shall be presented to the DOE.

Present a clear comparison between the indicator values obtained for the various baseline scenario alternatives and the benchmark.

a) If the value of indicator for the project activity is such that it is not the most attractive amongst various baseline scenario options to produce the similar services and outputs, then the project activity shall be deemed additional.

b) If the indicator for the project activity is less favorable than the benchmark then the project activity cannot be considered the financially attractive or the most financially attractive and can be thus regarded as additional.

Sensitivity analysis

A sensitivity analysis shall be included to show whether the conclusion regarding the financial/economic attractiveness of the project activity without VCS is robust to reasonable variations in the critical assumptions. The investment analysis provides a valid argument in favor of additionality only if it consistently supports (for a realistic range of assumptions) that the project activity without VCS credits is unlikely to be the most financially/economically attractive option to the project developer.

The project proponent, who applies the new VCS methodology, shall provide evidences for the figures applied and used in the excel work sheets in order to be able to fully retrace the assumptions and calculations made under the investment analysis.

Determination of the most plausible baseline scenario

The most plausible baseline scenario shall be considered to be either of the following:

- the most economically attractive of the realistic and credible baseline scenario alternatives identified in Substep 1 b above that is in compliance with existing regulations, provided the emissions that would result from its implementation would be less than those resulting from the "continuation of existing practice" or "business-as-usual" baseline scenario alternative. If this is not the case, the baseline scenario shall be considered to be the continuation of the existing practice;

- the continuation of existing practice, in cases in which the only other possible baseline scenario alternative is for a project developer to invest in the project activity, but which has been determined not to be the most likely baseline scenario given the outcome of the investment analysis described above.

OPTION 2. BARRIER ANALYSIS

Determine whether the proposed project activity faces barriers that:

a) prevent the implementation of this type of project activity; and

b) do not prevent the implementation of at least one of the alternatives

The identified barriers are only sufficient grounds for demonstration of additionality if they would prevent the project developer from carrying out the proposed project activity undertaken without being registered as a VCS project activity. Barriers that prevent customers from purchasing the Electricity and thermal energy which the project activity produces are taken as barriers which the developer must also overcome.

The following sub-steps shall be used

Substep 2a: Identify the barriers that would prevent the implementation of the proposed VCS project activity

(1) Identify realistic and credible barriers that would prevent the implementation of the proposed project activity from being carried if the project activity was not

registered as a VCS project. Barriers must be addressed for both the project developer and the project customer (s).

(a) Investment barriers, other than economic/financial barriers in Step 2 above, inter alia:

   i. similar cogeneration activities have been implemented, but only through grants or other non commercial terms. Similar activities being those that rely on a broadly similar technology or practices, are of a similar scale, take place in a comparable energy sector environment with respect to the regulatory framework and are undertaken in the relevant country/region

   ii. no private capital is available from domestic or international capital markets due to real or perceived risks, as demonstrated by the country credit ratings or other country investment reports of a reputed origin

   iii. the investment required to deliver the energy produced by the project facility to the project customer (e.g. power lines, steam and hot water piping) is significant and the project developer is unable or unwilling to undertake it

(b) Technological barriers, inter alia:

   i. Skilled and/or properly trained labor to operate and maintain the technology are not available in the relevant country/region, which leads to an unacceptably high risk of equipment disrepair and malfunctioning or other underperformance.

   ii. Lack of infrastructure for implementation and logistics for maintenance of the technology.

   iii. Risk of technological failure: the technology failure risk in the local circumstances is significantly greater than for other technologies that provide the electricity, steam and/or hot water in quantities, grades and quality as those of the proposed project activity, as demonstrated by relevant scientific literature or technology manufacturer information. This is risk being a concern to both the project developer and the project customer.

(c) Barriers due to prevailing practice

   i. the project is the “first of its kind” either from a technological or business standpoint

(d) Barriers that prevent project customers from purchasing electricity, steam and/or hot water from the project facility

(e) Other barriers that the project developer or the project customer may face

Substep 2b. Show that the identified barriers would not prevent the implementation of at least one of the baseline scenario alternatives besides the propose project activity

(2) if the identified barriers also affect other baseline scenario alternatives identified as part of step 1, explain in what way those baseline scenario alternatives are less strongly affected by them than the proposed VCS project activity is. In other words, demonstrate that the identified barriers do not prevent the implementation of at least one of the baseline scenario alternatives. Any baseline scenario alternative that would be prevented by any barriers indicated above cannot be considered a "viable" alternative to the proposed project activity and shall thus be eliminated from further consideration.

Determination of additionality and the most plausible baseline scenario

- if there is only one baseline scenario alternative that is not prevented by any of the identified barriers and this scenario is not the project activity without being registered under the VCS, then this baseline scenario alternative shall be taken as the most plausible baseline scenario. In this case it shall be explained as indicated in the "Combined tool to identify the baseline scenario and demonstrate additionality" by using qualitative or quantitative arguments, how the registration of the VCS project activity will alleviate the barriers that prevent the proposed project activity from occurring.

- if there are more than one baseline scenario alternatives that are not prevented by any of the barriers, and these alternatives do not include the project activity without taking into account VERs, the project proponent shall explain how the registration of the VCS project activity will alleviate the barriers that prevent the proposed project activity from occurring.

  If the VCS alleviates those barriers, the project proponent may apply investment analysis to identify the most economically attractive of the baseline scenario alternatives that are not prevented by any of the barriers that the project activity faces. If the most economically attractive baseline scenario is a more carbon intensive alternative than the continuation of current practice then the project proponents may proceed to the following sections of this methodology, provided the baseline scenario is taken to be production of electricity by grid connected power sources and the production of steam and/or hot water is obtained from existing generating facilities. If on the other hand, it is determined that the most economically attractive scenario is a less GHG intensive alternative than the continuation of existing practice, then the methodology cannot be a applied.

Step 2.2: Common practice analysis

Demonstrate that the project activity is not common practice in the relevant country and sector by applying STEP 4 "Common Practice Analysis" as described in the latest version of the "Tool for the demonstration and assessment of additionality"

The relevant geographical area for undertaking the common practice analysis should in principle be the host country of the proposed CDM project activity. A region within the country could be the relevant geographical area if the framework conditions vary significantly within the country.

PROJECT BOUNDARY

The project boundary includes the site of the project facility(s) and the sites of the project customer(s).

CALCULATION OF EMISSION REDUCTIONS FROM THE PROJECT ACTIVITY

The emissions sources are given in table one below.

Table 1: Emissions sources included in or excluded from the project boundary

	Source	Gas	Included	Explanation/Justification
Baseline	Combustion of fossil fuels to produce electricity, steam and/or hot water at the project customer(s)' site, which provide steam and or hot water to the project customer site, and the power generating facilities connected to the grid.	CO_2	Yes	Main emissions source in the combustion of fossil fuel.
		CH_4	No	Excluded for simplification
		N_2O	No	Excluded for simplification.
Project activity	Combustion of natural gas to produce electricity, steam and/or hot water at the site of the project activity.	CO_2	Yes	Main emissions source in the combustion of natural gas.
		CH_4	No	Excluded for simplification
		N_2O	No	Excluded for simplification.

PROCEDURE FOR ESTIMATING LIFETIME OF THE BOILER(S)

The following approaches shall be taken into account to estimate the remaining lifetime of the boilers that would provide steam and hot water in the absence of the project activity:

a) The typical average technical lifetime of the type of equipment may be determined taking into account common practices in the sector and country (e.g. based on industry surveys, statistics, technical literature, etc.);

b) The practices of the responsible company regarding replacement schedules may be evaluated and documented (e.g. based on historical replacement records for similar equipment).

The time to replacement of the existing equipment in the absence of the project activity should be determined in on a case-by-case basis thus taking into consideration local conditions, existing practices and possible barriers to implementation of new projects or regulatory acts relating to the continuation of existing practices regarding steam and hot water generating equipment.

If in any year of the crediting period, new steam or hot water generating equipment is installed at the project customer's installations or at the installations that supply steam and or hot water to the project customer, it shall be assumed that all steam and or hot water that is displaced by the project activity would have otherwise been produced by using equipment with such performance characteristics.

In other words, should such situations occur during the crediting period, the baseline emissions factor will be recalculated based on Option B given for steam and hot water production (equations 8, 15 and 20), to reflect the assumption that in the absence of the project activity, the steam and hot water which is produced by the project facility would have been produced by more efficient steam and hot water generation technology.

The project proponents may opt to assume though that new more efficient equipment would have been installed to generate steam and hot water. In this case they shall assume that best available fossil fuel based steam or hot water generation technology would have been used. Or if they prefer, may opt to assume that the thermal generation efficiency of the equipment that would be installed is 100%. Either option may only be applied though in cases where the project proponents can demonstrate that the use of biomass is not likely to constitute a viable alternative to produce the heat that the project activity displaces

CALCULATION OF THE BASELINE EMISSIONS

The following approach to calculate the baseline emissions is only applicable to projects in which the most plausible baseline scenario has been identified to be the continuation of the existing practice, i.e. electricity supplied by the grid and steam and/or hot water produced by a district heating plant or sourced from a district heating plant.

The baseline scenario shall indicate what the baseline fuels are. The project proponent shall assess the potential for fuel switching and energy efficiency improvements under the baseline scenario as indicated below.

For the purpose of establishing the baseline emissions the project developer shall consider any changes that may impact on the baseline alternatives CO_2e intensity of the steam and/or hot water which it displaces. In this sense attention shall be paid to:

Fuel switching

- fuel switching taking place in the centralized steam and/or hot water generating facility that provides these sources of energy to the steam and hot water grids:

    - the project proponent first determines if the fuel changes are technically feasible using existing thermal energy generating equipment. This exercise is not carried out for electricity generation. For instance the proponents shall determine if the existing equipment is capable of utilizing more that one fuel, without major capital investment. This can be verified during validation. If not, then no additional considerations need to be undertaken in the crediting period and it will be assumed that the same fuel would have been used as has been in the past. If a fuel switch constitutes a possibility given the existing equipment, the project proponent shall monitor this on a yearly basis.

    - Alternatively, the project proponents may assume that natural gas is being used as the baseline fuel, in which case no monitoring in this respect shall be required. The project proponent may apply this default approach during the entire crediting period or for any specific year of the crediting period. This shall be clearly indicated in the monitoring reports presented the verifier.

Energy efficiency improvements

Energy efficiency improvements in thermal energy generation (when the project customer is a district heating plant) and transport of thermal energy to the project customer’s factory gate (when the project customer is an end user) include:

- energy efficiency measures and projects the improve the efficiency with which thermal energy is generated at the thermal energy generating facility;

- improvements to the steam transport system from the point of generation to the point of delivery to a customer connected to the grid that lead to a reduction in the amount of energy losses, and hence CO_2 emissions per unit of thermal energy delivered to the point at which the project activity steam and or hot water are delivered to the project customer. This needs to be considered in cases in which the project proponents chose to apply a GHG intensity factor which is based on measured data;

- activities that increase the amount heat returned to the central generating system boiler house in the form of hot condensate and flash steam, which therefore reduce the CO_2 intensity of the steam which is produced.

The impact of such measures on the baseline emissions are dealt with in the baseline emissions calculation and monitoring sections of this methodology. Alternatively, the project proponents may apply default factors as suggested in this methodology. In either case the DOE shall verify the appropriateness of the data/factors applied.

This methodology is only applicable to situations in which the baseline scenario is the continuation of the current practice for producing electricity and heat from fossil fuel

The baseline emissions for this particular methodology are the sum of emissions from resulting from the generation of electricity, steam and hot water.

$$BE_y = BE_{el,y} + BE_{th,y} \quad (1)$$

Where:

$BE_{el,y}$ Baseline emissions resulting from electricity generation in the year y (in tonnes of CO_2e). Calculated below as per equation (2);

$BE_{th,y}$ Baseline emissions resulting from the production of steam and/or hot water supplied to project customer i in the year y (in tonnes of CO_2). Calculated below as per equation (3).

BASELINE EMISSIONS FROM ELECTRICITY GENERATION

Baseline emissions from electricity generation are calculated by multiplying the net electricity generated at the project plant ($EG_{P,y}$) with a baseline electricity grid CO_2 emission factor ($EGEF_{BL,CO_2,y}$) as follows:

$$BE_{el,y} = EG_{P,y} \cdot EGEF_{BL,CO_2,y} \quad (2)$$

For construction of large new power capacity additions under the CDM, there is a considerable uncertainty relating to which type of other power generation is substituted by the power generation of the project plant. As a result of the project activity, the construction of an alternative power generation technology could be avoided, or the construction of a series of other power plants could simply be delayed. Furthermore, if the project were installed sooner than these other projects might have been constructed, its near-term impact could be largely to reduce electricity generation in existing plants. This depends on many factors and assumptions (e.g. whether there is a supply deficit) that are difficult to determine and which change over time. In order to address this uncertainty in a conservative manner, project participants shall use for ($EGEF_{BL,CO_2,y}$) the lowest emission factor among the following options:

For the first crediting period:

Option 1 The build margin, calculated according to “Tool to calculate emission factor for an electricity system”; and

Option 2 The combined margin, calculated according to “Tool to calculate emission factor for an electricity system”, using a 50/50 OM/BM weight.

BASELINE EMISSIONS FROM HEAT GENERATION

The baseline emissions from heat production ($BE_{th,y}$) are the sum of emissions from steam generation and hot water generation for sale to project customers:

$$BE_{th,y} = BE_{st,y} + BE_{hw,y} \tag{3}$$

Where:

$BE_{st,y}$ Baseline emissions resulting from the production of steam supplied to project customer i in the year y (in tonnes of CO_2). Calculated below as per equation (4);

$BE_{hw,y}$ Baseline emissions resulting from the production of hot water supplied to project customer i in the year y (in tonnes of CO_2). Calculated below as per equation (11).

The maximum amount of thermal energy in the form of steam and/or hot water, which is produced by the project activity during year y and which can be used for the purpose of determining the emissions reductions upon which VERs can be claimed, is defined as the maximum annual amount of thermal energy produced in the form of steam and/or hot water that has been produced over the three most recent years for which data is available in the pre-project steam and or hot water production facilities.

I. Baseline emissions from production of steam that is supplied to project customer i in year y (in tonnes of CO_2):

$$BE_{st,y} = \sum_i \sum_j \left(SC_{BL,j,y} \cdot SEF_{BL,i,y} \right) \qquad (4)$$

Where:

$SC_{BL,j,y}$ The amount of energy consumed in the form of steam by the project customer i, which is supplied by the project facility j in year y (in TJ). It is further obtained from equation (5).

$SEF_{BL,i,y}$ The baseline emission factor corresponding to the steam produced in project customer i's steam generating plant or sourced from the produced in a steam generating plant that supplies steam to a project customer i (in t CO_2/TJ), and obtained from equation (6) below.

The amount of energy consumed in the form of steam by the project customer i which is supplied by the project facility j in year y is given by:

$$SC_{BL,j,y} = SP_{BL,j,y} \cdot SDEN_{BL,j,y} \qquad (5)$$

Where:

$SP_{BL,j,y}$ Quantity of steam produced by the project facility j and supplied to the project customer i for year y, (in tonnes)

$SDEN_{BL,j,y}$ Specific enthalpy of steam leaving the project facility j (in TJ/tonne of steam supplied). This data shall be obtained from steam tables, using temperatures and pressure of the steam purchased.

The following options are provided to determine the baseline CO_2 emissions factor, $SEF_{BL,i,y}$ for the steam produced by the project customer i or by a steam generating plant that supplies a project customer i with steam (in tonnes of CO_2/TJ of steam) produced in year y.

Option I.A.

When actual data for the amount of fuel consumed and steam generated by the project customer i's steam generating plant or by the steam generating plant that supplies steam to a customer i is available, the baseline emission factor for the steam generated may be calculated as:

$$SEF_{BL,i,y} = \frac{44}{12} \cdot \frac{\sum_i \left(CEF_{FF,i,y} \cdot HEC_{BL,FF,st,i,y} \right)}{\sum_i HSC_{BL,i,y}} \qquad (6)$$

Where:

$CEF_{FF,i,y}$ Carbon emission factor in year y corresponding to fossil fuel used by project customer i to generate steam or that which is used in a given steam generating plant to produce the steam which is sourced by the project customer i (in tonnes of C/TJ), shall be determined from the technical literature, from the project customer i, or the steam generating plant which supplies steam to the project customer i.

$HEC_{BL,FF,st,i,y}$ The energy associated with the fossil fuel consumed by the project customer i or the steam generating facility that supplied steam to the project customer i, in year y (in TJ). Calculated below in equation (7).

$HSC_{BL,i,y}$ The amount of energy contained in the steam generated by the customer i or the steam generating facility that supplied steam to the project customer i by burning fossil fuel (in TJ) in year y.

The present methodology offers two options upon which to establish $HEC_{BL,FF,st,i,y}$:

Option I.A.a.

The energy associated with the fossil fuel that was consumed by the project customer i for self-generation of steam or by the steam generating facility that supplied steam to the project customer is given by:

$$HEC_{BL,FF,st,i,y} = HFC_{BL,FF,st,i,y} \cdot NCV_{FF,i,y} \qquad (7)$$

Where:

$HFC_{BL,FF,st,i,y}$ The quantity of fossil fuel consumed for steam generation by project customer i or that which was consumed by the steam generating plant that provided steam to the project customer i in year y (in tonnes)

$NCV_{FF,i,y}$ Net calorific value of the fossil fuel used by the project customer i in the scenario of self-generation or used by the steam generating plant that supplied steam to the project customer i in year y. Specific data may be provided by the project customer or from the technical literature (TJ/tonne)

Option I.A.b.

Alternatively, $HEC_{BL,FF,st,i,y}$ may be calculated from records of steam produced and the temperature and pressure conditions at which boiler feed water is supplied to and the steam generated from the boilers, as follows:

$$HEC_{BL,FF,st,i,y} = \frac{(HSC_{BL,i,y} - HSP_{BL,i,y} \cdot HSEN_{w,y}) \cdot 100}{\eta_{BL,st,i}} \quad (8)$$

Where:

$HSC_{BL,i,y}$	The amount of energy contained in the steam which was generated by the customer i or that which was generated by the steam generating facility that provided steam to the project customer i, and which was obtained by burning fossil fuel (in TJ) in year y.
$HSEN_{w,y}$	The specific enthalpy of water entering the boiler at project customer i's steam generating facilities or the water entering the boiler at the steam generating facilities which supplied steam to the project customer i in year y.
$HSP_{BL,i,y}$	The quantity of steam produced by the project customer i or that which was produced by the generating facility that supplied the steam to the project customer i in year y (in tonnes of steam produced).
$\eta_{BL,st,i}$	The efficiency of project customer i's boiler or the efficiency of the boiler that supplied steam to the project customer i based on NCV (in %). This parameter shall be one of the following:

i) the highest measured value of boiler efficiency recorded over full range boiler test;

ii) the boiler's peak thermal efficiency as per manufacturer's information;

iii) efficiencies of boilers of similar design;

iv) a default boiler efficiency of 100%;

Note: heat losses associated with the transmissions and distribution of steam are assumed to be zero

Energy content (in TJ) of the steam generated by customer i or by the facility that supplied steam to the project customer i is given by:

$$HSC_{BL,i,y} = HSP_{BL,i,y} \cdot HSEN_{BL,i,y} \quad (9)$$

Where:

$HSP_{BL,i,y}$	The quantity of steam produced by the project customer i or produced by the steam generating facility that supplied steam to the project customer i in year y (in tonnes of steam produced)
$HSEN_{BL,i,y}$	The specific enthalpy of the steam produced by project customer i or by the steam generating facilities that supplied steam to the project customer i in year y (in TJ/ tonne of steam produced).

Note for monitoring during the crediting period.

Option 1.A

Changes may be made to certain elements of the project customer's steam system (e.g. the condensate recovery system) that could result in a lower baseline emissions factor during the years of the crediting period. Additionally, changes in the type of fuel used may occur in any year y during the crediting period, which are likely to have occurred also in the absence of the project activity.

For the purpose of establishing the steam baseline emission factor in any given year y during the crediting period, the project proponent shall therefore:

a) establish the lowest specific heat consumption per unit of steam energy given by $\min(HEC_{BL,FF,st,i,y} / HSC_{BL,i,y})$ up till year y

b) multiply this value with the value of $\left(\frac{44}{12} \cdot CEF_{FF,i,y}\right)$ of the fuel used in year y

The baseline emissions factor for year y shall be the lowest between the value so calculated and that obtained from equation (6) above.

The purpose of this approach is to identify which year is the least energy intensive one, and assume that the improved performance would have not been lost over time. That is, in any year y it is always assumed that steam will be produced with the minimum amount of fossil fuel derived energy. It also aims to reflect the fact that changes in the fuel type being used in any year y may change to what has been previously the case, and that furthermore such changes would have also occurred in the absence of the project activity. If however in any year y, there is no fossil fuel consumption at the project customer's steam generating facility because all is displaced by the project activity, then the project proponent shall apply the lowest baseline emissions factor amongst the historical value for the three most recent years prior to the implementation of the project for which data is available and the values obtained during the years of the crediting period leading up to year y.

Note for cases in which a project customer uses steam produced by another steam generating plant:

Where the project customer is one that imports steam from generating facility, heat losses in transmission and distribution of that steam shall be considered nil. In other words, enthalpy data applied into the equations above shall be that which corresponds to the temperature and pressure conditions of the steam produced at the steam generating facility and not those existing of the steam at the point of off-take by the project customer. In this case, the steam baseline emissions factor shall be monitored as per the preceding note.

Option I.B.

The baseline CO_2 emissions factor per TJ of steam energy generated by customer i or by the steam generating facility that supplied steam to the project customer i, in the absence of the project activity can also be determined from boiler manufacturer's design data for customer i, and the fraction of heat recovered in the form of condensate, assuming no heat losses occur along the steam transmission and distribution lines, as follows:

$$SEF_{BL,i,y} = \frac{44}{12} \cdot \frac{CEF_{FF,i,y} \cdot (1 - X_{c,y}).100}{\eta_{BL,st,i}} \qquad (10)$$

Where:

$CEF_{FF,i,y}$ Carbon emission factor (in tonnes of C/TJ), corresponding to the fossil fuel consumption by customer i or the facility that provided steam to the project customer i in year y;

$\eta_{BL,st,i}$ Project customer i's boiler efficiency or the boiler efficiency of the steam generating plant that supplied steam to a project customer, based on NCV (in %).In the absence of boiler performance data, $\eta_{BL,st,i}$ can be determined by one of the following:

i) the highest measured value of boiler efficiency recorded over full range boiler test;

ii) the boiler's peak thermal efficiency as per manufacturer's information;

iii) efficiencies of boilers of similar design;

iv) a default boiler efficiency of 100%.

$X_{c,y}$ The fraction of the total energy contained in the steam which is produced by the steam generating facilities which is returned as hot condensate and flash steam where applicable, to the boiler house in year y. The values of $X_{c,y}$ can be obtained as follows:

Option 1. Based on historical/actual measured data

- from historical data:

Option 1a. When the mass of condensate and temperature and pressure conditions at which the condensate is returned to the boiler house condensate tank are known:

If this option is to be applied, then this calculation must be performed yearly during the crediting period to ensure that no improvements have been made that might lead to a further increase in the amount of energy recovered from the condensate. Should the value of the fraction so obtained in any year y be less than the historical maximum value (spanning the first year of the historical data used to establish the initial value of $X_{c,y}$ till year y-1 in the crediting period), the maximum value of $X_{c,y}$ during this period shall be taken. Energy returned to the boiler house in the form of hot condensate as well as from any flash steam recovered and thereafter used in a deaerator shall be accounted for.

Option 1.b When the mass of condensate recovered unknown, but temperature at which the condensate is returned to the condensate tank is known:

Calculate the heat recovered from the condensate entering the condensate tank by assuming that all the steam that condensed throughout the steam system is routed back to the boiler house condensate recovery tank, based upon the maximum temperature observed from historical records. In other words, assume that:

- no steam is used directly in a process
- all the steam that is condensed in heat exchangers is returned, i.e. no losses due to leaks (neither condensate nor live steam). Flash losses that occur across the steam traps are calculated by carrying out an enthalpy balance around

the condensate recovery tank at the tank's operating conditions

If this option is to be applied, then this calculation must be performed yearly to ensure that no improvements have been made that might lead to a further increase in the amount of energy recovered in the form of condensate that was present in the heat exchangers (e.g. if a condensate flash steam recovery project were to be implemented). Select the maximum condensate recovery temperature (at the condensate recovery tank) in the period spanning the first year of the historical data used to establish the initial value of $X_{c,y}$ till year y-1 in the crediting period, and use this value to establish the heat recovered from the condensate which is returned to the boiler in the form of condensate.

Option 2. Based on Default values

The following options assume that there are neither losses of condensate along the condensate piping nor losses to direct heating processes. The above assumptions overestimate the amount energy which can be recovered from this part of a steam system.

Option 2a If the existing condensate system is of the atmospherically vented condensate system type:

If the quantity and temperature at which the condensate is returned to the boiler house are not known, apply option 1b above but assume that the condensate which is obtained from the bottom of the condensate flash tank is pumped to the deaerator at 100°C to calculate the heat returned to the boiler in the form of hot condensate.

The proponents shall confirm annually if any changes to the design of the condensate system have been made that enable it to operate at a higher pressure, and thus recover more energy from the condensate routed to the condensate tank. Should this be the case, this default can no longer be applied.

Note: For such system condensate cannot exceed 100°C otherwise pump impeller cavitation /capitation would occur. Hence there is a practical limit to the amount of heat that can be recovered; in fact it would probably be somewhat lower than 100°C.

Option 2b. The project proponent may chose to calculate $X_{c,y}$ assuming that all the heat contained in the condensate in the heat transfer equipment is returned to the boiler. The calculation shall be performed based on enthalpy values of water, h_f, corresponding to the conditions at which the steam is generated according to the boiler manufacturer's design or the actual conditions.

II. Baseline emissions from production of hot water

The baseline emissions from the production of hot water in project customer i's installation or produced in the installation that supplied hot water to the project customer i are given by:

$$BE_{hw,y} = \sum_i \sum_j \left(HWC_{BL,j,y} \cdot HWEF_{BL,i,y} \right) \tag{11}$$

Where:

$HWC_{BL,j,y}$ The energy content in the hot water produced by the project facility j, which is purchased by project customer i in year y (in TJ);

$HWEF_{BL,i,y}$ The CO_2 baseline emissions factor corresponding to the hot water produced by the project customer i or produced by the hot water production plant that produces hot water which the project customer i uses in year y (in t CO_2/TJ)

The energy content in the hot water produced by the project facility j, which is purchased by project customer i in year y is obtained by the following equation:

$$HWC_{BL,j,y} = HWP_{BL,j,y} \cdot HWEN_{BL,j,y} \tag{12}$$

Where:

$HWP_{BL,j,y}$ The amount of hot water produced by project facility j and supplied to project customer i in year y (in tonnes);

$HWEN_{BL,j,y}$ The specific enthalpy of hot water produced by the project facility j in the year y (in TJ/tonne of water).

This part of the methodology considers situations in which a project customer i would have produced or obtained hot water from a hot water production plant. This hot water in the absence of the project activity would have been derived from either of the following sources of energy:

- fossil fuel, in directly fired hot water boilers, hwb (Option II.A.)

- steam, in steam to water heat exchangers, sthx (Option II.B.)

Option II.A. Hot water produced in boilers firing fossil fuels

The following alternatives are provided to determine the baseline CO_2 emissions factor associated to the production hot water in tonnes of CO_2/TJ where historical data is available.

Option II.A.a.

The baseline CO_2 emission factor associated with hot water production in boilers running on fossil fuel can be calculated as:

$$HWEF_{BL,i,y} = \frac{44}{12} \cdot \frac{\sum_i (CEF_{FF,i,y} \cdot HEC_{BL,FF,hwb,i,y})}{\sum_i HHWC_{BL,hwb,i,y}} \qquad (13)$$

$CEF_{FF,i,y}$ Carbon emission factor corresponding to the fossil fuel used by the project customer i to produce hot water or used by the plant which supplied hot water to a project customer i in year y (in tonnes of C/TJ). Obtained from the relevant hot water generating plant or from the technical literature.

$HEC_{BL,FF,hwb,i,y}$ The energy associated with the fossil fuel consumed by customer i to self-generate hot water in a hot water boiler or that consumed by a hot water production plant that provides the hot water to the project customer i (in TJ) in year y.

$HHWC_{BL,hwb,i,y}$ The energy contained in the hot water, which was generated by the customer i from burning natural gas (in TJ) or which was produced by the facility that provided hot water to the project customer i in year y.

The present methodology offers two options upon which to determine $HEC_{BL,FF,hwb,i,y}$:

Option II.A.a.i

The energy associated with the fossil fuel consumed by a customer i to self-generate hot water in a hot water boiler or that which is used to generate hot water in a facility that supplied hot water to a project customer i given by:

$$HEC_{BL,FF,hwb,i,y} = HFC_{BL,FF,hwb,i,y} \cdot NCV_{FF,i,y} \qquad (14)$$

Where:

$HFC_{BL,FF,hwb,i,y}$ The quantity of fossil fuel consumed for hot water generation in hot water boilers by the project customer i or by the plant that generated the hot water which customer i used for year y. This can be reported as mass units of the baseline fuel or in units of volume if data is provided on the mass density of the fossil fuel used (in tonnes)

$NCV_{FF,i,y}$ Net calorific value of the fossil fuel used in the hot water generating plant, whether this is the project customer i's facility or the plant that generated the hot water which the project customer i used, whichever is applicable,or specific data to be provided by the project customer for year y

Option II.A.a.ii

Alternatively, in the absence of suitable historical data for fossil fuel consumption or if preferred, $HEC_{BL,FF,hwb,i,y}$ may be calculated as follows:

$$HEC_{BL,FF,hwb,i,y} = \frac{(HHWC_{BL,hwb,i,y} - HHWP_{BL,hwb,i,y} \cdot HSEN_{w,y}) \cdot 100}{\eta_{BL,hwb,i}} \quad (15)$$

Where:

$HHWC_{BL,hwb,i,y}$ The energy contained in the hot water, which was generated by the customer i or by the plant that provided the hot water to the project customer i, from burning fossil fuel (in TJ) in year y

$HSEN_{w,y}$ The specific enthalpy of water entering the hot water boiler in year y

$\eta_{BL,hwb,i}$ Customer i's hot water boiler's efficiency or that of the hot water generating plant that supplied hot water to the project customer i, based on NCV. The value of this parameter shall be one of the following:

a. the highest measured value of boiler efficiency recorded over full range boiler test;

b. the boiler's peak thermal efficiency as per manufacturer's information;

c. efficiencies of boilers of similar design;

d. a default boiler efficiency of 100%

The energy content of the hot water self-generated by project customer i, or by the hot water generating facility that supplies hot water to customer i, is given by:

$$HHWC_{BL,hwb,i,y} = HHWP_{BL,hwb,i,y} \cdot HHWEN_{BL,hwb,i,y} \tag{16}$$

Where:

$HHWP_{BL,hwb,i,y}$ The mass of hot water self-generated in hot water boilers by the project customer i or by the hot water generating plant that supplies hot water to customer i, in year y (in tonnes)

$HHWEN_{BL,hwb,i,y}$ The specific enthalpy of the hot water leaving project customer i's installation or that of the hot water leaving the facility that supplies hot water to the project customer i, in year y (in TJ/tonne of water)

Note for monitoring during the crediting period.

Option II Aa is based on actual performance data. However changes may be made to certain elements of the project customer's hot water system (e.g. the improved insulation) could result in a lower hot water baseline emissions factor during the years of the crediting period. Additionally, changes in the type of fuel used may occur in any year y during the crediting period, which are likely to have occurred also in the absence of the project activity.

The project proponents shall therefore:

a) establish the lowest specific heat consumption per unit of thermal energy given by $\min\left(HEC_{BL,FF,st,i,y} / HHWC_{BL,hwb,i,y}\right)$ up till year y

b) multiply the above value with $\left(\frac{44}{12} \cdot CEF_{FF,i,y}\right)$ of the fuel used in year y

The baseline hot water emissions factor for year y shall be the lowest between the value so calculated and that obtained from equation (13).

The purpose of this approach is to identify which year is the least energy intensive one, and assume that the improved performance would have not been lost over time. That is, in any year y it is always assumed that hot water will be produced with the minimum amount of fossil fuel derived energy. It also aims to reflect the fact that changes in the fuel type being used in any year y may change to what has previously been the case, and that furthermore such changes would have also occurred in the absence of the project activity. If however in any year y, there is no fossil fuel consumption at the project customer's hot water generating facility because all is displaced by the project activity, then the project proponent shall apply the lowest hot water baseline emissions factor amongst the one for the three most recent years prior to the implementation of the project for which data is available and the values obtained during the years of the crediting period leading up to year y.

Note for cases in which a project customer uses hot water produced by another hot water generating plant:

Where the project customer is one that imports hot water from a generating facility, heat losses in transmission and distribution of that hot water shall be considered nil. In other words, enthalpy data applied into the equations above shall be that which corresponds to the temperature of the water produced at the hot water generating facility and not those existing at the point of off-take by the project customer. In this case, the hot water emissions factor shall be monitored during the crediting period as per the preceding note.

Option II.A.b.

The baseline specific CO_2 emissions factor for a project customer "i" of the hot water generating facility that supplies hot water to a project customer i, can be determined from the hot water boiler manufacturer's design data and monitoring the difference between the boiler hot water outlet and inlet return temperatures as follows:

$$HWEF_{BL,i,y} = \frac{44}{12} \cdot \frac{CEF_{BL,i,y} \cdot 100}{\eta_{BL,hwb,i}} \cdot \frac{\Delta T_{P,i,y}}{\Delta T_{BL,i}} \qquad (17)$$

Where:

$CEF_{BL,i,y}$ Carbon emissions factor in tonnes CO_2/TJ corresponding to the fossil fuel used by customer i to produce the hot water, or by the hot water production plant that supplies the hot water which the project customer uses in year y

$\eta_{BL,hwb,i}$ Customer i's hot water boiler's efficiency or the efficiency of the facility that produces the hot water which project customer i uses, based on the NCV. The value of this parameter shall be one of the following:

a. the highest measured value of boiler efficiency recorded over full range boiler test;

b. the boiler's peak thermal efficiency as per manufacturer's information;

c. efficiencies of boilers of similar design;

d. a default boiler efficiency of 100%.

$\Delta T_{BL,i}$ — Temperature difference between the water exiting the boiler and the water returning to it. The value applied shall be the lowest mean annual temperature difference over the three most recent years for which historical data is available. Alternatively, the design annual mean temperature difference may be considered as a default;

$\Delta T_{P,i,y}$ — Temperature difference between the water exiting boiler and water returning in year y. The applied value shall be the lowest value during the historical period considered and the current year. Alternatively, the design annual mean temperature difference may be considered as a default.

Option II.B. Hot water produced from steam using heat exchangers

The following alternatives are provided to determine the baseline CO_2 emissions factor associated to the production hot water in tonnes of CO_2/TJ when this is produced from steam.

Option II.B.a.

The CO_2 baseline emission factor associated with hot water production in steam heat exchangers can be calculated based upon historical data as:

$$HWEF_{BL,i,y} = \frac{44}{12} \cdot \frac{\sum_i (SEF_{BL,i,y} \cdot HEC_{BL,st,sthx,i})}{\sum_i HHWC_{BL,sthx,i}} \tag{18}$$

$SEF_{BL,i,y}$ — The baseline emission factor for the production of steam which is used to produce the hot water (in tonnes CO_2/TJ), and obtained from equation (4).

$HHWC_{BL,sthx,i,y}$ — The energy contained in hot water self generated by project customer i from steam or by the supplier of the hot water to a project customer i in a steam-to-water heat exchanger (in TJ) in year y

$HEC_{BL,st,sthx,i,y}$ — The energy associated with the steam consumed by customer i to self-generate hot water or that which is consumed by the hot water production plant which produces the hot water that a project customer i uses, in a steam-to-water heat exchanger (in TJ) in year y

The energy contained in hot water self generated by project customer i from steam or obtained from the hot water generating plant that supplied this hot water to a project customer i, by means of a steam-to-water heat exchanger can be obtained by:

$$HHWC_{BL,sthx,i,y} = HHWP_{BL,sthx,i,y} \cdot HHWEN_{BL,hw,sthx,i,y} \quad (19)$$

$HHWP_{BL,sthx,i,y}$ The mass of hot water self-generated by the project customer i or by the hot water production plant that produced the hot water that a project customer i uses, by means of a steam-to-water heat exchanger during year y (in tonnes)

$HHWEN_{BL,hw,sthx,i,y}$ Specific enthalpy of water leaving the steam-to-water heat exchanger or exchangers of the project customer i, during year y.

The amount of energy consumed in the form of steam to produce hot water in the absence of the project activity (in TJ), $HEC_{BL,st,sthx,i,y}$, is given by:

Option II.B.a.i.

$$HEC_{BL,st,sthx,i,y} = HFC_{BL,NG,hwb,i,y} \cdot HHWEN_{BL,st,sthx,i,y} \quad (20)$$

$HFC_{BL,st,stbx,i,y}$ Quantity of steam consumed by the project customer i or the facility that generates the hot water which a project customer i used in year y (in tonnes)

$HHWEN_{BL,st,sthx,i,y}$ Difference of the specific enthalpy of steam entering and condensate leaving the heat exchanger in year y (in TJ/tonne of water)

Option II.B.a.ii.

Alternatively, in the absence of suitable actual steam consumption data, or if preferred, $HEC_{BL,st,sthx,i,y}$ may be calculated as follows:

$$HEC_{BL,st,sthx,i,y} = \frac{(HHWC_{BL,sthx,i,y} - HHWP_{BL,sthx,i,y} \cdot HSEN_{w,y}) \cdot 100}{\eta_{BL,sthx,i}} \quad (21)$$

Where

$HSEN_{w,y}$ The specific enthalpy of water entering the steam to water heat exchanger in year y

$\eta_{BL,sthx,i}$ The steam-to-water exchanger efficiency (%) of customer i's hot water generating plant or that of the hot water generating plant that provides hot water to customer i, based on one of the following:

a. the highest measured annual value of heat exchanger efficiency;

b. the design heat exchanger efficiency;

c. efficiencies of steam-to-water heat exchangers of similar design;

d. a default heat exchanger efficiency of 100%.

Note for monitoring during the crediting period.

Changes may be made during the crediting period to elements of the hot water distribution system (e.g. improved insulation) that may reduce the amount of steam required to meet the thermal loads), which in turn will lead to changes in the baseline emissions factor of the hot water produced.

Changes may also occur to elements of the steam system from which the heat exchangers are fed, which may also lead to changes in the baseline emissions factor of the steam, and hence impact the baseline emissions factor for the hot water.

In establishing the value of the hot water baseline emissions factor to be applied in year y the project proponents shall therefore:

c) establish the lowest specific heat consumption per unit of thermal energy given by $\min(HEC_{BL,st,sthx,i,y} / HHWC_{BL,sthx,i,y})$ up till year y

d) multiply the above value with $SEF_{BL,i,y}$ corresponding to the year y

The baseline hot water emissions factor for year y shall be the lowest between the value so calculated and that obtained from equation (18).

The purpose of this approach is to identify which year is the least energy intensive one, and assume that the improved performance achieved in the hot water system would have not been lost over time. That is, in any year y it is always assumed that hot water will be produced with the minimum amount of steam energy.. If however in any year y, there is no steam consumption in the steam – hot water heat exchanger at the project customer's hot water generating facility because all of it is displaced by the project activity, then the project proponent shall apply the lowest hot water baseline emissions factor amongst the one obtained from the average of the three most recent years prior to the implementation of the project for which data is available and the values obtained during the years of the crediting period leading up to year y.

The project proponent shall ensure the steam baseline emissions factor is monitored annually and updated accordingly when applied to the above equations. The value for the baseline emissions factor of the steam to be applied in any year y shall be that obtained as per Section I above.

Option II.B.b.

The baseline CO_2 emissions factor for a customer i can be determined without having to resort to historical data of steam and/or hot water production from the steam-to-water heat exchanger manufacturer design data as follows:

$$HWEF_{BL,i,y} = \frac{44}{12} \cdot \frac{SEF_{BL,i,y} \cdot 100}{\eta_{BL,sthx,i}} \qquad (22)$$

Where:

$SEF_{BL,i,y}$ The baseline emission factor corresponding to the steam that is utilized either by the project customer i or the hot water production plant that supplies hot water to customer i in year y, whichever is the case (in tonnes CO_2/TJ). Obtained from equation 4.

$\eta_{BL,sthx,i}$ The efficiency of steam-to-water exchanger efficiency at customer i's installations or at the facility which supplies hot water to customer i, based on one of the following:

a. the highest measured annual value of heat exchanger efficiency;

b. the design heat exchanger efficiency;

c. efficiencies of heat exchangers of similar design;

d. a default heat exchanger efficiency of 100%.

Note for monitoring during the crediting period

Changes may be made during the crediting period to elements of the steam system from which the heat exchangers are fed may lead to changes in the baseline emissions factor of the steam used, and hence impact the baseline emissions factor for the hot water which is produced.

Therefore, the project proponent shall ensure the steam baseline emissions factor is monitored annually and updated accordingly when applied to the above equations. The value for the baseline emissions factor of the steam to be applied in year y shall be that obtained as per Section I above.

CALCULATION OF THE PROJECT EMISSIONS

Project emissions within the project boundary result from the combustion of natural gas within the project boundary:

$$PE_y = PE_{NG,P,y} \quad (23)$$

Where:

$PE_{NG,P,y}$ Project emissions resulting from combustion of natural gas within the project boundary (in t CO_2e) for the year y.

Those project emissions are respectively calculated as follows:

$$PE_{NG,P,y} = FC_{NG,P,y} \cdot NCV_{NG} \cdot EF_{NG,CO2,p} \quad (24)$$

Where:

$FC_{NG,P,y}$ Natural gas consumed within the project facility "j" (in tonnes/ normal m^3) in the year y.

NCV_{NG} Lower heating value of the natural gas combusted (in TJ/t or TJ/normal m^3). As per certificates from the natural gas supplier or from IPCC figures.

$EF_{NG,CO2,p}$ CO_2 emission factor for the combustion of natural gas (in t CO2/TJ). As per certificates from the natural gas supplier or from IPCC figures.

When calculating the term $FC_{NG,P,y}$, the project proponent may resort to using the formula below:

$$FC_{NG,P,y} = FC_{NG,P,C,y} + FC_{NG,P,H,y} \quad (25)$$

Where:

$FC_{NG,P,C,y}$ Natural gas consumed by the main equipment within the boundaries of the project facility j in year y (in tonnes/ normal m^3)

$FC_{NG,P,H,y}$ Natural gas consumed for supplementary firing within the boundaries of the project facility j in year y (in tonnes/ normal m^3).

CALCULATION OF THE LEAKAGE EMISSIONS

The project proponent should estimate the size of leakage emission from electricity consumption and assess if those leakages are higher than 1% of the calculated emission reductions from that project activity, in the event that the project activity were to draw electricity from the grid. If that is the case, those leakage emissions should be included in the leakage calculations.

Upstream emissions from fuel extraction, processing, liquefaction, transportation and regasification of Natural Gas (to be considered only when the project fuel is Natural Gas)

In this methodology, the following leakage emission sources shall be considered:

- Fugitive CH_4 emissions associated with fuel extraction, processing, liquefaction, transportation, regasification and distribution of natural gas used in the project plant and fossil fuels used in the grid in the absence of the project activity ($LE_{CH_4,y}$).
- In the case LNG is used in the project plant: CO_2 emissions from fuel combustion/electricity consumption associated with the liquefaction, transportation, re-gasification and compression into a natural gas transmission or distribution system ($LE_{LNG,CO_2,y}$).

$$LE_{US,y} = LE_{CH_4,y} + LE_{LNG,CO_2,y} \qquad (26)$$

Where:

$LE_{CH_4,y}$	Leakage emissions due to fugitive upstream CH4 emissions in the year y in t CO2e
$LE_{LNG,CO_2,y}$	Leakage emissions due to fossil fuel combustion / electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system during the year y in t CO2e

Fugitive methane emissions

For the purpose of determining fugitive methane emissions associated with the production – and in case of natural gas, the transportation and distribution of the fuels – project participants should multiply the quantity of natural gas consumed in all element processes i with a methane emission factor for these upstream emissions ($EF_{NG,upstream,CH_4}$), and subtract for all fuel types k which would be used in the absence of the project activity the fuel quantities multiplied with respective methane emission factors ($EF_{NG,upstream,CH_4}$), as follows:

$$LE_{CH_4,y} = \left[FF_{\Pr oject,y} \cdot NCV_{NG,y} \cdot EF_{NG,upstream,CH_4} - \sum_k FF_{Baseline,k,y} \cdot NCV_{NG,k} \cdot EF_{NG,upstream,CH_4} \right] \cdot GWP_{CH_4} \quad (27)$$

Where:

$LE_{CH_4,y}$	Leakage emissions due to upstream fugitive CH4 emissions in the year y in t CO2e
$FF_{\Pr oject,y}$	Quantity of natural gas combusted in all element processes during the year y in m³
$NCV_{NG,y}$	Average net calorific value of the natural gas combusted during the year *y* in /m³
$EF_{NG,upstream,CH_4}$	Emission factor for upstream fugitive methane emissions from production, transportation and distribution of natural gas in t CH4 per TJ fuel supplied to final consumers
$FF_{Baseline,k,y}$	Quantity of fuel type *k* (a coal or oil) that would be combusted in the absence of the project activity in all element processes during the year *y* in a volume or mass unit
$EF_{NG,upstream,CH_4}$	Emission factor for upstream fugitive methane emissions from production, transportation and distribution of natural gas in t CH4 per TJ fuel supplied to final consumers
GWP_{CH_4}	Global warming potential of methane valid for the relevant commitment period

Where reliable and accurate national data on fugitive CH4 emissions associated with the production, and in case of natural gas, the transportation and distribution of the fuels is available, project participants should use this data to determine average emission factors by dividing the total quantity of CH4 emissions by the quantity of fuel produced or supplied respectively. Where such data is not available, project participants may use the default values provided in Table 2 below. In this case, the natural gas emission factor for the location of the project should be used, except in cases where it can be shown that the relevant system element (gas production and/or processing/transmission/distribution) is predominantly of recent vintage and built and operated to international standards, in which case the US/Canada values may be used.

Note that the emission factor for fugitive upstream emissions for natural gas ($EF_{NG,upstream,CH_4}$) should include fugitive emissions from production, processing, transport and distribution of natural gas, as indicated in the Table 2 below. Note further that in case of coal the emission factor is provided based on a mass unit and needs to be converted in an energy unit, taking into account the net calorific value of the coal.

Table 2: Default emission factors for fugitive CH_4 upstream emissions

Activity	Unit	Default emission factor	Reference for the underlying emission factor range in Volume 3 of the *1996 Revised IPCC Guidelines*
Coal			
Underground mining	t CH4 / kt coal	13.4	Equations 1 and 4, p. 1.105 and 1.110
Surface mining	t CH4 / kt coal	0.8	Equations 2 and 4, p.1.108 and 1.110
Oil			
Production	t CH4 / PJ	2.5	Tables 1-60 to 1-64, p. 1.129 - 1.131
Transport, refining and storage	t CH4 / PJ	1.6	Tables 1-60 to 1-64, p. 1.129 - 1.131
Total	t CH4 / PJ	4.1	
Natural gas			
USA and Canada			
Production	t CH4 / PJ	72	Table 1-60, p. 1.129
Processing, transport and distribution	t CH4 / PJ	88	Table 1-60, p. 1.129
Total	t CH4 / PJ	160	
Eastern Europe and former USSR			
Production	t CH4 / PJ	393	Table 1-61, p. 1.129
Processing, transport and distribution	t CH4 / PJ	528	Table 1-61, p. 1.129
Total	t CH4 / PJ	921	
Western Europe			
Production	t CH4 / PJ	21	Table 1-62, p. 1.130
Processing, transport and distribution	t CH4 / PJ	85	Table 1-62, p. 1.130
Total	t CH4 / PJ	105	
Other oil exporting countries / Rest of world			
Production	t CH4 / PJ	68	Table 1-63 and 1-64, p. 1.130 and 1.131
Processing, transport and distribution	t CH4 / PJ	228	Table 1-63 and 1-64, p. 1.130 and 1.131
Total	t CH4 / PJ	296	

Note: The emission factors in this table have been derived from IPCC default Tier 1 emission factors provided in Volume 3 of the 1996 Revised IPCC Guidelines, by calculating the average of the provided default emission factor range.

CO_2 emissions from LNG

Where applicable, CO2 emissions from fuel combustion / electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system ($LE_{LNG,CO_2,y}$) should be estimated by multiplying the quantity of natural gas combusted in the project with an appropriate emission factor, as follows:

$$LE_{LNG,CO_2,y} = FF_{Project,y} \cdot EF_{CO_2,upstream,LNG} \qquad (28)$$

Where:

$LE_{LNG,CO_2,y}$ Leakage emissions due to fossil fuel combustion / electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or

	distribution system during the year y in t CO2e
$FF_{Project,y}$	Quantity of natural gas combusted in all element processes during the year *y* in m³
$EF_{CO_2,upstream,LNG}$	Emission factor for upstream CO2 emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, regasification and compression of LNG into a natural gas transmission or distribution system

CALCULATION OF THE EMISSION REDUCTIONS

The GHG emission reductions resulting from the project activity in the year y (ER_y) are calculated as in the equation below:

$$ER_y = BE_y - PE_y - LE_y \quad (29)$$

Where:

BE_y	Emissions in the baseline scenario for the year y. Calculated as in the equation given above.
PE_y	Emissions resulting from the project activity in the year y. Calculated as in the equation given above.
LE_y	Net leakage emissions resulting from the implementation and operation of the project activity. Calculated as in the equation given above.

The project proponent, who applies the new VCS methodology, should provide evidences for the figures applied and used in the excel work sheets in order to be able to fully retrace the assumptions and calculations made to determine the emissions reductions.

Data and parameters not monitored:

Data/parameter:	$SC_{BL,j,y}$
Data unit:	TJ
Description:	The amount of energy consumed in the form of steam by the project customer i, which is supplied by the project facility “j” in year y.
Source of data:	Calculated on the basis of the steam generation and the data for the steam enthalpy.

Measurement procedures (if any):	If applicable, energy content of steam can be directly measured.
QA/QC procedures	
Any comment:	-
Uncertainty level	Low: this parameter is calculated from variables which are monitored and subject to their own QA/QC procedures ($SP_{BL,j,y}$ and $SDEN_{BL,j,y}$). Alternatively, this could be measured by a heat meter, calibrated also following the QA/QC procedures applied in the data and parameters to be monitored section, which is similar also to that applied in other CDM approved methodologies such as AM0048.

Data/parameter:	$SEF_{BL,i,y}$
Data unit:	t CO_2/TJ
Description:	The baseline emission factor for the production of steam in project customer i for year y.
Source of data:	Actual performance data that is publicly available will be used for purpose. Otherwise, the project proponent may resort to historical data for the three most recent years for which data is available.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: two options are given in the meth to determine SEF: Option I.A., based on publicly available energy performance data on the amount of energy produced in the form of steam and energy consumed to produce it. The uncertainty level is in theory dependent mostly upon the how the amount of fossil fuel energy consumed is determined, namely $HEC_{BL,FF,st,i,y}$. The uncertainty level of this parameter is in turn considered to be low per se, and two options are given in turn to determine it as discussed in the table for $HEC_{BL,FF,st,i,y}$ Option I.B, based on default values and varying degrees of condensate recovery percentages with respect to the total amount of steam generated. Hence, the uncertainty level in this option is dependent primarily on how the fraction of heat recovered in the form of condensate is determined. This option relies on the use of efficiency values which are taken conservatively as those of the steam generating facilities of the project customers. It assumes that there are no transmission losses

	of heat. Such assumptions lead to a highly conservative estimate for the specific emissions because it assumes that once steam is generated from the boilers, there is no further loss of energy until the point of use. In practice, heat losses due to transmission tend to be of the order of 10%. The fossil fuel that needs to be burned to make up for these losses is ignored in our calculations, and this we feel is more than sufficient to compensate for even uncertainties, which as discussed we feel are low anyhow. Furthermore, all the options used to estimate the amount of energy recovered from the condensate that is formed assume that there are no condensate, nor heat losses between the point of condensate formation and entrance to the condensate recovery tank. This of course is highly conservative per se. There are two options given to determine Xc depending upon the availability of historical and actual data for quantity of condensate recovered and sent to the boiler house and condensate conditions of temperature and pressure. Where actual data is used, the maximum historical values are assumed, thereby assuming maximum energy recovery. The second option involves the use of default factors and requires annual verification to be carried out that the no changes have occurred that warrant a change in the applied default value.

Data/parameter:	$HEC_{BL,FF,st,i,y}$
Data unit:	TJ
Description:	The energy associated with the fossil fuel that was consumed by the project customer "i" during year y
Source of data:	Calculated on the basis of actual fuel consumption data that is publicly available.
Measurement procedures (if any):	-
QA/QC procedures	Ensure suitable standards for determining efficiency are applied if parameter is not determined from public sources. Check consistency with previously derived values and equipment design efficiency values
Any comment:	
Uncertainty level	There are two options given to determine $SEF_{BL,i,y}$, one based on a publicly reported data (Option 1 A) and the other based on default values (Option 1 B). Option 1A. The uncertainty level is considered to be low for this option if the central heating plant has to publicly report it heat production and fuel consumption figures to energy regulators. However if the central generating facility has only to report publicly its heat production figures and not its fossil fuel consumption ones, then in this case the uncertainty is potentially

	higher and additional measures need to be in place to ensure a low level of uncertainty. The methodology offers two alternatives to determine what the fossil energy consumption may be: Option I.A.a, which is based on publicly reported fuel consumption figures and fuel properties, which can be obtained from fuel suppliers, and which therefore is considered to be of low uncertainty Option I.A.b is based on the actual heat or steam production figures and conditions of boiler feedwater and steam, and the efficiency of the steam generating system. The efficiency of the steam generating equipment enables the project proponent to apply four options, each of which are more conservative than the other. Three of those options are: the manufacturer's quoted peak boiler efficiency, efficiencies of boilers of similar design, or a default value of 100% efficiency. The uncertainty level of these is low. The forth option is based on peak measured efficiencies, but this must be carried out by applying the standard procedures for boiler efficiency determinations. The use of a standard method, which relies on calibrated equipment and involves applying the highest value obtained over a full load range text in our opinion lead to a low level of uncertainty in the determination of the boiler efficiency in the event this option were to be applied. Option I B, which does not rely on reported energy production and consumption data but rather relies on similar boiler efficiency options given above. It offers an even lower uncertainty level In both cases above heat losses throughout the transmission system are ignored. Heat losses in steam transmission alone can amount to 5 – 10 % , and sometime even more in old systems, of energy produced by the generating facility. The calculations in the meth assume zero losses, and thus fuel to steam efficiency is significantly higher than what is in typical. Hence, the extra fossil fuel that needs to be burned to make up for these losses is not considered for the purpose of determining the amount of fossil fuel energy supplied to the steam generating facilities. This leads to a lower CO_2 emissions factor per unit energy of steam produced that will be the case in reality.

Data/parameter:	$HSC_{BL,i,y}$
Data unit:	TJ
Description:	The amount of energy contained in the steam which was generated by the customer i by burning fossil fuel during year y

Source of data:	Actual data that is publicly available will be used for purpose, or calculated using measured data (quantity of stem produced by customer i or the facility that supplies steam to customer i.
Measurement procedures (if any):	-
QA/QC procedures	Check for consistency with historical values if option involving the use of measured data is applied.
Any comment:	
Uncertainty level	Low: this data is publicly available and presented to energy authorities and the result of heat supplied to customers, or optional derived from monitored parameters subject to common QA/QC applied to measure similar parameters

Data/parameter:	$HFC_{BL,FF,st,i,y}$
Data unit:	tonnes
Description:	The quantity of fossil fuel consumed for steam generation by project customer i during year y.
Source of data:	Actual data that is publicly available will be used for this purpose.
Measurement procedures (if any):	-
QA/QC procedures	
Any comment:	
Uncertainty level	Low: if this is provided by the supplier of the steam as part of its duty to report this consumption to outside stakeholders. Data can also be crosschecked against historical data and compared to the amount of heat produced in the form of steam and supplied to the customers.

Data/parameter:	$\eta_{BL,st,i}$
Data unit:	**%**
Description:	Project customer i's boiler efficiency based on NCV (in %).
Source of data:	The highest measured value of boiler efficiency recorded over full range boiler test; the boiler's peak thermal efficiency as per manufacturer's information or a default boiler efficiency of 100%;
Measurement procedures (if any):	Full range boiler test if applicable
QA/QC procedures	Ensure suitable standards for determining efficiency are applied if relevant to the option chosen. Check consistency with similarly derived historical values and equipment design efficiency values
Any comment:	
Uncertainty level	Low: even in the case in which boiler efficiency is determined based measurements, these have to be done according to acceptable standards. It also involves taking the highest value of a full boiler efficiency load test which leads to a conservative determination of efficiency under this option. The remaining

	options involve an even higher degree of efficiency and to do not rely on any measured data, but rather on published data or very high conservative assumptions for boiler efficiency.

Data/parameter:	$HWC_{BL,j,y}$
Data unit:	TJ
Description:	The energy content in the hot water produced by the project facility j, which is purchased by project customer i in year y
Source of data:	If applicable, energy content of hot water can be directly measured.
Measurement procedures (if any):	-
QA/QC procedures	Where applicable meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data. Crosscheck with invoices at project facility site
Any comment:	
Uncertainty level	Low: determined using QA/QC procedures commonly used in the CDM to temperature measurements.

Data/parameter:	$HWEF_{BL,i,y}$
Data unit:	t CO_2/TJ
Description:	The CO_2 emissions factor for the hot water produced in year y.
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: based partly on publicly reported data for heat production and fossil fuel consumption required to comply with energy legislation, or if applicable based on conservative and low level of uncertainty values of efficiency and publicly reported heat production figures, or in the absence of these on default values of low uncertainty level.

Data/parameter:	$HEC_{BL,FF,hwb,i,y}$
Data unit:	TJ
Description:	The energy associated with the fossil fuel consumed by customer i to self-generate hot water in a hot water boiler during year y.
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	

Uncertainty level	Low: same as for $HEC_{BL,FF,st,i,y}$ given above.

Data/parameter:	$HHWC_{BL,hwb,i,y}$
Data unit:	TJ
Description:	The energy contained in the hot water, which was generated by the customer i from burning fossil fuel during year y.
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: this data is publicly available and presented to energy authorities and the result of heat supplied to customers

Data/parameter:	$HFC_{BL,FF,hwb,i,y}$
Data unit:	tonnes
Description:	The quantity of fossil fuel consumed for hot water generation in hot water boilers by project customer i during year y. This can be reported as mass units of the baseline fuel or in units of volume if data is provided on the mass density of the natural gas used (in tonnes)
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	- .
Any comment:	
Uncertainty level	Low: if this is provided by the supplier of the hot water as part of its duty to report this consumption to outside stakeholders. Data can also be crosschecked against historical data and compared to the amount of heat produced in the form of steam and supplied to the customers.

Data/parameter:	$\eta_{BL,hwb,i}$
Data unit:	
Description:	Project customer i's hot water boiler's efficiency based on NCV.
Source of data:	The highest measured value of boiler efficiency recorded over full range boiler test; the boiler's peak thermal efficiency as per manufacturer's information or a default boiler efficiency of 100%
Measurement procedures (if any):	A full range boiler test if applicable.
QA/QC procedures	Ensure suitable standards for determining efficiency are applied if relevant to the option chosen. Check consistency with similarly derived historical values and equipment design efficiency values
Any comment:	

Uncertainty level	Low: even in the case in which boiler efficiency is determined based measurements, these have to be done according to acceptable standards. It also involves taking the highest value of a full boiler efficiency load test which leads to a conservative determination of efficiency under this option. The remaining options involve an even higher degree of efficiency and to do not rely on any measured data, but rather on published data or very high conservative assumptions for boiler efficiency.

Data/parameter:	$HHWC_{BL,sthx,i,y}$
Data unit:	TJ
Description:	The energy contained in hot water self generated by project customer i from steam, in a steam-to-water heat exchanger (in TJ) during year y.
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: if this data is publicly available and presented to energy authorities and the result of heat supplied to customers.

Data/parameter:	$HHWP_{BL,sthx,i,y}$
Data unit:	tonnes
Description:	The mass of hot water self-generated by the project customer i by steam-to-water heat exchanger during year y.
Source of data:	Actual data that is publicly available will be used for purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: this data is publicly available and presented to energy authorities and quantifies the result of heat supplied to customers.

Data/parameter:	$HFC_{BL,st,stbx,i,y}$
Data unit:	tonnes
Description:	Quantity of steam consumed by the project customer for hot water production during year y.
Source of data:	Actual data that is publicly available will be used for this purpose.
Measurement procedures (if any):	-
QA/QC procedures	-
Any comment:	
Uncertainty level	Low: this data is publicly available and presented to energy

	authorities and quantifies the result of heat supplied to customers.

Data/parameter:	$\eta_{BL,sthx,i}$
Data unit:	
Description:	customer i's (in %) steam-to-water exchanger efficiency based on one of the following
Source of data:	The highest measured annual value of heat exchanger efficiency; the design heat exchanger efficiency or a default heat exchanger efficiency of 100%.
Measurement procedures (if any):	-
QA/QC procedures	Ensure suitable standards for determining efficiency are applied if relevant to the option chosen. Check consistency with similarly derived historical values and equipment design efficiency values if applicable.
Any comment:	
Uncertainty level	Low: provided suitable tests are conducted. Low: if any default value is chosen.

MONITORING METHODOLOGY

Monitoring procedures

Data for carbon content of fuel sources may be taken from IPCC. In the event that more recent or accurate scientific studies are produced and approved by the UNFCCC these data shall be used.

Official electricity generation and transmission company statistics is used to determine the grid electricity coefficient. This data is gathered from the utilities, whether on the national, regional or local level, as appropriate.

It is assumed that the data provided for the electricity grid and from individual facilities are available and transparent, in order to calculate the carbon coefficient of the electricity and steam and or hot water being displaced from project customers by the project activity.

Vintage and spatial level of data: the data is gathered on a national or regional power grid level to determine the combined margin.

As for the vintage of the data, the project developer should try and get three years of data prior to project implementation where to required in the baseline methodology. If three years of data is not available, then the project developer must use at least one complete year (two when it exists) and must demonstrate using evidence from credible sources to the DOE that additional data does not exist. Non-representative data is included unless there is a major outlying event. Should the project developer wish to exclude non-representative data they must be able to document why this is removed and this should be approved during validation.

When IPCC data is available, project proponents shall take into consideration that the Board agreed that the IPCC default values should be used only when country or project specific data are not available or difficult to obtain.

The project developer will have to ensure the completeness and accuracy of the data set during the baseline measurement year by installing, repairing, and calibrating meters as appropriate. Completeness/accuracy of data should be relatively easy to verify, and emissions reductions will not be included if the evidence does not demonstrate this point clearly. The project developer should obtain data on metering in the project and try and ascertain that the meter accuracy is 95% or greater – and that quality control procedures are in place to deal with defective meters and/or recalibrate them on a regular basis.

The project proponent shall also provided simplified diagrams illustrating the location of the monitoring points.

Data and parameters monitored

Data/parameter:	$EG_{P,y}$
Data unit:	MWh
Description:	Net electricity supplied to the power grid by the proposed project facility ‘j’ in year ‘y’(MWh/yr).
Source of data:	Electricity meter at the project facility ‘j’
Measurement procedures (if any):	Read electricity meter and store information until 2 years after the end of the crediting period.
Monitoring frequency	Monthly
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data. Crosscheck with invoices and electricity supply data at project facility site.
Any comment:	
Uncertainty level	Low, it follows QA/QC procedures and monitoring frequencies which are common to other CDM Monitoring methodologies such as AM0048

Data/parameter:	$CEF_{BL/P,FF,y}$
Data unit:	t C/TJ
Description:	Carbon emission factor corresponding to the fossil fuel used to produce steam or hot water as applicable. Carbon emission factor in year y corresponding to fossil fuel used by project customer i to generate steam/hot water or that which is used in a given steam/hot water generating plant to produce the steam/hot water which is sourced by the project customer i (in tonnes of C/TJ), shall be determined from the technical literature, from the project customer i, or the steam/hot water generating plant which supplies steam/hot water to the project customer i.
Source of data:	Obtained from the project customer ‘i’ / project facility ‘j’ or technical literature.
Measurement procedures (if any):	When IPCC data is available, project proponents shall take into consideration that the Board agreed that the IPCC default values should be used only when country or project specific data are not available or difficult to obtain.
Monitoring frequency	-
QA/QC procedures	-
Any comment:	-

Uncertainty level	Low, given external sources that provide it (fuel suppliers/government bodies, IPCC)

Data/parameter:	$EF_{BL,CO_2,y}$
Data unit:	t CO_2/MWh
Description:	Emission factor of the electricity grid to which the project facility "j" supplies the electricity generated. Determination of the emission factor will be made once at the validation stage based on an ex ante assessment, and once again at the start of each subsequent crediting period (if applicable). Regardless of whether option 1 (BM) or option 2 (CM) is chosen, the emission factor is also calculated ex-post as described in the "Tool to calculate emission factor for an electricity system".
Source of data:	Publicly available data on electricity generation within the respective power grid.
Measurement procedures (if any):	
Monitoring frequency	Calculated ex-post each year.
QA/QC procedures	As per "Tool to calculate emission factor for an electricity system"
Any comment:	-
Uncertainty level	Low, the data upon which the parameter is determined is obtained for official electricity sector statistics whilst the treatment of the data to the determine the parameter uses an approved CDM tool

Data/parameter:	$EF_{NG,upstream,CH_4}$
Data unit:	t CH_4/TJ
Description:	Emission factor for upstream fugitive methane emissions from production, transportation and distribution of natural gas.
Source of data:	Obtained from the project facility 'j' or table in the leakage section.
Measurement procedures (if any):	When IPCC data is available, project proponents shall take into consideration that the Board agreed that the IPCC default values should be used only when country or project specific data are not available or difficult to obtain.
Monitoring frequency	-
QA/QC procedures	-
Any comment:	-
Uncertainty level	Low, the source is an official third party (IPCC) or a host country official source

Data/parameter:	$EF_{CO_2,upstream,LNG}$
Data unit:	tCO_2/TJ

Description:	Emission factor for upstream CO_2 emissions due to fossil fuel combustion/electricity consumption associated with the liquefaction, transportation, regasification and compression of LNG into a natural gas transmission or distribution system
Source of data:	Where reliable and accurate data on upstream CO_2 emissions due to fossil fuel combustion / electricity consumption associated with the liquefaction, transportation, re-gasification and compression of LNG into a natural gas transmission or distribution system is available, project participants should use this data to determine an average emission factor. Where such data is not available, project participants may assume a default value of 6 tCO_2/TJ as a rough approximation
Measurement procedures (if any):	When IPCC data is available, project proponents shall take into consideration that the Board agreed that the IPCC default values should be used only when country or project specific data are not available or difficult to obtain.
Monitoring frequency	-
QA/QC procedures	-
Any comment:	-
Uncertainty level	Low, the source is an official third party (IPCC) or a host country official source

Data/parameter:	$SDEN_{BL,j,y}$
Data unit:	TJ/tonne
Description:	Specific enthalpy of steam leaving the project facility 'j' (in TJ/tonne of steam supplied).
Source of data:	This data shall be obtained from steam tables, using temperatures and pressure of the steam purchased.
Measurement procedures (if any):	Use monitored pressure and temperature of the steam to obtain specific enthalpy from steam tables.
Monitoring frequency	Monthly
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	-
Uncertainty level	Low, parameter is obtained from temperature and pressure data that is monitored and subject to QA/QC procedures applied in CDM monitoring methodologies such as AM0048 and AM0029, and publicly available steam tables

Data/parameter:	Steam temperature
Data unit:	°C
Description:	Temperature of steam purchased by project customer 'i'.

Source of data:	Temperature meters at project facility ‘j’
Measurement procedures (if any):	Read temperature meter daily and calculate monthly average. Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurements and monthly average.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	-
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures applied in CDM monitoring methodologies such as AM0048

Data/parameter:	Steam pressure
Data unit:	MPa
Description:	Pressure of steam purchased by project customer ‘i’.
Source of data:	Pressure meters at project facility ‘j’
Measurement procedures (if any):	Read pressure meter daily and calculate monthly average. Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurements and monthly average.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	-
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures applied in CDM monitoring methodologies such as AM0048

Data/parameter:	$FC_{NG,P,y}$
Data unit:	Tonnes or m^3
Description:	Natural gas consumed within the boundary of the project facility (in tonnes/normal m^3) in the year y.
Source of data:	Purchase records and fuel data logs.
Measurement procedures (if any):	Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurement and monthly recorded.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data. Crosscheck with purchase records.
Any comment:	-
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures applied in CDM monitoring methodologies such as AM0029

Data/parameter:	GWP_{CH_4}
Data unit:	tCO_2/tCH_4
Description:	Global warming potential of CH_4 valid for the commitment period. Obtained from IPCC.
Source of data:	-
Measurement procedures (if any):	-
Monitoring frequency	-
QA/QC procedures	-
Any comment:	-
Uncertainty level	Low, given external source that provides it (IPCC)

Data/parameter:	NCV_{NG} / $NCV_{FF,i,y}$
Data unit:	TJ/t
Description:	Lower heating value of the natural gas/fossil fuel combusted (in TJ/t or TJ/10^3 normal m^3).
Source of data:	As per purchase certificates or IPCC default data.
Measurement procedures (if any):	-
Monitoring frequency	-
QA/QC procedures	-
Any comment:	-
Uncertainty level	Low, the source is a credible host country source such as the fuel supplier of an third part source such as the IPCC.

Data/parameter:	$HWEN_{BL,j,y}$
Data unit:	TJ/tonne
Description:	The specific enthalpy of hot water produced by the project facility j in the year y (TJ/ tonne).
Source of data:	This data shall be obtained using temperature of the hot water purchased measured at the project facility 'j' using data from the steam tables.
Measurement procedures (if any):	Use monitored temperature of the hot water produced by the project facility 'j' to obtain specific enthalpy.
Monitoring frequency	Monthly
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	If heat meter is available, separate temperature readings are not

	required.
Uncertainty level	Low, provided the given QA/QC procedures and monitoring frequencies are adhered to. Where the parameter is determined based on measured temperature the enthalpy is determined from steam tables. Hence uncertainty is also low.

Data/parameter:	Hot water temperature
Data unit:	°C
Description:	Temperature of hot water purchased by project customer 'i'.
Source of data:	Temperature meters at project facility 'j'.
Measurement procedures (if any):	Read temperature meter daily and calculate monthly average. Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurements and monthly average.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	-
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures and monitoring frequency applied in CDM monitoring methodologies such as AM0048 to similar variables

Data/parameter:	Water return temperature
Data unit:	°C
Description:	Temperature of warm water returned to hot water generating facility.
Source of data:	Temperature meters at project facility 'j'.
Measurement procedures (if any):	Read temperature meter daily and calculate monthly average. Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurements and monthly average.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	To be applied when using Option II.A.b.
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures and monitoring frequency applied in CDM monitoring methodologies such as AM0048 to similar variables

Data/parameter:	Steam condensate temperature
Data unit:	°C
Description:	Temperature of condensate from existing heat exchanger used by customer 'i ' to produce hot water or by the supplier of hot water

	to customer i
Source of data:	Temperature meters
Measurement procedures (if any):	Store information until 2 years after the end of the crediting period.
Monitoring frequency	Daily measurements and monthly average.
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data.
Any comment:	To be used when applying Option II.B.a.i
Uncertainty level	Low, parameter is monitored and subject to QA/QC procedures and monitoring frequency applied in CDM monitoring methodologies such as AM0048 to similar variables. Where defaults are used, the validity of these defaults is verified annually to determine if significant changes have been made to operating conditions (pressure) of the condensate system or if flash steam recovery system is added or it operating pressure increased.

Data/parameter:	$HWP_{BL,j,y}$
Data unit:	tonnes/yr
Description:	The amount of hot water produced by project facility ‘j’ and supplied to project customer ‘i’ in the year y (in tonnes)
Source of data:	Measured at the project facility ‘j’.
Measurement procedures (if any):	Read hot water meter and store information until 2 years after the end of the crediting period.
Monitoring frequency	Monthly
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data. Crosscheck with purchase receipts and hot water supply data at project site.
Any comment:	-
Uncertainty level	Low, the parameter is monitored and subject to QA/QC procedures which are common to those demanded in other CDM methodologies such as AM0029 and AM0048. It can be cross checked with billing information

Data/parameter:	$SP_{BL,j,y}$
Data unit:	tonnes/yr
Description:	Quantity of steam produced by the project facility ‘j’ and supplied to the project customer ‘i’ in the year y, (in tonnes)
Source of data:	Measured at the project facility ‘j’.
Measurement procedures (if any):	Read steam meter and store information until 2 years after the end of the crediting period.

Monitoring frequency	Monthly
QA/QC procedures	Meters shall be calibrated as per their data book. Measuring conditions shall be as per meters data book. Check consistency with historical monitored data. Crosscheck with invoices and steam supply data at project site.
Any comment:	-
Uncertainty level	Low, the parameter is monitored and subject to QA/QC procedures which are common to those demanded in other CDM methodologies such as AM0029 and AM0048. It can be cross checked with billing information

GUIDANCE TO THE APPLICATION OF THE METHODOLOGY AND THE PREPARATION OF THE VCS PROJECT DESCRIPTION

1. Project location including geographic and physical information allowing the unique identification and delineation of the specific extent of the project should be provided in the PDD.

2. In line with the requirements of the VCS PD format, the project proponent, who applies the new VCS methodology, should provide a detailed description of:

(a)The scenario existing prior to the start of the implementation of the project activity, with a list of the equipment(s) and systems in operation at that time;

(b) The scope of activities/measures that are being implemented within the project activity, with a list of the equipment(s) and systems that will be installed and/or modified within the project activity/activities.

The project implementation schedule (precise schedule of works) should be described in detail with indication of the current status. Project proponents should indicate the source for the technical data provided in the PDD.

3. The technical specifications of the equipment installed at the site of the project activity should be disclosed together with the consumption of fuel, electricity, net calorific value of the fuel used together with detailed information on quality and quantity of heat and power generated.

4. When designing the monitoring plan in the VCS PD the project proponent should provide where possible an organigram illustrating the monitoring and reporting system organizational structure. Where possible, names of the staff with monitoring and reporting functions should be included in the PD.

5. The project proponent who applies the VCS methodology should describe how staff responsible for monitoring, recording and maintenance and calibration of monitoring equipment shall be trained.

6. Project emissions which are not addressed in the new methodology shall be calculated and compared with 1% of the overall average annual emissions reductions. They can only be excluded from further analysis they represent less than 1% of the total expected emission reductions."

7. In cases where the project activity results in the decommissioning of a steam and/or hot water generating facility at the project customer's site, the project proponent shall describe if there is any possibility that this may result in leakage. If it is deemed that leakage may occur, then the project proponent shall describe a means of estimating in a conservative manner what such leakage may be.

If however it is argued that the project activity results in the replacement of equipment and that the leakage due to the use of the replaced equipment in another activity can be neglected because the replaced equipment is scrapped, then an independent monitoring of the scrapping of the replaced equipment shall be implemented. The monitoring should include a check to ensure that the name plate of the equipment scrapped corresponds to that which has been replaced. For this purpose, scrapped equipment should be stored until such correspondence has been checked. The scrapping of replaced equipment should be documented and independently verified.

Approved VCS Methodology

VM0003

Version 1.2

29 August 2013

Sectoral Scope 14

Methodology for Improved Forest Management Through Extension of Rotation Age (IFM ERA)

Methodology developed by:

ecotrust

721 NW Ninth Ave, Suite 200
Portland, OR 97209
www.ecotrust.org

Table of Contents

1 SOURCES

This methodology is based on elements from the following methodologies:

- AR-ACM0001 *Afforestation and reforestation of degraded land*
- The *Combined tool to identify the baseline scenario and demonstrate additionality in A/R CDM project activities*

This methodology also refers to the latest approved versions of the following tools:

- The CDM Additionality Tests (available at: http://cdm.unfccc.int/methodologies/PAmethodologies/tools/am-tool-01-v5.2.pdf)
- The UNFCCC *Tool for testing significance of GHG emissions in A/R project activities* (available at: http://cdm.unfccc.int/methodologies/ARmethodologies/tools/ar-am-tool-04-v1.pdf)
- The UNFCCC tool for the *Calculation of the number of sample plots for measurements within A/R CDM project activities* (available at: http://cdm.unfccc.int/methodologies/ARmethodologies/tools/ar-am-tool-03-v2.pdf)

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology quantifies the GHG emission reductions and removals generated from improving forest management practices to increase the carbon stock on land by extending the rotation age of a forest or patch of forest before harvesting. By extending the age at which trees are cut, projects increase the average carbon stock on the land and remove more emissions from the atmosphere.

3 DEFINITIONS

Terms

Clear Cut: The harvest of all trees in an area

Logging Slash: Branches, other dead wood residues, and foliage left on the forest floor after timber removal

Patch Cut: A clear cut on a small area (less than one hectare)

Seed Tree: A variant system on clear cut with limited mature trees being left to provide seeds for regeneration

Group Selection: A variant on clear cut with groups of trees being left for wildlife habitat, wind firmness, soil retention or other silvicultural goals

Tree: A perennial woody plant with a diameter at breast height > 5 cm and a height greater than 1.3 m.

List of acronyms

A/R	Afforestation/Reforestation (under CDM)
AFOLU Guidelines	Agriculture, Forestry and Other Land Uses section of the IPCC Guidelines for National Greenhouse Gas Inventories 2006.
CDM	Clean Development Mechanism
GPG LULUCF	Intergovernmental Panel on Climate Change's Good Practice Guidance for Land-Use Land Use Change and Forestry
IFM	Improved forest management
VCS	Verified Carbon Standard
VCU	Verified Carbon Unit
FSC	Forest Stewardship Council

4 APPLICABILITY CONDITIONS

This methodology is applicable to Improved Forest Management (IFM) project activities that involve an extension in rotation age (ERA).

The conditions under which the methodology is applicable are:

- Forest management in both the baseline and project scenariot involves harvesting techniques such as clear cuts, patch cuts, seed tree, continuous thinning or group selection practices.
- Forests which are not subject to timber harvesting, or managed without an objective for earning revenue through timber harvesting in the baseline scenario are not eligible under this methodology.
- Forests must be certified by the Forest Stewardship Council (FSC) by the start of the project crediting period. FSC certification must be demonstrated no later than at the time of the first verification event.
- Project proponents must define the minimum project length in their project description document.
- The project does not encompass managed peat forests and the proportion of wetlands are not expected to change as part of the project
- Project proponents must have a projection of management practices in both with and without project scenarios.
- If fire is used as part of forest management then fire control measures, such as installation of fire-breaks or back-burning, must be taken to ensure fire does not spread outside the project area—that is, no biomass burning must be permitted to occur beyond the project area due to forest management activities.
- There may be no leakage through activity shifting to other lands owned or managed by project proponents outside the bounds of the project area.

5 PROJECT BOUNDARY

5.1 GHG Sources and Sinks

The carbon pools included in or excluded from the project boundary are shown in Table 1.

Table 1: Selected Carbon Pools

Carbon pools	Selected (Yes or No)	Justification / Explanation of choice
Above-ground biomass	Yes	Major carbon pool subjected to the project activity.
Below-ground biomass	Yes	Below-ground biomass stock is expected to increase due to the implementation of the VCS IFM project activity. Belowground biomass subsequent to harvest is not assessed with the conservative assumption of immediate emission.
Dead wood	Conditional	Dead wood stocks can be conservatively excluded UNLESS the project scenario produces greater levels of slash than the baseline AND slash is burned as part of forest management. If slash produced in the project case is left in the forest to become part of the dead wood pool, dead wood may be conservatively excluded. Alternatively, project proponents may elect to include the pool (where included the pool must be estimated in both the baseline and with project cases) as long as the dead wood pool represents less than 50% of total carbon volume on the site in any given modeled year.
Litter	No	Changes in the litter pool will be *de minimis* as a result of rotation extension.
Soil organic carbon	No	Changes in the soil organic carbon pool will be *de minimis* as a result of rotation extension.

Wood products	Conditional	This stock may increase or decrease (when compared to baseline) due to implementation of the project activity. The methodology provides an approach for accounting for this pool, but it allows also for exclusion of the wood products pool if transparent and verifiable information can be provided that carbon stocks in wood products are rising faster in the project case than in the baseline or are decreasing faster in the baseline than in the project case.

The emission sources included in or excluded from the project boundary area shown in Table 2. Any one of these sources can be neglected, ie, accounted as zero, if the application of the most recent UNFCCC CDM *Tool for testing significance of GHG emissions in A/R project activities* (see section 10 References) leads to the conclusion that the emission source is insignificant.

Table 2: Emissions sources included in the project boundary

Sources	Gas	Included / Excluded	Justification / Explanation of choice
Burning of biomass	CO_2	Excluded	However, carbon stock decreases due to burning are accounted as a carbon stock change
	CH_4	Included	Non-CO_2 gas emitted from biomass burning
	N_2O	Excluded	Potential emissions are negligibly small

Following the guidance of the Executive Board of the CDM, emissions caused by combustion of fossil fuels and through the use of fertilizers are considered insignificant and are not considered here (UNFCCC CDM EB 44, UNFCCC CDM EB 42).

5.2 Project area and eligibility of land

The project area geographically delineates the improved forest management project activity under the control of the project proponents. The IFM project activity may contain more than one discrete area of land. At the time the project description is validated, the following must be defined:

- Each discrete area of land must have a unique geographic identification;
- Aggregation of forest properties with multiple landowners is permitted under the methodology with aggregated areas treated as a single project area;
- The project proponents must describe legal title to the forest, rights of access to the sequestered carbon (or avoided carbon emissions), current land tenure, and forest management for each discrete area of forest;

- The project proponents must justify that, during the project lifetime, each discrete area of land is expected to be subject to a change in forest management through activities under the control of the project proponents.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

6.1 Selected Baseline Approach

“Changes in carbon stocks in the pools within the project boundary from the most likely land use at the time the project starts”.

6.2 Preliminary screening based on the starting date of the IFM project activity

In accordance to the *VCS Standard v3*, or latest version, the start date for AFOLU projects can be earlier than 1 January 2002, provided that project validation and verification against the VCS has been completed by 1 October 2011, the project proponent can verifiably demonstrate that it had been designed and implemented as a climate change mitigation project from its inception, and that prior to 1 January 2002 the project engaged independent verifiers/monitoring experts and applied methodologies that now conform to this VCS-approved methodology to assess and quantify the project’s baseline scenario, leakage and net emissions reductions/removals.

If the project proponents claim that the start date of the IFM project activity is before the date of validation, then the project proponents must:

- Provide evidence that the starting date of the IFM project activity was after 1 January 2002, and
- Provide evidence that the incentive from the planned sale of VCUs was seriously considered in the decision to proceed with the project activity. This evidence must be based on (preferably official, legal and/or other corporate) documentation that was available to third parties at, or prior to, the start of the project activity.

6.3 Determination of Baseline Scenario

Step 1a. Identify credible alternative forest management scenarios to the proposed VCS project activity

As per the applicability conditions the project must demonstrate a baseline that involves clear cut, patch cut, seed tree, continuous thinning or group selection forest management techniques, using such evidence as management plans, forest inventories, assessments by reputable forestry consultants, the common practice of alternative land owners and common practice in the region. If such a baseline cannot be demonstrated then this methodology cannot be applied. Baseline scenarios with no timber harvesting or management without a timber revenue objective must be excluded as per the methodology applicability conditions.

Identify realistic and credible land-use scenarios that would have occurred on the land within the proposed project area in the absence of the IFM project activity under the VCS.[1] The scenario should be feasible for the project

[1] For example, continuation of the pre-project land-use or switch to land-use typical for region where the IFM project is planned

proponents or similar project proponents taking into account relevant national and/or sectoral policies[2] and circumstances, such as historical land uses, practices and economic trends. The identified land use scenario must be limited to forested land uses. This process should clearly identify barriers and benefits of all potential scenarios.

The possible land-use scenarios to be evaluated must include:

- Continuation of the pre-project forest management (Historical Baseline),
- Legal requirements for forest management in the region (Legal Baseline),
- Common practice forest management in the region (Common Practice Baseline), and
- Forest management as modeled under the project but in the absence of registration as an IFM project activity.

For identifying realistic and credible land-use scenarios, land use records, field surveys, data and feedback from stakeholders, and information from other appropriate sources, including Participatory Rural Appraisal (PRA)[3] may be used as appropriate. All current land uses within the boundary of the proposed IFM project activity may be deemed realistic and credible.

Project proponents should use the following guidelines to define these possible land-use scenarios.

Guidance for Defining the Legal Baseline

The Legal Baseline is defined by the forest management scenario that maximizes net present value to the forest owner(s) through timber harvesting while reflecting all legal requirements for forest management. In many cases, the specific management practices defined by the project proponent in the Legal Baseline may not be explicitly addressed in the relevant forest practices regulations, and the legality and plausibility of these practices must be confirmed by an independent forest consulting entity.

Guidance for Defining the Common Practice Baseline

Common practice in the project region must be defined by an independent forest consulting entity and should consider the following elements of forest management:

1) Harvest rotations,

---

to be located, establishing agricultural plantation, tourist resort, hunting area/farm, utilizing regionally typical forms of funds investment or other economically attractive activities.

[2] The Annex 3 to the report of the EB at its twenty-second meeting and the Annex 19 to the report of the EB at its twenty-third meeting clarify how the relevant national and/or sectoral policies must be taken into account during identification of a baseline scenario. See: http://cdm.unfccc.int/Reference/Guidclarif.

[3] Participatory rural appraisal (PRA) is an approach to the analysis of local problems and the formulation of tentative solutions with local stakeholders. It makes use of a wide range of visualisation methods for group-based analysis to deal with spatial and temporal aspects of social and environmental problems. This methodology is, for example, described in:

- Chambers R (1992): Rural Appraisal: Rapid, Relaxed, and Participatory. Discussion Paper 311, Institute of Development Studies, Sussex.
- Theis J, Grady H (1991): Participatory rapid appraisal for community development. Save the Children Fund, London.

2) Harvest methods,
3) Species harvested and planted,
4) No harvest zones,
5) Riparian management areas,
6) Areas of steep slope or unstable soils, and/or
7) Maximum patch cut areas.

Step 1b. Selection of a single baseline forest management scenario

IFM project proponents must evaluate the identified plausible baseline management regimes relative to:

- A documented history of the operator (eg, operator must have at least 20 years of management records to show normal historical practices). Common records to document history include data on timber cruise volumes, inventory levels, harvest levels, etc. on the property;
- The legal requirements for forest management and land use in the area; and,
- A common practice standard among similar landowners in the area.

In all cases these three scenarios must be described by the project proponent, then reviewed, and approved as plausible and accurate by an independent forest consulting entity. Requirements for forest consultant qualifications will vary by region, however, the verifier should consider the following elements when reviewing consultant qualifications:

1) In those regions where a legally recognized certified forester designation exists, the forest consulting entity must have that designation
2) In those areas where there are no legal certified forester designations, the consultant must have either:
    a. Accreditation under a widely recognized elective accreditation program that grants “certified forester” designation (eg, Society of American Foresters); or,
    b. Publicly filed management plans or harvest plans that demonstrate the participation of the consulting entity and their qualifications to review the required documentation. The alternative/land use scenario that is not prevented by any barrier or is the most financially viable must be identified as the baseline scenario.

IFM project proponents should use the following guidelines to select the most plausible baseline scenario to be modeled.

Historical Baseline

The Historical Baseline must be selected as the most plausible baseline scenario if the following documents exist for the forest property:

1) Historical records of forest management exist for 20 or more years preceding the project start date.

2) Historical records indicate that the management practices have surpassed the legal barriers provided by conforming with all local and regional forest legislation.

3) Historical records that indicate that the historical management surpasses financial barriers by providing above average market returns.[4]

If these documents do not exist, the project must be developed using the Legal or Common Practice Baselines.

Legal Baseline

If the Historical Baseline is not applicable based on the criteria above, the Legal Baseline must be selected as the most plausible baseline scenario if regulations of forest management practices exist and are readily enforced within the project region.

Regulations and/or other legally-binding restrictions on forest management must pertain to specific forest management practices (eg, diameter limit regulattions) to be considered as the foundation of a Legal Baseline. If forest management in the project area is constrained only by more general regulations which do not pertain to specific forest management practices (eg, the Endangered Species Act), the project must select the Common Practice Baseline. In any case, projects subject to regulation and enforcement of specific forest management practices (ie, those that would select the Legal Baseline) must still also incorporate any management restrictions stemming from more general regulations (eg, the Endangered Specids Act) into the Legal Baseline.

An independent forest consulting entity must confirm that the practices defined in the Legal Baseline by the project proponent are plausible considering verifiable evidence. During validation the forest consultant must share with the validation/verification body evidence for their determination of the plausibility of the Legal Baseline. Such evidence must in all situations be considered confidential and must not be published or shared by the validation/verification body. Such evidence may include, for example: management plans, records of timber sales or harvesting by the project proponent within the project area or in other properties under their control; management plans, records of timber sales, or harvesting by other entities similar to the project proponent in the region; national or regional government statistics on forest management in the region; published data and analyses on forest management in the region; and/or spatial analyses on management options and/or carbon stocks in the focal region. As needed, the validation/verification body may consult additional independent forest consulting entities to verify the opinion provided by the independent forest consulting entity selected by the proponent and to determine that the Legal Baseline is plausible.

Common Practice Baseline

The Common Practice Baseline must be selected as the most plausible baseline scenario whenever there is insufficient documentation to utilize the Historical Baseline and where regulations pertaining to specific forest management practices do not exist or are not readily enforced in the project region.

---

[4] Below-market returns must be defined as 80% or less of the current prevailing internal rate of return for forestland investment in comparable forest types and locations, after considering the full array of timber, non-timber and ecosystem service net revenues associated with the property, averaged over the last five years. Forestland investment in comparable forest types and locations must be defined as the common practice management.

It is possible that the Common Practice Baseline and project scenarios are the same, in which case the project scenario would not be considered additional.

During validation the forest consultant must share with the validation/verification body evidence for their determination of common practice. Such evidence must in all situations be considered confidential and must not be published or shared by the validation/verification body. Such evidence may include, for example: management plans, records of timber sales or harvesting by the project proponent within the project area or in other properties under their control; management plans, records of timber sales, or harvesting by other entities similar to the project proponent in the region; national or regional government statistics on forest management in the region; published data and analyses on forest management in the region; and/or spatial analyses on management options and/or carbon stocks in the focal region.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

The project proponent must test the additionality of the project using the current UNFCCC CDM *Tool for the demonstration and assessment of additionality* (see Section 10). In application of the Additionality Tool the project scenario as described ex-ante using this methodology and monitored using this methodology mustmust be evaluated alongside the baseline scenario identified in Step 1. If a financial analysis or a demonstration of barriers does not lead the preclusion of the project scenario then the project mustmust be considered non-additional.

8 QUANTIFICATION OF EMISSION REDUCTIONS AND REMOVALS

8.1 Stratification

If the project area is not homogeneous, stratification must be carried out to improve the accuracy and precision of carbon stock estimates. Different stratifications may be required for the baseline and project scenarios in order to achieve optimal accuracy and precision of the estimates of net GHG emissions reductions or GHG removal by sinks.

For estimation of baseline carbon stocks strata must be defined on the basis of parameters that are key variables in any method used to estimate changes in managed forest carbon stocks, for example:

- Management regime,
- Site index / anticipated growth rates,
- Forest species, or
- Age class.

For this methodology it will be important to stratify by management regime so that all areas to be clear cut or patch cut within a given year or within the years between monitoring events must be a stratum with further division if differences exist in site index, species and/or age class.

The project area must be stratified *ex-ante*. Further stratification beyond the parameters given above is not usually warranted. However, other parameters (eg, soil type, climate) may be useful for *ex-post* stratification.

Note: In the equations used in this methodology, the letter i is used to represent a stratum and the letter M for the total number of strata: M_B is the number of *ex-ante* defined baseline strata as determined with the procedures above; M_B remains fixed. M_{PS} is the number of strata in the project scenario as determined *ex-ante*. *Ex-post* adjustments of the project scenario strata may be needed if unexpected disturbances occur during the project crediting period (eg, due to fire, pests or disease outbreaks), severely affecting different parts of an originally homogeneous stratum or stand, or when forest management (thinning, harvesting, replanting) occurs at different intensities, dates and spatial locations than originally planned. In such a situation the project area affected by the disturbance and / or variation in forest management may be delineated as a separate stratum for the purpose of monitoring the carbon stock changes.

8.2 Baseline Net GHG Removals by Sinks

The baseline net removals are averaged over a modeled 100 year period to remove fluctuations and the impact of fluctuations on the difference between the baseline and the project cases.

The baseline net GHG Removals by sinks will be determined as:

$$\Delta C_{BSL} = \Delta C_{BSL,P} - GHG_{BSL,E} \tag{1}$$

where:

ΔC_{BSL} Baseline net greenhouse gas removals by sinks; t CO_2-e

$\Delta C_{BSL,P}$ Carbon stock changes in all pools in the baseline; t CO_2-e

$GHG_{BSL,E}$ Greenhouse gas emissions as a result of forest management activities within the project area in the baseline; t CO_2-e

$$\Delta C_{BSL,P} = \Delta C_{BSL,tree} + \left(\Delta C_{BSL,DW}\right) + \left(\Delta C_{BSL,WP}\right) \tag{2}$$

where:

$\Delta C_{BSL,P}$ Carbon stock changes in all pools in the baseline; t CO_2-e

$\Delta C_{BSL,tree}$ Carbon stock changes in trees in the baseline; t CO_2-e

$\Delta C_{BSL,DW}$ Carbon stock changes in dead wood in the baseline; t CO_2-e

$\Delta C_{BSL,WP}$ Carbon stock changes in wood products in the baseline; t CO_2-e

Dead wood may conservatively be excluded. Wood products may also conservatively be excluded if it can be shown that carbon stocks in the baseline scenario can be expected to decrease more or increase less, relative to the project scenario.

$$\Delta C_{BSL,tree} = \frac{\left(\sum_{i=1}^{M_B} \Delta C_{BSL,AG|BG,i,100} * \frac{44}{12} \right)}{100} * t^* \quad (3)$$

where:

$\Delta C_{BSL,tree}$	Carbon stock changes in above-ground and below-ground biomass of trees in the baseline; t CO_2-e
$\Delta C_{BSL,AG\|BG,i,100}$	Summed annual net carbon stock change in above-ground and below-ground biomass for stratum *i*, (summed over the 100 year modeled baseline); t C
i	1, 2, 3 …M_B strata in the baseline scenario
t	1, 2, 3, … t^* years elapsed since the start of the IFM project activity
44/12	Ratio of molecular weight of CO_2 to carbon, t CO_2-e t C^{-1}

If dead wood is selected in Table 1:

$$\Delta C_{BSL,DW} = \frac{\left(\sum_{i=1}^{M_B} \Delta C_{BSL,DW,i,100} * \frac{44}{12} \right)}{100} * t^* \quad (4)$$

where:

$\Delta C_{BSL,DW}$	Carbon stock changes in dead wood in the baseline; t CO_2-e
$\Delta C_{BSL,DW,i,100}$	Summed annual net carbon stock change in dead wood for stratum *i*, (summed over the 100 year modeled baseline); t C
i	1, 2, 3 …M_B strata in the baseline scenario
t	1, 2, 3, … t^* years elapsed since the start of the IFM project activity
44/12	Ratio of molecular weight of CO_2 to carbon, t CO_2-e t C^{-1}

If wood products are selected in Table 1:

$$\Delta C_{BSL,WP} = \frac{\left(\sum_{i=1}^{M_B} \Delta C_{BSL,WP,i,t} * \frac{44}{12}\right)}{100} * t^* \qquad (5)$$

where:

$\Delta C_{BSL,WP}$ Carbon stock changes in wood products in the baseline; t CO_2-e

$\Delta C_{BSL,WP,i,t}$ Baseline annual net carbon stock change in wood products for stratum *i*, at time *t*; t C yr^{-1}

i 1, 2, 3 …M_B strata in the baseline scenario

t 1, 2, 3, … t^* years elapsed since the start of the IFM VCS project activity

44/12 Ratio of molecular weight of CO_2 to carbon, t CO_2-e t C^{-1}

8.3 Carbon Stock Changes in the Baseline

$\Delta C_{BSL,AG|BG}$, $\Delta C_{BSL,DW}$ and $\Delta C_{BSL,WP}$ must be estimated using models of forest management across the baseline period. Modeling can be conducted with relative ease and confidence using a peer-reviewed forestry model. The PD must detail what model is being used and what variants have been selected. All model inputs and outputs must be available for inspection by the validator. The baseline must be modeled over 100 years.

The model must not assume the immediately release of carbon stock in the dead wood pool, as set out in the most recent version of the VCS *AFOLU Requirements*.

Examples of appropriate models include:

- US Forest Service's FVS: Forest Vegetation Simulator
- SPS: Stand Projection System
- FPS: Forest Projection System by Forest Biometrics
- CRYPTOS and CACTOS: California Conifer Timber Output Simulator

Models must be:

- Peer reviewed in a process involving experts in modeling and biology/forestry/ecology
- Used only in scenarios relevant to the scope for which the model was developed and evaluated
- Parameterized for the specific conditions of the project

In countries and regions where specific forestry models do not exist or are not available it is valid to employ a simple spreadsheet based model (including common simple growth models such as the Chapman Richards model of tree growth appropriately parameterized). Such models must be clearly labeled with all assumptions and justifications for assumptions presented. Spreadsheet models may also be necessary to extrapolate some growth models to include additional pools and harvest schedules.

It is inevitable that the input to models will be inventory data. However, the exact form of the input data is not prescribed here as this will vary by model but may include: cruised volumes, stand tables or plot data. The equations given in Section 5 must be used and detailed in full in the project description.[5]

The output of the models must be the annual changes in stocks of carbon in live aboveground tree biomass ($\Delta C_{BSL,AG|BG,i,t}$), dead wood ($\Delta C_{BSL,DW,i,t}$)and wood products ($\Delta C_{BSL,WP,i,t}$) by strata in the baseline scenario through the duration of the project.[6] If the model output is the annual stock (C) the change (ΔC) would be calculated as: $C_{t2} - C_{t1}$.

If the output for the tree is the volume then this must be converted to biomass and carbon using equations 13-18 in Section 5. If processing of alternative data on dead wood and wood products is necessary, equations 24-35 may be used.

8.4 Baseline Emissions

The GHG emissions in the baseline within the project area can be estimated as:

$$GHG_{BSL,E} = \sum_{t=1}^{t^*} \left(E_{BSL,BiomassBurn,t} \right) \quad (6)$$

where:

$GHG_{BSL,E}$ — Greenhouse gas emissions as a result of forest management activities within the project area in the baseline; t CO_2-e

$E_{BSL,\ BiomassBurn,t}$ — Non-CO_2 emissions due to biomass burning as part of forest management during the year t in the baseline; t CO_2-e

t — *1, 2, 3 …*t^* years elapsed since the start of the IFM project activity

GHG emission sources included or excluded from the project area can be neglected, ie, accounted as zero, if the application of the most recent version of the CDM Additionality Tools (see section 10 References) leads to the conclusion that the emission source is insignificant.

8.4.1 Estimation of baseline non-CO2 emissions due to biomass burning

The non-CO_2 emissions due to biomass burning as part of forest management ($E_{BiomassBurn}$) mustmust be estimated by:

5 Input data including precision bounds must be made available to verifying organizations

6 Where modeling produces changes in carbon stocks over five year periods the numbers must be annualized to give a stock change number for each year.

$$E_{BiomassBurn,t} = E_{BiomassBurn,CH_4,t} \qquad (7)$$

where:

$E_{BiomassBurn,t}$	Non-CO_2 greenhouse gas emission at time *t* as a result of biomass burning due to forest management; t CO_2-e
$E_{BiomassBurn,CH4,t}$	CH_4 emissions at time *t* as a result of forest management; t CO_2-e

Estimation of CH_4 emissions based on the carbon stock loss from biomass burning during forest management is based on the biomass of logging slash burned, *BS* calculated using equation 9. This is multiplied by factors that adjust for the mass of CH_4 versus carbon released, and for the global warming potential of CH_4.

$$E_{BiomassBurn,CH_4,t} = BS_{BSL,t} * ER_{CH_4} * \frac{16}{12} * GWP_{CH_4} \qquad (8)$$

where:

$E_{BiomassBurn,CH4,t}$	CH_4 emissions at time *t* as a result of forest management; t CO_2-e
$BS_{BSL,t}$	Carbon stock in logging slash subject to burning as part of forest management; t C
ER_{CH4}	Emission ratio for CH_4 (if local data on combustion efficiency is not available or if combustion efficiency can not be estimated from fuel information, use IPCC default value, 0.012[7]); kg C as CH_4 (kg C burned)$^{-1}$
GWP_{CH4}	Global warming potential for CH4 (IPCC default: 21 for the first commitment period of the Kyoto Protocol); t CO_2-e (t CH_4)$^{-1}$
16/12	Ratio of molecular weights of CH_4 and C; mol mol^{-1}
t	1, 2, 3, … t years elapsed since the start of IFM VCS project activities

If logging slash is not burned as part of forest management then:

$BS_{BSL,t} = 0$, otherwise:

$$BS_{BSL,t} = \sum_{j=1}^{S_{BSL}} \sum_{l=1}^{N_{j,t}} \left(\left(\left(f_j(DBH,H) \right) - \left(V_{l,j,t} * D_j \right) \right) * CF_j \right) \qquad (9)$$

[7] Table 3A.1.15, Annex 3A.1, GPG-LULUCF (IPCC 2003)

where:

$BS_{BSL,t}$	Carbon stock in logging slash subject to burning as part of forest management; t C
$V_{l,j,t}$	Harvested merchantable volume of tree *l* of species *j* at time *t,* m^3
D_j	Basic wood density of species *j*; t d.m.m^{-3}
$f_j(DBH,H)$	Allometric equation for species *j* linking diameter at breast height (*DBH*) and possibly height (*H*) to above-ground biomass of living trees; t d.m. $tree^{-1}$
CFj	Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)
l	Sequence number of trees harvested
j	*1, 2, 3 …* S_{BSL} tree species in the baseline scenario
t	1, 2, 3, … t years elapsed since the start of IFM VCS project activities

8.5 Project net GHG removals by sinks

The actual net greenhouse gas removals mustmust be estimated using the equations in this section. When applying these equations for the *ex-ante* calculation of net anthropogenic GHG removals by sinks, project participants mustmust provide estimates of the values of those parameters that are not available before the start of monitoring activities.[8] Project proponents must retain a conservative approach in making these estimates.

$$\Delta C_{ACTUAL} = \Delta C_P - GHG_E \tag{10}$$

where:

ΔC_{ACTUAL}	Actual net greenhouse gas removals by sinks; t CO_2-e
ΔC_P	Sum of the changes in above-ground biomass, dead wood and wood products in the project scenario; t CO_2-e
GHG_E	Increase in GHG emissions as a result of the implementation of the proposed IFM project activity within the project area; t CO_2-e

Note: In this methodology Equation (14) is used to estimate actual net greenhouse gas removals by sinks for the period of time elapsed between project start (*t* = 1) and the year *t* = *t**, *t** being the year for which actual net

[8] For the ex-ante estimation of changes in above-ground biomass, dead wood and wood products in the project scenario projects must model the expected changes in stocks through the with-project management scenario using methods as described in Section 4.1

greenhouse gas removals by sinks are estimated. The “stock change” method must be used to determine annual, or periodic values.

8.5.1 Estimation of changes in the carbon stock

The verifiable changes in the carbon stock in tree above-ground biomass, dead wood and wood products are estimated using the following approach[9]:

$$\Delta C_P = \sum_{t=1}^{t^*} \Delta C_t * \frac{44}{12} \qquad (11)$$

where:

ΔC_P Sum of the changes in above-ground biomass, dead wood and wood products in the project scenario; t CO_2-e

ΔC_t Annual change in carbon stock in all selected carbon pools for year *t*; t C yr^{-1}

t *1, 2, 3* … t^* years elapsed since the start of the IFM project activity

44/12 Ratio of molecular weights of CO_2 and carbon; t CO_2 t^{-1} C

ΔC_t mustmust be estimated using the following equation:

$$\Delta C_t = \sum_{i=1}^{M_{PS}} \left(\Delta C_{AG,i,t} + \Delta C_{BG,i,t} + \Delta C_{DW,i,t} + \Delta C_{WP,i,t} \right) \qquad (12)$$

where:

ΔC_t Annual change in carbon stock in all selected carbon pools for year *t*; t C yr^{-1}

$\Delta C_{AG,i,t}$ Annual carbon stock change in above-ground biomass of trees for stratum *i*, (possibly average over a monitoring period); t C yr^{-1}

$\Delta C_{BG,i,t}$ Annual carbon stock change in below-ground biomass of trees for stratum *i*, (possibly average over a monitoring period); t C yr^{-1}

$\Delta C_{DW,i,t}$ Annual change in the dead wood carbon pool for stratum *i*, (possibly average over a monitoring period); t C yr^{-1}

[9] IPCC GPG-LULUCF 2003, equation 3.2.3

$\Delta C_{WP,i,t}$	Annual change in the wood products carbon pool for stratum *i*, (possibly average over a monitoring period); t C yr^{-1}
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 …* t^* years elapsed since the start of the IFM project activity

Changes in carbon pools that are conservatively excluded from accounting mustmust be set equal to zero.

8.5.1.1 Tree Biomass

The mean carbon stock in aboveground biomass per unit area is estimated based on field measurements in sample plots. Plots may be permanent or temporary[10], they may have a defined boundary or be variable radius plots. Two methods are available: the Biomass Expansion Factors (*BEF*) method, and the Allometric Equations method.

Method 1: BEF method

Step 1: Determine based on available data, eg, volume tables (*ex-ante*) and measurements (*ex-post*), the diameter (*DBH*, at typically 1.3 m [4.5 ft] above-ground level), and also preferably height (*H*), of all the trees above some minimum *DBH* in the sample plots.

Step 2: Estimate the volume of the commercial (merchantable) component of trees based on available equations or yield tables (if locally derived equations or yield tables are not available use relevant regional, national or default data as appropriate). It is possible to combine Steps 1 and 2 if there are field instruments (eg, a relascope) that measure the volume of each tree more directly.

Step 3: Choose *BEF*, and root-shoot ratio *R* – see Section II.8 for guidance on source of data. If relevant information is available the *BEF* and *R* should be adjusted for forest type or stand structure.

Step 4: Convert the volume of the commercial component of the trees into the mean plot level carbon stock biomass of the commercial component of trees via wood density and carbon fraction:

$$CV_{AB\_plot,i,t} = \sum_{j=1}^{S_{PS}} \sum_{l=1}^{N_{j,i,sp,t}} (V_{l,j,i,sp,t} * D_j * CF_j) \quad (13)$$

where:

$CV_{AB\_plot,sp,i\,t}$	Carbon stock of the commercial component of trees in plot *sp*, in stratum *i* at time *t*; t C
$V_{l,j,i,sp,t}$	Merchantable volume of tree *l* of species *j* in plot *sp* in stratum *i* at time *t,* m^3 (if necessary convert from ft^3 to m^3 by multiplying by 0.0283)

[10] Note that due to covariance tighter precision and hence fewer measurements can be used if permanent plots are elected. See guidance in IPCC Good Practice Guidance for Land Use, Land Use Change and Forestry – Section 4.3. Available at: http://www.ipcc-nggip.iges.or.jp/public/gpglulucf/gpglulucf_files/Chp4/Chp4_3_Projects.pdf

D_j	Basic wood density of species *j*; t d.m.m^{-3}
CFj	Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)
l	Sequence number of trees on plot *sp*
i	*1, 2, 3, …*M_{PS} strata in the project scenario
j	*1, 2, 3 …* S_{PS} tree species in the baseline scenario
t	*1, 2, 3 … t* years elapsed since start of IFM project activity

Step 5: Calculate the carbon stock in the commercial component of the trees for each stratum:

$$CV_{AB,i,t} = \sum_{sp=1}^{P_i} \frac{10000}{Ap} * CV_{AB\_plot,i,t} \quad (14)$$

where:

$CV_{AB,i,t}$	Carbon stock of the commercial component of trees in stratum *i* at time *t*; t C ha^{-1}
$CV_{AB\_plot,sp,i\ t}$	Carbon stock of the commercial component of trees in plot *sp*, in stratum *i* at time *t*; t C
Ap	Area of sample plot; m^2 (if necessary convert from ft^2 to m^2 by multiplying by 0.0929)
sp	*1, 2, 3 … Pi* sample plots in stratum *i* in the project scenario
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 … t* years elapsed since the start of the IFM VCS project activity

If point sampling/basal area prism sampling is used then under Step 4 each tree should be multiplied by the number of trees per acre that it represents and under Step 5 the – 10000/Ap – factor should be omitted.

Step 6: Convert the mean carbon stock in the commercial component of the trees for each stratum into the total carbon stock in aboveground biomass via the BEF:

$$C_{AB,i,t} = CV_{AB,i,t} * BEF \quad (15)$$

where:

$C_{AB,i,t}$	Carbon stock in above-ground biomass of trees in stratum *i* at time *t*; t C ha^{-1}
$CV_{AB,i,t}$	Carbon stock of the commercial component of trees in stratum *i* at time *t*; t C ha^{-1}

BEF	Biomass expansion factor for conversion of merchantable biomass to total above-ground tree biomass; dimensionless
i	*1, 2, 3, …*M_{PS} strata in the project scenario
t	*1, 2, 3 … t* years elapsed since the start of the IFM project activity

Step 7: Calculate the carbon stock in below-ground biomass of all trees present in stratum *i* at time *t*:

$$C_{BB,i,t} = C_{AB,i,t} * R \quad (16)$$

where:

$C_{AB,i,t}$	Carbon stock in above-ground biomass of trees in stratum *i* at time *t*; t C ha^{-1}
$C_{BB,i,t}$	Carbon stock in below-ground biomass of trees in stratum *i* at time *t*; t C ha^{-1}
R	Root-shoot ratio appropriate for biomass stock; dimensionless
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 … t* years elapsed since the start of the IFM project activity

Alternatively, the equations of Cairns et al. (1997)[11] may be used to calculate below-ground biomass stock (t ha^{-1}) from aboveground biomass stock (t ha^{-1})

If an appropriate equation exists to calculate belowground biomass directly from DBH it would be equally valid in this step.

Step 8: Calculate the mean carbon stock in tree biomass for each stratum:

$$C_{tree,i,t} = A_i * (C_{AB,i,t} + C_{BB,i,t}) \quad (17)$$

where:

$C_{tree,i,t}$	Carbon stock in trees in stratum *i* at time *t*; t C
$C_{AB,i,t}$	Carbon stock in above-ground biomass of trees in stratum *i* at time *t*; t C ha^{-1}
$C_{BB,i,t}$	Carbon stock in below-ground biomass of trees in stratum *i* at time *t*; t C ha^{-1}
A_i	Area of stratum *i*; ha

[11] Cairns, M. A., S. Brown, E. H. Helmer, and G. A. Baumgardner. 1997. Root biomass allocation in the world's upland forests. Oecologia 111: 1-11

i   *1, 2, 3 …* M_{PS} strata in the project scenario

t   *1, 2, 3 … t* years elapsed since the start of the IFM project activity

Step 8: Calculate the mean carbon stock change:

$$\Delta C_{AG,i,t} + \Delta C_{BG,i,t} = \frac{C_{tree,i,t2} - C_{tree,i,t1}}{T} \quad (18)$$

where:

$\Delta C_{AG,i,t}$	Annual carbon stock change in above-ground biomass of trees for stratum *i*; t C yr^{-1}
$\Delta C_{BG,i,t}$	Annual carbon stock change in below-ground biomass of trees for stratum *i*; t C yr^{-1}
$C_{tree,i,t}$	Carbon stock in trees in stratum *i* at time *t*; t C
T	Number of years between monitoring time *t*1 and *t*2 (*T* = *t*2 – *t*1); yr
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 … t* years elapsed since the start of the IFM VCS project activity

Method 2: Allometric method

Step 1: As with Step 1 of the *BEF* method.

Step 2: Select or develop an appropriate allometric equation (if possible species-specific, or if not from a similar species) – see Section II.8 for additional guidance.

Step 3: Estimate carbon stock in above-ground biomass for each individual tree *l* of species *j* in the sample plot located in stratum *i* using the selected or developed allometric equation applied to the tree dimensions resulting from Step 1, and sum the carbon stocks in the sample plot:

$$C_{AB\_tree,j,i,sp,t} = \sum_{l=1}^{N_{j,sp}} f_j(DBH,H) * CF_j \quad (19)$$

where:

$C_{AB\_tree,l,j,i,sp,t}$	Carbon stock in above-ground biomass of trees of species *j* in plot *sp* in stratum *i* at time *t*; t C $tree^{-1}$
CFj	Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)
$f_j(DBH,H)$	Allometric equation for species *j* linking diameter at breast height (*DBH*) and possibly height (*H*) to above-ground biomass of trees; t. d.m. $tree^{-1}$

i	*1, 2, 3, …*M_{PS} strata in the project scenario
j	*1, 2, 3 …* S_{PS} tree species in the baseline scenario
l	*1, 2, 3, …*$N_{j,sp}$ sequence number of individual trees of species *j* in sample plot *sp*
t	*1, 2, 3 … t* years elapsed since start of IFM project activity

Step 4: Convert the carbon stock in above-ground biomass to the carbon stock in below-ground biomass via root-shoot ratio, given by:

$$C_{BB\_tree,j,i,sp,t} = C_{AB\_tree,j,i,sp,t} * R \quad (20)$$

where:

$C_{BB\_tree,l,j,i,sp,t}$	Carbon stock in below-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at time *t*, t C tree^{-1}
$C_{AB\_tree,l,j,i,sp,t}$	Carbon stock in above-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at time *t*, t C tree^{-1}
R_j	Root-shoot ratio appropriate for biomass stock; dimensionless

If an appropriate equation exists to calculate belowground biomass directly from DBH it would be equally valid in this step.

Step 5: Calculate total carbon stock in the biomass of all trees present in the sample plot *sp* in stratum *i* at time *t*

$$C_{tree,i,sp,t} = \sum_{j=1}^{S_{PS}} \left(C_{AB\_tree,j,i,sp,t} + C_{BB\_tree,j,i,sp,t} \right) \quad (21)$$

where:

$C_{tree,i,sp,t}$	Carbon stock in trees in plot *sp* of stratum *i* at time *t*, t C
$C_{AB\_tree,l,j,i,sp,t}$	Carbon stock in above-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at time *t*; t C tree^{-1}
$C_{BB\_tree,l,j,i,sp,t}$	Carbon stock in below-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at time *t*, t C tree^{-1}
$N_{j,i,sp,t}$	Number of trees of species *j* in plot *sp* of stratum *i* at time t
i	*1, 2, 3, …*M_{PS} strata in the project scenario

j	*1, 2, 3 …* S_{PS} tree species in the baseline scenario
t	*1, 2, 3 …* t years elapsed since the start of the IFM project activity

Step 6: Calculate the mean carbon stock in tree biomass for each stratum:

$$C_{tree,i,t} = \frac{A_i}{Asp_i} \sum_{sp=1}^{P_i} C_{tree,i,sp,t} \tag{22}$$

where:

$C_{tree,i,t}$	Carbon stock in trees in stratum i at time t; t C
$C_{tree,i,sp,t}$	Carbon stock in trees in plot sp of stratum i at time t, t C
Asp_i	Total area of all sample plots in stratum i; ha
A_i	Area of stratum i; ha
sp	*1, 2, 3 …* P_i sample plots in stratum i in the project scenario
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 …* t years elapsed since the start of the IFM project activity

Step 7: Calculate the mean carbon stock change:

$$\Delta C_{AG,i,t} + \Delta C_{BG,i,t} = \frac{C_{tree,i,t2} - C_{tree,i,t1}}{T} \tag{23}$$

where:

$\Delta C_{AG,i,t}$	Annual carbon stock change in above-ground biomass of trees for stratum i; t C yr^{-1}
$\Delta C_{BG,i,t}$	Annual carbon stock change in below-ground biomass of trees for stratum i; t C yr^{-1}
$C_{tree,i,t}$	Carbon stock in trees in stratum i at time t; t C
T	Number of years between monitoring time $t1$ and $t2$ ($T = t2 - t1$); yr
i	*1, 2, 3 …* M_{PS} strata in the project scenario
t	*1, 2, 3 …* t years elapsed since the start of the IFM project activity

Note that for permanent plots with tagged trees, change in carbon stocks are tracked directly through estimates of carbon stock increments in individual trees summed across plots and strata. For detailed guidance see Pearson et al 2005.[12]

8.5.1.2 Dead wood (if selected in Table 1)

Dead wood included in the methodology comprises two components only – *standing dead wood* and *lying dead wood* (that is, below-ground dead wood is conservatively neglected). Considering the differences in the two components, different sampling and estimation procedures mustmust be used to calculate the changes in dead wood biomass of the two components. In all cases, dead wood modeling must include a decay function that is a 10-year linear decay or a more conservative alternative for dead wood that reflects a pattern of carbon loss over time.

$$\Delta C_{DW,i,t} = \frac{C_{DW,i,t2} - C_{DW,i,t1}}{T} \tag{24}$$

where:

$\Delta C_{DW,i,t}$	Annual carbon stock change in dead wood for stratum *i*, (averaged over a monitoring period); t C yr^{-1}
$C_{DW,i,t2}$	Carbon stock of dead wood in stratum *i* at time *t=2*; t C
$C_{DW,i,t2}$	Carbon stock of dead wood in stratum *i* at time *t=1*; t C
T	Number of years between monitoring *t*2 and *t*1 (*T =t2-t1*); yr
i	*1, 2, 3* … M_{PS} strata in the project scenario
t	*1, 2, 3* … *t* years elapsed since the start of the IFM project activity

The methods to be followed in the measurement of the standing dead wood and the lying dead wood biomass are outlined below:

$$C_{DW,i,t} = (B_{SDW,i,t} + B_{LDW,i,t}) * CF_{DW} \tag{25}$$

where:

$C_{DW,i,t}$	Carbon stock of dead wood in stratum *i* at time *t*; t C
$B_{SDW,i,t}$	Biomass of standing dead wood in stratum *i* at time *t*; t d.m.
$B_{LDW,i,t}$	Biomass of lying dead wood in stratum *i* at time *t*; t d.m.

[12] Pearson, T., Walker, S. and Brown, S. 2005. Sourcebook for Land Use, Land-Use Change and Forestry Projects. Winrock International and the World Bank Biocarbon Fund. 57pp. Available at: http://www.winrock.org/Ecosystems/files/Winrock-BioCarbon_Fund_Sourcebook-compressed.pdf

CF_{DW} Carbon fraction of dry matter in dead wood; t C t^{-1} d.m.

i *1, 2, 3 …* M_{PS} strata in the project scenario

t *1, 2, 3 … t* years elapsed since the start of the IFM project activity

Method: Standing Dead Wood

Step 1: Standing dead trees mustmust be measured using the same criteria and monitoring frequency used for measuring live trees. The decomposed portion that corresponds to the original above-ground biomass is discounted. Stumps must be inventoried as if they are very short standing dead trees.

Step 2: The decomposition class of the dead tree and the diameter at breast height must be recorded and the standing dead wood is categorized under the following four decomposition classes:

- Tree with branches and twigs that resembles a live tree (except for leaves);
- Tree with no twigs but with persistent small and large branches;
- Tree with large branches only;
- Bole only, no branches.

Step 3: Biomass must be estimated using an allometric equation for live trees in the decomposition class 1. When the bole is in decomposition classes 2, 3 or 4, it is recommended to limit the estimate of the biomass to the main trunk of the tree.

If the top of the standing dead tree is missing, then the top diameter:

- May be assumed to be zero;
- May be measured if reachable or the broken top is identifiable on the ground or by using an instrument such as a relascope or laser inventory instrument;
- May be calculated proportionally to height assuming that the height of the intact dead tree would be equal to average height of all intact dead trees present in the same sample plot.

Step 4: The volume of dead wood is converted to biomass using the appropriate dead wood density class.

Method: Lying Dead Wood

The lying dead wood pool is highly variable, and stocks may or may not increase as the stands age depending if the forest was previously unmanaged (mature or unlogged) where it would likely increase or logged with logging slash left behind where it may decrease through time.

Step 1: Lying dead wood must be sampled using the line intersect method (Harmon and Sexton 1996).[13,14] Two 50-meter lines (164 ft) are established bisecting each plot and the diameters of the lying dead wood (≥ 10 cm diameter [≥ 3.9 inches]) intersecting the lines are measured.

Step 2: The dead wood is assigned to one of the three density states (sound, intermediate and rotten) using the 'machete test', as recommended by *IPCC Good Practice Guidance for LULUCF* (2003), Section 4.3.3.5.3.

Step 3: The volume of lying dead wood per unit area is calculated using the equation (Warren and Olsen 1964)[15] as modified by Van Wagner (1968)[16] separately for each density state:

$$V_{LDW,i,t} = \frac{\pi^2 * \left(\sum_{n=1}^{N} D_{n,i,t}{}^2 \right)}{8 * L} \quad (26)$$

where:

$V_{LDW,i,t}$	Volume of lying dead wood per unit area in stratum *i* at time *t*; m^3 ha^{-1}
$D_{n,i,t}$	Diameter of piece n of dead wood along the transect in stratum *i* at time *t*; cm (if necessary convert inches to cm by multiplying by 2.54)
N	Total number of wood pieces intersecting the transect; dimensionless
L	Length of the transect; m (if necessary convert ft to me by multiplying by 0.3048)
i	*1, 2, 3* … M_{PS} strata in the project scenario
t	*1, 2, 3* … *t* years elapsed since the start of the IFM project activity

To convert this to a mass per unit area multiply the volumes of each density state by their respective wood densities.

Step 4: Volume of lying dead wood must be converted into biomass using the following relationship:

$$B_{LDW,i,t} = A_i * \sum_{dc=1}^{3} V_{LDW,i,t} * D_{DW,dc} \quad (27)$$

[13] Harmon, M.E. and J. Sexton. (1996) Guidelines for measurements of wood detritus in forest ecosystems. US LTER Publication No. 20. US LTER Network Office, University of Washington, Seattle, WA, USA.

[14] A variant on the line intersect method is described by Waddell, K.L. 2002. Sampling coarse wood debris for multiple attributes in extensive resource inventories. Ecological Indicators 1: 139-153. This method may be used in place of Steps 1 to 3.

[16] Van Wagner, C.E. (1968). The line intersect method in forest fuel sampling. *Forest Science* 14: 20-26.

where:

$B_{LDW,i,t}$ Biomass of lying dead wood per unit area in stratum *i* at time *t*; d.m. ha^{-1}

$V_{LDW,i,t}$ Volume of lying dead wood per unit area in stratum *i* at time *t*; m^3 ha^{-1}

$D_{DW,dc}$ Basic wood density of dead wood in the density class – sound (1), intermediate (2), and rotten (3); t d.m. m^{-3}

A_i Area of stratum *i*; ha

i *1, 2, 3 …* M_{PS} strata in the project scenario

t *1, 2, 3 … t* years elapsed since the start of the IFM project activity

8.5.1.3 Wood Products (if selected in Table 1)

The Wood Products pool is calculated through the following general steps for each harvest period *h*:

Step 1: Calculate the carbon in harvested timber removed from the project site based on wood densities and standard carbon conversions from biomass volumes

Step 2: Calculate the total carbon in harvested timber that will enter the wood products pool based on mill efficiencies and product disposition percentages

Step 3: Calculate the total carbon that will be stored for the short lived (≤3 years), medium lived (>3 years to 100 years) and long lived (100+ years)

The annual change in carbon stored in wood products is given in the following equation:

$$\Delta C_{WP,t1,t2} = \frac{C_{WP,t2} - C_{WP,t1}}{T} \tag{28}$$

where:

$\Delta C_{WP,t1,t2}$ Annual carbon stock change in wood products between time t1 and t2, (averaged over a monitoring period); t C yr^{-1}

$C_{WP,t2}$ Carbon stock of wood products at time *t=2*; t C

$C_{WP,t1}$ Carbon stock of wood products at time *t=1*; t C

T Number of years between monitoring *t*2 and *t*1 (*T =t2-t1*); yr

t *1, 2, 3 … t* years elapsed since the start of the IFM VCS project activity

To calculate wood products two methods are available. The direct (*1605b*) method is only applicable within the 48 contiguous United States and for limited vegetation types. The less direct (*Winjum et al.*) method can be applied to any vegetation types throughout the world.

Method 1: 1605b Method

The method uses the Forestry Appendix of the Technical Guidelines of the US Department of Energy's Voluntary Reporting of Greenhouse Gases Program (known as Section 1605(b)).[17] All harvested wood will be categorized by species and wood product (sawnwood or pulpwood). Wood density values for each species in the project area will be used to determine carbon volume for each cubic volume of wood delivered to processing facilities.

Regional data supplied in Table 1.4 and Table 1.5 of the 1605(b) document provide values to determine the percentage of harvested softwoods and hardwoods that will be converted to sawnwood and pulpwood.

Step 1: Calculate the total carbon in harvested timber removed from the project site. This is calculated by taking the biomass of the total volume extracted from the start of the project to date from within the project area with extracted timber differentiated into hardwood, softwood, sawnwood and pulpwood classes (if necessary convert volumes in ft^3 to m^3 by multiplying by 0.0283):

$$EXC_{WP,ty} = \sum_{h=1}^{H_{PS}} \sum_{j=1}^{S_{PS}} (V_{ex,h,s|p,j} * D_j * CF_j) \tag{29}$$

where:

$EXC_{WP,ty}$	The summed stock of extracted biomass carbon from within the project area by wood product disposition (hardwood sawnwood/hardwood pulpwood/softwood sawnwood/softwood pulpwood) *ty*; t C
$V_{ex,h,s\|p,j,}$	The volume of timber extracted from within the project area during harvest *h* by species *j* and wood product disposition *ty*; m^3
D_j	Basic wood density of species *j*; t d.m. m^{-3}
CFj	Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)
h	*1, 2, 3 …*number of harvests since the start of the IFM project activity
j	*1, 2, 3 …* S_{PS} tree species in the baseline scenario
s|p	Wood product disposition – defined here as sawnwood or pulpwood

[17] http://www.eia.doe.gov/oiaf/1605/Forestryappendix[1].pdf Also available as a US Forest Service General Technical Report at: http://www.fs.fed.us/ne/durham/4104/papers/ne_gtr343.pdf

Step 2: Calculate the total carbon that will enter the wood products pool. All projects must calculate the total carbon in harvested biomass that enters the wood products pool after deducting harvest slash left on site, bark biomass and waste calculated through mill efficiencies. For the purposes of this protocol Tables 1.4, 1.5 and 1.6 can be used to estimate these values for different regions within the United States. Examples 1.4 and 1.5 are given on pages 25-27 of the 1605(b) document which demonstrate the methods that can be followed with different existing data sets.

Step 3: Calculate the total amount of carbon stored in short lived, medium lived and long lived wood products. For the purposes of this methodology the proportion of harvested carbon stored in wood products is equivalent to the proportion listed in the "In Use" column of Table 1.6 of the 1605(b) document for any given year after harvest.

Each year's harvested carbon volume must be categorized into one of the following categories:

- Short lived wood products: harvested wood products and wood waste that will decay within 3 years.
- Medium lived wood products: harvested wood products and wood waste that will be retired between 3 and 100 years from the date of harvest.
- Long lived wood products: harvested wood products and wood waste that may be considered permanent (stored for 100 years or more).

To determine the proportion of harvested wood products that fall into each category, refer to the "In Use" column in the appropriate regional version of Table 1.6 of the 1605(b) document. For each harvested wood type (hardwood/softwood/pulpwood/sawnwood), two values are taken from the table: $P_{3\text{-year}}$, the percentage of total carbon stored in wood products after 3 years; and $P_{100\text{-year}}$, the proportion of harvested wood stored for 100 years. Three different values are calculated from this data, the short lived fraction (P_{SLF}), medium lived fraction (P_{MLF}), and long lived fraction (P_{LLF}):

$$P_{SLF} = 1-P_{3\text{-year}}$$

$$P_{MLF} = P_{3\text{-year}} - P_{100\text{-year}}$$

$$P_{LLF} = P_{100\text{-year}}$$

Each category of wood products will store carbon according to the following rules:

- Short lived wood products – immediate loss of all carbon upon harvest
- Medium lived wood products – no loss of carbon upon harvest, but carbon stored will decrease by $1/20^{th}$ for the next 20 years after harvest
- Long lived wood products – no loss of carbon

$$C_{WP,t,ty} = \sum_{h=0}^{t}((C_{Mill,ty,h} * P_{LLF}) + [(C_{Mill,ty.h} * P_{MLF}) * ((20-h)/20)] \quad (30)$$

Where:

$C_{WP,t,ty}$ The total carbon removed from the project site that remain stored in harvested wood products at Year *t* for harvest category *ty* (hardwood, softwood, sawnwood, pulpwood)

$C_{Mill,\ ty,h}$ the total carbon volume stored in wood products for harvest *h,* after deducting for mill efficiencies and product dispositions

h Year of harvest

$P_{SLF,MLF,LLF}$ The proportion of carbon stored in sawn hardwood/softwood or pulp hardwood/softwood "In Use" for the appropriate term. For short lived wood products this is 0. For medium lived wood products this must be reduced by 1/20 for 20 years after harvest. 20 years after harvest the medium lived term becomes zero. Long lived storage proportion is 1 for the 100 years of the project life.

Method 2: The Winjum et al. Method

Step 1: Calculate the biomass of the total volume extracted from the start of the project to date from within the project area (if necessary convert volumes in ft^3 to m^3 by multiplying by 0.0283).

$$EXC_{WP,ty} = \sum_{h=1}^{H_{PS}} \sum_{j=1}^{S_{PS}} (V_{ex,h,ty,j} * D_j * CF_j) \quad (31)$$

where:

$EXC_{WP,ty}$ The summed stock of extracted biomass carbon from within the project area class of wood product *ty*; t C

$V_{ex,h,ty,j,}$ The volume of timber extracted from within the project area during harvest *h* by species *j* and wood product class *ty*; m^3

D_j Basic wood density of species *j*; t d.m.m^{-3}

CFj Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)

h *1, 2, 3 …*number of harvests since the start of the IFM project activity

j *1, 2, 3 …* S_{PS} tree species in the baseline scenario

ty Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other

Step 2: Calculate the total carbon in harvested timber that will enter the wood products pool based on mill efficiencies and product disposition percentages. All factors are derived from Winjum et al.1998.[18]

$$C_{Mill,ty} = \sum_{s,w,oir,p}^{ty} EXC_{WP,ty} * (1 - WW) \qquad (32)$$

Where:

$C_{Mill,ty}$	Carbon in wood products after milling for category *ty*
$EXC_{WP,ty}$	Total extracted wood volumes over all types *ty*
WW	Wood waste fraction based on mill efficiency
s,w,oir,p	Wood product categories: sawnwood, woodbase panels, other industrial roundwood, paper and paperboard

<u>Wood waste fraction (WW):</u>

Winjum et al indicate that the proportion of extracted biomass that is oxidized (burning or decaying) from the production of commodities to be equal to 19% for developed countries, 24% for developing countries. *WW* is therefore equal to $EXC_{WP,ty}$ multiplied by 0.19 for developed countries and 0.24 for developing countries (Winjum et al., p. 278).

Step 3: Calculate the total carbon that will be stored for the short lived (≤3 years), medium lived (>3 years to 100 years) and long lived (100+ years).

Each year's harvested carbon volume must be categorized into one of the following categories:

- Short lived wood products: harvested wood products and wood waste that will decay within 3 years.
- Medium lived wood products: harvested wood products and wood waste that will be retired between 3 and 100 years from the date of harvest.
- Long lived wood products: harvested wood products and wood waste that may be considered permanent (stored for 100 years or more).

For each year's harvests, the calculation of carbon in wood products follows this formula:

$$C_{WP,ty} = \sum_{s,w,oir,p}^{ty} \left(\left(\left(C_{Mill,ty} \right) - SLF \right) + MLF \right) \qquad (33)$$

[18] Winjum, J.K., Brown, S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. *Forest Science* 44: 272-284

where:

$C_{WP,ty}$	Total carbon for all wood product categories
$C_{Mill,ty}$	The summed stock of carbon remaining in wood products after milling from within the project area by class of wood product *ty*; t C
SLF	Fraction of wood products that will be emitted to the atmosphere within 3years of timber harvest; t C
MLF	Fraction of wood products in products stored between 3and 100 years that decay each year. This decay will be deducted linearly over 20 years from the year of harvest; t C
ty	Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board
t	*1, 2, 3* … *t* years elapsed since the start of the IFM project activity

<u>Short-lived fraction (SLF)</u>

Winjum et al., 1998 defines the following proportions as the amount of carbon that each product category will lose over the first 5 years after harvest (applicable internationally):

Sawnwood	0.2
Woodbase panels	0.1
Other industrial roundwood	0.3
Paper and Paperboard	0.4

Assuming a linear decay rate, convert these values to annualized proportions as follows:

Sawnwood	0.04 annually
Woodbase panels	0.02 annually
Other industrial roundwood	0.06 annually
Paper and paperboard	0.08 annually

To convert this to 3 year percentage reductions as required by the AFOLU Requirements we multiply the annual values by 3 to come up with the final value for “short lived proportion” for each product category.

Sawnwood	0.12
Woodbase panels	0.06
Other industrial roundwood	0.18
Paper and paperboard	0.24

The methodology makes the assumption that this proportion of wood and all other classes of wood products are 100% oxidized immediately..

Therefore SLF will be equal to:

$$SLF = \left(C_{Mill,ty}\right) * slp \qquad (34)$$

where:

SLF Fraction of wood products that will be emitted to the atmosphere within 3 years of timber harvest; t C

$C_{WP,ty}$ The summed stock of extracted biomass carbon from within the project area by class of wood product *ty*; t C

slp Short-lived proportion -

ty Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other

<u>Medium lived fraction (MLF)</u>

Winjum et al., 1998 gives annual oxidation fractions for each class of wood products split by forest region (boreal, temperate and tropical). This methodology projects these fractions over 97 years to give the additional proportion that is oxidized between the 3rd and 100th years after initial harvest (Table 3):

Table 3: Proportion of remaining wood products oxidized between 3 and 100 years after initial harvest by wood product class and forest region (MLF)

Wood Product Class	*OF*		
	Boreal	**Temperate**	**Tropical**
Sawnwood	0.39	0.62	0.86
Woodbase panels	0.62	0.86	0.98
Other industrial roundwood	0.86	0.98	0.99
Paper and paperboard	0.39	0.62	0.99

To reflect a 20-year linear decay as required by the VCS AFOLU Requirements, the , 1/20th of these proportions must be deducted from the harvested wood products pools each year after harvest. 20 years after harvesting, the MLF term will be equal to zero.

However, for the first twenty years after each harvest cycle, the value of MLF for that harvest is therefore equal to

$$MLF = \left(\left(C_{Mill,ty}\right) - SLF\right) * ((20 - h)/20) * fo$$

(35)

where:

MLF	Fraction of wood products that is considered stored for the medium term and will be emitted to the atmosphere each year after harvest for twenty year; t C
$C_{Mill,ty}$	The summed stock of extracted biomass carbon after milling from within the project area by class of wood product *ty*; t C
SLF	Fraction of wood products that will be emitted to the atmosphere within 3 years of timber harvest; t C
fo	Fraction oxidized – see Table 3 for defaults; t C t C^{-1}
ty	Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other
h	year after harvest

8.5.2 Estimation of GHG emissions within the project area

The change in GHG emissions as a result of the implementation of the proposed IFM project activity within the project area can be estimated as:

$$GHG_{PS,E} = \sum_{t=1}^{t^*}\left(E_{PS,BiomassBurn,t}\right) \quad (36)$$

where:

$GHG_{PS,E}$	Greenhouse gas emissions as a result of forest management activities within the project area in the project scenario; t CO_2-e
$E_{PS, BiomassBurn,t}$	Non-CO_2 emissions due to biomass burning as part of forest management during the year *t* in the project scenario; t CO_2-e
t	*1, 2, 3 …*t^* years elapsed since the start of the IFM project activity

The monitoring of emissions by sources is only required if significant; if insignificant, evidence must be provided (eg, as relevant part of the monitoring of the project implementation) that the assumptions for the exclusion made in the *ex-ante* assessment still hold in the *ex-post* situation.

8.5.2.1 Estimation of non-CO2 emissions due to biomass burning

The non-CO_2 emissions due to biomass burning as part of forest management ($E_{BiomassBurn}$) must be estimated by:

$$E_{BiomassBurn,t} = E_{BiomassBurn,CH_4,t} \tag{37}$$

where:

$E_{BiomassBurn,t}$	Non-CO_2 greenhouse gas emission at time *t* as a result of biomass burning due to forest management; t CO_2-e
$E_{BiomassBurn,CH4,t}$	CH_4 emissions at time *t* as a result of forest management; t CO_2-e

Estimation of CH_4 emissions is based on the carbon stock loss from biomass burning during forest management is based on the biomass of logging slash burned, *BS* calculated using equation 30. This is multiplied by factors that adjust for the mass of CH_4 versus carbon released, and for the global warming potential of CH_4.

$$E_{BiomassBurn,CH_4,t} = BS_{PS,t} * ER_{CH_4} * \frac{16}{12} * GWP_{CH_4} \tag{38}$$

where:

$E_{BiomassBurn,CH4,t}$	CH_4 emissions at time *t* as a result of forest management; t CO_2-e
$BS_{PS,t}$	Carbon stock in logging slash subject to burning as part of forest management in the project scenario; t C
ER_{CH4}	Emission ratio for CH_4 (if local data on combustion efficiency is not available or if combustion efficiency can not be estimated from fuel information, use IPCC default value, 0.012[19]); kg C as CH_4 (kg C burned)$^{-1}$
GWP_{CH4}	Global warming potential for CH4 (IPCC default: 21 for the first commitment period of the Kyoto Protocol); t CO_2-e (t CH_4)$^{-1}$
16/12	Ratio of molecular weights of CH_4 and C; mol mol^{-1}
t	1, 2, 3, … t years elapsed since the start of IFM project activities

If logging slash is not burned as part of forest management then:

$BS_{PS,t} = 0$, otherwise:

[19] Table 3A.1.15, Annex 3A.1, GPG-LULUCF (IPCC 2003)

$$BS_{PS,t} = \sum_{j=1}^{S_{PS}} \sum_{l=1}^{N_{j,t}} \left(\left(\left(f_j(DBH, H) \right) - \left(V_{l,j,t} * D_j \right) \right) * CF_j \right) \qquad (39)$$

where:

$BS_{PS,t}$	Carbon stock in logging slash subject to burning as part of forest management; t C
$V_{l,j,t}$	Harvested merchantable volume of tree *l* of species *j* at time *t,* m^3
D_j	Basic wood density of species *j*; t d.m.m^{-3}
$f_j(DBH,H)$	Allometric equation for species *j* linking diameter at breast height (*DBH*) and possibly height (*H*) to above-ground biomass of living trees; t d.m. $tree^{-1}$
CFj	Carbon fraction of biomass for tree species *j*; t C t^{-1} d.m. (IPCC default value = 0.5 t C t^{-1} d.m.)
l	Sequence number of trees harvested
j	*1, 2, 3 …* S_{PS} tree species in the project scenario
t	1, 2, 3, … t years elapsed since the start of IFM project activities

8.6 Leakage

Under the applicability conditions of this methodology the type of leakage emissions to be calculated is: GHG emissions due to market effects resulting from a shift in harvest through time.[20]

Therefore, leakage must be estimated as follows:

$$LK = LK_{MarketEffects} \qquad (40)$$

where:

LK	Total GHG emissions due to leakage; t CO_2–e
$LK_{MarketEffects}$	Total GHG emissions due to impacts of project on timber supply and demand; t CO_2-e

Note: In this methodology the equation above is used to estimate leakage for the period of time elapsed between project start (*t*=1) and the year $t=t^*$, t^* being the year for which actual net greenhouse gas removals by sinks are estimated.

[20] GHG emissions through fossil fuel use outside the boundaries of the project are not considered based on guidance from the CDM Executive Board: http://cdm.unfccc.int/EB/044/eb44rep.pdf

8.6.1 Leakage due to Activity Shifting

As per the applicability conditions there may be no leakage due to activity shifting.

If the project is able to demonstrate that any decrease in wood products produced by the project relative to the baseline is less than 5% and any temporal displacement in the total production of wood products is less than 5 years then:

$$LK_{ActivityShifting} = 0 \tag{41}$$

If the project decreases wood product production by >5% relative to the baseline then the project proponent and all associated land owners must demonstrate that there is no leakage within their operations – ie, on other lands they manage/operate outside the bounds of the IFM project. Such a demonstration may include:

Historical records showing trends in harvest volumes paired with records from the with-project time period showing no deviation from historical trends forest management plans prepared ≥24 months prior to the start of the project showing harvest plans on all owned/managed lands paired with records from the with-project time period showing no deviation from management plans.

Leakage due to market effects is equal to the baseline emissions from logging multiplied by a leakage factor:

$$LK_{MarketEffects} = LF_{ME} * \left(\Delta C_{ACTUAL} - \Delta C_{BSL}\right) \tag{42}$$

Where:

$LK_{MarketEffects}$	Total GHG emissions due to market- effects leakage through decreased timber harvest; t CO_2-e
LF_{ME}	Leakage factor for market-effects calculations; dimensionless
ΔC_{ACTUAL}	Actual net greenhouse gas removals by sinks; t CO_2-e
ΔC_{BSL}	Baseline net greenhouse gas removals by sinks; t CO_2-e

The leakage factor is determined by considering where in the country logging will be increased as a result of the decreased supply of the timber caused by the project. If the areas liable to be logged have a higher carbon stock than the project area it is likely that the proportional leakage is higher and vice versa:

LF_{ME} = 0, where it can be demonstrated that no market-effects leakage will occur within national boundaries, (eg, if no new concessions are being assigned AND annual extracted volumes cannot be increased within existing national concessions AND illegal logging is absent (or *de minimis*) in the host country); or,

Where the project is able to demonstrate that any decrease in wood products produced by the project relative to the baseline is less than 5% and any temporal displacement in the total production of wood products is less than 5 years.

LF_{ME} $=$ 0.1, where rotations are moderately extended (5-10 years) leading to a shift in harvests across time periods but a change in total timber harvest equal to ≤25% over the project lifetime[21]

Where rotations are extended by >10 years and/or harvest is decreased by >25% over the project lifetime as per VCS AFOLU Requirements

The amount of leakage is determined by where harvesting would likely be displaced to. If in the forests to which displacement would occur a lower proportion of forest biomass in commercial species is in merchantable material than in project area , then in order to extract a given volume higher emissions should be expected as more trees will need to be cut to supply the same volume. In contrast if a higher proportion of the total biomass of commercial species is merchantable in the displacement forest than in the project forests then a smaller area would have to be harvested and lower emissions would result.

Each project thus must calculate within each stratum the proportion of total biomass in commercial species that is merchantable (PMP_i). This must then be compared to mean proportion of total biomass that is merchantable for each forest type (PML_{FT}).

Merchantable biomass is defined as: "Total gross biomass (including bark) of a tree 5 inches (12.7 cm) DBH or larger from a 1 foot (30.48 cm) stump to a minimum 4 inches top DOB of the central stem" *Definition from US Forest Service FIA Program*

The following deduction factors (LF_{ME}) must be used:

Where:

PML_{FT} *is equal (± 15%) to* PMP_i, $LF_{ME} =$ 0.4

PML_{FT} *is > 15% less than* PMP_i $LF_{ME} =$ 0.7

PML_{FT} *is > 15% greater than* PMP_i, $LF_{ME} =$ 0.2

Where:

PML_{FT} Mean merchantable biomass as a proportion of total aboveground tree biomass for each forest type; % (default values see parameter table)

PMP_i Merchantable biomass as a proportion of total aboveground tree biomass for stratum *i* within the project boundaries; %

LF_{ME} Leakage factor for market-effects calculations; dimensionless

[21] Defined here as the minimum project lifetime elected by project proponents in their project description document. If the project is extended beyond this time period harvests may not be decreased by more than 25% across through each additional crediting/baseline period

8.7 Summary of the GHG Emission Reduction and/or Removals

The net anthropogenic GHG removals by sinks is the actual net GHG removals by sinks minus the baseline net GHG removals by sinks minus leakage, therefore, the following general formula can be used to calculate the net anthropogenic GHG removals by sinks of a IFM project activity (C_{IFM}) in t CO_2-e.

$$C_{IFM} = \Delta C_{ACTUAL} - \Delta C_{BSL} - LK \quad (43)$$

where:

C_{IFM}	Net anthropogenic greenhouse gas removals by sinks; t CO_2-e
ΔC_{ACTUAL}	Actual net greenhouse gas removals by sinks; t CO_2-e
ΔC_{BSL}	Baseline net greenhouse gas removals by sinks; t CO_2-e
LK	Total GHG emissions due to leakage; t CO_2–e

8.7.1 Calculation of Uncertainty

Estimated carbon emissions and removals arising from AFOLU activities have uncertainties associated with the uncertainties associated with measures/estimates of: area or other activity data, carbon stocks, biomass growth rates, expansion factors, and other coefficients. It is assumed that the uncertainties associated with the estimates of the various input data are available, either as default values given in IPCC Guidelines (2006), IPCC GPG-LULUCF (2003), or estimates based of sound statistical sampling. Uncertainties arising from the measurement and monitoring of carbon pools and the changes in carbon pools must always be quantified.

Indisputably conservative estimates can also be used instead of uncertainties, provided that they are based on verifiable literature sources. In this case the uncertainty is assumed to be zero. However, this module provides a procedure to combine uncertainty information and conservative estimates resulting in an overall project uncertainty.

Uncertainty at all times is defined as the 90% confidence interval as a percentage of the mean.

<u>Planning to Diminish Uncertainty</u>

It is important that the process of project planning consider uncertainty. Procedures including stratification, and the allocation of sufficient measurement plots can help ensure that low uncertainty results and ultimately full crediting can result.

It is good practice to consider uncertainty at an early stage to identify the data sources with the highest uncertainty to allow the opportunity to conduct further work to diminish uncertainty.

<u>Estimation of Uncertainty for Pools and Emissions Sources</u>

For each measurement pool calculate both the mean and the 90% confidence interval. In all cases uncertainty should be expressed as the 90% confidence interval as a percentage of the mean.

For modeled results use the confidence interval of the input inventory data.

For wood products use the confidence interval of the stocks of extracted timber.

For biomass burning emissions use the confidence interval of the preburning stocks.

For both the baseline and the with-project case the total uncertainty is equal to the square root of the sum of the squares of each component uncertainty.

Total Uncertainty of the IFM Project

The total project uncertainty is calculated at the time of reporting through propagating the error in the baseline stocks and the error in the project stocks:

$$C_{IFM\_ERROR} = \sqrt{\mathrm{Uncertainty_{BSL}}^2 + \mathrm{Uncertainty_P}^2} \tag{44}$$

Where:

CIFM_ERROR Total uncertainty for IFMProject; %

UncertaintyBSL Total uncertainty in baseline scenario; %

UncertaintyP Total uncertainty in the with-project scenario; %

The uncertainty in the baseline and in the project should be defined as the square root of the summed errors in each of the measurement pools. The errors in each pool can be weighted by the size of the pool so that projects may reasonably target a lower precision level in pools that only form a small proportion of the total stock.

8.7.2 Uncertainty Deduction

If CIFMS_ERROR ≤ 10% of CIFM- then no deduction should result for uncertainty

If CIFM-_ERROR > 10% of CIFM- then the modified value for CIFM- to account for uncertainty should be:

$$= \frac{100 - C_{IFM\_ERROR}}{100} * C_{IFM} \tag{45}$$

Where:

CIFM- Net anthropogenic greenhouse gas removals by sinks; t CO2-e

CIFM-_ERROR Total uncertainty for IFMProject; %

8.7.3 Calculation of VCUs

To estimate the amount of VCUs that can be issued at time *t*=*t*2 (the date of verification) for monitoring period *T*=*t*2-*t*1, this methodology uses the following equation:

$$VCUs = \left(C_{IFM,t2} - C_{IFM,t1}\right) - BRR \qquad (46)$$

where:

VCUs	Number of Verified Carbon Units
CIFM-,t2	Net anthropogenic greenhouse gas removals by sinks, as estimated for t*=t2; t CO2-e
CIFM-,t1	Net anthropogenic greenhouse gas removals by sinks, as estimated for t*=t1; t CO2-e
BRR	Portion of carbon credits to be withheld as a buffer reserve

Buffer reserve should be calculated using *VCS Tool for AFOLU Non-Permanence Risk Analysis and Buffer Determination*.

The number of VCUs eligible for crediting in any one monitoring period may not exceed the ex-ante projected total number of VCUs for the defined project lifetime unless it can be demonstrated the ex-ante estimate created through modeling has been conservatively underestimated (eg, through growth rates in excess of projection or increases in harvest efficiency/decreases in harvest volumes).[22]

9 MONITORING

9.1 Data and Parameters Not Monitored

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

In choosing key parameters or making important assumptions based on information that is not specific to the project circumstances, such as in use of existing published data, project proponents must retain a conservative approach: that is, if different values for a parameter are equally plausible, a value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.

Data / parameter:	$A_{BSL,i}$
Data unit:	Ha

[22] This requirement ensures through forest management rotations with growth and harvesting projects are not overcredited. Crediting should not occur to the peaks of growth if harvest is going to immediately follow.

Used in equations:	Implicitly used in Section 4.1
Description:	Area of baseline stratum, *i*
Source of data:	GPS coordinates and/or Remote Sensing data and/or legal parcel records
Measurement procedures (if any):	N/A
Any comment:	

Data / parameter:	*BEF*
Data unit:	Dimensionless
Used in equations:	15
Description:	Biomass expansion factor for conversion of annual net increment (including bark) in stem biomass to total above-ground tree biomass increment for species *j*
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: (a) Existing local and forest type-specific; (b) National and forest type-specific or eco-region-specific (eg, from national GHG inventory); (c) Forest type-specific or eco-region-specific from neighboring countries with similar conditions. Sometimes (c) might be preferable to (b); (d) Globally forest type or eco-region-specific (eg, IPCC literature: Table 3A.1.10 of GPG-LULUCF)
Measurement procedures (if any):	
Any comment:	- BEFs are age dependent, and use of average data may result in significant errors for both young and old stands – as BEFs are usually large for young stands and quite small for old stands.

Data / parameter:	*CF*
Data unit:	t C t^{-1} d.m.

Used in equations:	9, 10, 19, 29, 31, 39
Description:	Carbon fraction of dry matter
Source of data:	Default value 0.5 t C t^{-1} d.m. can be used, or species specific values from the literature
Measurement procedures (if any):	
Any comment:	

Data / parameter:	*D*
Data unit:	t d.m. m^{-3}
Used in equations:	9, 29, 31, 39
Description:	Basic wood density
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: (a) National and species-specific or group of species-specific (eg, from National GHG inventory); (b) Species-specific or group of species-specific from neighboring countries with similar conditions. Sometimes (b) may be preferable to (a); (c) Globally species-specific or group of species-specific (eg, IPCC GPG-LULUCF).
Measurement procedures (if any):	N/A
Any comment:	

Data / parameter:	D_{DW}
Data unit:	t d.m. m^{-3}
Used in equations:	27
Description:	Basic wood density of dead wood in the density class – sound (1), intermediate (2) and rotten (3)

Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: (a) Research publications relevant to the project area; (b) National and species-specific or group of species-specific (eg, from National GHG inventory); (c) Species-specific or group of species-specific from neighboring countries with similar conditions. Sometimes (b) may be preferable to (a); (d) Globally species-specific or group of species-specific (eg, IPCC GPG-LULUCF).
Measurement procedures (if any):	Project-specific determination of density is most likely necessary
Any comment:	

Data / parameter:	$f_j(DBH,H)$
Data unit:	t d.m. tree^{-3}
Used in equations:	9, 19, 39
Description:	Allometric equation for species j linking diameter at breast height (DBH) and possibly height (H) to above-ground biomass of living trees
Source of data:	Whenever available, use allometric equations that are species-specific or group of species-specific, provided the equations have been derived using a wide range of diameters and heights, based on datasets that comprise at least 20 trees. Otherwise, default equations from IPCC literature, national inventory reports or published peer-reviewed studies may be used – such as those provided Tables 4.A.1 to 4.A.3 of the GPG-LULUCF (IPCC 2003).
Measurement procedures (if any):	
Any comment:	It is necessary to verify the applicability of equations used. Allometric equations can be verified by both: 1. Verification of equation conditions: Justification should be provided for the applicability of the equation to the project locations. Such justification should include identification of climatic, edaphic, geographical and taxonomic similarities between the project location and the location in which the equation was derived. Any equation used should have an r^2 value of greater than 0.5

	(50%) and a p value that is significant (<0.05 at the 95% confidence level). 2. Additional field verification For field verification either of the two methods below may be used: A. Destructive Sampling ▪ Selecting at least 5 trees covering the range of DBH existing in the project area, and felling and weighting the above-ground biomass to determine the total (wet) weight of the stem and branch components; ▪ Extracting and immediately weighing subsamples from each of the wet stem and branch components, followed by oven drying at 70^{o}C to determine dry biomass; ▪ Determining the total dry weight of each tree from the wet weights and the averaged ratios of wet and dry weights of the stem and branch components. B. Limited Measurements ▪ Select at least 10 trees per species distributed across the age range (but excluding trees less than 15 years old for which there is rarely a great relative inaccuracy in equations) ▪ Calculate volume of tree from basal and top diameters and tree height. Multiply by species-specific density to gain biomass of bole. Add an additional percentage to approximately cover biomass of branches: 15% for spruce/fir, 5% for pines and 20% for broadleaf forests[23] If the biomass of the harvested trees is within ±10% of the mean values predicted by the selected default allometric equation, and is not biased – or if biased is wrong on the conservative side (ie, use of the equation results in under- rather than over-estimate of project net anthropogenic removals by sinks) – then mean values from the equation may be used.

Data / parameter:	*OF,, WW*
Data unit:	kg kg^{-1}.
Used in equations:	32
Description:	WW = Fraction of extracted biomass effectively emitted to the atmosphere during production

[23] Calculated conservatively from the biomass expansion factors used to calculate total tree biomass from the biomass of the bole in IPCC Good Practice Guidance for Land Use, Land Use Change and Forestry (2003), Table 3A.1.10.

Source of data:	The source of data is the published paper of Winjum et al. 1998[24]
Measurement procedures (if any):	
Any comment:	

Data / parameter:	PML_{FT}
Data unit:	%
Used in equations:	Leakage Section 6.2
Description:	Mean merchantable biomass as a proportion of total aboveground tree biomass for each forest type
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: 1. Peer-reviewed published sources (including carbon/biomass maps or growing stock volume[25] maps with a scale of at least 1km) 2. Official Government data and statistics 3. Original field measurements The forest types considered must be only those relevant for the specific market effects leakage ie. only forest types with active timber production. An appropriate source of data will be Government records on annual allowable cuts for the areas of commercial forests. Where volumes are used the source of data wood density is required to convert to merchantable biomass. The source of data on wood densities must be chosen with priority from higher to lower preference as follows: 1. Knowledge on commercial species and thus an appropriately weighted wood density derived from the density of these species 2. A region-specific mean wood density as given eg, in Brown 1997[26]

[24] Winjum, J.K., Brown, S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. *Forest Science* 44: 272-284

[25] Volumes must be converted to merchantable biomass using wood densities/specific gravities. A weighted wood density must be used to convert multi-species data on growing stock volume to merchantable biomass

For the lower 48 US States the following defaults have been calculated[27] from the US Forest Service Forest Inventory Analysis Database and must be used where appropriate:

Forest Type Group	Merchantable Biomass as Proportion of Total Biomass
White Red Jack Pine	77%
Spruce Fir	58%
Longleaf Slash Pine	73%
Loblolly Shortleaf Pine	73%
Ponderosa Pine	64%
Oak Pine	71%
Oak Hickory	73%
Oak Gum Cypress	72%
Elm Ash Cottonwood	73%
Maple Beech Birch	76%
Aspen Birch	61%
Douglas Fir	70%
Western White Pine	62%
Fir-Spruce/Mountain Hemlock	62%
Lodgepole Pine	64%
Hemlock/Sitka Spruce	67%
Western Larch	66%
Redwood	43%
Western Oak	69%

[26] Brown, S. 1997. Estimating biomass and biomass change of tropical forests: a Primer. FAO Forestry Paper 134. http://www.fao.org/docrep/W4095E/W4095E00.htm

[27] The FIA mapmaker program (http://www.ncrs2.fs.fed.us/4801/fiadb/fim30/wcfim30.asp) was used. For the lower 48 states the total biomass and merchantable biomass by forest type were downloaded in order to calculate the proportions given here

Measurement procedures (if any):	
Any comment:	

Data / parameter:	*R*
Data unit:	kg kg^{-1}.
Used in equations:	16, 20
Description:	Root-shoot ratio appropriate for biomass increment of forest type / biome
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: (a) Research publications relevant to the project area; (b) National and forest type-specific or eco-region-specific (eg, from National GHG inventory); Sometimes (b) may be preferable to (a)[28] (c) Forest type-specific or eco-region-specific from neighboring countries with similar conditions.; (d) Globally forest type-specific or eco-region-specific (eg, IPCC GPG-LULUCF).
Measurement procedures (if any):	
Any comment:	Guidelines for Conservative Choice of Default Values: 1. If in the sources of data mentioned above, default data are available for conditions that are similar to the project (same vegetation genus; same climate zone; similar forest type), then mean values of default data may be use d and considered conservative. 2. Global values may be selected from Table 3A.1.8 of the GPG-LULUCF (IPCC 2003), or equivalently Table 4.4 of the AFOLU Guidelines (IPCC 2006), by choosing a climatic zone and species that most closely matches the project circumstances.

[28] (b) must only be used instead of (a) when the dataset is significantly larger and the relationship between root and shoot tighter for National and forest type-specific or eco-region-specific (b). For example projects may elect to use IPCC defaults in the 2006 Guidelines for National Greenhouse Gas Inventories: Volume 4 AFOLU – Table 4.4. Available at: http://www.ipcc-nggip.iges.or.jp/public/2006gl/pdf/4_Volume4/V4_04_Ch4_Forest_Land.pdf

Data / parameter:	*SLF*
Data unit:	unitless
Used in equations:	30, 33, 34, 35
Description:	Short lived fraction - proportion of wood products that oxidize immediately in the first three years after harvesting
Source of data:	The Forestry Appendix of US Department of Energy's Technical Guidelines for The Voluntary Reporting of Greenhouse Gas Program (Section 1605b) http://www.eia.doe.gov/oiaf/1605/Forestryappendix[1].pdf Also available as a US Forest Service General Technical Report at: http://www.fs.fed.us/ne/durham/4104/papers/ne_gtr343.pdf Winjum et al,. 1998
Measurement procedures (if any):	
Any comment:	

Data / parameter:	*MLF*
Data unit:	unitless
Used in equations:	30, 33, 35
Description:	Medium lived fraction -- Proportion of wood products that decay over a 20 year period after harvest
Source of data:	The Forestry Appendix of US Department of Energy's Technical Guidelines for The Voluntary Reporting of Greenhouse Gas Program (Section 1605b) http://www.eia.doe.gov/oiaf/1605/Forestryappendix[1].pdf Also available as a US Forest Service General Technical Report at: http://www.fs.fed.us/ne/durham/4104/papers/ne_gtr343.pdf Winjum et al., 1998
Measurement procedures (if any):	

Any comment:	

Data / parameter:	*LLF*
Data unit:	unitless
Used in equations:	30
Description:	Long lived fraction - proportion of wood products that remain stored for 100 years after harvest
Source of data:	The Forestry Appendix of US Department of Energy's Technical Guidelines for The Voluntary Reporting of Greenhouse Gas Program (Section 1605b) http://www.eia.doe.gov/oiaf/1605/Forestryappendix[1].pdf Also available as a US Forest Service General Technical Report at: http://www.fs.fed.us/ne/durham/4104/papers/ne_gtr343.pdf Winjum et al., 1998
Measurement procedures (if any):	
Any comment:	

9.2 Description of Monitoring Plan

All data collected as part of monitoring must be archived electronically and be kept at least for 2 years after the end of the project. 100% of the data must be monitored if not indicated otherwise in tables below. All measurements must be conducted according to relevant standards. In addition, the monitoring provisions in the tools referred to in this methodology apply.

9.2.1 Monitoring of Project Implementation

Information must be provided, and recorded in the project description, to establish that:

i. The geographic position of the project area is recorded for all areas of land;
   - The geographic coordinates of the project area (and any stratification inside the boundary) are established, recorded and archived. This can be achieved by field survey (eg, using GPS), or by using georeferenced spatial data (eg, maps, GIS datasets, orthorectified aerial photography or georeferenced remote sensing images).

ii. Commonly accepted principles of forest inventory and management are implemented;

- Standard operating procedures (SOPs) and quality control / quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of SOPs already applied in national forest monitoring, or available from published handbooks, or form the *IPCC GPG LULUCF 2003*, is recommended;
- The forest management plan, together with a record of the plan as actually implemented during the project must be available for validation and verification, as appropriate.

9.2.2 Sampling Design and Stratification

Stratification of the project area into relatively homogeneous units can either increase the measuring precision without increasing the cost unduly, or reduce the cost without reducing measuring precision because of the lower variance within each homogeneous unit. Project proponents must present in the project description an *ex-ante* stratification of the project area or justify the lack of it. The number and boundaries of the strata defined *ex-ante* may change during the project crediting period (*ex-post*).

Updating of strata

The *ex-post* stratification must be updated due to the following reasons:

- Unexpected disturbances occurring during the project crediting period (eg, due to fire, pests or disease outbreaks), affecting differently various parts of an originally homogeneous stratum;
- Forest management activities (cleaning, planting, thinning, harvesting, coppicing, re-planting) may be implemented in a way that affects the existing stratification.

Established strata may be merged if reasons for their establishing have disappeared.

9.2.3 Sampling framework

To determine the sample size and allocation among strata, this methodology uses the latest version of the UNFCCC tool for the "Calculation of the number of sample plots for measurements within A/R CDM project activities" (see section References) approved by the CDM Executive Board. The targeted precision level for biomass estimation across the project is +/- 10% of the mean at a 90% confidence level. In contrast to the CDM tool note that temporary plots are permissible under this methodology.

9.2.4 Data and Parameters Monitored

The following parameters must be monitored during the project activity. When applying all relevant equations provided in this methodology for the *ex-ante* calculation of net anthropogenic GHG removals by sinks, project proponents must provide transparent estimations for the parameters that are monitored during the project crediting period. These estimates must be based on measured or existing published data where possible and project proponents must retain a conservative approach: that is, if different values for a parameter are equally plausible, a value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.

Future developments may allow remote sensing of carbon stocks and changes in carbon stocks, however, a new version of this methodology will be necessary to accommodate the currently unknown components of such future technology.

Data / parameter:	A_i
Data unit:	ha
Used in equations:	17, 22, 27
Description:	Area of stratum *i*
Source of data:	Monitoring of strata and stand boundaries must be done preferably using a Geographic Information System (GIS), which allows for integrating data from different sources (including GPS coordinates and Remote Sensing data).
Measurement procedures (if any):	
Monitoring frequency:	
QA/QC procedures:	
Any comment:	It must be assumed ex-ante that stand boundaries and strata areas must not change through time

Data / parameter:	Ap
Data unit:	m^2
Used in equations:	14
Description:	Area of sample plot
Source of data:	Recording and archiving of size of sample plots
Measurement procedures (if any):	
Monitoring frequency:	
QA/QC procedures:	

Any comment:	Ex-ante the size of plots must be defined and recorded in the monitoring plan

Data / parameter:	$D_{n,i,t}$
Data unit:	cm
Used in equations:	26
Description:	Diameter of piece *n* of dead wood along the transect in stratum *i*, at time *t*
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	Lying dead wood must be sampled using the line intersect method (Harmon and Sexton 1996[29]). Two 50-meter lines are established bisecting each plot and the diameters of the lying dead wood (≥ 10 cm diameter) intersecting the lines are measured. Minimum measurement diameter for all sites must not be less than 10 cm.
Monitoring frequency:	
QA/QC procedures:	
Any comment:	Ex-ante the change in carbon stocks in all applicable pools will be modeled following the requirements in Section 4.1

Data / parameter:	*DBH*
Data unit:	cm
Used in equations:	9, 19, 38
Description:	Diameter at breast height of tree
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	Typically measured 1.3m above-ground. Measure all trees above some minimum *DBH* in the sample plots that result from the IFM project activity. The minimum *DBH* for all sites must not be more than 20cm.

Description:	Total number of wood pieces intersecting the transect
Source of data:	Field measurements
Measurement procedures (if any):	
Monitoring frequency:	
QA/QC procedures:	
Any comment:	Ex-ante the change in carbon stocks in all applicable pools will be modeled following the requirements in Section 4.1

Data / parameter:	PMP_i
Data unit:	%
Used in equations:	Leakage section 6.2
Description:	Merchantable biomass as a proportion of total aboveground tree biomass for stratum *i* within the project boundaries
Source of data:	Within each stratum divide the summed merchantable biomass (defined as "Total gross biomass (including bark) of a tree 5" (12.7 cm) DBH or larger from a 1' (30.48 cm) stump to a minimum 4" (10.2 cm) top DOB of the central stem") by the summed total aboveground tree biomass
Measurement procedures (if any):	

Monitoring frequency:	At least every five years at the time of verification
QA/QC procedures:	
Any comment:	Ex-ante a time zero measurement must be made of this factor

Data / parameter:	*T*
Data unit:	yr
Used in equations:	18, 23, 24, 28
Description:	Number of years between monitoring time *t* and *t1* (*T* = *t2* – *t1*)
Source of data:	
Measurement procedures (if any):	
Monitoring frequency:	
QA/QC procedures:	
Any comment:	Ex-ante the monitoring plan must detail the planned monitoring intervals through the project life

9.2.5 Conservative Approach and Uncertainties

To help reduce uncertainties in accounting of emissions and removals, this methodology uses, whenever possible, the proven methods from the GPG-LULUCF, GPG-2000, the IPCC's Revised 2006 Guidelines and the tools and methodologies of the CDM Executive Board. Tools and guidance from the CDM Executive Board on conservative estimation of emissions and removals are also used. Despite this, potential uncertainties still arise from the choice of parameters to be used. Uncertainties arising from, for example, biomass expansion factors (*BEFs*) or wood density, would result in uncertainties in the estimation of both baseline net GHG removals by sinks and the actual net GHG removals by sinks – especially when global default values are used.

It is recommended that project proponents identify key parameters that would significantly influence the accuracy of estimates. Local values that are specific to the project circumstances must then be obtained for these key parameters, whenever possible. These values must be based on:

- Data from well-referenced peer-reviewed literature or other well-established published sources[30]; or
- National inventory data or default data from IPCC literature that has, whenever possible and necessary, been checked for consistency against available local data specific to the project circumstances; or
- In the absence of the above sources of information, expert opinion may be used to assist with data selection. Experts will often provide a range of data, as well as a most probable value for the data. The rationale for selecting a particular data value must be briefly noted in the project description. For any data provided by experts, the project description must also record the expert's name, affiliation, and principal qualification as an expert (eg, that they are a member of a country's national forest inventory technical advisory group) – plus inclusion of a 1-page summary CV for each expert consulted, included in an annex.

In choosing key parameters of making important assumptions based on information that is not specific to the project circumstances, such as in use of default data, project proponents must select values that will lead to an accurate estimation of net GHG removals by sinks, taking into account uncertainties. If uncertainty is significant, project proponents must choose data such that it tends to under-estimate, rather than over-estimate, net GHG removals by sinks.

DOCUMENT HISTORY

Version	Date	Comment
v1.0	13 May 2010	Initial version released. The initial version was developed by Ecotrust Forest Management, Inc., and assigned version '4 May 2010' for development purposes and assessed as version 4 May 2010 for reference in the first and second assessment reports. It has been redesignated version 1 for the purposes of finalization and approval by the VCSA.
v1.1	20 Nov 2012	The methodology was revised to account for the decay of carbon from the harvested wood products pool and to make explicit that the decay of the dead wood pool must not be assumed to be immediate. Revisions were made to Section 8.5.1.3. Other minor updates have also been incorporated into the methodology. Specifically, the applicability conditions were revised to clarify the types of forest management techniques which are eligible activities under this methodology and a modification was made with respect to the timing by which FSC certification must be in place to allow projects to achieve certification by the start of the project crediting period.
v1.2	29 Aug 2013	Clarified Section 6.3 with respect to selection of the most plausible baseline scenario.

Methodology for Improved Forest Management: Conversion of Low Productive to High Productive Forest

Table of Contents

1 SOURCES

This methodology is written to conform with the VCS rules that apply to Improved Forest Management projects (conversion of low-productive forests to high-productive forests (LtHP)) and has been prepared by Silvestrum on behalf of Face the Future, both based in the Netherlands. The methodology draws on elements from VCS methodologies VM0007 and VM0011, and CDM methodology AR-ACM0002.

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology facilitates the quantification of the net GHG benefits of Improved Forest Management projects in natural Evergreen Tropical Rainforests that achieve carbon benefits in one of, or a combination of, two activities:

- Avoiding emissions from re-logging of already logged-over forest; and,
- Rehabilitation of previously logged-over forest by cutting climbers and vines, or liberation thinning, or enrichment planting, or a combination of these activities.

The baseline scenario therefore consists of a logged-over natural Evergreen Tropical Rainforest, normally with no or insignificant regrowth, that may or may not be relogged. To determine the emissions in the baseline, the following components are quantified: volume of timber removed during relogging (expanded to include emissions from total associated biomass losses); the amount of dead wood left after relogging; the carbon stored in harvested wood products; if absence of regrowth cannot be substantiated, regrowth of the residual stand; and, emissions associated with the establishment of infrastructure and fuel consumption.

Because baselines often become counter factual once the project gets implemented, this methodology facilitates the quantification of the above components in two ways:

- On the basis of a-spatial data in a pre-relogging situation in the project area, in combination with, for instance, logging information in a management plan; or,
- By the determination of the carbon stock components after relogging has occurred in a reference area for which similarity to the project area is demonstrated.

The relationship between the two baseline options and the project area is then established by analyzing the logging rates in the various strata in the baseline, determining the same strata in the project area, and applying the stratum-specific logging rates to the strata in the project area.

The methodology allows for the use of both approaches together, if either of the two cannot be supported with a complete set of information, with the following examples: (1) While obtaining spatially explicit post-relogging carbon stock data from a reference area through direct measurements, spatially explicit pre-relogging data based on direct measurements may be lacking. Once the similarity of the reference area and the project area has been ensured, pre-relogging carbon stock data may also be obtained from the project area. (2) If spatially explicit pre-relogging carbon stock data based on direct measurements is lacking, similarity between the reference area and the project area may be justified by reconstructing pre-relogging carbon stocks from the post-relogging data of the reference area and harvesting volumes from management files of the forest management unit, and comparing these with pre-relogging carbon stock data from the project area. The validity of reconstructed pre-relogging carbon stocks may be supported by other inventory data of the reference area (eg, inventories of commercial timber prior to relogging), the supporting data being subject to the scrutiny of the validator. (3) While using a-spatial data for assessing baseline carbon stock changes, carbon stocks in dead wood may be derived from a reference area.

While ensuring conservative results for net GHG project benefits, these options support the implementation of FM project activities in areas where data collection has not been organized in such a way that it facilitates compliance *a priori* with international carbon standards, which is very often the case.

The with-project scenario constitutes the avoidance of relogging, or rehabilitation of previously logged-over forest, or both. Rehabilitation, if any, is achieved by cutting climbers and vines, or liberation thinning, or enrichment planting, or a combination of these activities. To determine the emissions and removals in the with-project scenario, the following components are quantified: carbon stocks before the intervention; increases in carbon stocks over time; and emissions due to site preparation and project implementation.

An additional feature of this methodology is the determination of the regrowth of the residual forest in both the baseline and the with-project scenario. If regrowth occurs in the baseline scenario this is assumed to be small compared to regrowth in the with-project scenario.

The removal of herbaceous vegetation (including climbers and vines) is deemed an insignificant emissions source and therefore is not accounted for in the with-project scenario.

The methodology also provides for the quantification of leakage.

Finally, the methodology provides for the determination of the project's net GHG benefits and the resulting Verified Carbon Units (VCUs) that are generated. The methodology details the steps necessary to come to the final calculation of the project's net GHG benefits, represented by ΔC_{IFM}.

$$\Delta C_{IFM} = \Delta C_{BSL} - \Delta C_{WPS} - \Delta C_{LK} \quad (1)$$

Where:

Parameter	Description
ΔC_{IFM}	Total net GHG emission reductions from the IFM project activity
ΔC_{BSL}	Sum of the carbon stock changes and greenhouse gas emissions under the baseline scenario
ΔC_{WPS}	Sum of the carbon stock changes and greenhouse gas emissions under the with-project scenario

ΔC_{LK}	Sum of the carbon stock changes and greenhouse gas emissions due to leakage

Thus, the basis of the methodology is the estimation of total carbon benefits from the IFM project activity as the result of the total carbon loss in the baseline scenario (ΔC_{BSL}) avoided due to the project activity and the net removals through the enhancement of forest growth due to liberation thinning and enrichment planting (ΔC_{WPS}), minus any leakage (ΔC_{LK}) that might occur.

Additionality	Project Method
Crediting Baseline	Project Method

3 DEFINITIONS

This methodology does not use any methodology-specific definitions.

4 APPLICABILITY CONDITIONS

This methodology is applicable to Improved Forest Management (IFM) activities, as defined by the VCS rules.

Only areas that have been designated, sanctioned or approved for such activities (eg, as logging concessions) by the national or local regulatory bodies are eligible for crediting under this VCS Improved Forest Management (IFM) category.

In particular, this methodology is applicable to improved forest management practices that achieve the conversion of low-productive forest to high-productive forest (LtHP) through the protection of logged-over, degraded forest from further logging or the adoption of silvicultural techniques increasing the density of tree vegetation, or a combination of these activities.

This methodology is applicable to situations whereby the original forest is natural *Evergreen Tropical Rainforest*, using the FAO definition where the term “Evergreen Tropical Rainforest” is defined as follows: “Evergreen Tropical Rainforests occur where the annual rainfall is greater than 2,500 mm, where forests grow mostly at low elevations, are evergreen, luxuriant, predominantly of hardwood species, have a complex structure and are rich in both plants and animals. Soils tend to be mustow and poor in nutrients, features having a marked effect on forest management practices.”[1]

The applicability conditions for this methodology are the following:

- Project activities aim at the avoidance of relogging of logged-over, degraded natural Evergreen

[1] Source: http://www.fao.org/docrep/W8212E/w8212e03.htm#a definition of tropical forests

Tropical Rainforest, or the rehabilitation of logged-over natural Evergreen Tropical Rainforest through direct human intervention such as cutting of climbers and vines, liberation thinning and/or enrichment planting, or a combination of these activities;

- Land within the project area must have qualified as forest;
- In the baseline, the logged-over forest in the project area is unlikely to revert to normal regrowth patterns due to vines and climbers, which may include climbing bamboos, resulting from high-intensity logging operations in the past. In such cases, and subject to appropriate substantiation, regrowth of tree biomass before and following relogging in the baseline can be assumed to be zero. Where this is not the case, ex-ante estimates of regrowth must be made and monitoring of the baseline for ex-post confirmation of regrowth rates must be conducted;
- The soil carbon pool within the project boundary is either in a steady state at project commencement, or, if not, the soil carbon pool is only expected to increase more or decrease less in the with-project scenario in comparison to the baseline, and may therefore, conservatively be omitted;[2]
- Site preparation is carried out so as to avoid levels of soil disturbance or soil erosion sufficient to significantly reduce the soil carbon pool over the project lifetime;
- The use of nitrogen fertilizer in the project activities is prohibited;
- During the project crediting period, harvesting must not occur in the with-project scenario[3].
- Biomass burning, fuel gathering, removal of litter, or removal of dead wood do not occur in the baseline scenario and in the with-project scenario within the project boundary;
- A reference area may be used to derive relevant parameter values for the baseline scenario. This area must be of similar size as the project area, or larger (ie, 75% of the project area or more), for which similarity with the project area can be demonstrated using criteria outlined in this methodology, and for which it can be demonstrated that the management is not affected by its selection as a reference area; and,
- Flood irrigation or drainage of primarily saturated soils are not permitted as part of the project activity, so associated non-CO2 greenhouse gas emissions can be neglected.
- There is no peatland[4] within the project area or emissions associated with peatland are not significant.
- The methodology is not applicable to grouped projects.

[2] Project proponents must use the A/R CDM approved tool 6 to demonstrate insignificance.

[3] If harvesting is planned or expected to occur after the project crediting period, the associated carbon sink reversal will be addressed in the non-permanence risk assessment.

[4] See VCS definition.

5 PROJECT BOUNDARY

5.1 Land eligibility and Geographic boundaries

No land use change is occurring in the project area: it is forest land remaining forest land. Where the activity takes place in a country that has adopted a forest definition under the Kyoto Protocol, those thresholds must be adhered to. Otherwise, the definition used in the national GHG Inventory must be used.

Only areas that have been designated, sanctioned or approved for such activities (eg, as logging concessions or plantations) by the national or local regulatory bodies are eligible for crediting under the VCS Improved Forest Management (IFM) category. This will be determined according to the legally sanctioned logging laws, regulations and codes of practice of the relevant national or sub-national regulatory authority. These laws may be defined in absolute terms (hectares) or via prescription (relative per cent). Areas within the project area, where logging has been prohibited due to environmental, cultural or other reasons, must be determined through maps and spatial analysis and be excluded from the estimations of emission reductions or removals.

The boundary of the IFM activity must be clearly delineated and defined and include only land qualifying as “forest”.

Project proponents must clearly define the spatial boundaries of a project so as to facilitate accurate measuring, monitoring, accounting, and verifying of the project’s emissions reductions and removals.

The IFM project activity may contain more than one discrete area of land. Each discrete area of land must have a unique geographical identification.

When describing physical project boundaries (for both the project areas and, if any, the reference area), the following information must be provided per discrete area:

- Name of the project area (including compartment numbers, local name (if any)
- Unique identifier for each discrete parcel of land
- Map(s) of the area in digital format)
- Geographic coordinates obtained from a GPS or from a geo-referenced digital map)
- Total land area
- Details of forest land rights holder and user rights

Following the VCS definition of market leakage, the geographic boundaries for leakage from market effects are those of the country in which the project area occurs.

In this methodology, the project area (the geographic area in which the project activity is implemented) may exceed the area eligible for carbon accounting, ie, the forest area protected against relogging, rehabilited, or both. This may exclude areas that do not contain merchantable timber and/or that are inaccessible for legislative, technical or economic reasons. A justification for the in- or exclusion of areas within the project area must be provided in the project description of the actual project applying this methodology.

A reference area is an area that is representative of the project area in the baseline scenario and thus meets the criteria set out by the applicability conditions (minimum size) and those elaborated below (similarity to project area), where the volume of biomass that would have been removed from the project area over the lifetime of the project can be assessed.

5.2 Temporal boundaries

The temporal boundary for projects applying this methodology is equal to the project crediting period.

Project proponents must determine the project crediting period, the project crediting period start date and the project start date and provide verifiable evidence when the 1st monitoring period started and when the project begins to reduce or avoid GHG emissions.

5.3 Carbon pools

The carbon pools that must be included and that may be excluded from the project boundary are shown in Table 1.

Carbon pools and emissions sources may be neglected, ie, accounted as zero, if the application of the most recent version of the "Tool for testing significance of GHG emissions in A/R CDM project activities"[5] leads to the conclusion that the pool or emission source (see Table 2) is insignificant.

Table 1: Selection and justification of carbon pools

Carbon pools	Selected	Justification/Explanation of choice
Above-ground tree biomass	Yes	Major carbon pool assumed to significantly decrease in the baseline, or increase in the project, or both.
Above-ground non-tree biomass	No	Pool need not to be measured because it is not subject to significant changes or potential changes are transient in nature.
Below-ground biomass	Optional	Major carbon pool assumed to significantly decrease in the baseline, or increase in the project, or both. Not accounting for below-ground biomass is conservative.
Dead wood	Yes	Carbon pool likely to decrease as a result of the project

[5] Available at: http://cdm.unfccc.int/methodologies/ARmethodologies/tools/

		activity. Accounting for dead wood as zero in the with-project scenario is conservative. Accounting for dead wood occurring prior to re-logging as zero is conservative.
Litter	No	Conservative approach - unlikely to decrease as a result of the project activity, or increase in the baseline
Soil organic carbon	No	Conservative approach - unlikely to decrease as a result of the project activity, or increase in the baseline
Wood products	Yes	Carbon pool likely to decrease as a result of the project activity. Accounting for wood products as zero in the with-project scenario is conservative.

5.4 Greenhouse gases

The emissions sources included in or excluded from the project boundary are shown in Table 2. In addition, insignificance of sources can be determined by the tool referred to above.

Table 2: Gases considered from emissions by sources other than resulting from changes in stocks in carbon pools

Gas	Sources	Selected	Justification/explanation of choice
Carbon dioxide (CO_2)	Combustion of fossil fuel in vehicles / machinery	Yes or No	Included subject to materiality if relogging is the baseline activity
	Removal of herbaceous vegetation	No	Excluded based on VCS guidance
Methane (CH_4)	Combustion of fossil fuel in vehicles / machinery	Yes or No	Included as CO_2 equivalent emission if relogging is the baseline activity
	Burning of biomass	No	Not included – no burning allowed; not accounting for methane emissions in the baseline scenario is conservative
Nitrous oxide (N_2O)	Combustion of fossil fuel in vehicles / machinery	Yes or No	Included as CO_2 equivalent emission if relogging is the baseline activity
	Nitrogen based fertilizer	No	Not included – no use of fertilizer allowed

	Burning of biomass	No	Not included – no burning allowed; not accounting for N_2O emissions in the baseline scenario is conservative

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

The baseline scenario must reflect what most likely would have occurred in the absence of the project. It consists of a logged-over natural Evergreen Tropical Rainforest, normally with no or insignificant regrowth that may or may not be relogged.

The following information must be provided to prove that the project proponent meets the minimum acceptable standards outlined for this baseline scenario:

- A documented history of the operator (operator must have at least 5 years of management records to show logging intensities and normal historical practices). Common records would include data on timber cruise volumes, inventory levels, harvest levels, etc. on the property that demonstrate what the normal practice in the area is. The documented history must also indicate the periodicity in logging operations in the area and in management planning (eg, interval between two subsequent logging coupes according to management plans (past or current) and in reality); and

- The legal requirements for forest management and land use in the area; however if these are not enforced then this requirement does not have to be met; and

- Proof that their environmental practices equal or exceed those commonly considered a minimum standard among similar landowners in the area.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

The project proponent must demonstrate that the project is additional through the use of the latest version of the VCS Tool for the Demonstration and Assessment of Additionality in IFM Project Activities.

8 STRATIFICATION

If the project activity area at the start of the project is not homogeneous, stratification may be carried out to improve the accuracy and the precision of carbon stock estimates. Different stratifications may be required for the baseline and with-project scenarios in order to achieve optimal accuracy of the estimates of net GHG emissions or removal.

Strata must be spatially discrete and defined on the basis of forest carbon stocks or expected changes in forest carbon stocks. Stratum sizes must be known. Areas of individual strata must sum to the total project area. Strata must be identified with spatial data (eg, maps, GIS coverage, classified imagery, or sampling grids) from which the area can be determined accurately. Land use/land cover maps in particular must be ground-truthed and current, less than 10 years old. Strata must be discernible taking into account good practice in terms of the accuracy requirements for the definition of strata limits / boundaries. This must be indicated in the project description and the choice must be justified.

For estimation of baseline net GHG emissions or removals, or estimation of project net GHG emissions or removals, strata must be defined on the basis of parameters that are key entry variables used to estimate changes in biomass stocks.

The project area may be stratified *ex ante*, and this stratification may be revised *ex post* for monitoring purposes. Strata need only reflect consistent differences in biomass stocks and not for example species composition or ecological variables. Established strata may be merged if reasons for their establishment have disappeared or have proven irrelevant to key variables for estimating forest carbon stocks or changes in forest carbon stocks.

For baseline net GHG emissions or removals: Stratification is carried out according to pre-project carbon stocks. This stratification must be determined prior to the project activity. For each stratum, assumptions must be made as to how the carbon stocks would be affected in the business as usual scenario. In case of relogging, this must be based on the relogging that has taken place in an appropriately selected reference area or on the basis of reliable management or logging plans for the project area indicating anticipated logging intensities. The remaining carbon stocks per stratum must be determined.

For project net GHG emissions and removals. The *ex-ante* estimations must be based on the project plan, which must include a timetable for and scheduling of the silvicultural interventions, such as for example liberation thinning and enrichment planting. The *ex-post* stratification must be based on the actual implementation of the projected activities. The *ex-post* stratification may be affected by natural or anthropogenic impacts if they add variability to growth pattern in the treated project area.

Baseline stratification must occur only once and remain fixed for the lifetime of the project, unless baseline monitoring occurs in a reference area.

Stratification in the with-project scenario must be updated at the time of each and every monitoring campaign prior to verification based on recent developments.

For *ex-ante* and *ex-post* stratification, project proponents may optionally make use of remote sensing data and analysis platforms acquired close to the time the project commences.

9 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

9.1 Baseline Emissions

9.1.1 General Approach

The baseline scenario is characterized by emissions from relogging, which in the with-project scenario are avoided, or an absent or limited regrowth of the residual forest, which in the with-project scenario may be enhanced, or a combination of these two.

If relogging occurs in the baseline scenario, the volume of biomass that would have been removed from the project area over the lifetime of the project can either be determined by:

1. Harvesting levels, defined in terms of cubic meters, as determined in advance and reflected for example in management plans for the project area; or

2. Post-relogging carbon stocks in a reference area.

In the first case above, the baseline net GHG emissions are estimated based on available information on the volume of timber removed and damage to the residual stand due to relogging, carbon storage in dead wood and harvested wood products, regrowth and project emissions.

'Harvested volume' or 'volume of timber removed' ($V_{harvest,i,j}$:) is measured as cubic meters removed from the forest and as reported in available information mostly based on for instance truck loads of timber that have been transported off-site. Most often timber is measured at the landing / yard before loading and freight bills accompany the timber to the place where it is transported to. Volumes are normally measured by authorities such as the Forest Department, or as a minimum inspected by such authorities, after which volumes of timber are reported. Volumes are normally calculated on the basis of diameter measurement on both sides of the log at the landing / yard with calipers and the length of the log, and specified per species.

In the second case, net emissions are estimated as the pre-relogging carbon stock minus the post-relogging carbon stock in biomass, dead wood and harvested wood products, taking also into account regrowth and project emissions.

Regrowth, if any, of the residual stand may be estimated on the basis of existing, peer-reviewed literature, quantifying regrowth in comparable areas, or in a reference area.

If a reference area is used for the estimation of baseline net GHG emissions or removals, this area is selected through the identification of areas where degradation and loss of biomass from relogging is expected to be similar to what would occur in the project area. Justification must be provided in the project description that the selected reference area is representative for the project area in the baseline scenario, and that the management of the reference area is not affected by its selection as such. The latter can be based on documented evidence that the planning of relogging occurred prior to the assignment as reference area by the IFM project proponent.

Alternatively, a sample of reference areas can be taken. The reference areas together must meet the criteria set out by the applicability conditions (minimum size) and those elaborated in this section (similarity to project area).

If emissions due to avoided timber harvesting in the baseline are determined based on activity levels in a reference area, project proponents must demonstrate that the quantification of avoided emissions in the with-project scenario is taking into account:

a. Similarity of strata and timber quantities:

Similar strata in the project area and in the reference area will have similar quantities of timber, and therefore, it can reasonably be assumed that logging intensities in those strata in the project area are the same as the logging intensity that took place in the reference area;

b. Areas for infrastructure establishment:

The same percentages of land are likely to be liberated for roads and log landings in the project area compared with the reference area; and,

c. Areas that do not contain merchantable timber and/or, are inaccessible for legislative, technical or economic reasons:

Such areas must be excluded from the area for which the changes in carbon stocks are estimated because they would have remained untouched in the baseline in any case.

Similarity of the reference area(s) to the project area can be demonstrated through meeting the following conditions, based on own measurements, literature recourses, datasets or a combination of these:

- Supporting comparable quantities of pre-relogging carbon stocks in above-ground woody biomass, or tree biomass with $DBH \geq 5$ cm, and dead wood before relogging and comparable predicted yields of commercial timber (all ±20%). If project proponents conservatively choose not to account for dead wood in the with-project scenario, similarity for the dead wood carbon pools between the reference area and the project area does not need to be demonstrated. In case of a larger difference than 20%, the project proponent must demonstrate that due to a larger or smaller carbon stock in above-ground tree biomass and/or dead wood in the reference area compared to the project area the value for relogging carbon stock losses is at least underestimated and thus a conservative result for the net GHG benefits of the project is obtained (eg, if biomass in forest in the reference area is greater than in the project area and relogging rates will be the same). Supporting documentation may include geo-referenced data in one or more of the following: management and/or logging plans, measurement data, peer-reviewed literature, maps and/or remotely sensed footage; and

- Having been subjected to the same management regime for first-round logging, as evidenced in management and/or logging plans; and

- Having comparable legal rights and harvesting rights.

This methodology accounts for carbon stock in above-ground tree biomass (AGB), below-ground biomass (BGB – optional), dead wood (DW) and carbon stored in wood products (WP). However, $C_{BSLpre,i}$ and $C_{BSLpost,i}$ below refer only to the AGB and DW carbon pools. These stocks are estimated through fieldwork, possibly combined with carbon stock determination methods using aerial photography or remote sensing, or the use of peer-reviewed default factors for the project area. Below-ground biomass is not included in the calculation of $\Delta C_{REL,i,t}$ because that would result into an overestimation of CO_2 emissions due to relogging in the baseline scenario.

The net baseline GHG emissions and removals can be estimated through one of the two following approaches:

1. Using Pre-relogging A-spatial Data; and,

2. Using Post-relogging Mid to High Resolution Spatial Data.

In both cases, the net CO_2 equivalent emissions in the baseline will be determined as:

$$\Delta C_{BSL} = \sum_{t=1}^{t*} \sum_{i=1}^{M_{BSL}} \left(\Delta C_{REL,i,t} + \Delta C_{tree-exist,i,t}\right) + GHG_{BSL-E,t} \quad (2)$$

Where:

Parameter	Description	Unit
ΔC_{BSL}	Net CO_2 equivalent emissions in the baseline scenario up to year *t**	t CO_2-e
$\Delta C_{REL,i,t}$	Net carbon stock change due to relogging in the baseline scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$\Delta C_{tree-exist,i,t}$	Net carbon stock change in existing tree vegetation[6] in the baseline scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$GHG_{BSL-E,t}$	Greenhouse gas emissions as a result of relogging within the project boundary in stratum *i* at year *t*	t CO_2-e yr^{-1}
i	1, 2, 3 …M_{BSL} strata in the baseline scenario	
t	1, 2, 3, … t^* years elapsed since the project start	

9.1.2 Pre-relogging A-spatial Data for $\Delta C_{REL,i,t}$

Estimates of the levels of forest degradation and therefore biomass loss can be obtained based on a-spatial information contained in either management or logging plans, harvesting records, or in legal documentation for the concession. Preferably this information relates to the project area, but if such information is not available it can be obtained from a reference area, provided that similarity requirements as described above are met or that it results in an underestimated value of relogging carbon stocks losses and thus a conservative result for the net GHG benefits for the project. Loss of biomass is estimated through predicted volumes of timber removals per hectare combined with

6 With *DBH* ≥ 5 cm.

estimates of damage to the residual stand and carbon storage in wood products. The estimated post-relogging carbon stock in dead wood at year *t* is quantified as being emitted over 10 years with a linear decay function, following the procedure described in the VCS AFOLU Requirements v3.3, section 4.5.3.

$$\Delta C_{REL,i,t} = \begin{pmatrix} A_{REL,i,t} \times \left(C_{harvest,i} + \left(C_{damage,i} - C_{DW,i,t}\right) - \left(\mathrm{C}_{\mathrm{WP100,i}} + C_{WP20,i,t}\right)\right) \\ + \sum_{t-20}^{t}\left(A_{REL,i,t} \times C_{WP20,i,t} \times \frac{1}{20}\right) + \sum_{t-10}^{t}\left(A_{REL,i,t} \times C_{DW,i,t} \times \frac{1}{10}\right) \end{pmatrix} \times \frac{44}{12} \qquad (3)$$

Where:

Parameter	Description	Unit
$\Delta C_{REL,i,t}$	Net carbon stock change due to relogging in the baseline scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$A_{REL,i,t}$	Area relogged in baseline stratum *i* at year *t*	ha yr^{-1}
$C_{harvest,i}$	Carbon stock in harvested timber in stratum *i*	t C ha^{-1}
$C_{damage,i}$	Carbon loss due to damage to the residual stand in stratum *i*	t C ha^{-1}
$C_{DW,I,t}$	Post-relogging carbon stock in dead wood in the baseline scenario (stock emitted is quantified over 10 years with a linear decay function) in stratum *i* at year *t*	t C ha^{-1}
$C_{WP100,i}$	Post-relogging carbon stock stored in long-term wood products (stock remaining in wood products after 100 years) in the baseline scenario in stratum *i*	t C ha^{-1}
$C_{WP20,i,t}$	Post-relogging carbon stock stored in short-term and medium-term wood products (stock emitted is quantified over 20 years with a linear decay function) in the baseline scenario in stratum *i* at year *t*	t C ha^{-1}
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
44/12	The ratio of molecular weight of carbon dioxide to carbon	t CO_2-e t C^{-1}

If no relogging occurs, $\Delta C_{REL,i,t}$ is equal to zero and Equation 3 does not need to be used.

The actual or predicted volume of timber to be harvested from each stratum, is estimated via the below equations.

Carbon Stock in Harvested and Damaged Wood

$$C_{harvest,i} = \sum_{j=1}^{S} (V_{harvest,i,j} \times D_j \times CF) \quad (4)$$

Where:

Parameter	Description	Unit
$C_{harvest,i}$	Carbon stocks in harvested timber in the baseline scenario in stratum *i*	t C ha^{-1}
$V_{harvest,i,j}$	Volume of timber harvested in the baseline scenario of species *j* in stratum *i*	m^3 ha^{-1} yr^{-1}
D_j	Basic density of the harvested wood of species *j*	t d.m. m^{-3}
CF	Carbon fraction of dry matter[7]	t d.m.$^{-1}$
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
j	1, 2, 3 … *S* tree species	

$$C_{damage,i} = C_{harvest,i} \times f_{damage} \quad (5)$$

Where:

Parameter	Description	Unit
$C_{damage,i}$	Loss of carbon due to damage to the residual stand in the baseline scenario, in stratum *i*	t C ha^{-1}
$C_{harvest,i}$	Carbon stocks in harvested timber in the baseline scenario in stratum *i*	t C ha^{-1}
f_{damage}	Factor for damage to the residual stand caused by relogging	

[7] IPCC default value = 0.50

i	1, 2, 3 … M_{BSL} strata in the baseline scenario	

C_{damage} represents all carbon in damaged biomass, including dead wood, resulting from logging. Accounting for C_{damage} as zero in the baseline scenario is therefore conservative and in this case accounting for C_{DW} can be omitted as well. If project proponents want to account for C_{damage}, both C_{damage} and C_{DW} must be estimated.

f_{damage} must be determined using appropriate measurement techniques such as those described in the project description of the Noel Kempff Mercado Climate Action Project (NKM-CAP), version 02.02, dated 7/11/2005, or other similar established emission quantification approaches. Alternatively, peer reviewed literature may be used to derive f_{damage} from areas for which it can be shown that they are representative for the project area or general f_{damage} proxies for natural Evergreen Tropical Rainforests for conventional and/or Reduced Impact Logging (eg, Pulkki (1997)).

If C_{DW} for the project area cannot be derived from peer-reviewed literature, data can be obtained using appropriate measurement techniques applied in areas for which it can be shown that they are representative for the project area. The method for estimating the carbon stock in dead wood from field measurements is outlined below.

Harvested Wood Products

In line with the VCS guidelines on wood products, long-term storage in this pool is accounted for using the below equations. In case no reliable assumptions can be made as to the timber classes of the harvested wood and its end use, general information from Forest Departments from that area reflecting breakdown of timber classes as they are normally harvested from this forest type and area may be used (eg, plywood, round logs, sawn timber, etc.).

This methodology follows the conceptual framework detailed in Winjum *et al.* (1998).[8]

Step 1: Estimate the biomass carbon of the volume extracted by wood product type *ty* at year *t* from within the project boundary:

$$C_{XB,ty,i,t} = \frac{1}{A_i} \times \sum_{j=1}^{S} \left(V_{ex,ty,j,i,t} \times D_j \times CF \right) \tag{6}$$

8 Winjum, J.K., Brown, S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. *Forest Science* 44: 272-284

Where:

Parameter	Description	Unit
$C_{XB,ty,i,t}$	Mean stock of extracted biomass carbon by class of wood product *ty* from stratum *i* at year *t*	t C ha^{-1}
A_i	Total area of stratum *i*	ha
$V_{ex,ty,j,i,t}$	Volume of timber extracted from within stratum *i* (does not include slash left onsite) by species *j* and wood product class *ty* at year *t*	m^3
D_j	Mean wood density of species *j*	t d.m.m^{-3}
CF	Carbon fraction of biomass	t C t^{-1} d.m.
t	1, 2, 3, … t^* years elapsed since the project start	
j	1, 2, 3 … *S* tree species	
ty	Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other	

Mean wood density of species (Dj)

Values for *Dj* can be taken from tables generally used in the local or regional timber and forest industry, or from peer-reviewed literature applicable to the region. If no species-specific values for *Dj* are available, the average value across all species can be used, increased by 20% to ensure a conservative (higher) estimate of $C_{WP100,i,t}$ and $C_{WP20,i,t}$ below.

Step 2: Estimate the proportion of biomass carbon extracted at year *t* that remains sequestered in long-term wood products after 100 years, and estimate the proportion of biomass carbon extracted at year *t* that is expected to be emitted from short-term and medium-term wood products over 20 years with a linear decay function.

$$C_{WP100,i,t} = \sum_{s,w,oir,p,o}^{ty} C_{XB,ty,i,t} \times (1 - ww_{ty}) - C_{WP20,i,t} \qquad (7a)$$

$$C_{WP20,i,t} = \sum_{s,w,oir,p,o}^{ty} \left(\left(C_{XB,ty,i,t} \times slp_{ty} \right) + \left(C_{XB,ty,i,t} \times \left(1 - slp_{ty} \right) \times fo_{ty} \right) \right) \qquad (7b)$$

Where:

Parameter	Description	Unit
$C_{WP100,i,t}$	Carbon stock in long-term wood products pool (stock remaining in wood products after 100 years) in stratum *i* at year *t*	t C ha^{-1}
$C_{WP20,i,t}$	Post-relogging carbon stock in short-term and medium-term wood products pool (stock emitted is quantified over 20 years with a linear decay function) in the baseline scenario in stratum *i* at year *t*	t C ha^{-1}
$C_{XB,ty,i,t}$	Mean stock of extracted biomass carbon by class of wood product *ty* from stratum *i* at year *t*	t C ha^{-1}
ww_{ty}	Wood waste fraction. The fraction immediately emitted through mill inefficiency	
slp_{ty}	Fraction of wood products that will be emitted to the atmosphere within 5 years of timber harvest	
fo_{ty}	Fraction of wood products that will be emitted to the atmosphere between 5 and 100 years of timber harvest	
ty	Wood product class – defined here as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other	
i	*1, 2, 3, …* M_{BSL} strata in the baseline scenario	
t	1, 2, 3, … t^* years elapsed since the project start	

Wood waste fraction (ww_{ty}):

Winjum *et al*. (1998) indicate that the proportion of extracted biomass ($C_{XB,ty}$) that is oxidized (burning or decaying) from the production of commodities to be equal to 19% for developed countries and 24% for developing countries. The fraction ww_{ty} is therefore equal to 0.19 for developed countries and 0.24 for developing countries.

Short-lived proportion (slp)

Winjum *et al.* (1998) give the following proportions for wood products with short-term (<5 yr) uses (*slp*) after which they are retired and oxidized (applicable internationally):

Wood Product Class	slp
Sawnwood	0.2
Woodbase panels	0.1
Other industrial roundwood	0.3
Paper and Paperboard	0.4

The methodology makes the assumption that all other classes of wood products are 100% oxidized within 5 years.

Additional oxidized fraction (fo)

Winjum *et al*. (1998) gives annual oxidation fractions for each class of wood products split by forest region. This methodology uses the fractions for tropical wood products, projected over 95 years to give the additional proportion that is oxidized between the 5th and 100th years after initial harvest:

Wood Product Class	*fo* (tropical)
Sawnwood	0.84
Woodbase panels	0.97
Other industrial roundwood	0.99
Paper and paperboard	0.99

9.1.3 Post-relogging Mid to High Resolution Spatial Data for $\Delta C_{REL,i,t}$

Where available, spatial data from a reference area that has undergone relogging can be combined with field sampling to produce post-relogging values of remaining biomass and dead wood. In case a sample of various reference areas is taken, the equation below provides for the calculations to be performed for each stratum *i* in these reference areas. The outcome of the equation must be the weighted average across similar strata in all reference areas, where the weighing factor is the total area of stratum *i* in each of the reference areas.

$$\Delta C_{REL,i,t} = \begin{pmatrix} A_{REL,i,t} \times \left(C_{BSLpre,i} - \left(C_{BSLpost,i} + \left(C_{DW,i,t} - C_{DWpre,i,t}\right) + \mathrm{C}_{\mathrm{WP100,i}} + C_{WP20,i,t}\right)\right) \\ + \sum_{t-20}^{t}\left(A_{REL,i,t} \times C_{WP20,i,t} \times \frac{1}{20}\right) + \sum_{t-10}^{t}\left(A_{REL,i,t} \times \left(C_{DW,i,t} - C_{DWpre,i,t}\right) \times \frac{1}{10}\right) \end{pmatrix} \times \frac{44}{12} \quad (8)$$

Where:

Parameter	Description	Unit
$\Delta C_{REL,i,t}$	Net carbon stock change due to relogging in the baseline scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$A_{REL,i,t}$	Area relogged in baseline stratum *i* at year *t*	ha yr^{-1}
$C_{BSLpre,i}$	Pre-relogging carbon stock in above-ground biomass in the baseline scenario in stratum *i*	t C ha^{-1}
$C_{DWpre,I,t}$	Pre-relogging carbon stock in dead wood (stock emitted is quantified over 10 years with a linear decay function) in stratum *i* at year *t*	t C ha^{-1}
$C_{BSLpost,i}$	Post-relogging carbon stock in above-ground biomass in the baseline scenario in stratum *i*	t C ha^{-1}
$C_{DW,i,t}$	Post-relogging carbon stock in dead wood in the baseline scenario (stock emitted is quantified over 10 years with a linear decay function in stratum *i* at year *t*	t C ha^{-1}
$C_{WP100,i}$	Carbon stock in long-term wood products pool (stock remaining in wood products after 100 years) in stratum *i* at year *t*	t C ha^{-1}
$C_{WP20,i,t}$	Post-relogging carbon stock in short-term and medium-term wood products pool (stock emitted over 20 years with a linear decay function) in the baseline scenario in stratum *i* at year *t*	t C ha^{-1}
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
44/12	The ratio of molecular weight of carbon dioxide to carbon	t CO_2-e t C^{-1}

If no relogging occurs, $\Delta C_{REL,i,t}$ is equal to zero and Equation 8 does not need to be used.

Pre-relogging Carbon Stocks in Above-ground Tree Biomass

Above-ground tree biomass carbon stocks prior to relogging ($C_{BSLpre,i}$) can be determined on the basis of previously conducted fieldwork or surveys or peer-reviewed proxies in the reference area. They can be estimated using the method outlined in Estimation of $\Delta C_{AGB,i,t}$.

In case data for $C_{BSLpre,i}$ cannot be obtained from the reference area (eg, because relogging has already occurred throughout the reference area), such information may also be obtained from parts of the project area that have not been treated with silvicultural techniques. Or, in case for the reference area data on $C_{BSLpost,i}$ and harvesting levels are available, $C_{BSLpre,i}$ can be approximated by the following equation:

$$C_{BSLpre,i} = C_{BSLpost,i} + C_{harvest,i} + C_{damage,i} \quad (9)$$

Values for $C_{harvest,i}$ and $C_{damage,i}$ must be obtained from management or logging plans, harvesting records and peer-reviewed literature as described previously.

Post-relogging Carbon Stocks in Above-ground Tree Biomass

$C_{BSLpost,i}$ can be estimated using the method outlined in Estimation of $\Delta C_{AGB,i,t}$ below.

Carbon Stock in Dead Wood

Estimating the baseline carbon stocks in dead wood as a result of relogging comprises of two components – *standing dead wood* and *lying dead wood*, both of which are estimated through field measurements within permanent sample plots. The methods for each of these two components are detailed below. Accounting for dead wood occurring prior to relogging as zero is conservative.

Standing Dead Wood

Step 1: Standing dead trees must be measured using the same techniques and criteria (eg, minimum *DBH*) used for measuring living trees, taking account of equations provided in Step 3. Stumps must be inventoried as if they are very short standing dead trees.

Step 2: The decomposition class (not to be confused with dead wood density class) of the dead tree must be recorded and the standing dead wood is categorized under two decomposition classes:

1. Tree with branches and twigs that resembles a live tree (except for leaves);

2. Tree with signs of decomposition (other than loss of leaves) including loss of twigs, branches, or crown.

Step 3: Biomass is estimated using an allometric equation or BEF calculation for live trees in the decomposition class 1; with no outward signs of decomposition (ie, twigs remaining) wood density is assumed to be comparable to live tree. Calculations for dealing with above-ground tree biomass are described above. In decomposition class 2, the estimate of biomass should be limited to the main trunk (bole) of the tree, in which case the biomass is calculated converting volume to biomass using the appropriate dead wood density class. Volume is estimated as either the volume of a cone if the top diameter cannot be measured (and is assumed to be zero), or a cylinder if the top diameter can be measured directly or by using an instrument such as a relascope or laser inventory instrument. Height/length is determined as either the total height in case of a standing bole or the height at the base of the crown if the crown is persistent[9].

[9] It is conservative and, therefore, acceptable to take the normal species' wood densities in case dead wood

For decomposition class 2, the biomass of standing dead trees is estimated as:

$$B_{SDW,l,sp,i,t} = \frac{1}{3} \times \pi \times \left(\frac{BDia_{SDW,l,sp,i,t}}{200} \right)^2 \times H_{SDW,l,sp,i,t} \times D_{DW,dc} \qquad (10)$$

Where:

Parameter	Description	Unit
$B_{SDW,l,sp,i,t}$	Biomass of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*;	t d.m.
$BDia_{SDW,l,sp,i,t}$	Basal diameter of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*;	cm
$H_{SDW,l,sp,i,t}$	Height of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*	m
$D_{DW,dc}$	Mean wood density of dead wood in the density class (dc) – sound (1), intermediate (2), and rotten (3);	t d.m. m^{-3}
sp	1, 2, 3 … P_i sample plots in stratum *i*	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3 … years elapsed since the start of the project activity	
l	1, 2, 3 … $N_{i,sp,t}$ standing dead trees in sample plot *sp* of stratum *i* at year *t*	

or (where top diameter is measured):

$$B_{SDW,l,sp,i,t} = \frac{BDia_{SDW,l,sp,i,t} + TD_{SDW,l,sp,i,t}}{200} \times H_{SDW,l,sp,i,t} \times D_{DW,dc} \qquad (11)$$

Where:

Parameter	Description	Unit
$B_{SDW,l,sp,i,t}$	Biomass of standing dead tree *l* from sample plot *sp* in stratum	t d.m.

density classes are not known.

	i at year *t*;	
$BDia_{SDW,l,sp,i,t}$	Basal diameter of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*;	cm
$TD_{SDW,l,sp,i,t}$	Top diameter of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*	cm
$H_{SDW,l,sp,i,t}$	Height of standing dead tree *l* from sample plot *sp* in stratum *i* at year *t*	m
$D_{DW,dc}$	Mean wood density of dead wood in the density class (dc) – sound (1), intermediate (2), and rotten (3);	t d.m. m^{-3}
sp	1, 2, 3 … P_i sample plots in stratum *i*	
I	1, 2, 3 … M_{BSL} strata in the baseline scenario	
T	1, 2, 3 … years elapsed since the start of the project activity	
I	1, 2, 3 … $N_{i,sp,t}$ standing dead trees in sample plot *sp* of stratum *i* at year *t*	

In selecting one of the 2 approaches provided above, project proponents must ensure that in the baseline scenario conservative estimates for dead wood are obtained.

Step 4: Estimate total carbon stock in standing dead trees present in the sample plot *sp* in stratum *i* at year *t*.

$$B_{SDW,sp,i,t} = \sum_{l=1}^{N_{sp,i,t}} B_{SDW,l,sp,i,t} \tag{12}$$

Where:

Parameter	Description	Unit
$B_{SDW,sp,i,t}$	Biomass of standing dead wood in sample plot *sp* in stratum *i* at year *t*;	t d.m
$B_{SDW,l,sp,i,t}$	Biomass of standing dead tree *l* in sample plot *sp* in stratum *i* at year *t*;	t d.m
sp	1, 2, 3 … P_i sample plots in stratum *i*	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	

t	1, 2, 3 … *t** years elapsed since the start of the project activity	
$N_{sp,i,t}$	Number of standing dead trees in sample plot *sp* of stratum *i* at year *t*	
l	1, 2, 3 … $N_{i,sp,t}$ standing dead trees in sample plot *sp* of stratum *i* at year *t*	

Step 5: Estimate the mean biomass stock per unit area in standing dead wood for each stratum at year *t*:

$$B_{SDW,i,t} = \frac{1}{A_{sp,i,t}} \times \sum_{sp=1}^{P_i} B_{SDW,sp,i,t} \qquad (13)$$

Where:

Parameter	Description	Unit
$B_{SDW,i,t}$	Biomass of standing dead wood in stratum *i* at year *t*	t d.m. ha^{-1}
$B_{SDW,sp,i,t}$	Biomass of standing dead wood in sample plot *sp* in stratum *i* at year *t*	t d.m
$A_{sp,I,t}$	Total area of all sample plots in stratum *i* in year *t*	ha
sp	1, 2, 3 … P_i sample plots in stratum *i*	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Lying Dead Wood

Step 1: Lying dead wood can be sampled using the line intersect method of Harmon and Sexton (1996)[10] or other peer reviewed and published methods. Harmon and Sexton prescribe two 50-meter lines to be established bisecting each sample plot and the diameters of the lying dead wood (≥ 10 cm diameter) intersecting the lines are measured.

---

10 Harmon, M.E. and J. Sexton. (1996) Guidelines for measurements of wood detritus in forest ecosystems. US LTER Publication No. 20. US LTER Network Office, University of Washington, Seattle, WA, USA.

Step 2: The dead wood is assigned to one of the three density states (sound, intermediate and rotten) using the ‘machete test’, as recommended by *IPCC Good Practice Guidance for LULUCF* (2003), Section 4.3.3.5.3.

Step 3: The volume of lying dead wood per unit area is estimated using the equation (Warren and Olsen 1964)[11] as modified by Van Wagner (1968)[12] separately for each density state:

$$V_{LDW,i,t} = \frac{\pi^2 \times \left(\sum_{n=1}^{N} Dia_{n,i,t}{}^2 \right)}{8 \times L} \qquad (14)$$

Where:

Parameter	Description	Unit
$V_{LDW,i,t}$	Volume of lying dead wood per unit area in stratum *i* at year *t*	$m^3\ ha^{-1}$
$Dia_{n,i,t}$	Diameter of piece *n* of dead wood along the transect in stratum *i* at year *t*	cm
n	1, 2, 3 … *N* wood pieces intersecting the transect	
L	Length of the transect	m
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

To convert this to a mass per unit area multiply the volumes of each density state by their respective wood densities as outlined below:

Step 4: Volume of lying dead wood must be converted into biomass using the following relationship:

$$B_{LDW,i,t} = \sum_{dc=1}^{3} V_{LDW,i,t} \times D_{DW,dc} \qquad (15)$$

[11] Warren, W.G. and Olsen, P.F. (1964) A line intersect technique for assessing logging waste. *Forest Science* 10: 267-276.

[12] Van Wagner, C.E. (1968). The line intersect method in forest fuel sampling. *Forest Science* 14: 20-26.

Where:

Parameter	Description	Unit
$B_{LDW,i,t}$	Biomass of lying dead wood per unit area in stratum *i* at year *t*	t d.m. ha^{-1}
$V_{LDW,i,t,}$	Volume of lying dead wood per unit area in stratum *i* at year *t*	m^3 ha^{-1}
$D_{DW,dc}$	Mean wood density of dead wood in the density class (dc) – sound (1), intermediate (2), and rotten (3)	t d.m. m^{-3}
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Total carbon stock in dead wood for each stratum is then calculated as the sum of standing and lying dead wood components.

$$C_{DW,i,t} = \left(\left(B_{SDW,i,t} + B_{LDW,i,t}\right) \times CF_{DW}\right) \quad (16)$$

Where:

Parameter	Description	Unit
$C_{DW,i,t}$	Carbon stock of dead wood in stratum *i* at year *t*	t C ha^{-1}
$B_{SDW,i,t}$	Biomass of standing dead wood in stratum *i* at year *t*	t d.m. ha^{-1}
$B_{LDW,i,t}$	Biomass of lying dead wood in stratum *i* at year *t*	t d.m. ha^{-1}
CF_{DW}	0.5 Default carbon fraction of dry matter in dead wood	t C t d.m.$^{-1}$
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Carbon stocks in Wood Products

The procedure to determine the carbon stocks stored in wood products in the baseline scenario is provided in the previous section.

9.1.4 Logging rate

To estimate the baseline net carbon loss for the entire project area, the total net loss of carbon in the baseline scenario for relogged strata as estimated using one of the above methods, must be multiplied with the rate at which logging would have occurred across the project area. Where a management plan exists outlining the phasing of logging activities for either the project area, or the reference area, that management plan may be used.

$$A_{i,t} = D\%_{i,t} \times A_{TOT,i} \tag{17}$$

Where:

Parameter	Description	Unit
$A_{i,t}$	Area logged in stratum *i* at year *t*	ha
$D\%_{i,t}$	Projected annual proportion of land that will be logged in stratum *i* at year *t*. If actual annual proportion is known and documented (eg, 25% per year for 4 years), set to proportion	% yr^{-1}
$A_{TOT,i}$	Total area logged in stratum *i*	ha
i	1, 2, 3 …M_{BSL} strata in the baseline scenario	
t	1, 2, 3, … t^* years elapsed since the project start	

Where no rate is available, it can be established through an examination of a reference area. This is done using the below equation:

$$D\%_{planned,i,t} = \sum_{pn=1}^{pn^*} \left(\left(D\%_{pn,i} / Yrs_{pn} \right) / n \right) \tag{18}$$

Where:

Parameter	Description	Unit
$D\%_{planned,i,t}$	Projected annual proportion of land that will be logged in stratum *i* at year *t*. If the actual annual proportion is known and documented (eg, 25% per year for 4 years), set to proportion	% yr^{-1}
$D\%_{pn,i}$	Percent of logged area in land parcel *pn* in stratum *i* of the	%

	reference area	
Yrs_{pn}	Number of years over which relogging occurred in land parcel *pn* in the reference area	yr
pn	1, 2, 3 … pn^* land parcels in the reference area	
n	Total number of land parcels examined	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	

9.1.5 Forest Regrowth

If no or insignificant regrowth occurs following first and subsequent logging, eg, due to the complete colonization by climbers and vines, this must be demonstrated by sampling above-ground carbon stocks in woody biomass in a time series of logging coupes (eg, in tranversal studies). The length of the time series must not be shorter than 75% of the length of the project crediting period.

When accounting for regrowth*, ex-ante* estimates of tree biomass regrowth in the baseline can be based on peer-reviewed literature providing values for regrowth from comparable residual forest types in comparable areas.

If regrowth occurs in the baseline scenario this is assumed to be small compared to regrowth in the with-project scenario. Furthermore, regrowth in the relogged residual stand is assumed to be smaller than regrowth in the pre-relogged residual stand. Therefore, as a conservative approach, the regrowth in the baseline case is estimated as the regrowth of the pre-relogged residual forest applied to the entire area of the stratum, despite any relogging in that stratum.

Estimates of changes in carbon stocks due to regrowth of tree biomass in the baseline, can be obtained from a (part of a) reference area that has not been relogged, or from parts of the project area that have not been treated with silvicultural techniques, as follows:

$$\Delta C_{tree-exist,i,t} = A_{i,t} \times \sum_{j=1}^{S} \Delta C_{tree-exist,j,i,t} \qquad (19)$$

Where:

Parameter	Description	Unit
$\Delta C_{tree-exist,i,t}$	Change in carbon stock in existing tree vegetation[13] in the	$t\ CO_2\text{-e}\ yr^{-1}$

[13] With *DBH* ≥ 5 cm.

	baseline in stratum *i* at year *t*	
$A_{i,t}$	Area of baseline stratum *i* at year *t*	ha
$\Delta C_{tree\text{-}exist,j,i,t}$	Change in carbon stock in existing tree vegetation in the baseline in species *j* in stratum *i* at year *t*	t CO_2-e ha^{-1} yr^{-1}
j	1, 2, 3 … *S* tree species	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3, … t^* years elapsed since the project start	

$\Delta C_{tree\text{-}exist,j,i,t}$ is estimated as follows:

$$\Delta C_{tree-exist,j,i,t} = \Delta C_{tree-exist-AB,j,i,t} + \Delta C_{tree-exist-BB,j,i,t} \tag{20}$$

Where:

Parameter	Description	Unit
$\Delta C_{tree\text{-}exist,j,i,t}$	Change in carbon stock in existing tree vegetation in the baseline in species *j* in stratum *i* at year *t*	t CO_2-e ha^{-1} yr^{-1}
$\Delta C_{tree\text{-}exist\text{-}AB,j,i,t}$	Change in above-ground carbon stock in trees in the baseline in species *j* in stratum *i* at year *t*	t CO_2-e ha^{-1} yr^{-1}
$\Delta C_{tree\text{-}exist\text{-}BB,j,i,t}$	Change in below-ground carbon stock in trees in the baseline in species *j* in stratum *i* at year *t*	t CO_2-e ha^{-1} yr^{-1}
j	1, 2, 3 … *S* tree species	
i	1, 2, 3 … M_{BSL} strata in the baseline scenario	
t	1, 2, 3, … t^* years elapsed since the project start	

To estimate $\Delta C_{tree\text{-}exist\text{-}AB,j,i,t}$ see subsection: “Changes in C Stock in Above-ground Tree Biomass”. The inclusion of below-ground biomass is optional. If below-ground biomass is included, $\Delta C_{tree\text{-}exist\text{-}BB,j,i,t}$ can be estimated as in subsection: “Changes in C Stock in Below-ground Tree Biomass”.

9.1.6 Estimation of the Carbon Stock in Trees at t0

The carbon stock in tree biomass at t0 is defined as $C_{AGB,i,t}$ (plus optionally below-ground biomass by using a root:shoot ratio as defined above) at t0 and can be estimated as follows.

1. As $C_{BSL,pre,i}$
2. Based on an inventory of above-ground tree carbon stocks from Parts of the project area that have not been treated with silvicultural techniques.

9.1.7 Baseline Activity Emissions

A number of emission sources can arise from the implementation of baseline activities. Project proponents may choose to omit accounting for those sources as that leads to conservative estimates of the overall carbon benefits of the project.

Possible emission sources include, but may not be limited to: timber harvesting/logging operations, emissions due to infrastructure establishment, log extraction and transport of logs to the wharf for export or to the local sawmill or to the local depot for onwards sale.

This methodology does not foresee in the quantification of emissions due to timber procession, whether it is grid or generator powered.

Therefore, the emissions associated with activities in the baseline are estimated as:

$$GHG_{BSL\text{-}E,t} = E_{clearing,t} + E_{harvesting,t} + E_{extraction,t} + E_{transport,t} \quad (21)$$

Where:

Parameter	Description	Unit
$GHG_{BSL\text{-}E,t}$	Baseline emissions from sources in the baseline scenario at year *t*	t CO_2-e yr^{-1}
$E_{clearing,t}$	Emissions due to the new establishment of infrastructure such as the construction of roads or log landings for baseline logging at year *t*	t CO_2-e yr^{-1}
$E_{harvesting,t}$	Emissions due to the harvesting operations such as felling and debranching, etc. at year *t*	t CO_2-e yr^{-1}
$E_{extraction,t}$	Extraction of logs from the tree stump to the log landing at year *t*	t CO_2-e yr^{-1}
$E_{transport,t}$	Emissions due to transport of the logs from the log landing to the wharf for export, the sawmill, or to the depot for onward sale at year *t*	t CO_2-e yr^{-1}
t	1, 2, 3, … t^* years elapsed since the project start	

$E_{clearing,t}$: Emissions due to clearing of the area for infrastructure establishment

Emissions due to the establishment of infrastructure such as the construction of roads and log landings is estimated by considering the emissions due to the removal of biomass, the emissions from the equipment used to remove the biomass and the emissions from the equipment used to grade the roads (fuel emissions).

$$E_{clearing,t} = E_{biomass,t} + E_{felling,t} + E_{grading,t} \quad (22)$$

Where:

Parameter	Description	Unit
$E_{clearing,t}$	Emissions due to the establishment of infrastructure at year *t*	t CO_2-e yr^{-1}
$E_{biomass,t}$	Emissions due to the removal of the biomass itself at year *t*	t CO_2-e yr^{-1}
$E_{felling,t}$	Emissions due to the equipment use for felling the biomass (fuel emissions) at year *t*	t CO_2-e yr^{-1}
$E_{grading,t}$	Emissions due to the equipment used for the grading of the roads (fuel emissions) at year *t*	t CO_2-e yr^{-1}

To determine the emissions due to the removal of the biomass present at locations where infrastructure is being established, the area used for such purposes needs to be determined. This can be done on the basis of remote imagery (photographs or satellite) or by using a reported percentage that is typical for the area. Such a percentage has to be derived from peer-reviewed literature applicable to the area, or from Pulkki (1997) who reported for conventional logging in Evergreen Tropical Rainforests, a conservative percent of area cleared for infrastructure of 12%.[14]

To estimate the emissions from the removal of the biomass the area can be multiplied by an average carbon stock value per hectare that is representative of the project area.

Emissions due to the loss of biomass from felling is quantified as follows:

$$E_{biomass,t} = C_{biomass} \times A_{infrastructure,t} \times (44/12) \quad (23)$$

[14] Pulkki, R.E. (1997). Literature synthesis on logging impacts in moist tropical forests. FAO Working Paper GFSS/WP/06. Here a range of 12-17% is reported and hence for the baseline scenario a value of 12% is considered conservative.

Where:

Parameter	Description	Unit
$E_{biomass,t}$	Emissions due to the removal of the biomass on the area dedicated to infrastructure at year *t*	t CO_2-e yr^{-1}
$C_{biomass}$	Carbon in biomass lost due to the clearing for infrastructure	t C ha^{-1}
$A_{infrastructure,t}$	Area designated for infrastructure at year *t*	ha yr^{-1}
44/12	The ratio of molecular weight of carbon dioxide to carbon	t CO_2-e t C^{-1}

$C_{biomass}$ equals the area-weighed C_{BSLpre}, see Equation 45.

$E_{felling,t}$: emissions due to the use of equipment for the removal of the biomass

Emissions due to the use of equipment for the removal of biomass are quantified as follows:

$$E_{felling,t} = FC_{equip} \times EF_{fuel} \times V_{infrastructure,t} \qquad (24)$$

Where:

Parameter	Description	Unit
$E_{felling,t}$	Emissions due to the use of equipment for removal of the biomass on the area dedicated to infrastructure at year *t*	t CO_2-e yr^{-1}
FC_{equip}	Fuel consumption of equipment employed for felling	kL m^{-3}
EF_{fuel}	Fuel emission factor	t CO_2-e kL^{-1}
$V_{infrastructure,t}$	Volume of trees felled to clear the area designated for infrastructure at year *t*	m^3 yr^{-1}

$E_{grading,t}$: emissions due to the use of equipment for the grading of the roads

Emissions due to the use of equipment for grading roads are quantified as follows:

$$E_{grading,t} = FC_{grader} \times EF_{fuel} \times A_{infrastructure,t} \qquad (25)$$

Where:

Parameter	Description	Unit
$E_{grading,t}$	Emissions due to road grading at year *t*	t CO_2-e yr^{-1}
FC_{grader}	Fuel consumption of equipment employed for road grading	kL ha^{-1}
EF_{fuel}	Fuel emission factor	t CO_2-e kL^{-1}
$A_{infrastructure,t}$	Area designated for infrastructure at year *t*	ha yr^{-1}

$E_{harvesting,t}$: emissions due to the extraction of logs from the forest

Emissions are estimated as:

$$E_{harvesting,t} = FC_{equip} \times EF_{fuel} \times V_{harvested,t} \quad (26)$$

Where:

Parameter	Description	Unit
$E_{harvesting,t}$	Emissions due to harvesting at year *t*	t CO_2-e yr^{-1}
FC_{equip}	Fuel consumption of the equipment employed for harvesting	kL m^{-3}
EF_{fuel}	Fuel emission factor	t CO_2-e kL^{-1}
$V_{harvested,t}$	Volume harvested at year *t*	m^{-3} yr^{-1}

Volume harvested in the baseline is determined through Section 9.1.

This methodology in Section 9.1 facilitates the quantification of the volume harvested in two ways:

- On the basis of a-spatial data in a pre-relogging situation in the project area (for instance on the basis of information in a management plan); or,
- By the determination of the four components after relogging has occurred in a reference area for which similarity to the project area is demonstrated.

This quantification exercise determines amongst other the relationship between cubic meters of timber removed/harvested in the baseline. The correlation between the two baseline options and the project area is established by analyzing the logging rates in the various strata in the baseline, determination of the same strata in the project area, and the application of the stratum specific logging rates to the strata in the project area. This is a valid approach because the reference area is subjected to strict selection criteria that ascertain similarity to the project area. That parameter value determined by this approach is also used in this section as the harvested volume.

Alternatively, $E_{harvesting,t}$ can be determined on the basis of fuel consumed by the company for the purpose of its felling and debranching activities.

As default fuel consumption (FC) 1.28 – 1.73 liter per m^3 can be used. For new and efficient machinery the parameter value of 1.28 can be applied. For old and inefficient machinery 1.73 must be used.

$E_{extraction,t}$: emissions due to the extraction of the timber

Timber extraction from the forest to the log landing can be conducted with various types of machines. This methodology provides a quantification approach for extraction with medium sized bulldozers for transport to road side and trucks or trailers for transport to the log landings.

Emissions from log extraction and transport to log landing are estimated as:

$$E_{extraction,t} = (D_{extr\_total} / Eff_{fuel}) \times EF_{fuel} \quad (27)$$

$$D_{extr\_total} = D_{aver\ extrac} \times N_{trucks} \times 2 \quad (28)$$

$$N_{trucks} = V_{extr} / Cap_{truck} \quad (29)$$

Where:

Parameter	Description	Unit
$E_{extraction,t}$	Emissions due to extraction of timber from the forest to the log landings at year *t*	t CO_2-e yr^{-1}
D_{extr_total}	Total timber extraction distance	km
Eff_{fuel}	Fuel efficiency for medium-sized bulldozers/trucks/trailers	km kL^{-1}
EF_{fuel}	Fuel emission factor	t CO_2-e kL^{-1}
$D_{aver\ extrac}$	Average extraction distance of logs from stump to log landing	km
N_{trucks}	Number of trucks	
V_{extr}	Volume of timber extracted from the forest	m^{-3}
Cap_{truck}	Capacity of the truck	m^3 $truck^{-1}$

Default parameter values for medium sized bulldozers are estimated to be similar to those of truck and trailers. The defaults, including those for associated emission factors and fuel efficiency are derived from Kinjo et al. (2005) as cited in Carbon Planet (2009) and are: truck / trailer load capacity (10 m^3 $truck^{-1}$); EF_{fuel} (2.9 t CO_2-e kL^{-1}); and, Eff_{fuel} (3000 km kL^{-1}).

$E_{transport,t}$: emissions due to the transport of the logs from the log landing to the point of onward transport (eg, to a wharf in case of export) or point of (local) sale

Emissions from log extraction and transport to log landing are estimated as:

$$E_{transport,t} = (D_{trans\_total} / Eff_{fuel}) \times EF_{fuel} \quad (30)$$

$$D_{trans\_total} = D_{aver\ trans} \times N_{trucks} \times 2 \quad (31)$$

$$N_{trucks} = V_{trans} / Cap_{truck} \quad (32)$$

Where:

Parameter	Description	Unit
$E_{transport,t}$	Emissions due to the transport of the timber from the log landings to point of onward sale/transport at year *t*	t CO_2-e yr^{-1}
D_{trans_total}	Total timber transport distance	km
Eff_{fuel}	Fuel efficiency for medium-sized bulldozers/trucks/trailer	km kL^{-1}
EF_{fuel}	Fuel emission factor	t CO_2-e kL^{-1}
$D_{aver\ trans}$	Average transport distance of logs log landing to point of onward sale/transport	km
N_{trucks}	Number of trucks	
V_{trans}	Volume of timber transported	m^{-3}
Cap_{truck}	Capacity of the truck	m^3 $truck^{-1}$

9.2 Project Emissions

The net greenhouse gas emission reduction and removals in the with-project scenario must be estimated using the equations in this section. When applying these equations for the *ex-ante* estimation of total net GHG emission reduction by the IFM project activity, project proponents must provide estimates of the values of those parameters that are not available before the start of the project crediting period and commencement of monitoring activities. Project proponents must retain a conservative approach in making these estimates.

GHG emissions and removals in the with-project scenario are related to regrowth of the residual forest, silvicultural interventions such as climber cutting, liberation thinning, enrichment planting and/or harvesting, or a combination of these activities, and project implementation activities, such as the ones listed in Section 9.1.7.

Net CO_2 equivalent emissions in the with-project scenario (WPS) are estimated as:

$$\Delta C_{WPS} = \sum_{t=1}^{t*} \sum_{i=1}^{M_{WPS}} \Delta C_{P,i,t} + GHG_{WPS-E,t} \quad (33)$$

Where:

Parameter	Description	Unit
ΔC_{WPS}	Net CO_2 equivalent emissions in the with-project scenario up to year *t**	t CO_2-e yr^{-1}
$\Delta C_{P,i,t}$	Net carbon stock change due to forest regrowth and silvicultural interventions in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$GHG_{WPS-E,t}$	Greenhouse gas emissions related to project implementation at year *t*	t CO_2-e yr^{-1}

9.2.1 Net carbon stock changes due to forest regrowth and silvicultural interventions

Estimation of $\Delta C_{P,i,t}$

Net carbon stock changes due to forest regrowth and silvicultural interventions in the with-project scenario are estimated as follows:

$$\Delta C_{P,i,t} = \Delta C_{AGB,i,t} + \Delta C_{BGB,i,t} + \Delta C_{DW,i,t} + \Delta C_{WP,i,t} - E_{biomassloss,i,t} \quad (34)$$

Where:

Parameter	Description	Unit
$\Delta C_{P,i,t}$	Net carbon stock change due to forest regrowth and silvicultural interventions in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$\Delta C_{AGB,i,t}$	Net carbon stock change in above-ground tree biomass[15] in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}

[15] With *DBH* ≥ 5 cm.

$\Delta C_{BGB,i,t}$	Net carbon stock change in below-ground tree biomass in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$\Delta C_{DW,i,t}$	Net carbon stock change in dead wood in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$\Delta C_{WP,i,t}$	Net carbon stock change in wood products in the with-project scenario in stratum *i* at year *t*	t CO_2-e yr^{-1}
$E_{biomassloss,i,t}$	Emissions due to site preparation for project activities in stratum *i* at year *t*	t CO_2-e yr^{-1}
t	1, 2, 3 … *t** years elapsed since the start of the project activity	
i	1, 2, 3 … M_{WPS} strata in the with-project scenario	

Accounting for dead wood in the with-project scenario as zero is conservative. Accounting for wood products in the with-project scenario as zero is conservative.

Estimation of $\Delta C_{AGB,i,t}$

The changes in the carbon stock in above-ground tree biomass within the project boundary are estimated using the following approach:

$$\Delta C_{AGB,i,t} = A_{i,t} \times (C_{AGB,i,t} - C_{AGB,i,t-T}) \times 44/12 / T \qquad (35)$$

Where:

Parameter	Description	Unit
$\Delta C_{AGB,i,t}$	Net carbon stock change in above-ground tree biomass in stratum *i* at year *t*	t CO_2-e
$C_{AGB,i,t}$	Carbon stock in above-ground tree biomass in stratum *i* at year *t*	t C ha^{-1}
t	1, 2, 3 … ***t**** years elapsed since the start of the project activity	
i	1, 2, 3 … M_{WPS} strata in the with-project scenario	
44/12	Ratio of molecular weights of CO_2 and carbon	t CO_2-e t C^{-1}

$A_{i,t}$	Area of stratum *i* at year *t*	ha
T	Number of years between monitoring times t_m *and* t_{m-1}	

Changes in C Stock in Above-ground Tree Biomass[16]

The mean carbon stock in above-ground tree biomass per unit area is estimated for each stratum on the basis of field measurements in permanent sample plots. Two methods are available: the Biomass Expansion Factors (*BEF*) method and the Allometric Equations method.

<u>BEF method</u>

Step 1: Determine on the basis of available data, eg, volume tables (*ex ante*) and measurements (*ex post*) the diameter at breast height (*DBH,* at typically 1.3 m above-ground level), and also preferably height (*H*), of all the trees above some minimum *DBH* in the permanent sample plots. The exact tree dimensions to be measured will be specified by the information obtained in Step 2.

Step 2: Estimate the stem volume of trees based on available equations or yield tables (if locally derived equations or yield tables are not available use relevant regional, national or default data as appropriate).

It is possible to combine Steps 1 and 2 if volume tables allow for deriving average volume of trees, or field instruments (eg, a relascope) that measure the volume of each tree directly are applied.

Step 3: Choose *BEF*

Step 4: Convert the stem volume of trees into carbon stock in above-ground tree biomass via basic wood density, the *BEF* and the carbon fraction:

$$C_{AGB,l,j,i,sp,t} = V_{l,j,i,sp,t} \times D_j \times BEF_j \times CF_j \quad (36)$$

[16] This section, with the Biomass Expansion Factors (*BEF*) method and the Allometric Equations method, including a number of additional steps to expand AGB to include below-ground biomass, etc., are part of several CDM EB approved methodologies, including for instance AR-ACM0002.

Where:

Parameter	Description	Unit
$C_{AGB,l,j,i,sp,t}$	Carbon stock in above-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at year *t*	$t\ C\ tree^{-1}$
$V_{l,j,sp,t}$	Stem volume of tree *l* of species *j* in plot *sp* in stratum *i* at year *t*	$m^3\ tree^{-1}$
D_j	Basic wood density of species *j*	$t\ d.m.\ m^{-3}$
BEF_j	Biomass expansion factor for conversion of stem biomass to above-ground tree biomass for species *j*	
CF_j	Carbon fraction[17] of biomass for tree species *j*	$t\ C\ t\ d.m.^{-1}$
l	1, 2, 3 … $N_{j,i,sp,t}$ individual trees of species *j* in sample plot *sp* in stratum *i* at year *t*	
i	1, 2, 3 … M_{WPS} strata in the with-project scenario	
j	1, 2, 3 … S_{WPS} tree species in the with-project scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Step 5: Calculate carbon stock in above-ground biomass of all trees present in plot *sp* in stratum *i* at time *t* (ie, summation over all trees *l* by species *j* followed by summation over all species *j* present in plot *sp*).

$$C_{AGB,i,sp,t} = \sum_{j=1}^{S_{WPS}} \sum_{l=1}^{N_{j,i,sp,t}} C_{AGB,l,j,i,sp,t} \qquad (37)$$

[17] IPCC default = 0.5

Where:

Parameter	Description	Unit
$C_{AGB,i,sp,t}$	Carbon stock in above-ground biomass of trees on plot *sp* of stratum *i* at time *t*	t C
$C_{AGB,l,j,i,sp,t}$	Carbon stock in above-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at time *t*	t C tree^{-1}
l	1, 2, 3 … $N_{j,i,sp,t}$ individual trees of species *j* in sample plot *sp* in stratum *i* at year *t*	
i	1, 2, 3 … M_{WPS} strata in the with-project scenario	
j	1, 2, 3 … S_{WPS} tree species in the with-project scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Step 6: Estimate the mean carbon stock in above-ground tree biomass for each stratum:

$$C_{AGB,i,t} = \frac{1}{A_{sp_i}} \sum_{sp=1}^{P_i} C_{AGB,i,sp,t} \tag{38}$$

Where:

Parameter	Description	Unit
$C_{AGB,i,t}$	Above-ground carbon stock in trees in stratum *i* at year *t*	t C ha^{-1}
$C_{AGB,i,sp,t}$	Above-ground carbon stock in trees on plot *sp* of stratum *i* at year *t*	t C
$A_{sp,i}$	Total area in all sample plots in stratum *i*	ha
sp	1, 2, 3 … *Pi* sample plots in stratum *i* in the with-project scenario	
i	1, 2, 3 … M_{WPS} strata in the project scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Allometric Equations Method

Step 1: Proceed as in Step 1 of the *BEF* Method. The exact tree dimensions to be measured will be specified by the equation selected in Step 2.

Step 2: Select or develop an appropriate allometric equation (if possible species-specific, or if not, from a similar species).

If default allometric equations are available for conditions that are similar to the project (same vegetation genus; same climate zone; similar forest type), then the equation may be used and considered conservative. Otherwise, it is necessary either to use conservatively assessed values, or to verify the applicability of the equation if mean predicted values are to be used.

When allometric equations developed from a biome-wide database, such as those in Annex 4A.2, Tables 4.A.1and 4.A.2 of GPG LULUCF, or updated in IPCC 2006 Guidelines for AFOLU, are used, allometric equations can be verified by:

- Selecting at least 5 trees covering the range of *DBH* existing in the project area, and felling and weighing the above-ground tree biomass to determine the total (wet) weight of the stem and branch components;

- Determining the total dry weight of each tree from the wet weights and the averaged ratios of wet and dry weights of the stem and branch components.

If the biomass of the harvested trees is within about ±10% of the mean values predicted by the selected default allometric equation, and is not biased—or if biased is wrong on the conservative side (ie, use of the equation results in an under- rather than over-estimate of project net anthropogenic removals by sinks)—then mean values from the default equation may be used. (IPCC Good Practice Guidance for LULUCF, 2003, Section 4.3.3.5.1, under direct approach Step 3).

When allometric equations are used that are not developed from a biome-wide database as mentioned above, a one-sided t-test (with alpha = 0.05) should be applied to determine whether the biomass predicted by the allometric equation does not exceed the biomass from the harvested trees. To obtain biomass from the harvested trees, the same procedure as described above should be used.

Step 3: Estimate carbon stock in above-ground biomass for each individual tree *l* of species *j* in the sample plot located in stratum *i* using the selected or developed allometric equation applied to the tree dimensions determined in Step 1, and sum the carbon stocks in the sample plot:

$$C_{AGB,j,i,sp,t} = \sum_{l=1}^{N_{j,sp}} f_j(X, Y, ...) \times CF_j \tag{39}$$

Where:

Parameter	Description	Unit
$C_{AGB,j,i,sp,t}$	Carbon stock in above-ground biomass of trees of species *j* on sample plot *sp* of stratum *i* at year *t*;	t C
CF_j	Carbon fraction of dry matter for species or type *j*	t C t^{-1} d.m.

$f_j(X, Y, …)$	Allometric equation for species *j* linking measured tree dimension variables (eg, diameter at breast height (*DBH*) and possibly height (*H*)) to above-ground biomass of living trees	t d.m. $tree^{-1}$
i	1, 2, 3 … M_P strata in the with-project scenario	
j	1, 2, 3 … S_{WPS} tree species in the with-project scenario	
l	1, 2, 3 … $N_{j,i,sp,t}$ individual trees of species *j* in sample plot *sp* in stratum *i* at year *t*	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	

Step 4: Estimate the mean carbon stock in above-ground tree biomass for each stratum, as per the *BEF* method.

Estimation of $\Delta C_{BGB,i,t}$

The annual changes in below-ground tree biomass are estimated for each stratum on the basis of above-ground tree biomass. By using a root:shoot ratio, below-ground biomass is calculated from above-ground biomass, following Equation (40) below. Calculation of the parameter $\Delta C_{AGB,i,t}$ is described in "Estimation of $\Delta C_{AGB,i,t}$".

$$\Delta C_{BGB,i,t} = \Delta C_{AGB,i,t} \times R_j \quad (40)$$

Where:

Parameter	Description	Unit
$\Delta C_{BGB,i,t}$	Net carbon stock change in below-ground tree biomass in the with-project scenario in stratum *i* at year *t*	t CO_2 yr^{-1}
$\Delta C_{AGB,i,t}$	Net carbon stock change in above-ground tree biomass in the with-project scenario in stratum *i* at year *t*	t CO_2 yr^{-1}
R_j	Root:shoot ratio for tree species *j*	t root d.m. t^{-1} shoot d.m.
t	1, 2, 3 … ***t**** years elapsed since the start of the project activity	

i	1, 2, 3 … M_{WPS} strata in the with-project scenario	

9.2.2 Changes in carbon stocks in dead wood

Carbon stock changes in the project are monitored using the stock change method:

$$\Delta C_{DW,i,t} = (C_{DW,i,t} - C_{DW,i,t-T}) / T \quad (41)$$

Where:

Parameter	Description	Unit
$\Delta C_{DW,i,t}$	Annual net carbon stock change in dead wood for stratum *i*, at year *t*;	t CO_2-e ha^{-1} yr^{-1}
$C_{DW,i,t}$	Carbon stock in dead wood for stratum *i,* at year *t*;	t CO_2-e ha^{-1}
i	1, 2, 3 … M_P strata in the with-project scenario	
t	1, 2, 3 … *t** years elapsed since the start of the project activity	
T	Number of years between monitoring times t_m and t_{m-1}	

9.2.3 Changes in carbon stocks in wood products

Carbon stock changes in the project are monitored using the stock change method:

$$\Delta C_{WP,i,t} = (C_{WP,i,t} - C_{WP,i,t-T}) / T \quad (42)$$

Where:

Parameter	Description	Unit
$\Delta C_{WP,i,t}$	Annual net carbon stock change in wood products for stratum *i* at year *t*;	t CO_2-e ha^{-1} yr^{-1}
$C_{WP,i,t}$	Carbon stock in wood products for stratum *i* at year *t*;	t CO_2-e ha^{-1}
i	1, 2, 3 … M_P strata in the with-project scenario	

t	1, 2, 3 … t^* years elapsed since the start of the project activity	
T	Number of years between monitoring times t_m and t_{m-1}	

9.2.4 Emissions due to site preparation for project activities

If any site preparation occurs for liberation thinning and enrichment planting, then $E_{biomassloss}$ must be estimated when significant, using the most recent version of the CDM approved methodological tool "Estimation of emissions from clearing, burning and decay of existing vegetation due to implementation of an A/R CDM project activity"[18].

If however, the emissions due to changes in carbon stock in tree vegetation due to site preparation are insignificant they may be ignored. The removal of herbaceous vegetation (including climbers and vines) is deemed an insignificant emissions source and therefore is not accounted for in the with-project scenario.

9.2.5 GHG emissions as a result of the implementation of the project activity

There are various sources of emissions resulting from the general project implementation. These can include, but may not be limited to:

- Emissions due to administration, data-processing, and/or operating field station(s): grid or generator powered electricity;
- Emissions due to travel of project staff (ground transport, flights, etc.);
- Emissions due to travel and transport of external visitors (eg, auditing companies, consultants, etc.)

This will require information on kL fuel combusted, energy consumption or efficiency rates, km travelled, emission factors for various types of fuels, emissions associated with electricity generation, etc.

Approaches for estimating GHG_{WPS-E} are similar to those for GHG_{BSL-E}.

9.3 Leakage

9.3.1 Identification of sources of leakage

Leakage is defined as any increase in greenhouse gas emissions that occurs outside a project's boundary (but within the same country), that is measurable and attributable to the project activity. Its

18 Available at: <http://cdm.unfccc.int/>

effects on all carbon pools must be assessed and significant effects taken into account when estimating net emission reductions.

The applicability conditions determine that: “biomass burning, fuel gathering, removal of litter, or removal of dead wood do not occur in the baseline scenario and in the with-project scenario within the project boundary”. Therefore, this methodology only provides for the determination of leakage due to market effects.

$$\Delta C_{LK} = \Delta C_{LK\text{-}ME} \quad (43)$$

9.3.2 Quantification of leakage due to market effects

Option 1: This methodology applies to project activities, which reduce harvest levels in comparison with the baseline and possible reference areas. Therefore, the following leakage credit adjustment can be applied.

Project Action	Leakage Risk	Leakage credit adjustment (discount)
Substantially reduce harvest levels permanently (eg, RIL activity that reduces timber harvest by 25% or more across the project area; or, a forest protection/no logging project)	Moderate to High Depends on where timber harvest is likely to be shifted	Depends on where timber harvest is likely to be shifted to: • Similar carbon dense forests within the country: 40% • Less carbon dense forests within the country: 20% • More carbon dense forests within country: 70% • Out of country: 0% (according to stated VCS and CDM policy of not accounting for international leakage)

$$\Delta C_{LK\text{-}ME} = LF_{ME} \times \Delta C_{REL} \quad (44)$$

Where:

Parameter	Description	Unit
$\Delta C_{LK\text{-}ME}$	Total GHG emissions due to market-effects leakage	t CO_2-e
LF_{ME}	Leakage factor for market-effects calculations	

ΔC_{REL}	Emissions from relogging displaced through implementation of the project activities across strata	t CO_2-e

LF_{ME}, the leakage factor, depends upon where in the country logging might be increased, as a result of a decrease in timber supply from the project area.

$LF_{ME} = 0$ if it can be demonstrated to the verifier that no market-effects leakage will occur within national boundaries, eg, if no new concessions are being assigned AND annual extracted volumes per hectare in existing concessions have not increased in comparison to previously documented and projected and authorised extraction levels within existing concessions in the host country.

$LF_{ME} = 0.4$ if $C_{BSLpre} = NCS$

(if $C_{BSLpre} \leq NCS \times 1.15$ and $\geq NCS \times 0.85$)

$LF_{ME} = 0.7$ if $C_{BSLpre} < NCS \times 0.85$

$LF_{ME} = 0.2$ if $C_{BSLpre} > NCS \times 1.15$

Where:

Parameter	Description	Unit
LF_{ME}	Leakage factor for market-effects calculations	
NCS	The mean national forest carbon stock	t C ha^{-1}
C_{BSLpre}	Pre-relogging mean carbon stock in above-ground tree biomass across strata in the baseline scenario	t C ha^{-1}

Estimating C_{BSLpre} involves area-weighting the stocks across the strata:

$$C_{BSLpre} = \frac{\sum_{i=1}^{M_{BSL}} \left(C_{BSLpre,i} \times A_{REL,i} \right)}{\sum_{i=1}^{M_{BSL}} A_{REL,i}} \quad (45)$$

Where:

Parameter	Description	Unit
C_{BSLpre}	Mean carbon stock across strata in all pools selected in the	t C ha^{-1}

	baseline	
$C_{BSLpre,i}$	Carbon stock in all pools selected in the baseline in stratum *i*	t C ha^{-1}
$A_{REL,i}$	Area relogged in baseline stratum *i*	ha
I	1, 2, 3 …M_{BSL} strata in the baseline scenario	
M_{BSL}	The total number of strata in the baseline scenario	

ΔC_{REL} equals emissions from harvests displaced through implementation of the project activities as quantified in Sections 9.1.3 or 9.1.4, summed across strata.

Option 2: Instead of applying the default market leakage effect discount above, project proponents may opt to estimate the project's market leakage effect across the entire country and/or use analysis(es) from other similar projects to justify a different market leakage value.

9.4 Summary of GHG Emission Reduction and/or Removals

The total net GHG benefits from the IFM project activity (ΔC_{IFM}) are calculated as the result of the total carbon loss in the baseline scenario (ΔC_{BSL}) and the net removals through the enhancement of forest growth due to liberation thinning and enrichment planting (ΔC_{WPS}), minus any potential leakage (ΔC_{LK}) that might occur.

$$\Delta C_{IFM} = \Delta C_{BSL} - \Delta C_{WPS} - \Delta C_{LK} \quad (46)$$

Where:

Parameter	Description	Unit
ΔC_{IFM}	Total net GHG emission reductions from the IFM project activity up to year *t*	t CO_2-e
ΔC_{BSL}	Sum of the carbon stock changes and greenhouse gas emissions under the baseline scenario up to year *t*	t CO_2-e
ΔC_{WPS}	Sum of the carbon stock changes and greenhouse gas emissions under the with-project scenario up to year *t*	t CO_2-e
ΔC_{LK}	Sum of the carbon stock changes and greenhouse gas emissions due to leakage up to year *t*	t CO_2-e

ΔC_{IFM} must be corrected for uncertainty, as follows:

$$C_{IFM\_ERROR} = \sqrt{Uncertainty_{BSL}^{\ 2} + Uncertainty_{WPS}^{\ 2}} \tag{47}$$

Where:

Parameter	Description	Unit
C_{IFM_ERROR}	Total uncertainty for IFM project activity	%
$Uncertainty_{BSL}$	Total uncertainty in baseline scenario	%
$Uncertainty_{WPS}$	Sum of the carbon stock changes and greenhouse gas emissions under the with-project scenario up to year *t*	%

The procedure for estimating C_{IFM_ERROR} must be in accordance with the most recent version of the *Tool for Estimating Uncertainty in IFM Project Activities.*

If $C_{IFM\_ERROR} \leq 10\%$ of $\Delta C_{IFM,\,t}$ then no deduction must result for uncertainty.

If $C_{IFM\_ERROR} > 10\%$ of $\Delta C_{IFM,\,t}$ then the modified value for $\Delta C_{IFM,\,t}$ to account for uncertainty must be:

$$= \frac{100 - C_{IFM\_ERROR}}{100} \times C_{IFM,t} \tag{48}$$

Where:

Parameter	Description	Unit
$\Delta C_{IFM,\,t}$	Total net GHG emission reductions from the IFM project activity up to year *t*	$t\ CO_2$-e
C_{IFM_ERROR}	Total uncertainty for IFM project activity	%

Calculation of Verified Carbon Units

The number of Verified Carbon Units is calculated as follows:

$$VCU_{t2} = \left(\Delta C_{IFM,t2} - \Delta C_{IFM,t1}\right) \times \left(\frac{100 - C_{IFM\_ERROR}}{100}\right) - Bufferwithholding_{t2} \quad (49)$$

Where:

Parameter	Description	Unit
$VCU_{,t2}$	Number of Verified Carbon Units at year *t2*	
$\Delta C_{IFM,\ t1}$	Total net GHG emission reductions from the IFM project activity up to year *t1*	t CO_2-e
$\Delta C_{IFM,\ t2}$	Total net GHG emission reductions from the IFM project activity up to year *t2*	t CO_2-e
C_{IFM_ERROR}	Total uncertainty for IFM project activity	%
$Bufferwithholding_{t2}$	The number of VCU's to be withheld in the VCS AFOLU Pooled Buffer Account at year *t2*	

The percentage to be withheld in the VCS AFOLU Pooled Buffer Account is to be determined using the VCS Tool for AFOLU Non-Permanence Risk Analysis and Buffer Determination. This percentage is to be multiplied with the carbon stock changes within the project boundary at year *t2* in order to obtain the parameter $Bufferwithholding_{t2}$.

10 MONITORING

10.1 General

The monitoring plan must contain at least the following sections:

- Monitoring of stock changes and greenhouse gas emissions in the baseline (only under certain conditions)
- Monitoring of project carbon stock changes and greenhouse gas emissions
- Monitoring of leakage carbon stock changes and greenhouse gas emissions
- Estimation of ex-post total net carbon stock changes and greenhouse gas emissions.

This must include the following elements:

- A description of each monitoring task to be undertaken, and the technical requirements
- Parameters to be measured
- Data to be collected and data collection techniques
- Frequency of monitoring
- Quality Assurance and Quality Control (QA/QC) procedures
- Data archiving procedures
- Roles, responsibilities and capacity of monitoring team and management

All data collected as part of monitoring should be archived electronically and be kept at least for 2 years after the end of the last project crediting period. One hundred percent of the data should be monitored if not indicated otherwise in the tables below. All measurements should be conducted according to relevant standards. In addition, the monitoring provisions in the tools referred to in the most recent version of the CDM methodology AR-ACM0002, Version 1 or its replacement must apply.

Data archiving must take both electronic and paper forms, and copies of all data must be provided to each project participant. All electronic data and reports must also be copied on durable media such as CDs and copies of the CDs are stored in multiple locations. The archives must include:

- Copies of all original field measurement data, laboratory data, data analysis spreadsheet;
- Estimates of the carbon stock changes in all pools and non-CO2 GHG and corresponding calculation spreadsheets;

- GIS products;
- Copies of the measuring and monitoring reports

When applying all relevant equations provided in this methodology for the *ex-ante* estimation of net anthropogenic GHG removals by sinks, project proponents must provide transparent estimations for the parameters that are monitored during the project crediting period. These estimates must be based on measured or existing published data where possible and project proponents should retain a conservative approach: that is, if different values for a parameter are equally plausible, a value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.[19]

10.2 Monitoring of Regrowth in the Baseline Scenario

When monitoring regrowth in the baseline scenario using a reference area, the monitoring plan must provide specific monitoring procedures. These procedures must follow the same approach as provided below for the monitoring of the with-project scenario. Thus, the monitoring plan is to provide (justifications for) sampling frequency, sample size and field procedures for monitoring regrowth of residual forest in the baseline scenario.

Data and Parameters Not Monitored in the Baseline

Data / parameter:	A_i
Data unit:	Ha
Description:	Area of stratum *i*
Source of data:	Equation (2)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	GHG_{BSL-E}
Data unit:	t CO_2-e yr^{-1}
Description:	Greenhouse gas emissions as a result of relogging within the project boundary

[19] AR-ACM0002, Version 1

	in stratum *i*
Source of data:	Equation (2)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$A_{REL,i}$
Data unit:	Ha
Description:	Area relogged in baseline stratum *i*
Source of data:	Equation (3)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{harvest,i}$
Data unit:	$t\ C\ ha^{-1}$
Description:	Carbon stock in harvested timber in stratum *i*
Source of data:	Equation (3)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{damage,i}$
Data unit:	$t\ C\ ha^{-1}$
Description:	Carbon loss due to damage to the residual stand in stratum *i*
Source of data:	Equation (3)

Measurement procedures (if any):	
Any comment:	Accounting for C_{damage} as zero in the baseline scenario is conservative

Data / parameter:	$C_{WP100,i,t}$
Data unit:	t C ha^{-1}
Description:	Post-relogging carbon stock stored in long-term wood products (stock remaining in wood products after 100 years) in the baseline scenario in stratum i
Source of data:	Equation (3),(7a) and (8)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{WP20,i,t}$
Data unit:	t C ha^{-1}
Description:	Post-relogging carbon stock stored in short-term and medium-term wood products (stock is expected to be emitted over 20 years with a linear decay function) in the baseline scenario in stratum i at year t
Source of data:	Equation (3),(7b) and (8)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{DW,I,t}$
Data unit:	t C ha^{-1}

Description:	Post-relogging carbon stock in dead wood in the baseline scenario (stock emitted is quantified over 10 years with a linear decay function) in stratum *i* at year *t*
Source of data:	Equation (3) and (8)
Measurement procedures (if any):	
Any comment:	If C_{DW} for the project area cannot be derived from peer-reviewed literature, data can be obtained using appropriate measurement techniques applied in areas for which it can be shown that they are representative for the project area.

Data / parameter:	$V_{harvest,j,i}$
Data unit:	$m^3\ ha^{-1}\ yr^{-1}$
Description:	Volume of timber harvested in the baseline scenario of species *j* in stratum *i*
Source of data:	Equation (4)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	D_j
Data unit:	t d.m. m^{-3}
Description:	Basic wood density for species *j*
Source of data:	Equation (4) Values for *Dj* can be taken from tables generally used in the local or regional timber and forest industry, or from peer-reviewed literature applicable to the region. If no species-specific values for *Dj* are available, the average value across all species can be used, increased by 20% to ensure a conservative (higher) estimate of $C_{WPi,t}$. The source of data must be chosen with priority from higher to lower

	preference as follows: (a) National and species-specific or group of species-specific (eg, from national GHG inventory); (b) (Group of) Species-specific from neighbouring countries with similar conditions. Sometimes b) might be preferable to a); (c) Globally species-specific or group of species-specific (eg, IPCC GPG-LULUCF 2003).
Measurement procedures (if any):	NA
Any comment:	

Data / parameter:	CF
Data unit:	t d.m.$^{-1}$
Description:	Carbon fraction of dry matter
Source of data:	IPCC default value 0.5
Measurement procedures (if any):	NA
Any comment:	

Data / parameter:	f_{damage}
Data unit:	Dimensionless
Description:	Factor for damage to the residual stand caused by relogging
Source of data:	Equation (5) Determined using appropriate measurement techniques such as those described in the project description of the Noel Kempff Mercado Climate Action Project (NKM-CAP), version 02.02, dated 7/11/2005, or other similar established emission quantification approaches. Alternatively, peer reviewed

	literature may be used to derive f_{damage} from areas for which it can be shown that they are representative for the project area or general f_{damage} proxies for natural Evergreen Tropical Rainforests for conventional and/or Reduced Impact Logging (eg, Pulkki (1997)).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{XB,ty,i}$
Data unit:	t CO_2-e ha^{-1}
Description:	Mean stock of extracted biomass carbon by class of wood product *ty* from stratum *i*
Source of data:	Equation (6)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$V_{ex,ty,j,i}$
Data unit:	m^3
Description:	Volume of timber extracted from within stratum *i* (does not include slash left onsite) by species *j* and wood product class *ty*
Source of data:	Equation (6)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	ty
Data unit:	No dimension

Description:	Wood product class (eg, sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other)
Source of data:	Equation (6)
Measurement procedures (if any):	
Any comment:	Wood product classes are used to account for long-term storage of carbon in wood products. The share of timber ending up in the various wood product classes needs to be determined. In case no reliable assumptions can be made as to the timber classes of the harvested wood and its end use, general information from Forest Departments from that area reflecting breakdown of timber classes as they are normally harvested from this forest type and area may be used (eg, plywood, round logs, sawn timber, etc.).

Data / parameter:	ww_{ty}
Data unit:	No dimension
Description:	The fraction immediately emitted through mill inefficiency
Source of data:	Published paper of Winjum *et al*. 1998[20] (used in Equation (7a))
Measurement procedures (if any):	
Any comment:	

Data / parameter:	slp_{ty}
Data unit:	No dimension
Description:	Fraction of wood products that will be emitted to the atmosphere within 5 years of timber harvest

[20] Winjum, J.K., Brown, S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. *Forest Science* 44: 272-284

Source of data:	Published paper of Winjum *et al*. 1998[24] (used in Equation (7b))
Measurement procedures (if any):	
Any comment:	

Data / parameter:	fo_{ty}
Data unit:	No dimension
Description:	Fraction of wood products that will be emitted to the atmosphere between 5 and 100 years of timber harvest
Source of data:	Published paper of Winjum *et al*. 1998[24] (used in Equation (7b))
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{BSLpre,i}$
Data unit:	t C ha^{-1}
Description:	Pre-relogging carbon stock in above-ground tree biomass in the baseline scenario in stratum *i*
Source of data:	Equation (8)
Measurement procedures (if any):	$C_{BSLpre,i}$ can be determined on the basis of previously conducted fieldwork or surveys or peer-reviewed proxies in the reference area or can be approximated in case of a reference area as follows: $C_{BSLpre,i} = C_{BSLpost,i} + C_{harvest,i} + C_{damage,I}$
Any comment:	

Data / parameter:	$C_{BSLpost,i}$
Data unit:	t C ha^{-1}

Description:	Post-relogging carbon stock in above-ground tree biomass in the baseline scenario in stratum *i*
Source of data:	Equation (8)
Measurement procedures (if any):	$C_{BSLpost,i}$ can be estimated using the method outlined in (Estimation of $\Delta C_{P,i,t}$).
Any comment:	

Data / parameter:	$B_{SDW,l,sp,i}$
Data unit:	t d.m.
Description:	Biomass of standing dead tree *l* from sample plot *sp* in stratum *i*
Source of data:	Equation (10) and (11)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	BDia
Data unit:	cm
Description:	Basal diameter of standing dead tree
Source of data:	Field measurements in sample plots. Used in Equation (10) and (11)
Measurement procedures (if any):	Measured at ground level. Measure all trees above some minimum *BDia* in the sample plots, typically $\geq$ 10 cm.
Any comment:	

Data / parameter:	TD_{SDW}
Data unit:	cm
Description:	Top diameter of standing dead tree / from sample plot *sp* in stratum *i*

Source of data:	Field measurements in sample plots. Used in Equation (10) and (11)
Measurement procedures (if any):	Height measured from ground level to either the top of a standing bole or to the base of crown if crown is persistent. Height is measured either directly or by using an instrument such as a clinometers, relascope or laser inventory instrument.
Any comment:	

Data / parameter:	H_{SDW}
Data unit:	cm
Description:	Height of standing dead tree
Source of data:	Field measurements in sample plots. Used in Equation (10) and (11)
Measurement procedures (if any):	Height measured from ground level to either the top of a standing bole or to the base of crown if crown is persistent. Height is measured either directly or by using an instrument such as a clinometers, relascope or laser inventory instrument.
Any comment:	

Data / parameter:	$D_{DW,dc}$
Data unit:	t d.m. m^{-3}
Description:	Mean wood density of dead wood in the density class (dc) – sound (1), intermediate (2), and rotten (3); t d.m. m^{-3}
Source of data:	Equation (10) and (11) The source of data must be chosen with priority from higher to lower preference as follows: (a) Research publications relevant to the project area; (b) National species-specific or group of species-specific (eg, from National GHG inventory); (c) Species-specific or group of species-specific from neighboring countries with similar conditions. Sometimes (b) may be preferable to (a); (d) Global species-specific or group of species-specific (eg, IPCC GPG-

	LULUCF). Species-specific dead wood densities may not always be available, and may be difficult to apply with certainty to decomposed wood and in the typically species rich forests of the humid tropics, hence it is acceptable practice to use dead wood densities developed for forest types.
Measurement procedures (if any):	Project-specific determination of density is most likely necessary, requiring collection of representative samples from 10-20 trees from each decomposition class. Dead wood samples are cut in discs and thickness and diameter measured to estimate green volume. Samples are oven dried (70^{o} C) to a constant weight in the laboratory, and density calculated as dry weight (g) per unit green volume (cm^3).
Any comment:	Basic wood density for dominant species *DS* when *j=DS*

Data / parameter:	V_{LDW}
Data unit:	m^3 ha^{-1}
Description:	Volume of lying dead wood per unit area in stratum *i*
Source of data:	Field measurements in sample plots. Used in Equation (14)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$Dia_{n,i,t}$
Data unit:	m^3 ha^{-1}
Description:	Diameter of piece *n* of dead wood along the transect in stratum *i*
Source of data:	Field measurements in sample plots. Used in Equation (14)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$B_{LDW,i,t}$
Data unit:	t d.m. ha^{-1}
Description:	Biomass of lying dead wood per unit area in stratum *i*
Source of data:	Field measurements in sample plots. Used in Equation (15)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$V_{LDW,i,t}$
Data unit:	m^3 ha^{-1}
Description:	Volume of lying dead wood per unit area in stratum *i*
Source of data:	Field measurements in sample plots. Used in Equation (15)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$D\%_{,i}$
Data unit:	% yr^{-1}
Description:	Projected annual proportion of land that will be logged in stratum *i* at year *t*. If actual annual proportion is known and documented (eg, 25% per year for 4 years), set to proportion
Source of data:	Used in Equation (17)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{biomass}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to the removal of the biomass itself at year *t*
Source of data:	Remote imagery (photographs or satellite) or by using a reported percentage that is typical for the area.
Measurement procedures (if any):	To estimate the emissions from the removal of the biomass area has to be multiplied by an average carbon stock value per hectare that is representative of the project area.
Any comment:	

Data / parameter:	$E_{felling}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to the use of equipment for removal of the biomass on the area dedicated to infrastructure
Source of data:	Determined in Section 9.1
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{grading}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to road grading
Source of data:	Determined in Section 9.1
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{harvesting}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to harvesting
Source of data:	Determined in Section 9.1
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{extraction}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to extraction of timber from the forest to the log landings
Source of data:	Determined in Section 9.1
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{transport}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to the transport of the timber from the log landings to point of onward sale/transport
Source of data:	Determined in Section 9.1
Measurement procedures (if any):	
Any comment:	

Data and Parameters Monitored in the Baseline

Data / parameter:	$\Delta C_{tree\text{-}exist,i,}$
Data unit:	$t\ CO_2\text{-}e\ yr^{-1}$
Description:	Net carbon stock change in existing tree vegetation[21] in the baseline scenario in stratum *i*
Source of data:	Equation (2) Determined in Section 9.1 of methodology.
Measurement procedures (if any):	
Any comment:	

10.3 Monitoring of Project Implementation

Information must be provided, and recorded in the project description, to establish that:

(a) The geographic position of the project boundary is recorded for all areas of land:

a. The geographic coordinates of the project boundary (and any stratification inside the boundary) are established, recorded and archived. This can be achieved by field survey (eg, using GPS), or by using georeferenced spatial data (eg, maps, GIS datasets, orthorectified aerial photography or georeferenced remote sensing images).

(b) Commonly accepted principles of forest inventory and management are implemented:

a. Standard operating procedures (SOPs) and quality control/quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of SOPs already applied in national forest monitoring, or available from published handbooks, or from the IPCC GPG LULUCF 2003, is recommended;

b. Apply SOPs, especially, for actions likely to minimize soil disturbances in those circumstances in which site preparation or planting involves soil disturbance capable to increase soil erosion above the baseline value;

---

[21] With *DBH* ≥ 5 cm.

c. The project plan, together with a record of the plan as actually implemented during the project must be available for validation or verification, as appropriate.[22]

10.4 Monitoring of project carbon stock changes and greenhouse gas emissions

10.4.1 Updating of Strata

Stratification of the project area into relatively homogeneous units can either increase the measuring precision without increasing the cost unduly, or reduce the cost without reducing measuring precision because of the lower variance within each homogeneous unit. Project proponents should present in the project description an *ex-ante* stratification of the project area or justify the lack of it. The number and boundaries of the strata defined *ex-ante* may change during the project crediting period (*ex post*).

The *ex-post* stratification must be updated because of the following reasons:

- Unexpected disturbances occurring during the project crediting period (eg, due to fire, pests or disease outbreaks), affecting differently various parts of an originally homogeneous stratum;
- Forest management activities (cleaning, planting, thinning, harvesting, coppicing, re-planting) that are implemented in a way that affects the existing stratification.

Established strata may be merged if the reasons for their establishment have disappeared.[23]

10.4.2 Sampling Framework

The sampling framework, including sample size, plot size, plot shape, and determination of plot location should be specified in the project description.[24]

To determine the sample size and allocation among strata, this methodology uses the latest version of the tool for the “Calculation of the number of sample plots for measurements within A/R CDM project activities”[25], approved by the CDM Executive Board. The targeted precision level for biomass estimation within each stratum is ± 10% of the mean at a 95% confidence level.

10.4.3 Measuring and estimating carbon stock changes and GHG emissions over time

The change in carbon stocks must be estimated by taking measurements in plots at each monitoring event. Monitoring events must take place at intervals of 5, or preferably 3 years.

---

[22] This paragraph has been amended after AR-ACM0002 (ie, is not copied *verbatim*).

[23] AR ACM0002, Version 01

[24] Except for this sentence the entire Section 8.2.2 has been copied *verbatim* from AR-ACM0002.

[25] Available at: <http://cdm.unfccc.int/>

Data and parameters not monitored in the Project Scenario

Data / parameter:	BEF
Data unit:	dimensionless
Description:	Biomass expansion factor for the conversion of annual net increment (including bark) in stem biomass to total above-ground tree biomass increment for species *j*
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: a. Existing local and species-specific or group of species-specific; b. National and species-specific or group of species-specific (eg from national GHG inventory) c. Species-specific or group of species-specific from neighbouring countries with similar conditions (might be preferable to b under certain conditions) d. Climatic zone and forest type (eg IPCC literature: Table 3A.1.10 of the *GPG-LULUCF* (IPCC 2003) and Table 4.5 of the *AFOLU Guidelines* (IPCC 2006)
Measurement procedures (if any):	
Any comment:	• *BEFs* are age dependent, and use of average data may result in significant errors for both young and old stands—as *BEFs* are usually large for young stands and quite small for old stands; • *BEFs* in IPCC literature and national inventory are usually applicable to closed canopy forest. If applied to individual trees growing in open field it is recommended that the selected *BEF* be increased by a further 30%.[26]

[26] Applying a 30% increase to the BEF for solitary trees in severely logged over forest when estimating regrowth after logging in the baseline is leading to conservative estimates of carbon benefits of the project because it reduces net emissions in the baseline. In the project scenario less incidences of solitary trees will occur because the canopy will remain intact to a larger degree in comparison to the baseline.

Data / parameter:	R
Data unit:	t root d.m. t^{-1} shoot d.m.
Description:	Root:shoot ratio appropriate to species or forest type / biome
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: a. Existing local and species-specific or group of species-specific; b. National and species-specific or group of species-specific (eg from national GHG inventory) c. Species-specific or group of species-specific from neighbouring countries with similar conditions (might be preferable to b under certain conditions) d. Climatic zone and forest type (eg IPCC literature: Table 3A.1.8 of the *GPG-LULUCF* (IPCC 2003) and Table 4.4 of the *AFOLU Guidelines* (IPCC 2006)
Measurement procedures (if any):	
Any comment:	Guideline for conservative choice of default values: - If in the sources of data mentioned above, default data are available for conditions that are similar to the project (same vegetation genus; same climate zone; similar forest type), then mean values of default data may be used and considered conservative. - A root:shoot ratio for mature forest must be selected. Usually the root:shoot ratio for young trees is greater than for old trees. Applying a root:shoot ratio for mature forest is conservative, because it underestimates carbon in young trees in the project scenario (which are more abundant as a result of enrichment planting).

Data / parameter:	CF
Data unit:	t $d.m.^{-1}$

Description:	Carbon fraction of dry matter
Source of data:	IPCC default value 0.5. Used in Equation (39).
Measurement procedures (if any):	NA
Any comment:	

Data / parameter:	D_j
Data unit:	t d.m. m^{-3}
Description:	Basic wood density for species *j*
Source of data:	Values for *Dj* can be taken from tables generally used in the local or regional timber and forest industry, or from peer-reviewed literature applicable to the region. If no species-specific values for *Dj* are available, the average value across all species can be used, increased by 20% to ensure a conservative (higher) estimate of $C_{WPi,t}$. The source of data must be chosen with priority from higher to lower preference as follows: (a) National and species-specific or group of species-specific (eg, from national GHG inventory); (b) (Group of) Species-specific from neighbouring countries with similar conditions. Sometimes b) might be preferable to a); (c) Globally species-specific or group of species-specific (eg, IPCC GPG-LULUCF 2003).
Measurement procedures (if any):	NA
Any comment:	

Data / parameter:	$f_i(X, Y \ldots)$

Data unit:	t d.m. tree^{-1}
Description:	Allometric equation for species *j* linking, for example, diameter at breast height (*DBH*) and tree height (*H*) to above-ground biomass of living trees
Source of data:	Used in Equation (39). Whenever available, use allometric equations that are species-specific or group of species-specific, provided the equations have been derived using a wide range of diameters and heights, based on datasets that comprise at least 20 trees. Otherwise, default equations from IPCC literature, national inventory reports or published peer-reviewed studies may be used—such as those provided in Tables 4.A.1 to 4.A.3 of the *GPG-LULUCF* (IPCC 2003).
Measurement procedures (if any):	NA
Any comment:	If default allometric equations are available for conditions that are similar to the project (same vegetation genus; same climate zone; similar forest type), then the equation may be used and considered conservative. Otherwise, it is necessary either to use conservatively assessed values, or to verify the applicability of the equation if mean predicted values are to be used. Allometric equations can be verified by: • Selecting at least 5 trees covering the range of *DBH* existing in the project area, and felling and weighing the above-ground tree biomass to determine the total (wet) weight of the stem and branch components; • Extracting and immediately weighing sub-samples from each of the wet stem and branch components, followed by oven drying at 70ºC to determine dry biomass; • Determining the total dry weight of each tree from the wet weights and the averaged ratios of wet and dry weights of the stem and branch components. If the biomass of the harvested trees is within about ±10% of the mean values predicted by the selected default allometric equation, and is not biased—or if biased is wrong on the conservative side (ie, use of the equation results in an under- rather than over-estimate of project net anthropogenic removals by sinks)—then mean values from the default equation may be used. (IPCC Good Practice Guidance for LULUCF, 2003, Section 4.3.3.5.1, under direct approach step 3)

Data and Parameters Monitored in Project Scenario

Data / parameter:	$A_{i,t}$
Data unit:	Ha
Description:	Area of stratum *i* at year *t*
Source of data:	Monitoring of strata and stand boundaries must be done preferably using a Geographical Information System (GIS), which allows for integrating data from different sources (including GPS coordinates and Remote Sensing data). Used in Equation (35)
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$A_{sp,i}$
Data unit:	Ha
Description:	Total area of all sample plots in stratum *i*
Source of data:	Field measurements. Used in Equation (38).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	DBH
Data unit:	cm
Used in equations:	
Description:	Diameter at breast height of tree
Source of data:	Field measurement in sample plots
Measurement procedures (if any):	Typically measured 1.3 m above ground. Measure all the trees above 5 cm *DBH* in the permanent sample plots.

Any comment:	For *ex-ante* estimations, tree dimension variables (eg, diameter at breast height (*DBH*) and possibly height (*H*)) should be estimated for tree species *j* in stratum *i*, at year *t* using a growth model based on these tree dimensions.

Data / parameter:	H
Data unit:	m
Description:	Height of tree
Source of data:	Field measurement in sample plots
Measurement procedures (if any):	
Any comment:	For *ex-ante* estimations, tree dimension variables (eg, diameter at breast height (*DBH*) and possibly height (*H*)) should be estimated for tree species *j* in stratum *i*, at year *t* using a growth model based on these tree dimensions.

Data / parameter:	$Dia_{n,i,t}$
Data unit:	cm
Description:	Diameter of piece *n* of dead wood along the transect in stratum *i*, at year *t*
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	Lying dead wood can be sampled using the line intersect method (Harmon and Sexton 1996[27]). Two 50-meter lines are established bisecting each sample plot and the diameters of the lying dead wood (≥ 10 cm diameter) intersecting the lines are measured.
Any comment:	

---

[27] Harmon, M.E. and J. Sexton. (1996) Guidelines for measurements of woody detritus in forest ecosystems. US LTER Publication No. 20. US LTER Network Office, University of Washington, Seattle, WA, USA.

Data / parameter:	BDia
Data unit:	cm
Description:	Basal diameter of standing dead tree
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	Measured at ground level. Measure all trees above some minimum *BDia* in the sample plots, typically $\geq$ 10 cm.
Any comment:	

Data / parameter:	H_{SDW}
Data unit:	cm
Description:	Height of standing dead tree
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	Height measured from ground level to either the top of a standing bole or to the base of crown if crown is persistent. Height is measured either directly or by using an instrument such as a clinometers, relascope or laser inventory instrument.
Any comment:	

Data / parameter:	N
Data unit:	dimensionless
Description:	Total number of wood pieces intersecting the transect
Source of data:	Field measurements
Measurement procedures (if any):	
Any comment:	

Data / parameter:	V_{extr}
Data unit:	m^3
Description:	The volume of timber extracted from within the project boundary (does not include slash left onsite), preferably reported by species and wood product class. Where no direct information on volume by wood product class is available (eg, illegal logging) it is acceptable practice to assign gross percentages of volume extracted to wood product classes on the basis of local expert knowledge of harvest activities and markets.
Source of data:	Timber harvest records and/or estimates derived from field measurements or remote assessments with aerial photography or satellite imagery.
Measurement procedures (if any):	
Any comment:	Note that this volume does not include logging slash left onsite (tracked as part of the dead wood pool). Data compilers should also make sure that extracted volumes reported are gross volumes removed (ie, reported volume does not already discount for estimated wood waste, as is often the practice in harvest records)

Data / parameter:	t_2 and t_1
Data unit:	yr
Description:	Years of the monitoring activity
Source of data:	Field measurement in sample plots
Measurement procedures (if any):	
Any comment:	$T = t_2 - t_1$

Data / parameter:	$\Delta C_{P,i,t}$
Data unit:	$t\ CO_2\text{-}e\ yr^{-1}$

Description:	Net carbon stock change due to forest regrowth and silvicultural interventions in the with-project scenario in stratum *i* at year *t*
Source of data:	Used in Equation (34).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$\Delta C_{AGB,i,t}$
Data unit:	t CO_2-e yr^{-1}
Description:	Net carbon stock change in above-ground tree biomass[28] in the with-project scenario in stratum *i*
Source of data:	Used in Equation (34) and (35).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$\Delta C_{BGB,i,t}$
Data unit:	t CO_2-e yr^{-1}
Description:	Net carbon stock change in below-ground tree biomass in the with-project scenario in stratum *i*
Source of data:	Used in Equation (34) and (40).
Measurement procedures (if any):	
Any comment:	

[28] With *DBH* ≥ 5 cm.

Data / parameter:	$\Delta C_{DW,i,t}$
Data unit:	t CO_2-e yr^{-1}
Description:	Net carbon stock change in dead wood in the with-project scenario in stratum *i* at year *t*
Source of data:	Used in Equation (34) and (41).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$\Delta C_{WP,i,t}$
Data unit:	t CO_2-e yr^{-1}
Description:	Net carbon stock change in wood products in the with-project scenario in stratum *i* at year *t*
Source of data:	Used in Equation (34) and (42).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$E_{biomassloss,i,t}$
Data unit:	t CO_2-e yr^{-1}
Description:	Emissions due to site preparation for project activities in stratum *i* at year *t*
Source of data:	Used in Equation (34).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{AGB,l,j,sp,i,t}$
Data unit:	t C tree^{-1}
Description:	Carbon stock in above-ground biomass of tree *l* of species *j* in plot *sp* in stratum *i* at year *t*
Source of data:	Used in Equation (36), (37) and (39).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$V_{l,j,sp,i}$
Data unit:	m^3 tree^{-1}
Description:	Stem volume of tree *l* of species *j* in plot *sp* in stratum *i*
Source of data:	Used in Equation (36).
Measurement procedures (if any):	
Any comment:	

Data / parameter:	$C_{AGB,,sp,i,t}$
Data unit:	t C
Description:	Carbon stock in trees in plot *sp* in stratum *i* at year *t*
Source of data:	Used in Equation (37) and (38).
Measurement procedures (if any):	
Any comment:	

Leakage

Data and parameters not monitored (default, documented value, or possibly measured one time)

Data / parameter:	LF_{ME}
Data unit:	dimensionless
Description:	Leakage factor for market-effects calculations
Source of data:	Analysis of issuance of new concessions being assigned within the national boundaries, and associated annual extracted volumes. Used in Equation (44).
Measurement procedures (if any):	
Any comment:	Documented history of extracted volumes per hectare of existing concessions can be used as evidence.

Data / parameter:	NCS
Data unit:	t CO_2-e ha^{-1}
Description:	The mean national forest carbon stock
Source of data:	National statistics from Forest Department or other reliable sources
Measurement procedures (if any):	
Any comment:	

Data and parameters monitored

Data / parameter:	C_{BSL}
Data unit:	t CO_2-e ha^{-1}
Description:	Mean carbon stock across strata in all pools in the baseline
Source of data:	Determined in Section 9.1 of methodology
Measurement procedures (if any):	
Any comment:	

11 UNCERTAINTY AND QUALITY MANAGEMENT

Quality management procedures are required for the management of data and information, including the assessment of uncertainty, relevant to the project and baseline scenarios. As far as practical, uncertainties related to the quantification of GHG emission reductions and removals by sinks should be reduced.

To help reduce uncertainties in the accounting of emissions and removals, this methodology uses whenever possible the proven methods from the GPG-LULUCF, GPG-2000, and the IPCC's Revised 2006 Guidelines. As well, tools and guidance from the CDM Executive Board on conservative estimation of emissions and removals are also used. Despite this, potential uncertainties still arise from the choice of parameters to be used. Uncertainties arising from, for example, biomass expansion factors (BEFs) or wood density, would result in uncertainties in the estimation of both baseline net GHG removals by sinks and the actual net GHG removals by sinks - especially when global default values are used.

It is recommended that project proponent identifies key parameters that would significantly influence the accuracy of estimates. Local values that are specific to the project circumstances should then be obtained for these key parameters, whenever possible. These values should be based on:

- Data from well-referenced peer-reviewed literature or other well-established published sources;[29] or,

[29] Typically, citations for sources of data used should include: the report or paper title, publisher, page numbers, publication date etc (or a detailed web address). If web-based reports are cited, hardcopies should be included as annexes in the project description if there is any likelihood such reports may not be permanently available.

- National inventory data or default data from IPCC literature that has, whenever possible and necessary, been checked for consistency against available local data specific to the project circumstances; or

- In the absence of the above sources of information, expert opinion may be used to assist with data selection. Experts will often provide a range of data, as well as a most probable value for the data. The rationale for selecting a particular data value should be briefly noted in the project description. For any data provided by experts, the project description must also record the expert's name, affiliation, and principal qualification as an expert (eg, that they are a member of a country's national forest inventory technical advisory group) as well as a 1-page summary CV for each expert consulted, included in an annex.

In choosing key parameters, or making important assumptions based on information that is not specific to the project circumstances, such as in use of default data, project proponents should select values that will lead to an accurate estimation of net GHG removals by sinks, taking into account uncertainties.

If uncertainty is significant, project proponents should choose data such that it indisputably tends to under-estimate, rather than over-estimate, net GHG removals by sinks.

APPENDIX 1: TABLE FOR REPORTING THE CALCULATION OF TOTAL VCUS THROUGH NET CARBON STOCK CHANGES AND GREENHOUSE GAS EMISSION REDUCTIONS

Project year	Calendar year	ΔC_{BSL} Carbon stock changes		GHG emissions		ΔC_{WPS} Carbon stock changes		GHG emissions		ΔC_{LK} Carbon stock changes		GHG emissions		ΔC_{IFM} Carbon stocks

DOCUMENT HISTORY

Version	Date	Comment
v1.0	23 Nov 2010	Initial version released
v1.1	24 Aug 2011	Updates 1) Equation (7) of the wood products section is updated to correct for the error of applying carbon stocks in an equation intended for fractions (%). This makes the equations (8) and (9) redundant and they have been removed. 2) Equation (51) for the calculation of VCU's is updated to correct for the error of applying the buffer withholding percentage to GHG emissions and removals. 3) Various typographical errors: a. Reference to section 3.4.7 instead of 3.4.6 on page 17; b. delta symbols in table 3; and, c. other corrections
v1.2	23 Jul 2013	Updates 1) Procedures to account for the decay of carbon from the dead wood and harvested wood products pools have been included. 2) Minor edits to language were made (eg, the term 'must' has been used for required procedures).

VCS Methodology

VM0006

Methodology for Carbon Accounting for Mosaic and Landscape-scale REDD Projects

Version 2.2

17 March 2017

Sectoral Scope 14

Table of Contents

1 SOURCES

This methodology uses different elements from several approved methodologies, tools and modules. More specifically, this methodology is based on elements from the following approved methodologies:

- CDM Methodology - AR ACM0001 *Afforestation and reforestation of degraded land.* (Version 01).
- CDM Methodology - AR AM0002 *Restoration of degraded lands through afforestation/reforestation.* (Version 03).
- CDM Methodology - AR AM0006 *Afforestation/Reforestation with trees supported by shrubs on degraded land.* (Version 02).
- CDM Methodology – AMS.II.G*. Energy efficiency measures in thermal applications of non-renewable biomass. (*Version 5).

This methodology also refers to the following approved tools and modules, and the latest versions of these must be used:

- CDM A/R Methodological Tool *Estimation of carbon stocks and change in carbon stocks in dead wood and litter in A/R CDM project activities.*
- CDM A/R Methodological Tool 03 *Calculation of the number of sample plots for measurements within A/R CDM project activities.*
- CDM A/R Methodological Tool 06 *Procedure to determine when accounting of the soil organic carbon pool may be conservatively neglected.*
- CDM A/R Methodological Tool 09 *Estimation of GHG emissions related to displacement of grazing activities in A/R CDM project activity.*
- CDM Tool *Tool for testing significance of GHG emissions in A/R CDM project activities.*
- VCS Tool VT0001 *Tool for the demonstration and assessment of additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) project activities*.
- VCS Tool *Tool for calculating deforestation rates using incomplete remote sensing images*[1].

This methodology also refers to the following approved guidelines and requirements, of which the latest version shall be used:

- CDM Annex 23 *Guidelines on conservative choice and application of default data in estimation of the net anthropogenic GHG removals by sinks.*
- VCS *Jurisdictional and Nested REDD+ (JNR) Requirements*.

[1] At issuance of the this methodology, the VCS Tool, *Tool for calculating deforestation rates using incomplete remote sensing images*, is currently in development and is unavailable for use in this methodology until it is approved.

- VCS *Program Definitions*.
- VCS *Standard.*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology provides procedures for quantifying emission reductions and/or removals from activities aimed at reducing unplanned deforestation and forest degradation of the mosaic configuration. The methodology may be combined with Improved Forest Management (IFM) and Afforestation, Reforestation and Revegetation (ARR) methodologies to implement a landscape-scale Reduced Emissions from Deforestation and Forest Degradation (REDD+) project that addresses land and resource needs of communities in a holistic way. Emission reductions/removals from REDD+ activities are calculated by taking the difference between, on the one hand, *ex-post* monitored changes in carbon stocks in the project areas, and on the other hand *ex-ante* changes in baseline carbon stocks, *ex-post* monitored emissions from leakage, and *ex-post* monitored emission sources. Baseline emissions from unplanned deforestation and degradation in the project area are calculated based on historical deforestation or forest degradation rates in a reference region that is similar to the project area.

Under this methodology, new project activity instances referred to as discrete project parcels can be added after the start of the project as per VCS rules for grouped projects.

The main elements of the methodology are:

- Net emission reductions and removals (NERs) from avoided deforestation and avoided forest degradation are treated separately. When changes in forest biomass cannot be measured with sufficient accuracy, emissions reduction/removals from avoided forest degradation are excluded.
- The quantification of baseline deforestation and degradation rates is based on field-calibrated remote sensing analyses over a historical reference period. More specifically, the baseline rates of deforestation and degradation are quantified by classifying the discrete land cover classes, or forest strata, and analyzing transitions from one class or stratum to a different class or stratum over time.
- Leakage is monitored and quantified using a leakage belt approach for geographically constrained drivers, and a factor approach for geographically unconstrained drivers. Market-effect leakage is accounted for each project according to the discount factors provided in the VCS *AFOLU Requirements*.
- Increases in forest cover through natural regeneration are included in both the baseline and project scenarios. This is achieved by applying the empirically observed baseline regeneration rates in the reference region to the project and baseline scenarios. That is, the baseline scenario includes both projected degradation and deforestation, but also projected regeneration and reforestation in areas that were deforested. Similarly, the project scenario must include all forest class transitions, whether they are positive or negative.

- This methodology allows silvicultural activities and enrichment planting activities within degraded parts of the forests to accelerate the natural regeneration, promote forest regeneration, and provide opportunities for local employment. The accounting of these activities is based on a measured increase in biomass in the area in which such activities were executed.
- Projects with more accurate monitoring and verification are rewarded through a deduction mechanism based on the empirically observed accuracy. The accuracy is quantified based on (1) accuracy of remote sensing classification, and (2) the variance of biomass stock density.
- *Ex-ante,* the relative reduction in deforestation rates inside the project area is calculated by estimating the expected effect of a project activity on each driver. The simple spatial model calibrated previously is then used to divide the total deforestation and forest degradation rates in the project scenario into forest-strata specific rates. Subsequently, emission sources from project activities are calculated.
- Procedures to monitor and account for secondary emissions from increased rice production and intensification of livestock management are included in the methodology.

Note that where projects applying this methodology seek registration under a jurisdictional REDD+ program, the project must follow the requirements specified in the latest version of the VCS *Jurisdictional and Nested REDD+ (JNR) Requirements*.

Additionality and Crediting Method	
Additionality	Project Method
Crediting Baseline	Project Method

3 DEFINITIONS AND ACRONYMS

The following definitions and acronyms apply in the methodology.

3.1 Definitions Regarding Project Boundary

Baseline Validation Period
The period during which the *ex-ante* calculation of net GHG emissions under the baseline scenario is valid. As per VCS *AFOLU Requirements*, baselines are fixed for 10 years in all projects after which a new *ex-ante* baseline needs to be calculated and validated as per VCS rules.

Discrete Project Area Parcels
A project area that is contiguous or consists of multiple smaller adjacent and non-adjacent project areas that are equivalent to project activity instances when grouping procedures are applied.

Historical Reference Period
A fixed time period during which historical deforestation and forest degradation is analyzed in the reference region to set the forward-looking baseline. At validation, the historical reference period ends at the start of the crediting period. Once the project has started, and a baseline update is calculated, the historical reference period ends at the time at which the baseline is updated.

JNR Area
The geographic area registered under the jurisdictional REDD+ program.

Leakage Area
The sum of individual leakage belts which do not have to be contiguous.

Leakage Belt
The geographical area where leakage is expected around individual discrete project area parcels. Since leakage can occur on both forest land and non-forest land, such as woodland or grassland, the leakage belt may include any of these land types.

Project Area
The geographical area where the project participants will implement activities to reduce deforestation and forest degradation.

Reference Region
The region from which historical and current deforestation and forest degradation quantities and trends are obtained to predict future deforestation and degradation quantities in the absence of project activities (i.e., baseline scenario).

3.2 Definitions Regarding Classification, Stratification and Transition of Land Use and Land Cover

Forest Regeneration
The persistent increase of canopy cover and/or carbon stocks in an existing forest due to natural succession or human intervention, and falls under the IPCC GPG-LULCF 2003 land category of forest remaining forest.

Forest Strata
A division of forest land use and land cover (LULC) class determined by carbon stock density, native forest type, past and future management, landscape position, biophysical properties, and the degree of past disturbance.

Forest Stratification
The sub-division of the LULC class into narrower forest strata.[2]

[2] The minimum mapping unit established for LULC class is also applied to forest strata.

Increased Forest Cover

The transition of non-forest land into forest land, and encompasses both reforestation and natural succession.

Land Transition

A change from one LULC class or forest stratum into another within one geographical area. This methodology considers six main categories of transitions defined as deforestation, forest degradation, forest regeneration, increased forest cover, natural succession and reforestation.

Land Use and Land Cover (**LULC**) **Classes**

A land classification system that is hierarchical in nature. Specific definitions for cropland, grassland, settlement, wetland, and other land are provided in the IPCC Change's Good Practice Guidance for Land Use, Land-Use Change and Forestry 2003 report (IPCC GPG-LULCF 2003).

Minimum Mapping Unit

The minimum unit used for remote sensing and classification procedures. In this methodology, a minimum mapping unit of 1 hectare (ha) applies.

Natural Succession

The natural increase in forest covers without any human intervention.

3.3 Other Definitions

Agents of Deforestation or Forest Degradation (**Agent**, **Agent of Deforestation**, or **Agent of Degradation**)

The social group, community or other entity involved in deforestation or forest degradation.

Assisted Natural Regeneration (ANR).

Human-induced forest regeneration through silvicultural activities that induce or accelerate increase in forest biomass, as compared to natural regeneration. ANR silvicultural activities include thinning to stimulate tree growth, removal of invasive species, coppicing, and enrichment planting.

Commercial Timber Harvesting.

The extraction of timber wood for further sale on regional or global timber markets outside of the project area.

Cook Stove and Fuel Efficiency (CFE) Activities.

Activities that result in efficiency improvements in the thermal application of non-renewable biomass. Example of such activities include the introduction of high efficiency biomass fired cook-stoves, ovens, dryers and/or improvement of energy efficiency of existing biomass fired cookstoves, ovens, or dryers.

Driver of Deforestation and Forest Degradation (Driver, Driver of Deforestation, Driver of Forest Degradation)

The immediate activity executed by agents of deforestation or degradation that leads to deforestation/ degradation.

Subsistence Farming
A system of farming where all or almost all of the produce is used to meet the consumption needs of the farm family without any significant surplus for commercial sale.

3.4 Acronyms

AFOLU	Agriculture, Forestry, and Other Land Use
ARR	Afforestation, Reforestation, and Revegetation
CDM	Clean Development Mechanism
CP	Conference of the Parties
CV	Coefficient of Variation
DBH	Diameter at Breast Height (1.3 m)
DF	Deforestation
DG	Forest Degradation
DM	Dry Matter
DNA	Designated National Authority
EF	Emission Factor
GHG	Greenhouse Gas
GIS	Geographic Information System
GPG-LULUCF	Good Practice Guide for Land Use, Land Use Change and Forestry
GPS	Global Positioning System
GWP	Global Warming Potential
ha	Hectare
IPCC	Intergovernmental Panel on Climate Change
LCL	Lower Confidence Limit
Mg	Mega gram = 1 metric tons
MMU	Minimum Mapping Unit
tCO2e	Metric Tons of Carbon Dioxide Equivalents
NER	Net Greenhouse Gas Emission Reduction
PD	Project Document
QA/QC	Quality Assurance / Quality Control
RED	Reduced Emissions from Deforestation
REDD	Reduced Emissions from Deforestation and Forest Degradation
SOC	Soil Organic Carbon
VCS	Verified Carbon Standard
VCU	Verified Carbon Unit

4 APPLICABILITY CONDITIONS

4.1 General Applicability Conditions

The following applicability conditions apply. Note that in case the project area consists of multiple discrete project area parcels, each discrete project area parcel must also meet all applicability conditions below.

4.1.1 Conditions Related to Eligible Land Conditions

This methodology is applicable to areas where land prior to project implementation meets the following conditions:

- Land in the project area consists of either one contiguous area or multiple discrete project area parcels, and must meet an internationally accepted definition of forest, such as those based on UNFCCC host-country thresholds or FAO definitions, and must qualify as forest for a minimum of 10 years before the project start date.
- The project area must be deforested or degraded in absence of the REDD project activity and the deforestation and degradation must be mosaic in nature as described in the VCS *AFOLU Requirements.*
- Drivers of deforestation and forest degradation must fall into one or more of the following categories):
  - Conversion of forest land to cropland for subsistence farming.
  - Conversion of forest land to settlements.
  - Conversion of forest land to infrastructure, including new roads.
  - Logging of timber for commercial sale (eg, wood planks or poles for commercial sale).
  - Logging of timber for local enterprises and domestic uses.
  - Wood collection for commercial sale of fuelwood and charcoal.
  - Fuelwood collection for domestic and local industrial energy needs (eg, cooking, home heating, tobacco curing, brick making).
  - Cattle grazing in forests.
  - Extraction of understory vegetation (eg, thatch grass collection for roof and livestock bedding materials, shrubs and small trees for straw fences).
  - Forest fires to the extent that they are not part of natural ecosystem dynamics (eg, forest fires related to hunting, honey collection, intentional land clearing on land with a high fuel-load).

None of the drivers listed above must be planned in nature. If deforestation from a specific driver is occurring as a result of planned forest conversion activities, then such a driver must be excluded from analysis.

- This methodology is not applicable to organic soils or peatland.

4.1.2 Conditions Related to Eligible Project Activities

This methodology is applicable to projects that implement one or more of the following activities:

- Strengthening of land-tenure status and forest governance.
- Supporting the development and implementation of sustainable forest and land use management plans.
- Demarcating forest, tenure and ownership boundaries; promoting forest protection through patrolling of forests and forest boundaries; promoting social inclusion and stewardship in local communities; facilitating social fencing through capacity building; and creating mechanisms to alert law enforcement authorities of forest trespassing.
- Fire prevention and suppression activities including the construction of fire breaks, reduction of fuel loads, prescribed burning, education to minimize intentionally started fires, support for fire brigades, water cisterns, fire lookouts, and communication systems.
- Reducing fuelwood consumption and/or increasing energy efficiency by introducing fuel-efficient woodstoves or brick kilns and curing equipment.
- Creation of alternative sources of fuelwood through agroforestry, farm woodlots management and introduction/intensification of other renewable and non-fossil fuel based energy sources (such as solar).
- Sustainable intensification of agriculture on existing agricultural land.
- Development of local enterprises based on sustainably harvested non-timber forest products (NTFPs) such as honey, medicinal plants, etc.

4.2 Applicability Conditions for Optional Activities

4.2.1 Conditions Related to Optional Assisted Natural Regeneration Activities

Implementing Assisted Natural Regeneration Activities (ANR) activities as described in Section 8.2.5 is optional, but is only eligible under this methodology if all of the following applicability conditions are met:

- ANR activities must take place on degraded land on which no prior ANR activities have taken place. However, areas that were forest at the start of the project, but became deforested during the project crediting period are eligible as per the provisions under Section 9.3.7.
- ANR activities consist of thinning, removal of invasive species, enrichment planting, and coppicing.
- If harvesting takes place or is planned on areas on which ANR activities take place, this area must be considered area under harvest as specified in Section 8.2.7.

- The area on which emission reductions/removals from ANR activities are generated must never exceed the total area that would have been deforested under the baseline scenario . For example, if the baseline scenario includes 500 ha of deforestation per year of which 100 ha becomes forest again due to natural reforestation every year, ANR activities may only be planned for 400 ha in the first year, 800 ha, in the second and1200 ha in the third..

Note that the total size of the areas on which ANR activities are planned must be specified either in the project description (PD) or the monitoring report depending on when the ANR activities are implemented. For example, if ANR is implemented in a given area between the first and second verification, the total size of the area where ANR is to be implemented must be reported in the second monitoring report and the exact location of the ANR activities must be identified at verification.

4.2.2 Conditions Related to Optional Cookstove and Fuel Efficiency Activities

Implementing cookstove and fuel efficiency (CFE) activities as described in Section 8.2.6 are optional, but are only eligible under this methodology if all of the following applicability conditions are met:

- CFE activities must be implemented by the project proponent managing the project area that is being degraded or deforested, and must be targeted towards households and/or local institutions in the immediate vicinity of the project area,
- Fuelwood use such as collection of fuelwood, and charcoal production must be identified as one of the drivers of deforestation and degradation in the project according to the procedure under this methodology.
- The project forests and leakage belts must be the source for non-renewable biomass in the baseline scenario.
- In the baseline scenario, at least 50% of the households in the reference region must be using traditional cookstoves which can be demonstrated through appropriate local or regional statistics on fuelwood use.

4.2.3 Conditions Related to Optional Harvest Activities in the Project Area

Implementing harvesting in the project area as described in Section 8.2.7 is optional but is only is eligible under this methodology only if the following applicability conditions are met:

- The harvest plan and harvest activities must follow Best Management Practice (BMP) guidance of the country or jurisdiction, if such BMP guidance exists.
- The harvest plan must describe procedures to protect soil, water and residual trees in the harvest area and provide documentation on the presence/absence of any threatened or endangered species on the site, potential impacts on species and mitigation measures that will be employed.

- The harvest plan must describe the biophysical sustainability of the harvesting practices. At minimum, the biophysical sustainability must be demonstrated by ensuring that the net removal of biomass from harvesting is less than the net increment of the biomass in the forest. Where possible, the project proponent should use criteria and indicators such as from International Tropical Timber Organization (ITTO) to assess the sustainability of harvesting practices. In addition, it is recommended to obtain sustainability certification from third parties, such as the Forest Stewardship Council or the Sustainable Forestry Initiative.

4.2.4 Conditions Related to Optional Intensification of Annual Crop Production Systems as a Leakage Prevention Activity

Intensification of annual crop production systems as a leakage prevention activity (see Section 8.3.4.1) is optional, but is only eligible under this methodology if all of the following applicability conditions are met:

- The agricultural intensification measures must be implemented only on land that is located within the leakage belt.
- The agricultural intensification measures must be implemented on land on already under annual crop production systems at the time of validation.
- The agricultural intensification measures must not be implemented on organic soils.

4.2.5 Conditions Related to an Optional Increase in Flooded Rice Production Systems as a Leakage Prevention Activity

The introduction of flooded rice production systems as a leakage prevention activity (see 8.3.4.2) is optional, but is only eligible under this methodology only if all of the following applicability conditions are met:

- Flooded rice production systems must be implemented on land that is located within the leakage belt.
- Flooded rice production systems must be implemented on land that is already under annual crop production systems at the time of validation.
- The flooded rice production systems cannot be implemented on organic soils.
- The N_2O emissions from flooded rice production systems must be insignificant.

4.2.6 Conditions Related to an Optional Increase in Livestock Stocking Rates as a Leakage Prevention Activity

Increasing livestock stocking rates as a leakage prevention activity (see 8.3.4.3) is optional, but is only eligible under this methodology if all of the following applicability conditions are met:

- Increased stocking must only occur within the leakage belts of the project area, not within the project boundary.

- If the proposed activity produces forage to feed livestock, all forage must have a similar nutritional value and digestibility, and support only a single livestock group with a single manure management system.
- If the stocking rate is increased for animals that are already in a zero-grazing system or are moved to a zero-grazing system then the grazing activity that is monitored must be the production of fodder.
- Increased stocking rates must only occur on identified forest land, identified cropland, identified grassland, and unidentified land).
- Increased stocking rates must not occur on settlements, wetlands, or other lands as defined by the GPG LULUCF (i.e., bare soil, rock, ice, and all unmanaged land areas that do not fall into category of forest land, cropland, grassland, settlements or wetlands).

5 PROJECT BOUNDARY

5.1 Gases

This methodology requires accounting of all potential emissions of CO_2, N_2O and CH_4 from sources not related to changes in carbon pools, henceforward referred to as emission sources (Table 1). Insignificant emission sources may be excluded according to the VCS rules if insignificance can be demonstrated after using the latest version of CDM *Tool for testing significance of GHG emissions* in EB31 Appendix 16.

Table 1: GHG emissions from sources not related to changes in carbon pools (emission sources) to be included in the GHG assessment.

<table>
<tr><th colspan="2">Source</th><th>Gas</th><th>Include?</th><th>Justification/Explanation</th></tr>
<tr><td rowspan="3">Baseline</td><td rowspan="3">Baseline Deforestation and Forest Degradation</td><td>CO2</td><td>Optional</td><td>Emissions are related to changes in carbon pools. Include only when the degradation has not been included in the estimation of changes in carbon pools and if CFE activities are implemented.</td></tr>
<tr><td>CH_4</td><td>Optional</td><td>Conservatively omitted except when CFE activities are implemented.</td></tr>
<tr><td>N_2O</td><td>Optional</td><td>N_2O emissions from burning woody biomass are assumed negligible and conservatively excluded except when CFE activities are implemented.</td></tr>
<tr><td rowspan="2">Project</td><td rowspan="2">Cookstove and Fuel Efficiency (CFE) activities</td><td>CO_2</td><td>Optional</td><td>Emissions are already included in the changes of carbon pools. Include only when the degradation has not been included in the estimation of changes in carbon pools.</td></tr>
<tr><td>CH_4</td><td>Yes</td><td>CH_4 emissions of burning woody biomass in CFE activities are significant.</td></tr>
</table>

		N_2O	Yes	N_2O emissions of burning woody biomass in CFE activities are significant.
	Biomass burning from unplanned large and small scale fires	CO_2	No	Emissions are already included in the changes of carbon pools
		CH_4	No	CH_4 emissions of burning woody biomass from unplanned fires are insignificant. If the fires are catastrophic, CH_4 emissions must be estimated and demonstrated negligible or otherwise accounted for.
		N_2O	No	N_2O emissions of burning woody biomass from unplanned fires are insignificant, unless fires are catastrophic, N_2O emissions must be estimated and demonstrated negligible, or otherwise accounted for.
	Fossil fuel used during harvesting	CO_2	No	Emissions from fossil fuel combustion is considered de-minimis for REDD.
		CH_4	No	Insignificant
		N_2O	No	Insignificant
	Removal of woody biomass for fire prevention and suppression activities	CO_2	Yes	Emissions related to changes in carbon pools are taken into account
		CH_4	Yes	CH_4 emissions from removal of woody biomass are significant when prescribed burning is used to clear the land.
		N_2O	No	N_2O emissions from burning woody biomass are assumed negligible and conservatively excluded.
	Removal of woody biomass during assisted natural regeneration (ANR) activities	CO_2	Yes	Emissions related to changes in carbon pools are taken into account
		CH_4	Yes	CH_4 emissions from removal of woody biomass are significant when fire is used in preparing the land for ANR activities
		N_2O	No	N_2O emissions from burning woody biomass during ANR activities are assumed negligible and conservatively excluded.
	Fertilizer used during enrichment planting for assisting natural regeneration	CO_2	No	Assumed negligible
		CH_4	No	Assumed negligible
		N_2O	No	Assumed negligible per VCS guidance
	Increased area of	CO_2	No	Assumed negligible

	rice production systems	CH_4	Yes	CH_4 emissions from rice cropping systems are significant
		N_2O	No	Assumed negligible per VCS guidance
	Increased fertilizer use	CO_2	No	Not applicable
		CH_4	No	Not applicable
		N_2O	No	N_2O emissions related to increased fertilizer use are de minimis
	Increased livestock stocking rates	CO_2	No	Not applicable
		CH_4	Yes	CH_4 emissions related to increases in livestock stocking rates are significant
		N_2O	Yes	N_2O emissions related to increases in livestock stocking rates are significant

5.2 Carbon Pools

Table 2 summarizes the carbon pools that must be included in projects following this methodology.

Table 2: Selected Carbon Pools

Carbon Pool	Included?	Justification/ Explanation of Choice
Aboveground tree biomass	Yes	Major carbon pool affected by project activities
Aboveground non-tree biomass	Yes / Optional	Expected to increase from project activities. Must be included when the land cover under the baseline scenario is perennial tree crop. May be excluded when baseline land cover is annual crop or pasture grass.
Belowground biomass	Optional	Major carbon pool affected by project activities. May be conservatively excluded.
Dead wood	Optional	Major carbon pool affected by project activities. May be conservatively excluded. If included either or both of standing or lying deadwood may be included.
Litter	No	Excluded as per VCS *AFOLU Requirements*.
Soil organic carbon	Optional	Conservative to exclude since this pool is expected to decrease under the baseline scenario. However, may be only included per VCS *AFOLU Requirements* on the condition that the land cover under the baseline scenario is comprised of annual cropping systems.
Wood products	Yes	Major carbon pool affected by project activities

5.3 Spatial Boundaries

The spatial boundaries of (1) the project area, (2) the leakage area and (3) the reference region or the JNR Area if a project is nested within a jurisdictional REDD+ program. The spatial boundary must be unambiguously defined in the PD. Project proponent must provide digital (vector-based) files of the discrete project area parcels in Keyhole Markup Language (KML) file format or any other format required by *VCS Standard*. The project area may be contiguous or consist of multiple adjacent or non-adjacent parcels i.e., discrete project area parcel. A leakage belt for each discrete project area parcel must be defined, if applicable. The leakage area is the sum of the individual leakage belts. The reference region excludes the project and leakage areas. Therefore, as new project and leakage areas are defined over the course of the project crediting period as new project activity instances (i.e., discrete project area parcels) are added, project and leakage areas must be excluded from the reference region polygon.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

Under this methodology, the most plausible baseline scenario for a project is the existing or historical changes in carbon stocks in the carbon pools within the project boundary. This baseline scenario is consistent with scenario identified in the CDM Modalities and Procedures for afforestation and reforestation, project activities (Decision 5/CMP.1), paragraph 22, option (a):

Existing or historical, as applicable, changes in carbon stocks in the carbon pools within the project boundary.

This option was selected because under the mosaic typology of deforestation, the historical changes in land-use are representative for the most likely future changes in land-use. The most appropriate future scenario is that historical rates, change in rate, and dynamics of deforestation and forest degradation will continue in the future.

The net GHG sources and sinks under the baseline scenario must be estimated *ex-ante* for each year of the crediting period. Once validated, the baseline is to be used for the calculation of actual NERs. Baseline calculations remain valid only for a limited period of time and must be updated in accordance with the VCS rules on renewal of baselines. The procedure for updating the baseline is specified in Section 9.3.9.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Projects must apply the latest version of the VCS *Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities* to demonstrate additionality.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions for Projects

8.1.1 Select Spatial Boundaries

This step includes the demarcation of the project area and the reference region. Note that the demarcation of the leakage area is included in Section 8.3.2.2.

8.1.1.1 Describe Spatial Boundaries of the Discrete Project Area Parcels

The project proponent must provide digital (vector-based) files of the discrete project area parcels in Keyhole Markup Language (KML) file format as required by *VCS Standard*. A clear description must accompany each file, and the metadata must contain all necessary projection reference data. In addition, the PD must include a table containing the name of each discrete project area parcel, the centroid coordinate (latitude and longitude using a WGS1984 datum), the total land area in hectares (ha), details of tenure/ownership and the relevant administrative unit it belongs to (county, province, municipality, prefecture, etc.). New discrete project area parcels (referred to as new project instances) may be integrated into an existing project after the project starts and must be verified for crediting.

8.1.1.2 Select a Valid Reference Region

A reference region must be representative of the future trajectory of the project area in absence of the project activities. For a reference region to be fully representative, and selected without any bias, the following necessary conditions must be met:

- The minimum size of the reference region excluding the project area and leakage area must be 250,000 ha or the size of the project area at the start of the crediting period, whichever is greater. If the entire country or autonomous territory is less than this size, then the reference region must be equal to the entire country or that territory. When a project area is located on an island which is smaller than the required reference region, then it is sufficient to have the entire island as the reference region.
- The boundaries of the reference region must be unbiased and coincide with a combination of natural, geopolitical, satellite footprint, and/or watershed boundaries, or boundaries that were created by applying a distance buffer around the discrete project parcels. A natural boundary is a boundary of a naturally occurring phenomenon such as a river, mountain range, lake, ocean, or watershed. Where possible, natural boundaries that coincide with administrative or jurisdictional boundaries so that land-use and land cover related policies are consistent across the reference area must be selected.
- The project proponent must demonstrate that the reference region does not contain areas where agents of deforestation have restricted acces**s**. Include maps where the reference region and the project area have been overlaid with maps of protected areas, including:
    - National parks that are effectively protected.

- Military bases or installations.
- Areas under conservation that are effectively protected.
- Areas under a logging or economic land concession where access is effectively being restricted.
- Large plantations that are effectively protected.

- The reference region must exclude areas where planned deforestation activities took place. It must be demonstrated that planned deforestation areas have been excluded from the reference region or proof of non-existence of such areas within the reference region must be provided.
- The reference region must exclude deforested areas caused by natural (non-anthropogenic) large-scale, extraordinary events (e.g. geological and weather impacts which are infrequent but significant in their impact on the landscape). Such areas are excluded from the reference region since these are not likely to occur within the project area during the crediting period.
- The project proponent must demonstrate that the reference region contains, at minimum, 15% forest cover at the beginning of the crediting period**,** unless the reference region encompasses a whole country or island[3]. This condition must be explicitly checked using the classification that is developed under Section 8.1.2 of this methodology.
- The project proponent must compare a number of key variables between the reference region and project area according to the procedures outlined in Table 3 below. Areas in the potential reference region where one or more of these variables differ from the project area are not eligible and must be excluded from the reference region.

These conditions are designed as safeguards against biases caused by arbitrary boundary demarcation. However, it is impossible to provide a sufficient set of rules to avoid bias under all project circumstances. Therefore, at validation, the validation/verification body must determine that the selection of the reference region is truly unbiased.

The reference region may include project area and leakage belts initially, but the project area and leakage belts are excluded from the reference region after the start of the crediting period. Additionally, whenever new instances of project areas and leakage areas that were previously included in the reference region are added into the existing project area, the new added instances must be removed from the reference region.

[3] Given historical deforestation, the reference region is likely to have a significantly higher percentage of forest cover at the beginning of the historical reference period.

Table 3: Comparison variables to demonstrate similarity between project area and reference region.

Category	Variable	Comparison procedure	Explanation
Drivers of deforestation	Drivers of deforestation	All drivers that were identified in the project area must also be present in the reference region. A comparison of the existence of every driver between the project area and the reference region must be carried out. The similarity between the project area and the reference region drivers must be documented and justified with relevant evidence.	Since the reference region will be used to determine baseline deforestation and degradation rates in the project area, the drivers of deforestation must be similar in the reference area and the project area.
Landscape configuration	Distribution of native forest types	The proportion of each forest type within the reference region (see Section 8.1.2.2) at the beginning of the historical reference period must be within 10% of forest type proportions within the project area. Percentages must be calculated relative to the total area of forests, not the total land area.	Deforestation and land-use change dynamics are highly dependent on geographical conditions. For example, if the project is to protect montane forest at the top of a watershed then lowland and valley forests should not be used as a reference region.
	Elevation	The proportion of area contained within 500-m elevation classes of the reference region must be within 10% of these elevation class proportions in the project area.	
	Slope	The proportion of area contained within 5% slope classes of the reference region must be within 10% of these slope class proportions in the project area.	
Socio-economic and	Land-tenure status	The land-tenure system prevalent in the reference	The specific land tenure system impacts the rate of

cultural conditions		region must be demonstrated to be similar to the land-tenure system in the project area with reference to peer-reviewed literature, reports, or expert opinion. Any differences in land tenure systems between the project area and reference region must not affect the drivers of deforestation and degradation or the operation of the agents of deforestation and degradation	land use changes, and must therefore be similar between the project area and reference region, especially in terms of how the land tenure system may impact access and mobility of the agents or influence the drivers of deforestation and degradation.
	Policies and regulations	The reference region must be governed by an administrative unit that has comparable enforced policies, regulations and capacities as the administrative unit of the project area.	Different governing bodies may have a different legislative framework or capacity for enforcement. It has to be demonstrated that the forest is similar in the reference region and project area.
	Degree of urbanization	Proportion of urbanized and agriculture-based population within the reference region must be within 10% of this proportion in the project area.	People living in urban areas have a significantly different relation to forest land compared to people that are agriculture-based.

8.1.2 Analyze Historical Deforestation and Forest Degradation in the Reference Region

8.1.2.1 Describe Data Sources

The quantification of deforestation and forest degradation rates under this methodology is based in part on remote sensing and other spatial data. The selection of data sources must follow Chapter 3A.2.4 of the IPCC 2006 GL AFOLU. Table 4 below lists the data that are required. This table also outlines the information about these data that must be documented in the PD. At least three images of forest cover are required during the historical reference period, (1) at minimum one image from 0-3 year before project start date, (2) at minimum one image from 4-9 years before project start date, and (3) at minimum one image from 10-15 years before project start date. No images older than 15 years may be used for the historical reference period.

Table 4: Information to be reported with respect to remote sensing and other spatial data employed for assessing deforestation and forest degradation.

Data Source	Main Use for Data	Information Needed about the Data Collected
High to medium resolution (≤ 30 m) remote sensing data are required for at least three time points: (1) at least one image from 0-3 years before project start date, (2) at least one image from 4-9 years before project start date, and (3) at least one image from 10-15 years before project start date. No images older than 15 years may be used for the historical reference period.	Historical analysis of deforestation and forest degradation	Source Type Resolution (spatial and spectral) Acquisition date Coordinate system and pre-processing If different sources of remote sensing data are used, a formal comparison of the sensors should be added to the monitoring report to ensure consistency.
Readily available LULC maps which are already processed are complementary	Training of classification procedures Independent verification of the analysis of historical images	Minimum Mapping Unit (ha) Description of method used to produce these data Descriptions of the LULC classes and/or LULC-change categories Information on how these classes may match with IPCC classes and categories

Direct field observations or visually interpreted locations from remote sensing images are required for calibration of the classification and stratification procedures and validation of the calibration and classification accuracy.	Training of classification procedures. Ground-truthing and check of accuracy	Acquisition date Type of data coordinate system Location of coordinates

8.1.2.2 Define LULC Classes and Forest Strata

The ultimate goal of a classification and stratification system is to partition an analysis area, into LULC classes or forest strata that are homogeneous in carbon stock density, in a cost-effective and practically-feasible way. The exact number and type of LULC classes and forest strata used is project-specific and dependent on local conditions. A number of iterations between the remote sensing image analysis and LULC class and forest strata definitions may be necessary before an optimal classification is attained. The same LULC classification and forest stratification must be developed for and applied to all analysis areas (i.e. reference region, project area and leakage area) and crediting periods in order to avoid any spatial or temporal bias in carbon accounting.

The result of forest stratification reflects the current condition or state, and not the process of change or future evolution of a specific forest stratum. A degraded forest stratum will regenerate if drivers of deforestation are restricted. In contrast, a low-density, open forest may stay in a low-carbon state due to persistent biophysical conditions and constraints. Although their future evolution will be different, these two forest systems may share similar carbon stock densities for a time.

A sound definition of LULC classes and forest strata is crucial for accurate and conservative carbon accounting. The project proponent must demonstrate that the LULC classes and forest strata identified will not lead to systematic overestimation of carbon losses in the baseline and therefore overall emission reductions/removals attributed to the project. This assessment must be done after biomass density values are available for each LULC class or forest stratum, as described in Section 8.1.4.4.

LULC classification and forest stratification must be conducted for the whole analysis area, which is the union of the reference region, leakage area and project area, as follows:

- Include, at minimum, the six IPCC LULC classes (Forest Land, Crop Land, Grassland, Wetlands, Settlements, and Other Land) in the LULC class definitions. The definition of these classes must be consistent with Chapter 2 of the IPCC GPG-LULUCF 2003. In cases where the country has defined more specific LULC classes than the IPCC classes, these definitions must be used if they are accurate enough for project-specific classification.
- The minimum mapping unit for LULC classes must be less than 1 ha.

- To achieve the goal of defining classes that are homogeneous in carbon stock density, the forest LULC class must be sub-divided into forest strata. Forest land is usually heterogeneous in terms of local climate, soil condition, forest canopy cover, and forest type. Forest stratification can help define homogeneous units with reduced variance in terms of carbon stock density, and thereby increase the measurement precision without increasing cost, or reduce the measurement cost without reducing precision.
- If emissions from avoided degradation are included, appropriate forest strata representing regeneration stages must be included as well. Because emission reductions are discounted based on the uncertainty of the biomass inventory, stratifying forest may lead to increased emission reductions.
- It is recommended that forest stratification be based on an assessment of the key factors that influence carbon stocks in the included carbon pools such as soil features, local climate, landform (e.g., elevation, slope, and aspect), forest type, dominant tree species, soil erosion intensity, forest management, regeneration stage and human degradation intensity using a GIS analysis augmented with forest surveys.
- Managed forests must be divided into different forest strata according to the forest management regimes, unless the differences in management among regimes do not lead to significant differences in carbon density during the baseline validation period.
- The accuracy of stratification maps must be determined using the procedures described in Section 8.1.2.7
- All areas that will be subject to ANR activities within the project area[4] must be further divided into forest strata according to the specific silvicultural management activities that will be employed on these areas. The project proponent must present maps of the stratified project areas in the PD.
- All areas that will be subject to harvest activities within the project area must be further divided into forest strata according to the harvest plan. The project proponent must present maps of the stratified project areas in the PD.

8.1.2.3 Define Land Transitions between LULC Classes/Forest Strata

A list of the expected land transitions must be included in the PD in the form of a LULC and forest strata transition matrix.

Land that only temporarily transitions from forest to non-forest and transitions back to forest after a short while is considered temporarily unstocked forest and may not be counted towards the total deforestation and increased forest cover rates. For every deforestation transition, select the maximal period that the “from” forest stratum can be out of forest cover and is temporarily unstocked. Use a default value of two years, unless project-specific

[4] ANR activities are carried out only in areas that would otherwise be deforested in the baseline scenario which is different from Afforestation and Reforestation activities.

conditions demand a different period.

By definition, degradation is a process that must have persisted for at least 3 years. In other words, forest land that transitions from a stratum with a larger carbon density stock to a stratum with smaller carbon density stock can only be considered degradation if it has persisted for 3 years.

8.1.2.4 Analyze Historical LULC Class and Forest Strata Transitions

The historical rates of all LULC classes and forest strata transitions must be calculated on the union of the reference region, leakage area, and project area, based on a remote sensing analysis executed by the project proponent. However, existing classification or stratification maps can be used if (1) the classes or strata in these maps can be matched to the LULC class and forest strata definitions developed according to this methodology and (2) the accuracy of these maps is quantified using the procedures in Section 8.1.2.7.

A wide range of remote sensing products exist for LULC classification and forest stratification based on optical, multispectral, RADAR or LiDAR sources, and acquired from airborne or satellite platforms. The most appropriate data product is dependent on project conditions and requirements. The analysis of land cover change must be performed by processing and analyzing remote sensing data in three steps described in the following sections:

- Pre-processing of remote sensing data.
- LULC classification and forest stratification.
- Accuracy assessment and discounting factor determination.

8.1.2.5 Pre-processing of Remote Sensing Data

Pre-processing includes geometric correction and handling image data loss due to cloud cover.

- Geometric correction ensures that images in a time series overlay properly to each other and to other GIS maps used in the analysis (i.e. for post-classification stratification). The average location error between two images (RMSE) must be less than or equal to one pixel.
- Clouds or cloud shadows must be masked out and excluded from the calculation of deforestation rates. The maximum allowable cloud cover is ≤ 20% for a single image or ≤ 20% on average across image pairs used in the transition rate analysis.
- A forest benchmark map must be generated to show forest cover status in the project and leakage areas. The final LULC map in the historic series can be used as the forest benchmark map, however missing values within the project and leakage areas due to cloud and cloud shadow must be filled with RS data acquired within three years before the start of the crediting period to be eligible. Geographic areas for which no cloud-free or cloud-shadow-free imagery is available within three years of the project start must be excluded from the project area. These may only be added back to the project area at verification following the rules of

"Additions of New Project Area" set out in Section 9.3.

- Calculation of GHG benefits in the project and leakage areas after the project start must include only cloud-free imagery. When clouds and cloud shadows are present, calculation of the GHG benefits from these areas must be postponed until cloud-free remote sensing data is available in a subsequent monitoring period. These temporarily halted NERs may be added to the NERs generated in the subsequent monitoring period. This is only allowed on areas for which the forest status was unambiguously demonstrated at the beginning of the crediting period (see previous point).

Consult experts and literature for further advice on pre-processing techniques. Duly record all pre-processing steps for later reporting.

8.1.2.6 LULC Classification and Forest Stratification

LULC classification and forest stratification may be (sub-) pixel based or segment-based. Attribution of classes to pixels or segments must be done using widely accepted methods such as maximum likelihood, decision trees, or support vector machines. Ancillary data may be included to improve classification accuracy. Typical ancillary data includes climate, soil, elevation, slope, proximity to certain built or natural features (e.g. roads, settlements, or water bodies), and land tenure status (e.g. protected forest, logging concession, indigenous reserve, etc.). The minimum mapping unit for LULC classification and forest stratification must be set according to the forest definition employed for the project, but must be less than 1 ha (see Section 3.2).

If emission reductions from avoided degradation are included, a forest stratification model must be unambiguously defined at validation. The forest stratification model may use input data that includes a combination of optical remote sensing, radar and LiDAR measurements, as well as ancillary data such as topography or LULC classes. The model itself may be rule-based, regression-based, or machine-learning based. However, the parameters of the model may not be changed after validation (ie, the forest stratification model itself is fixed until the next baseline update). In addition, if biomass plot or biomass carbon stock density is used during the development of a forest stratification model, either to develop a regression model or to verify the stratification model, these data may not be used for calculating the biomass stock densities and emission factors of the strata.

8.1.2.7 Map Accuracy Assessment and Discounting Factor Determination

Different procedures to determine discounting factors for the broad classification into forest types or forest/non-forest land and the stratification of forest land into different carbon density classes are imposed.

Discounting factor for LULC classification, $u_{classification}$: The accuracy by which broad LULC classes can be discerned is used to discount emission reductions and/or removals from avoiding deforestation. The discounting factors for LULC classification are fixed until the next baseline update.

The accuracy assessment of LULC classification must be conducted for all LULC maps across the whole analysis area, i.e., the union of the project and leakage areas and the reference region. The accuracy must be assessed by comparing predicted LULC classes for a number of reference locations with independently determined LULC classes. Reference locations must be located throughout the reference region, leakage area, and project area. The LULC classes for these reference locations must be identified using field observations, in-situ maps, remote sensing data, and/or other ground-truthing data. At minimum 50 reference locations per LULC class must be used. If the area of the class exceeds 500 km^2 or the number of classes is more than 12, then, at minimum,75-reference locations per class must be used.[5] The reference locations within each LULC class must be systematically distributed to represent varying topography, parcels and other geographic features.

The accuracy of historic images may be assessed using historic medium to high-resolution images, aerial photographs or local topographic maps existing at the time when the historic image was acquired. At validation, the historic period is relative to the start of the crediting period. However, when a baseline update occurs, the historic period is relative to the current project year, and more historical data may become available to conduct an accuracy assessment at that time. See monitoring Section 9.3.2 for procedures to apply after the project start.

The discounting factor for the LULC classification is determined in three steps:

- **Step 1**: Determine the accuracy of LULC classification for each map by creating a confusion matrix. Report the overall accuracy, and the commission and omission errors (see Congalton 1991 and Pontius 2002 for an in-depth explanation of these concepts).
- **Step 2**: Multiply the accuracy of LULC classification from step 1 with a factor based on the smallest accuracy of all maps (see Table 5 below). If the accuracy of broad LULC classification is less than 70%, the project is not eligible under this methodology.

Table 5. Uncertainty deduction factors for LULC classification as a function of accuracy attained.

Accuracy attained	STEP 2 factor
≥85%	1.00
≥80 to <85%	0.80
≥75 to <80%	0.75
≥70 to <75%	0.70
<70%	Project is not eligible

[5] The specification of the number of reference locations is based on recommendations by Congalton (1991), Hay (1979) and Fenstermaker (1991).

- **Step 3**: Multiply the factor from Step 2 with a factor based on the number of images in the historical reference period to get $u_{classification}$, the total discounting factor for avoiding deforestation as indicated in Table 6, An absolute minimum of three images is required to quantify the historical deforestation rate.[6]

Table 6. Uncertainty deduction factors for LULC classification as a function of number of images in historical reference period.

Number of images in historical reference period	STEP 3 factor
1-2	Project is not eligible
3	0.90
>3	1.00

The classification accuracy of every map used for verification must be greater than the smallest accuracy obtained during the historical reference period. The $u_{classification}$ factor must be fixed at validation until the next baseline update, even when the classification accuracy improves after the start of the project.

Discounting factor for forest stratification, $u_{stratification}$: As forest strata are determined by their carbon content, the full uncertainty of stratification can be assessed in an unbiased way through the discounting factor for the carbon stock density of the stratum, as explained in Section 8.1.4.4. However, there are two important conditions for this statement to be true:

- The plots used in calculating the uncertainty of the carbon stock density were not used to develop the forest stratification model; and
- The plots used in calculating the uncertainty are randomly selected and represent all time points that are covered.

While the first is covered by the requirement that different plots must be used for creating the forest stratification model and determining the carbon stock density and its uncertainty, the second can only be fulfilled if biomass plot densities measured and assessed at multiple times are used in the calculation of the carbon stock density and the associated uncertainty following Section 8.1.4.4. Since it is unlikely that a project will have historical biomass inventories available, the methodology allows using biomass inventories collected at different time points after the project start date to estimate $u_{stratification}$, the discounting factor for forest stratification. Further, to incentivize a sound monitoring effort by the project proponent, the discounting factor for forest stratification is dependent on the number of time points available in biomass inventories. Note that there must be at least one year in between time points for biomass inventories. Finally, it is allowed to only use biomass inventories that are located within the project area on conditions that these plots do not cause any bias and that these plots are representative of the stratum and/or LULC of the reference region.

[6] Note that when baselines are updated during the crediting period, a similar procedure must be used to update baseline deforestation rates. The historical reference period always ends at the time of the baseline update. Therefore, gradually more data points will become available during the crediting period, and eventually eliminate this discounting.

Table 7. The discounting factor for forest stratification as a function of the number of time points available in biomass inventories.

Number of time points available in biomass inventories	$u_{stratification}$
1	0.75 for ex-ante; not eligible for ex-post
2	0.75
3	0.90
>3	1.00

For example, if validation is done separate from verification, only 1 set of biomass inventories is available at validation, therefore $u_{stratification}$ must be set to 0.75 for ex-ante calculations. At first verification, the project proponent is required to measure an additional set of biomass plots so that at least 2 time points of biomass inventories are available. Section 8.1.4.4 explains how to update the average carbon stock density values and the uncertainty associated with them when plot measurements from multiple times are available. Therefore, at first verification, $u_{stratification}$ remains 0.75 according to the table above. At second verification, the project proponent has a choice to either not measure additional plots and keep $u_{stratification}$ at 0.75, or measure a third set of biomass inventories and use 0.9 as $u_{stratification}$.

In contrast to $u_{classification}$, $u_{stratification}$ is not fixed at validation and may be updated at verification

8.1.2.8 Summarize all Historical Land Transitions

For every pair of subsequent images in the historical reference period, calculate the area of each land transition and report in a LULC and forest strata transition matrix. Note that for deforestation, lands should have been without forest cover for longer than the period defined as temporarily un-stocked. Likewise, for degradation, lands must have been in the smaller carbon stock density stratum for at least 3 years. Apply an appropriate temporal filter to ensure that only land that meets the three-year condition is designated as degradation. In addition, the PD must contain a table which contains the overall areas (ha) of deforestation, increased forest cover, forest degradation, and regeneration for each sub-period. These data will be used to project future land use change (Section 8.1.5.1).

8.1.3 Analyze the Agents and Drivers of Deforestation and Degradation

Deforestation can be the result of a short-term process (e.g., forest clear-cutting) or a gradual progressive process referred to as forest degradation (see definitions). Therefore, it is often challenging to distinguish agents/drivers of deforestation from agents/drivers of forest degradation. As a consequence, throughout this document, the term agents/drivers of deforestation is used for agents/drivers of deforestation and forest degradation. The drivers of deforestation and/or forest degradation must be those set out under the applicability conditions.

The PD must contain an analysis of the agents of deforestation and drivers similar to the analysis in Angelsen and Kaimowitz (1999) and Chomitz et al. (2006) by performing four steps, as described below.

8.1.3.1 Identify Agents and Drivers of Deforestation and Forest Degradation

For each of the ten included categories of drivers covered by this methodology that are present in the reference region, the main agents must be identified. Agents of deforestation may include small-scale farmers, encroachers, hunters, ranchers and loggers. In some cases, one or more of the listed categories of drivers need to be sub-divided into separate individual drivers based on main agents acting on particular drivers. A qualitative analysis of the broader underlying forces determining the agents' motivations for deforestation and forest degradation must be included. Where relevant to a driver, the following aspects must be considered in this analysis:

- Population pressure.
- Poverty.
- War and other types of conflicts and their effects.
- Changes in policies related to subsidies or payments for environmental services
- Property and land tenure regime.
- Market forces influencing land and commodity prices.

8.1.3.2 Assess the Relative Importance of the Drivers of deforestation

The relative contribution of each of the drivers of deforestation to the total historical deforestation and forest degradation is estimated in two steps: (1) estimating the absolute annual carbon loss per driver, and (2) estimate the relative contribution of each driver to the total carbon loss from deforestation and degradation.
Sub-Step 1: Estimating the absolute annual carbon loss per driver using the formulas in Table 8, which are based on GPG-LULUCF.

Table 8. Formulas to calculate the absolute annual carbon loss per deforestation or forest degradation driver category

No.	Driver category	Annual carbon loss
1	Conversion of forest land to cropland for subsistence farming	$$L(1) = CF \cdot \sum_{i=1}^{nrStrata} \left(\Delta area_{cropland,baseline}(i) \cdot \left(OM(i) - OM(cropland)\right)\right)$$ [EQ1] (Equation 3.3.8 from GPG LULUCF)
2	Conversion of forest land to settlements	$$L(2) = CF \cdot \sum_{i=1}^{nrStrata} \left(\Delta area_{settlement,baseline}(i) \cdot \left(OM(i) - OM(settlement)\right)\right)$$ [EQ2] (Equation 3.3.8 from GPG LULUCF)
3	Conversion of forest land to infrastructure such as roads, cell phone tower, power lines	$$L(3) = CF \cdot \sum_{i=1}^{nrStrata} \left(\Delta area_{infrastructure,baseline}(i) \cdot \left(OM(i) - OM(infrastructure)\right)\right)$$ [EQ3] (Analogous to Equation [EQ2])
4	Logging of timber for commercial sale	$$L(4) = CT_{baseline} \cdot \rho_{wood} \cdot BEF_2 \cdot CF$$ [EQ4] (Equation 3.2.7 from GPG-LULUCF)
5	Logging of timber for local enterprises, and domestic uses	$$L(5) = DT_{baseline} \cdot \rho_{wood} \cdot BEF_2 \cdot CF$$ [EQ5] (Equation 3.2.7 from GPG-LULUCF)
6	Wood collection for commercial on-sale of fuelwood and charcoal	$$L(6) = CFW_{baseline} \cdot \rho_{wood} \cdot BEF_2 \cdot CF$$ [EQ6] (Equation 3.2.8 from GPG-LULUCF)
7	Fuelwood collection for domestic and local industrial energy needs	$$L(7) = DFW_{baseline} \cdot \rho_{wood} \cdot BEF_2 \cdot CF$$ [EQ7] (Equation 3.2.8 from GPG-LULUCF)
8	Grazing	$$L(8) = CF.GR_{baseline}$$ [EQ8] (Adaption of Equation 1 of CDM A/R Methodological Tool *Estimation of GHG emissions related to displacement of grazing activities in A/R CDM project activity*)
9	Understory vegetation collection	$$L(9) = CF \cdot VG_{baseline}$$ [EQ9]

		(Analogous to Equation [EQ9])
10	Forest fires	$L(10) = CF.\sum_{i=1}^{nrStrata} \Delta area_{fire,baseline}(i) \cdot E \cdot P \cdot OM(i)$ [EQ10] (Equation 3.2.9 from GPG-LULUCF)

where:

$L(d)$	Annual carbon loss associated with driver d. [Mg C yr^{-1}]
ρ_{wood}	Basic wood density, estimated using Table GPG-LULUCF 3A.1.9. [Mg DM m^{-3}]
BEF_2	Biomass expansion factor for converting volumes of extracted round wood to total aboveground biomass (including bark), estimated using GPG-LULUCF Table 3A.1.10. [-]
CF	Carbon fraction of dry matter (default = 0.5). [Mg C (Mg DM)$^{-1}$]
$nrStrata$	Number of deforestation and forest degradation strata. [-]
$\Delta area_{fire,baseline}(i)$	Annual forest areas in the project area affected by disturbances from forest fires. [ha yr^{-1}]
E	Average combustion efficiency of the aboveground tree biomass. [-]
P	Average proportion of mass burnt from the aboveground tree biomass; estimate from GPG-LULUCF Table 3A.1.13 relative to C_{class1} . [-]
$OM(i)$	Average organic matter for forest stratum i. [Mg DM ha^{-1}]
$\Delta area_{cropland,baseline}(i)$	Forest area converted from forest stratum i to cropland at the beginning of the crediting period. [ha yr^{-1}]
$OM(cropland)$ $OM(settlement)$ and $OM(infrastructure)$	Average organic matter of cropland, settlement, developed infrastructure respectively; [Mg DM ha^{-1}]
$\Delta area_{settlement,baseline}(i)$	Average forest area converted from forest stratum i to settlement land. [ha yr^{-1}]
$\Delta area_{infrastructure,baseline}(i)$ =	Average forest area converted from forest stratum i to developed infrastructures such as, but not limited to, roads, power transmission lines, phone lines, towers etc. [ha yr^{-1}]
$CT_{baseline}$	Annually extracted volume of harvested timber, round wood for commercial on-sale. [m^3 yr^{-1}]
$DT_{baseline}$	Annually extracted volume of timber for domestic and local use, round wood. [m^3 yr^{-1}]
$CFW_{baseline}$	Annual volume of fuelwood gathered for commercial sale and charcoal production in the baseline scenario. [m^3 yr^{-1}]
$DFW_{baseline}$	Annual volume of fuelwood gathered for domestic as well as local energy needs in the baseline scenario. [m^3 yr^{-1}]

$GR_{baseline}$	Total dry matter intake by grazing animals under the baseline scenario. Calculate by multiplying the number of animals taking into account different types of grazing animals [Mg DM yr^{-1}]
$VG_{baseline}$	Biomass (dry matter) of understory vegetation extraction by project participants under the baseline scenario. Calculate by multiplying the number of households involved in extraction of vegetation with the average annual extraction rate by household for different vegetation types [Mg DM yr^{-1}]

Sub-Step 2: Estimating the relative contribution of each driver to the total carbon loss from degradation and deforestation. Carbon losses must be separated into losses from deforestation and losses from degradation. In case of conversion of forestland to cropland and settlements, all of the carbon loss is related to deforestation. However, drivers that have a more gradual carbon decrease (fuelwood collection, wildfires, and logging) will first lead to forest degradation, and eventually deforestation when biomass density becomes smaller than the arbitrary threshold implied under the forest definition. For example, a loss of 25 Mg biomass per hectare on a well-stocked forest of 200 Mg biomass per hectare may, according to the forest definition, be categorized as forest degradation, while the same loss on a poorly-stocked forest of 50 Mg standing biomass per hectare could be deforestation, because the final tree cover has become smaller than the forest cover threshold in the forest definition. The default proportion of the carbon loss from fuelwood collection, wildfires, and logging that leads to deforestation versus forest degradation is estimated depending on specific conditions outlined in Table 9. The default proportion can be modified when justification for such changes can be provided. Such justifications must be based on locally observed scientific publications.

Table 9. Proportion of carbon loss leading to deforestation vs. forest degradation for different drivers.

Driver	$proportion_{DF}(i)$	$proportion_{DG}(i)$
1. Conversion of forest land to cropland	100%	0%
2. Conversion of forest land to settlements	100%	0%
3. Conversion of forest land to infrastructure	100%	0%
4a. Logging for commercial sale by clear cutting[7].	100%	0%
4b. Logging for commercial sale by selection cutting (i.e. by employing either individual tree selection method and/or group selection).	0%	100%
5a. Logging for domestic use as clear cutting.	100%	0%
5b. Logging for domestic use by selection cutting (i.e. by employing either individual tree selection method and/or group selection).	0%	100%
6. Wood collection for commercial on-sale of fuelwood and charcoal.	5%	95%
7. Fuelwood collection for domestic and local industrial energy needs	5%	95%
8. Cattle grazing (i.e., in-forest grazing)	5 %	95%
9. Understory vegetation extraction (i.e., thatch grass collection for roof and livestock bedding materials, shrubs and small trees for straw fences)	50%	50%
10a. Small forest fires to the extent that they are not part of natural ecosystem dynamics	0%	100%
10b. Large crown fires to the extent that they are not part of natural ecosystem dynamics.	100%	0%

The total carbon loss due to deforestation versus forest degradation can be calculated as following:

$$\Delta C_{DF} = \sum_{d=1}^{nrDrivers} proportion_{DF}(d) \cdot L(d)$$

[7] Clear-cutting is defined as removing more than 75% of the trees on an area that is considered as forest in the forest definition used.

$$\Delta C_{DG} = \sum_{d=1}^{nrDrivers} proportion_{DG}(d) \cdot L(d)$$

where:

ΔC_{DF}	=	Total carbon loss due to deforestation. [Mg C yr^{-1}]
ΔC_{DF}	=	Total carbon loss due to degradation. [Mg C yr^{-1}]
$nrDrivers$	=	Number of drivers of deforestation or forest degradation. [-]
$proportion_{DF}(d)$ and $proportion_{DG}(d)$	=	Proportion of the gradual carbon loss that leads to deforestation or forest degradation, respectively, due to driver d. Estimate using the procedure detailed in Table 9.
$L(d)$	=	Annual carbon loss associated with driver d. [Mg C yr^{-1}]

The relative importance of the deforestation and forest degradation drivers can be calculated by combining the absolute carbon losses from Table 8 with the contributions from Table 9 using the following formula (as an example for the first driver):

$$contribution_{DF}(i) = \frac{proportion_{DF}(d) \cdot L(d)}{\Delta C_{DF}}$$

$$contribution_{DG}(i) = \frac{proportion_{DG}(i) \cdot L(d)}{\Delta C_{DG}}$$

where:

$contribution_{DF}(d)$	=	Relative contribution of driver i to the total deforestation. [-]
$contribution_{DG}(d)$	=	Relative contribution of driver i to the total forest degradation. [-]
$proportion_{DF}(d)$	=	Proportion of the gradual carbon loss that leads to deforestation. [-]
$proportion_{DG}(d)$	=	Proportion of the gradual carbon loss that leads to degradation. [-]
ΔC_{DF}	=	Total carbon loss due to deforestation. [Mg C yr^{-1}]
ΔC_{DG}	=	Total carbon loss due to degradation. [Mg C yr^{-1}]
$L(d)$	=	Annual carbon loss associated with driver d. [Mg C yr^{-1}]

8.1.3.3 Analyze of the Mobility of Each Deforestation and Forest Degradation Driver

The geographical extent of leakage is, in part, dependent on the mobility of each agent of deforestation. It must be determined how far each agent of deforestation is willing to go to acquire the forest resource or clear the land for cropland, grassland or settlement.

- For every driver of deforestation, report the main mode of transportation used by the main agent of deforestation of that driver: on foot, bike, scooter, motorcycle, car, or truck. Substantiate the choice with data from (lower-ranked options may only be used if higher-ranked options are not available) (1) social appraisals, (2) recent (preferably less than 10 years old) peer-reviewed scientific literature conducted among groups similar to the agents of deforestation of the project, (3) consultations with local socio-cultural and anthropological experts.
- Present a table of the average speed by which each identified mode of transportation can cross each of the LULC classes and forest strata and road categories, such as tracks, seasonally accessible small roads, and year-round accessible two-lane roads. Note the average speed on land with restricted access, such as national parks, as 0. Substantiate the choice with data from (lower-ranked options may only be used if higher-ranked options are not available) (1) social appraisals, (2) recent (preferably less than 10-year old) peer-reviewed scientific literature conducted among groups similar to the agents of deforestation of the project, (3) consultations with local socio-cultural and anthropological experts.
- Drivers that are less geographically constrained will still be confined to a “sphere of influence”. For example, illegal timber logging activities may shift outside of project boundary, possibly to outside of provincial boundary, upon inception of REDD project activity. In this case, the sphere of influence of the driver is national. However, for the purpose of this methodology, planned timber concessions, must not be considered within “sphere of influence”.

8.1.3.4 Identify the Quantitative Driving Variables of Deforestation and Forest Degradation

For each identified driver, provide potential spatial driving variables that explain the location of land cover change are also called “predisposing factors” (De Jong, 2007) (to be used in Section 8.1.5.2). The project proponent must select one or more of the following variables that potentially explain the location of deforestation and forest degradation.

- Access to forests (such as vicinity to existing roads, railroads, navigable rivers and coastal lines).
- Slope.
- Aspect.
- Proximity to markets.
- Proximity to industrial facilities (e.g., sawmills, agricultural products processing facilities, etc.).
- Proximity to forest edges.
- Proximity to settlements.

- Soil fertility and rainfall.
- Management category of the land (e.g., national park, logging concession.indigenous reserve, etc.).

Once the agents and drivers of deforestation have been identified, the project proponent must re-assess the similarity between the project area and the reference region, according to the procedure in Section 8.1.1.2. If necessary, adjust the area and location of the reference region to ensure that the same drivers of deforestation are present in both the reference region and the project area.

8.1.4 Determine Emission Factors for All Included Transitions

The project proponent must develop the emission factors following the requirements below.

For each LULC class or forest stratum that could be subject to a transition as identified in Section 8.1.2.3, it is necessary to determine the average carbon stock density, based on sampling plots. Plots may be either permanent or temporary, but the location of the plots must be known and available at the time of verification. Alternatively, on non-forest land, conservative defaults gathered from scientific literature may be used to quantify the carbon stock density. The applicability of these default values must be confirmed by the validator. The number of plots and their location must be determined in a stratified sampling design. The following steps are to be followed:

- Identify the LULC classes and forest strata for which carbon stocks are to be quantified.
- Review existing biomass stock density and biomass increment data for comparison with field measurements.
- Determine the sample size per LULC class or forest stratum.
- Measure carbon density stocks of each LULC class or forest stratum.
- Calculate emission factors for each land transition category.

8.1.4.1 Identify the LULC Classes and Forest Strata for which Carbon Stocks are to be Quantified.

Present a table of the LULC classes and forest strata that are likely to be subject to transitions within the project area or anticipated leakage area based on the land transition matrix.

8.1.4.2 Review Existing Data of Biomass Stock Densities and Biomass Net Annual Increments

Review existing data on biomass stock densities: For the purpose of sampling design and quality assurance of the measured values, all existing data on biomass stock densities must be reviewed. Sources that must be consulted include (lower-ranked options may only be used if higher-ranked options are not available): (1) peer-reviewed scientific literature conducted within the reference region, (2) peer-reviewed scientific literature from an area ecologically similar to the reference region, (3) non peer-reviewed reports or studies from the reference region or similar areas. Sources that contain a measure of the variation of the values (range, standard deviations, standard errors, or coefficients of variation) are specifically useful, since these can be used for preliminary determination of the number of sampling plots required during field sampling. For every data source used, note the following items:

- Methodology (field inventory, extrapolation from satellite imagery, ecosystem model, or GIS analysis).
- Number of measurement plots used.
- Whether all species are included in the sampling.
- The minimum DBH of measured trees in the biomass inventory or any other relevant threshold.
- Region in which the samples were taken.

The carbon stock density on non-forest land may be quantified using conservative defaults gathered from scientific literature. The applicability of these default values must be confirmed by the validator.

For project areas registered within a JNR area and where biomass stock data has been registered under the jurisdictional REDD+ program for the same LULC class and forest strata as in the project area, the most accurate estimates will be used, subject to any requirements specified within the jurisdictional REDD+ program.

Review existing data on net annual increments of biomass: Whereas the GHG benefits from avoided deforestation and avoided forest degradation are based on observed transitions between LULC classes and forest strata, the GHG benefits from ANR activities are based directly on the empirically observed increases in biomass stock densities. Therefore, for accurate ex-ante estimates, all existing data on net annual increments of biomass carbon stocks must be reviewed. Sources that must be consulted include (lower-ranked options may only be used if higher-ranked options are not available): (1) values measured by the project proponent in the project area using the methods used for forest inventories discussed in this methodology, (2) national or local growth curves and tables that are usually used in national or local forest inventories, (3) values from peer-reviewed literature, and (4) values from IPCC GPG-LULUCF (2003) Table 3A.1.5.

8.1.4.3 Determine the Sampling Design, i.e., Number, Location, and Layout of Plots

The determination of the sample size (number of sampling plots) required per LULC class and forest strata that are identified in 8.1.4.1 is dependent on (1) the required precision of at least 15% at a confidence level of 95% and (2) the anticipated variance in the specific LULC class and forest strata. Extra measurement plots must be installed within the ANR and harvest areas to reliably estimate the increase in carbon density. The CDM tool AR-AM Tool 03 *Calculation of the number of sample plots for measurements within A/R CDM project activities* may be used to determine the number of biomass sample plots required.

Further explanation on how to select the layout of sampling plots (form, nesting, etc.) can be found in textbooks such as Hoover (2008). For measuring and monitoring carbon density in the forest strata, a network of permanent or temporary forest sampling plots must be established. Due to the significant anthropogenic influence on non-forest land, it is not deemed feasible to install permanent sampling plots. Therefore, the average carbon stock density on non-forest LULC classes must be assessed using non-permanent sampling plots. Alternatively, conservative defaults gathered from scientific literature may be used to quantify the carbon stock density on non-forest land. The applicability of these default values must be confirmed by the validator.

Within a LULC class or forest stratum, the location of sample plots should be selected as random as practically feasible. However, in cases where access to the forest land is challenging, biomass plots located along a forest transects may be used instead of a stratified random sampling design on the condition that all forest classes and strata are represented in an unbiased way along the transect.. The randomization must be done *ex-ante* by a computer program. This is required to avoid subjective choice of plot locations. For each sample plot, record the observed LULC class, forest type, and estimated forest canopy closure. Note that stratification is usually an iterative process in which the stratification model – as defined in Section 8.1.2.6 - is adjusted based on biomass inventories and the stratum of a biomass inventory is guided by the stratification model. To avoid bias in the calculation of the uncertainty of stratification, the plots used to develop the forest stratification model must not be used to calculate the uncertainty of the carbon stock density of a specific stratum, as stipulated in Section 8.1.2.7.

This methodology allows implementing ANR and harvesting activities under certain conditions (see Section 8.2.5). The sample plots used to calculate the plant emission factors must not be located within areas in which ANR or harvest activities are planned. This requirement is necessary to prevent bias in the calculation of increases in forest biomass from natural regeneration and decreases in forest biomass due to harvesting.

Summarize the sampling framework following the guidance of Section 4.3.3.4 of GPG LULUCF in the PD and provide a map and the coordinates of all sampling locations.

8.1.4.4 Measure and Calculate Carbon Stock Density

Plot-based measurements must be aggregated within the LULC class or forest stratum they belong to.

- If degradation is not included, the LULC class of a specific biomass plot must be determined based on the LULC map that is closest in time to the time of measurement of the biomass plot. In case multiple measurements are available for one permanent biomass inventory plot, only the most recent value of the carbon stock density must be used.
- If degradation is included, the aggregations of non-forest LULC classes follow the procedures outlined above “if degradation is not included”. However, biomass inventory plots located in forest area must be assigned the appropriate forest stratum using the forest stratification model developed in Section 8.1.2.6. In case multiple measurements are available for one permanent biomass inventory plot, all values in time of the carbon stock density must be used in the aggregation and used to calculate the average and uncertainty metrics.

The carbon stock density from sampling plots must be kept separate for aboveground live biomass, aboveground dead biomass, belowground biomass, and soil organic carbon. The above ground dead plant carbon stock density can be calculated by summing the biomass carbon stock density in the lying deadwood and standing deadwood components. Likewise, the aboveground live plant carbon stock density can be calculated by summing the biomass carbon stock density in the aboveground tree and aboveground non-tree components.

$$OM_{AGD,plot\text{-}wise}(i,p) = OM_{LDW,plot\text{-}wise}(i,p) + OM_{SDW,plot\text{-}wise}(i,p) \quad \text{[EQ15]}$$

$$OM_{AGL,plot\text{-}wise}(i,p) = OM_{AGT,plot\text{-}wise}(i,p) + OM_{AGNT,plot\text{-}wise}(i,p) \quad \text{[EQ16]}$$

where:

$OM_{LDW,plot\text{-}wise}(i,p)$	=	Lying deadwood organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{SDW,plot\text{-}wise}(i,p)$	=	Standing deadwood organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{AGD,plot\text{-}wise}(i,p)$	=	Aboveground dead tree organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{AGL,plot\text{-}wise}(i,p)$	=	Aboveground live organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{AGT,plot\text{-}wise}(i,p)$	=	Aboveground live tree organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{AGNT,plot\text{-}wise}(i,p)$	=	Aboveground live non-tree organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]

In addition, the following symbols are used in subsequent equations, calculations as well as monitoring tables:

$OM_{BG,plot\text{-}wise}(i,p)$	=	Belowground tree organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]
$OM_{SOM,plot\text{-}wise}(i,p)$	=	Soil organic matter of plot p within LULC class or forest stratum i. [Mg DM ha^{-1}]

For the aboveground live (AGL), aboveground dead (AGD), belowground (BG), and soil organic matter (SOM) pools, the average stock densities of stratum $\boldsymbol{i}$ and associated statistics are calculated using the equations below. The “o” subscript indicates a pool out of the possible pools (AGL, AGD, BG, or SOM carbon).

$$OM_o(i) = average\left(OM_{o,plot\text{-}wise}(i,p)\right) \quad \text{[EQ17]}$$

$$stdev\big(OM_o(i)\big) = stdev\left(OM_{o,plot\text{-}wise}(i,p)\right) \quad \text{[EQ18]}$$

$$stderr\big(OM_o(i)\big) = \frac{stdev\big(OM_o(i)\big)}{\sqrt{n_i}} \quad \text{[EQ19]}$$

$$HCWI\big(OM_o(i)\big) = t_{0.95,n-1} \cdot stderr\big(OM_o(i)\big) \quad \text{[EQ20]}$$

$$CE_{inventory}(i) = \frac{\sqrt{\sum_o HWCI\big(OM_o(i)\big)^2}}{\sum_o OM_o(i)} \quad \text{[EQ21]}$$

$$u_{inventory}(i) = \begin{cases} 1 & \text{if } CE(i) \leq 0.15, \\ 1 - CE(i) & \text{if } 0.15 \ < CE_{inventory}(i) < 1, \\ 0 & \text{if } CE(i) \geq 1 \end{cases} \quad \text{[EQ22]}$$

where:

$OM_o(i)$	=	Average plant organic matter density of LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
$OM_{o,plot\text{-}wise}(i,p)$	=	Total biomass stock density of plot p within LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
$stdev\big(OM_o(i)\big)$	=	Standard deviation of the total plant-derived organic matter density of LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
$stderr\big(OM_o(i)\big)$	=	Standard error of the average of the total plant-derived organic matter density of LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
n_i	=	Number of sampling plots of LULC class or forest stratum i in pool o. [-]
$HCWI\big(OM_o(i)\big)$	=	Half-width of the confidence interval around the average of the total plant-derived organic matter density of LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
$t_{0.95,n-1}$	=	Value of t-statistics (i.e., from *t*-table) at 95% confidence interval and n-1 degree of freedom [-]
o	=	Carbon pool, either aboveground live (AGL), aboveground dead (AGD), belowground (BG) or soil organic matter (SOM).
$CE_{inventory}(i)$	=	Combined error in estimate of average biomass stock density of LULC class or forest stratum i. [−]
$u_{inventory}(i)$	=	Uncertainty of biomass stock density in stratum i. [−]

[EQ21] and [EQ22] are used in estimating the combined error, $CE_{inventory}(i)$, and the uncertainty, of the biomass stock density, $u_{inventory}(i)$, respectively. Note that procedures to calculate the uncertainty of the *difference* of two biomass stock densities due to a land transition are explained in the Section8.1.4.5. Estimation of combined error of the inventory, $CE_{inventory}(i)$ is prerequisite to estimation of uncertainty, $u_{inventory}(i)$. These two equations must be treated as generic and can be applied in estimating uncertainty for some specific project area when needed. For example, when uncertainty in estimated carbon stock density in harvest areas are needed, then inventory data from areas under harvest alone must be used in these two equations to estimate inventory uncertainty in harvest areas i.e., $u_{inventory,harvest}(i)$.

Stratum specific average organic matter can be estimated by summing organic matter in different carbon pools. Subsequently, the average total carbon stock is calculated by multiplication with the carbon fraction:

$$OM(i) = \sum_{o} OM_o(i) \quad \text{[EQ23]}$$

$$C_o(i) = CF \cdot OM_o(i) \quad \text{[EQ24]}$$

$$C(i) = \sum_{o} C_o(i) \quad \text{[EQ25]}$$

where:

$OM(i)$	=	Average plant-derived organic matter of LULC class or forest stratum i. [MG DM ha^{-1}]
$OM_o(i)$	=	Plant-derived organic matter of LULC class or forest stratum i in pool o. [Mg DM ha^{-1}]
$C_o(i)$	=	Average carbon stock density of LULC class or forest stratum i in pool o. [MT C ha^{-1}]
CF	=	Carbon fraction of dry matter in wood (default = 0.5). [Mg C (Mg DM)$^{-1}$]
$C(i)$	=	Average carbon stock density of LULC class or forest stratum i. [MT C ha^{-1}]

The exact measurement of aboveground and below tree carbon must follow international standards and follow IPCC GPG LULUCF 2003. These measurements are explained in detail in CDM approved methodology AR-AM0002 *Restoration of degraded lands through afforestation/reforestation*. A step-by-step Standard Operations Procedure for field measurements should be prepared ex-ante and contain a detailed, step-by-step explanation of all of the required field-work for both ex-ante and ex-post measurements. This document will ensure consistency during the crediting period by standardizing sampling procedures from year to year.

Aboveground organic matter, $OM_{AGT}(i,p)$. The aboveground organic matter must be determined by measuring the appropriate tree metric (e.g. DBH) of all trees using the appropriate cutoff DBH specified in the allometric equation (e.g., DBH ≥ 5 cm) within the sampling plot. The applicability of the allometric equation $f_{allometric}$ used must be specifically verified using the procedures Section. The allometric equation(s) must remain fixed during a baseline validation period. During a baseline update, the project proponent may replace previously used allometric equations, and BEF values by more accurate ones, if these would become available.

Aboveground non tree organic matter, $OM_{AGNT}(i,p)$. The above ground non-tree vegetation must be measured by destructive harvesting techniques. Alternatively, the aboveground organic matter can also be estimated using default values IPCC default values by following appropriate tool as the latest version of CDM Tool *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in AR CDM project activities*.

Belowground organic matter, $OM_{BG}(i,p)$. The below organic matter pool is estimated from the aboveground organic matter using a relationship $f_{belowground}$ between aboveground and belowground organic matter, such as a root-to-shoot ratio. Similar to the constants used for the aboveground organic matter, $f_{belowground}$ must be fixed during a baseline validation period. During baseline validation, the project proponent may replace a previously used $f_{belowground}$ by a more accurate one, if this would become available.

Lying deadwood organic matter, $OM_{LDW}(i,p)$. Lying deadwood must be sampled with the line intersect method (Harmon and Sexton, 1996) using the equation by Warren and Olsen (1964) as modified by Van Wagener (1968). Each piece of dead wood is assigned to one of three decay classes as (a) Sound, (b) Intermediate, or (c) Rotten, on the basis of a machete test . The estimated biomass for each dead wood piece is subject to density reduction factor. While the project proponent may use most applicable density reduction factor, the default density reduction factors are 1, 0.80, and 0.45 respectively for decay classes- sound, intermediate and rotten.

Standing deadwood organic matter, $OM_{SDW}(i,p)$. Standing dead trees must be measured using the same procedures used for measuring live trees with the addition of a decomposition class and the addition of an appropriate biomass reduction factor. Specifically, all the standing dead trees must be assigned with one of the two conditions (a) Dead trees which have lost only leaves and twigs, and (b) Dead trees which have lost leaves, twigs, and small branches (diameter < 10cm) and use an appropriate biomass reduction factor for each of the two conditions. The project proponent may use biomass reduction factors based on local or national data/study or use a default factor of 0.975 for trees in condition (a) and 0.80 for trees in condition (b). If the tree has lost all the branches, such a tree must be considered a Dead Tree Stump.

Dead tree stump organic matter, $OM_{DTS}(i,p)$*.* If the stump height is greater than the mid-point diameter of a stump or dead tree without branches, then the biomass must be estimated using the method found in Ormerod (1973). First, the volume of the dead tree stump must be estimated using Huber’s formula in which the cross-sectional area is estimated using the mid-point diameter of tree or tree stump multiplied with height of the stump. The estimated volume is subsequently multiplied by wood density. A density reduction factor is assigned to each of the decay classes, which is to be multiplied by the basic wood density of the species of the stump to obtain its estimated wood density. The following default values of the density reduction factors for the three decay classes must be used, unless project specific data is available for the decay class: (i) 1.0 for sound organic matter, (ii) 0.8 for organic matter in an intermediate decay class and (iii) 0.45 for rotten organic matter.

Soil organic matter, $OM_{SOM}(i,p)$. Soil organic carbon pool must be estimated using soil samples taken at different soil horizons. The depth to which the soil samples are taken and analyzed must be at least 30 cm as per the recommendation of the IPCC GPG-LULUCF (2003). In these samples, depth, bulk density and concentration of organic dry matter must be recorded.

Stratum-specific average organic matter density, $\boldsymbol{OM}(\boldsymbol{i})$ and its associated uncertainty, $\boldsymbol{u_{inventory}}(\boldsymbol{i})$ may also be (partially) estimated using other sampling approaches such as double sampling, regression estimators e.g. LiDAR on the condition that (1) it can be demonstrated that the use of such approach is conservative, and (2) valid and unbiased uncertainty estimators are provided for the biomass stock density that are equivalent to the uncertainty estimators used for plot-based measurements described in this methodology.

8.1.4.5 Calculate Emission Factors

Emission factors only include the carbon pool-related sources due to changes in carbon stock densities between the LULC classes and forest strata. Since N_2O and CH_4 emissions from forest fires increase emissions, they can be conservatively omitted for baseline calculations[8]. Once the carbon stock densities are calculated, biomass carbon emission factors and their uncertainties for each LULC class or forest stratum transition are calculated. A positive emission factor (i.e. EF_o) indicates a net sequestration of carbon, or an increase in the carbon stock, while a negative emission factor sign indications emission. The emission factor for aboveground live biomass is calculated as:

$$EF_{AGL}(CS1 \rightarrow CS2) = \frac{44}{12} \cdot \left(C_{AGL}(CS2) - C_{AGL}(CS1)\right) \quad \text{[EQ26]}$$

where:

$EF_{AGL}(CS1 \rightarrow CS2)$	=	Emission factor for change in aboveground live plant organic matter from an LULC Class or forest Stratum (CS) 1 to 2. [tCO_2e ha^{-1}]
$CS1 \rightarrow CS2$	=	Land transition from LULC class or forest stratum 1 to 2.
$C_{AGL}(i)$	=	Carbon density of aboveground plant organic matter of classes or forest stratum i. [MT C ha^{-1}]

The emission factor for aboveground deadwood must be gradually spread over time. The project proponent may propose their own temporal component (e.g., an exponential equation) if the conservative nature of the temporal component can be demonstrated using peer-reviewed literature or field measurements. If no temporal component is proposed by the project proponent, the default temporal component from the VCS must be used using the following formula:

For $t \leq 10$:

$$EF_{AGD}(CS1 \rightarrow CS2, t) = \frac{44}{12} \cdot \frac{\left(C_{AGD}(CS2) - C_{AGD}(CS1)\right)}{10} \quad \text{[EQ27]}$$

For $t > 10$:

$$EF_{AGD}(CS1 \rightarrow CS2, t) = 0 \quad \text{[EQ28]}$$

[8] Note that under the project scenario, N_2O emissions from prescribed burning must be included in the carbon accounting.

where:

$EF_{AGD}(CS1 \rightarrow CS2, t)$	=	Emission factor from change in above ground dead wood from an LULC Class or forest Stratum (CS) 1 to 2 at t years after transition. [tCO_2e ha^{-1}]
$CS1 \rightarrow CS2$	=	Land transition from LULC class or forest stratum 1 to 2.
$C_{AGD}(i)$	=	Carbon density of aboveground dead plant organic matter of classes or forest stratum i. [MT C ha^{-1}]

The total belowground biomass emission factor must also be must be gradually spread over time. The project proponent may propose their own temporal component (e.g., an exponential equation) if the conservative nature of the temporal component can be demonstrated using peer-reviewed literature or measurements conducted by the project proponent. If no temporal component is proposed by the project proponent, the default temporal component from the VCS must be used using the following formula:

For $t \leq 10$:

$$EF_{BG}(CS1 \rightarrow CS2, t) = \frac{44}{12} \cdot \frac{\left(C_{BG}(CS2) - C_{BG}(CS1)\right)}{10} \quad \text{[EQ29]}$$

For $t > 10$:

$$EF_{BG}(CS1 \rightarrow CS2, t) = 0 \quad \text{[EQ30]}$$

where:

$EF_{BG}(CS1 \rightarrow CS2, t)$	=	Emission factor for change in belowground plant organic matter from an LULC Class or forest Stratum (CS) 1 to 2 at t years after transition. [tCO_2e ha^{-1}]
$CS1 \rightarrow CS2$	=	Land transition from LULC class or forest stratum 1 to 2.
$C_{BG}(i)$	=	Carbon density of belowground plant organic matter of classes or forest stratum i. [MT C ha^{-1}]

The total soil emission factor must be gradually spread over time. The project proponent may propose their own temporal component (e.g., an exponential equation) if the conservative nature of the temporal component can be demonstrated using peer-reviewed literature or measurements conducted by the project proponent. If no temporal component is proposed by the project proponent, the temporal component from the IPCC GPG-LULUCF 2003 and used in following formula for the soil emission factor must be used:

For $t \leq 20$:

$$EF_{SOM}(CS1 \rightarrow CS2, t) = \frac{44}{12} \cdot \frac{\left(C_{SOM}(CS2) - C_{SOM}(CS1)\right)}{20} \quad \text{[EQ31]}$$

For $t > 20$:

$$EF_{BG}(CS1 \rightarrow CS2, t) = 0 \quad \text{[EQ32]}$$

where:

$EF_{SOM}(CS1 \rightarrow CS2, t)$	=	Emission factor for change in soil organic matter from LULC Class or forest Stratum (CS) 1 to 2 at t years after transition. [$tCO_2e\ ha^{-1}$]
$cs1 \rightarrow cs2$	=	Land transition from LULC class or forest stratum 1 to 2.
$C_{SOM}(i)$	=	Carbon density of soil organic matter plant of LULC class or forest stratum i. [MT C ha^{-1}]

For aboveground live, aboveground dead, belowground, or soil organic matter emission factor, the combined error in estimated biomass stock densities for a transition from one stratum to another is measured as:

$$CE_{transition}(CS1 \rightarrow CS2) = \frac{\sqrt{\sum_o \left(HWCI\left(OM_o(CS1)\right)^2 + HWCI\left(OM_o(CS2)\right)^2\right)}}{\left|\sum_o OM_o(CS2) - \sum_o OM_o(CS1)\right|}$$

The uncertainty discounting for estimated emissions factors for a transition from one stratum to another is estimated using

$$u_{transition}(CS1 \rightarrow CS2) = \begin{cases} 1 & \text{if } CE_{transition}(CS1 \rightarrow CS2) \leq 0.15, \\ 1 - CE_{transition}(CS1 \rightarrow CS2) & \text{if } 0.15 < CE_{transition}(CS1 \rightarrow CS2) < 1, \\ 0 & \text{if } CE_{transition}(CS1 \rightarrow CS2) \geq 1 \end{cases} \quad \text{[EQ34]}$$

where:

$u_{transition}(CS1 \rightarrow CS2)$	=	Discounting factor for the emission factor for the transition from LULC class or forest stratum 1 to class 2 according to the uncertainty of the biomass inventory. [-]
$HWCI\left(OM_o(i)\right)$	=	Half-width of the 95% confidence interval around the mean plant organic matter density of LULC class or forest stratum i in pool o. [$tCO_2e\ ha^{-1}$]
$CE_{transition}(CS1 \rightarrow CS2)$	=	Combined error in estimated biomass stock density change for a transition from one stratum to another. [-]

List the estimated emission factors, the associated uncertainties, and the lower confidence limit per LULC class and forest strata category in a table in the PD. The inventory must be iteratively expanded until for every transition, $u_{transition}(CS1 \rightarrow CS2)$ is greater than 0.75. This threshold serves to ensure a minimal accuracy of biomass inventories. Finally, it must be checked that all forest stratum transitions are compatible with the definition of degradation. More specifically, it must be checked that the carbon stock densities in two different strata differ at least by 10% of the carbon stock of strata with lower level of carbon stock. For example, if stratum "A" has 50 Mg C ha-1, then stratum "B" must have at least 55.1 Mg C ha-1.

8.1.5 Estimate Ex-ante Land Transition Rates under the Baseline Scenario

The goal of this step is to calculate all land transitions, including deforestation and increased forest cover, and forest degradation and regeneration under the baseline scenario. The procedure below calculates first the total deforestation and forest degradation rates, and also the relative regeneration and increased forest cover change rates per forest stratum and LULC class. Subsequently, the total rates of deforestation and forest degradation are split into LULC class and forest stratum specific rates using a geographical modeling approach, similar to the GEOMOD model[9]. Note that the exact location of future deforestation predicted by the model is not used as such for carbon accounting. Location-specific data on deforestation, forest degradation, and other LULC transitions are aggregated again into a land-use change transition matrix, which is the activity data on which the carbon accounting is based.

8.1.5.1 Calculate Total Rates of Deforestation and Forest Degradation in the Project Area

The total future deforestation and degradation rates are interpolated from past trends. However, scarcity of land may decrease rates to values below the maximal rates interpolated on past trends. This is accounted for in Section 8.1.5.4.

Create a graph of the historical deforestation rates in the reference region (hectares per year) versus time (years) for each consecutive pair of images in the historical reference period. Create a similar graph of the historical degradation rates versus time. From these graphs, calculate the future deforestation and degradation rates using two beta regression[10] equations, one for deforestation and one for forest degradation:

$$D_{referemceRegion,baselineScenario,DF}(t) = BetaReg_{DF}(t) \quad \text{[EQ35]}$$

$$D_{referenceRegion,baselineScenario,DG}(t) = BetaReg_{DG}(t) \quad \text{[EQ36]}$$

where:

[9] This approach is conservative since upon exhaustion of one forest stratum, the deforestation will be displaced to the stratum with the greatest likelihood of being deforested. In case stratum-specific deforestation rates were calculated up front, the displacement of deforestation to other forest strata would have been more challenging.

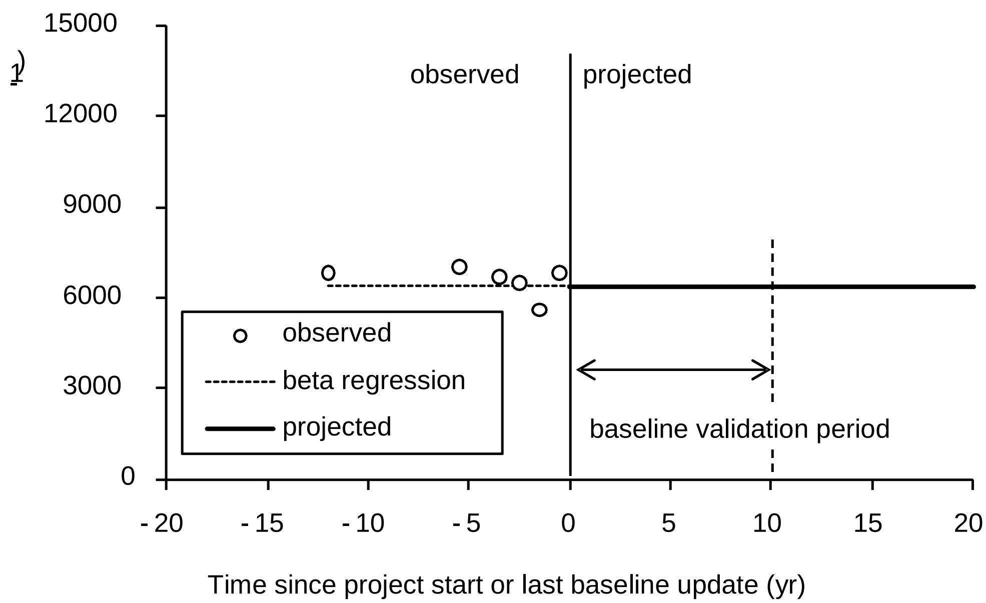
[10] Beta regression is commonly used to model variables that assume values in the standard unit interval (0; 1). Beta regression assumes that the dependent variable is beta-distributed and that its mean is related to a set of regressors through a linear predictor with unknown coefficients and a link function. Parameter estimation is performed by maximum likelihood.

$D_{referenceRegion,baselineScenario,DF}(t)$, $D_{referenceRegion,baselineScenario,DG}(t)$	=	Rate of deforestation/degradation within the reference region for during year t. [ha yr^{-1}]
$BetaReg_{DF}(t)$ and $BetaReg_{DG}(t)$	=	Beta regression model describing the relationship between time and deforestation/degradation rate in the reference region during the historical reference period. [ha yr^{-1}]
t	=	Time since project start (negative before project start). [yr]

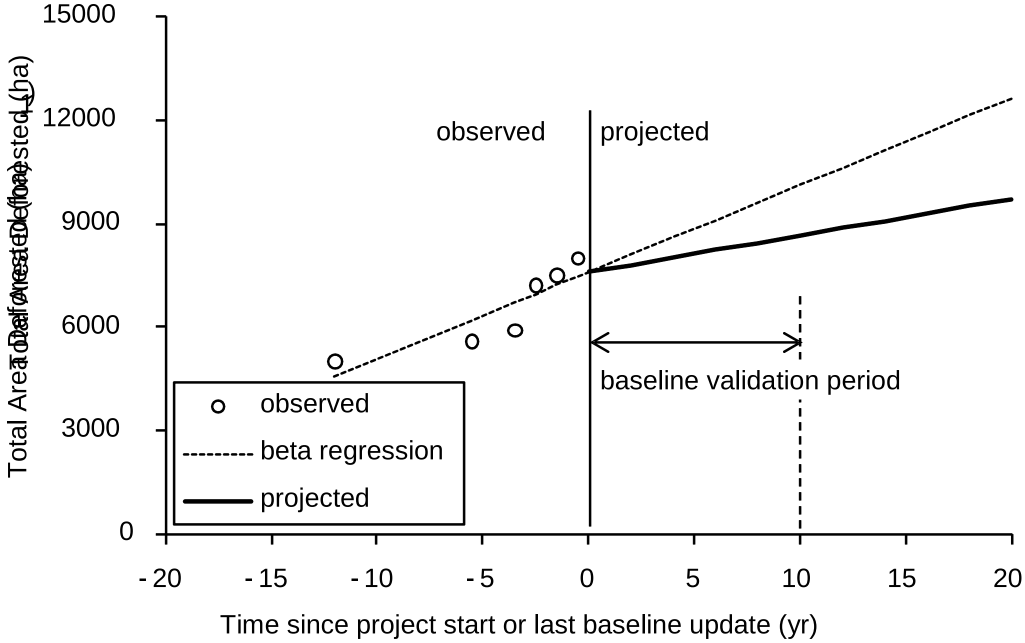
However, if only three images were included in the historical analysis, and, therefore, only two deforestation/degradation rates are available, the average of the two rates must be used instead of the extrapolation using the Beta regression.

The future deforestation and forest degradation must be calculated as follows:

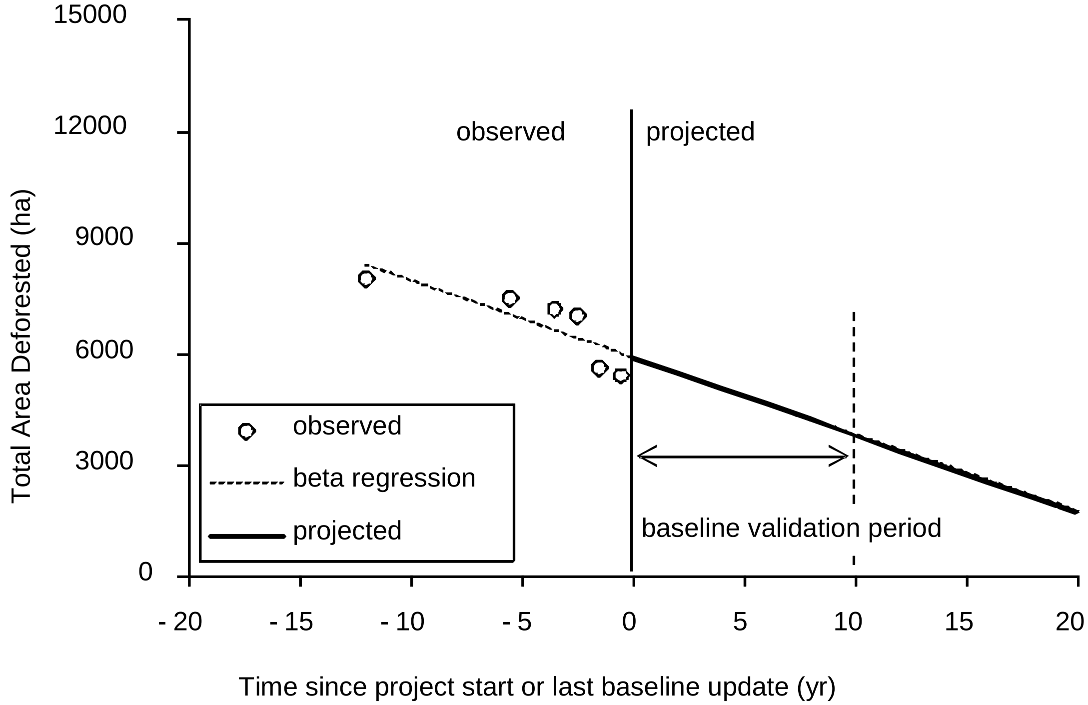
If the area of deforestation/degradation is constant (i.e. if the slope of the relation between deforestation/degradation quantities and time is not significantly different from 0 at the 95% confidence level), a constant future deforestation/degradation quantity is set as the mean of the observed deforestation/degradation amounts in the reference region.



If the deforestation/degradation quantity increases (i.e. if the slope of the relation between deforestation/degradation quantities and time is significantly larger than 0 at the 95% confidence level), the lower 95% confidence interval of the beta regression model must be used.

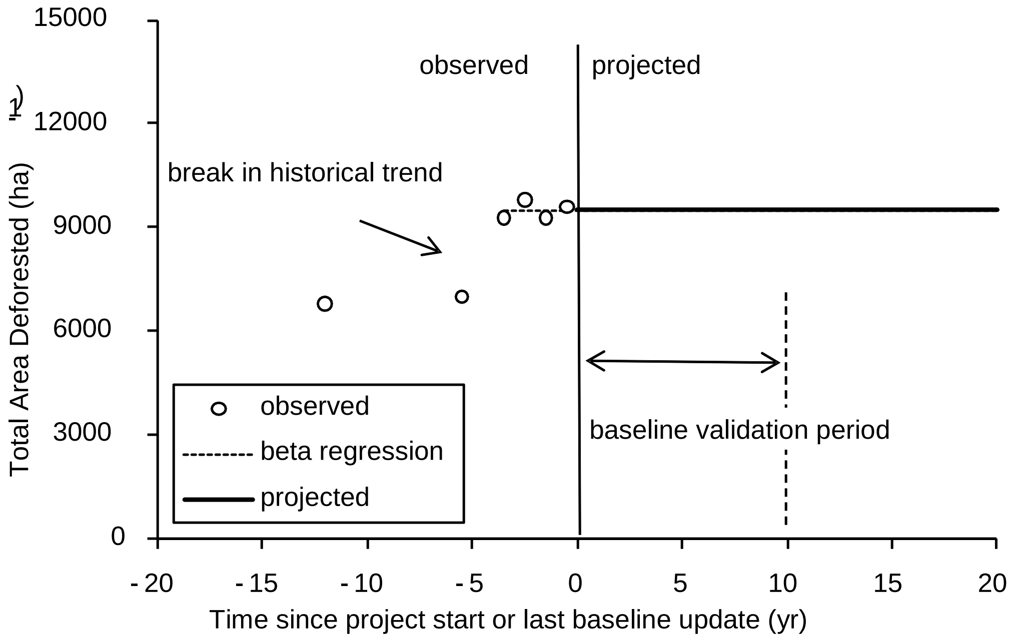


If the deforestation/degradation quantity decreases (i.e. if the slope of the relation between deforestation/degradation quantities and time is significantly smaller from 0 at the 95% confidence level), the original beta regression model must be used.

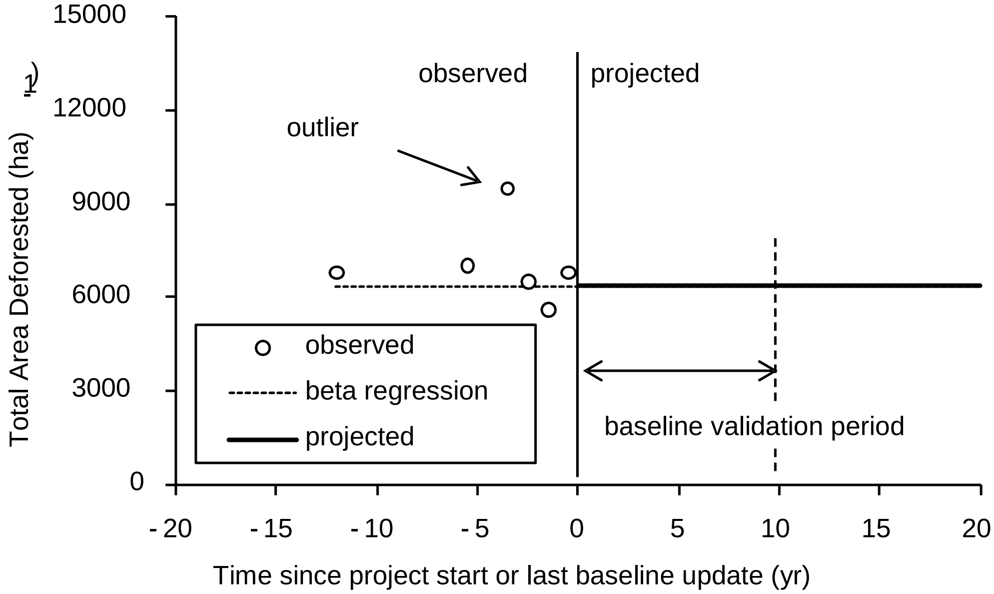


When there is a clear break in the historical trend, it is required to examine when the anomaly occurred, why it occurred, and whether the change is likely to be stable to determine whether to adjust the data points used in the beta regression. A break in the historical trend must only be considered when at least six points in time are available[11]. A break in the historical trend usually indicates a technological breakthrough, a policy reform, or change in land use practice. If it is demonstrated that the reasons for a break in the trend continued into the future, omit the observations occurring before the break to project the future deforestation quantity. The projected deforestation rate must be determined from the period that goes back no farther than the appearance of the breakpoint (Sataye and Andrasko, 2007). Use one of the approaches above depending on the trend observed after the break.

[11] Even though, often, only 3 or 4 data points will be available upon validation, increasingly more data points will become available during the crediting period. Therefore, when the baseline is updated, sufficient points may be available to detect a break.



Single outliers are most likely due to once-only anomalies (e.g., loss of forest land due to fire, hurricane or other natural disturbance). It is required that the cause of this single outlier be examined to determine if it may be removed. They may only be removed from the other points in the historical reference period if it is demonstrated that the occurrence of the outlier is due to specific conditions that are not present anymore (as would be the case for a natural disturbance). Use one of the approaches above depending on the trend observed after removing the outlier.



Once the coefficients from the beta regressions are determined, calculate the baseline total deforestation and degradation rates in the project area as:

$$D_{projectArea,baselineScenario,DF}(t) = BetaReg_{DF}(t) \cdot \frac{size_{projectArea}}{size_{referenceForest}} \quad \text{[EQ37]}$$

$$D_{projectArea,baselineScenario,DG}(t) = BetaReg_{DG}(t) \cdot \frac{size_{projectArea}}{size_{referenceForest}} \quad \text{[EQ38]}$$

where:

$D_{projectArea,baselineScenario,DF}(t)$, and $D_{projectArea,baselineScenario,DG}(t)$	=	Baseline rate of deforestation/degradation within the project area during year t. [ha yr^{-1}]
$BetaReg_{DF}(t)$ and $BetaReg_{DG}(t)$	=	Beta regression model describing the relationship between time and deforestation/degradation rate in the reference region during the historical reference period. [ha yr^{-1}]
t	=	Time since project start (negative before project start). [yr]
$size_{projectArea}$	=	Total size of the project area. [ha]
$size_{referenceForest}$	=	Total size of the forest area in the reference region. [ha]

The deforestation rate or degradation rate calculated from this procedure represents the gross deforestation rate, but not net deforestation or degradation rate. Therefore, all non-forest to forest transitions need to be explicitly included in the baseline to achieve a correct representation of the forest cover dynamics.

8.1.5.2 Calculate LULC Class or Forest Stratum-Specific Relative forest cover increase and Regeneration Rates

Although reforestation is not allowed as a project activity, the baseline scenario must include potential increases in forest cover or forest biomass that would have happened without project activities. There must be a full symmetry in carbon accounting: degradation in the baseline scenario may only be included if regeneration under the baseline is included as well. Likewise, both transitions from forest to non-forest and non-forest to forest (and that were forest at the start of the crediting period, per applicability condition 1) must be included in the baseline. Note that the quantification of transitions of non-forest to forest areas must not be based on areas on which large-scale reforestation has occurred as such areas should have been excluded from the reference region.

The extent of increase in forest cover or forest regeneration that would have happened under the baseline scenario is quantified based on historical observations in the reference region during the historical reference scenario. For every land class or forest stratum that transitions into a different class with higher biomass, calculate the relative regeneration or forest cover increase rate by dividing the area of the transition by the area of the "from" class:

for every transition for which $C(CS_2) > C(CS_1)$:

[EQ39]

$$RFRGrate(CS_1 \rightarrow CS_2) = \frac{\Delta area_{historical}(CS_1 \rightarrow CS_2, t_1 \rightarrow t_2)}{area_{historical}(CS_1, t_1) \cdot (t_2 - t_1)}$$

where:

CS_1 and CS_2	=	Class or Stratum 1 and 2, respectively
$C(CS_1)$ and $C(CS_2)$	=	Average carbon stock density of LULC class or forest stratum 1 and 2, respectively. [Mg C ha^{-1}]
$RFRGrate(CS_1 \rightarrow CS_2)$	=	Relative annual forest cover increase and regeneration factor for the transition from class or stratum 1 to 2. [yr^{-1}]. Multiply with 100 to obtain a forest cover increase and regeneration rate in percentage per year.
$\Delta area_{historical}(CS_1 \rightarrow CS_2, t_1 \rightarrow t_2)$	=	Area of transition from class or stratum 1 to 2 from time 1 to 2 during the historical reference period. [ha]
$area_{historical}(CS_1, t_1)$	=	Total area of class or stratum 1 at time 1. [ha]
t_1 and t_2	=	Time 1 and time 2, respectively. [years]

Calculate the LULC class or forest stratum-specific regeneration or forest cover increase rates for every pair of subsequent images in the historical reference period, and report the averages in a table in the PD.

8.1.5.3 Calibrate and Validate a Spatial Model to Predict the Suitability for Deforestation and Degradation

Deforestation and degradation do not occur randomly within the forest area, but occur preferentially at specific locations where predisposing factors are present (De Jong 2007). These factors are referred to as *spatial driver variables* and were identified in Section 8.1.3.4. By examining the impact of spatial driver variables on historical land use change, the likelihood of land-use change can be quantified; this likelihood relation can be extrapolated into the future to predict the location of future land use change. This Section focuses on examining the relation between spatial drivers and historical land use change, while Section 8.1.5.4 focuses on extrapolating this relation into the future. Spatial driver variables may be constant, meaning that they will never change during model execution, such as slope or elevation, or dynamic, meaning that they may change during project runs, such as distance to the nearest road, or forest density. In addition, they may be continuous, such as distance to the closest market, or categorical, such as soil type. Logistic regression models are one class of models that have been used successfully to quantify the suitability of deforestation and degradation (Lambin 1997, Verburg et al. 2004 and Boer et al. 2006). However, this methodology does not prescribe an exact form of a statistical model. The following steps are to be followed once to calibrate the deforestation model and once to calibrate the degradation model. For brevity, the steps below assume a deforestation model.

For each pair of two subsequent LULC classification maps developed as per Section**,** randomly select a large number (>10,000) of forested grid-cells/pixels from the first image. Use the second image of the pair to determine whether these grid-cells/pixels were deforested, degraded, or showed no change during the period in between the two images. Since grid-cells are selected randomly from the baseline LULC maps, pixels will be selected from degrading, deforested, and no-change areas in an unbiased way.

Calculate the value of each spatial driver variable based on the first LULC map of the image pair for each of the points selected in the previous step. Create a list containing the location, land transition category, and all values of each of the spatial driver variable identified in Section 8.1.3.4. In case of dynamic spatial driver variables, use a spatial driver at the time the first image was recorded. Deforestation and degradation usually occur in a clustered fashion. Therefore, include the distance to the forest edge, or forest fragmentation as spatial driver variables (Lambin et al., 1997).

Split this list randomly into a calibration dataset and a (statistical) validation dataset. The calibration data will be used to fit the deforestation and degradation statistical models and the validation data will be used to independently assess the quality of the model. 2/3 of the points should be used for calibration and 1/3 for validation.

Calibrate a statistical model for deforestation based on the values of spatial driver variables at the calibration point dataset. The statistical model must predict the suitability for deforestation for every location in the project area, and must therefore be bound by the interval [0,1]. A logistic regression model is an example of an appropriate statistical model. If necessary, apply mathematical transformations to make the effect of the spatial driver variables linear. For instance, the influence of a road on deforestation will decrease exponentially with distance to the road, and a log-transformation should be applied.

Calibrate a statistical model for degradation based on the values of spatial driver variables at the calibration point dataset.

Calibrate a statistical model to predict the LULC class of the new land use on cells selected for deforestation**.** In case that there are more than two potential new LULC classes, use multinomial logit model, which predicts a multilevel categorical variable bases on the spatial driver variables. Quality assurance: significance and goodness-of-fit. As a quality assurance step, report the significance of the statistical model. In case of a regression, report the results of a likelihood ratio test, and the significance of individual drivers of deforestation (t-tests). Both the full model and all individual drivers must be significant at the 95% confidence level. In addition, perform a goodness-of-fit test by predicting the new LULC classes and forest strata for the independent statistical validation data, and comparing the results with the measured data. Present a table of the empirically observed land-use change rates vs. the land-use change rate predicted using the statistical model. The difference in aggregated deforestation and forest degradation rates as well as forest stratum and LULC-class transition rates averaged over all the time periods (in between images of the reference period) between empirically observed and modeled rates may not be more than 15%. The capability of the model to adequately estimate likelihoods of deforestation and forest degradation must be confirmed by the validation/verification body.

8.1.5.4 Calculate All Class or Stratum-Specific Transition Rates.

Once the statistical models for deforestation and forest degradation, and the carbon density map are prepared, a simple cellular automata type model can be used to predict the future land use and land cover in each grid-cell and for each year of the crediting period. Even though the spatial model produces maps of the exact location of future deforestation, these maps are not used outside of the modeling step. The main output of the modeling step is a land-use change transition matrix. This matrix is calculated by aggregating the LULC class and forest stratum maps that are produced by the spatial model. In addition to the principles of neighborhood constraint and land suitability, as explained in Pontius (2002), the land-use change model incorporates the forest scarcity principle, the notion that deforestation rates decrease upon the gradual depletion of the native forest resources. Without forest scarcity, it is assumed that deforestation occurs linearly until all forest is gone, which will be incorrect in most circumstances and lead to an overestimate of net emission reductions. It is well documented that deforestation rates decrease when forest areas are gradually disappearing. The “forest transition” theory (Mather and Needle, 1998) explains how areas with vast forest areas which are initially characterized by rapid deforestation rates, stabilize their forest area after some time. To incorporate a decrease in deforestation rate upon a gradual depletion of forest resources, initial deforestation rates are multiplied with a “forest scarcity” factor, which is initially 1, but gradually decreases as the proportion of remaining forest decreases (Figure 1). This “scarcity factor” must be calibrated using scientific literature in an area close to the project area that has followed a more advanced deforestation route. Examples are neighboring countries, states or provinces that have undergone a more rapid deforestation course than the area where the project is located. Typically, deforestation rates start to decrease when around 50% of the original forest cover has disappeared. In addition, deforestation usually halts when around 80% of the forest area has disappeared. This pattern has been observed by Meyfroidt and Lambin (2008) in Vietnam. Deforestation rates started decreasing when 50% of forest cover remained, and halted in 1991-1993 at around 25% forest cover. However, the specific values of the forest cover when deforestation will decrease are dependent on project conditions and should be analyzed and substantiated within the project document at validation.

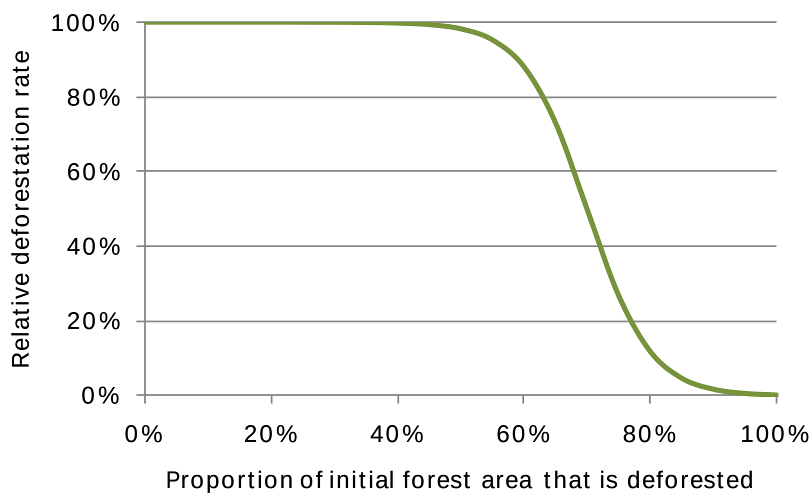


Figure 1. Example of “forest scarcity factor”: the relative Deforestation Rate as a Function of Proportion of Initial Forest Area that is Deforested.

The following equation must be used to model the scarcity factor:

$$f_{scarcity}(t) = \frac{1}{1 + e^{sc_1\left(sc_2 - \frac{area(t,nonForest)}{size_{projectArea}}\right)}} \qquad \text{[EQ40]}$$

Where:

$f_{scarcity}(t)$	=	Forest scarcity factor used to reduce the historical deforestation rate at time t. [-]
sc_1	=	First shape factor for the forest scarcity equation; steepness of the decrease in deforestation rate (greater is steeper). [-]
sc_2	=	Second shape factor for the forest scarcity equation; relative deforested area at which the deforestation rate will be 50% of the initial deforestation rate. [-]

$area(t, nonForest)$	=	Total area that is not forest within the project area at time t after project start. [ha]
$size_{projectArea}$	=	Total size of the project area. [ha]

The two shape factors sc_1 and sc_2 within this equation must be fitted using historical information in areas similar to the project area or data from peer-reviewed literature. Data sources that must be used are remotely sensed forest cover data in heavily deforested areas close to the project area such as neighboring provinces, states or countries. Values of sc_1 and sc_2 should be selected so that the carbon accounting is conservative. Lower values of sc_1 and higher values of sc_2 will result in lower deforestation, and are therefore more conservative. The project proponent must demonstrate that the source data used to fit this equation is appropriate. The following steps must be followed:

- Calculate the deforestation suitability for all forest cells using the logistic regression model.
- Sort the forest cells according to their deforestation suitability from highest suitability to lowest suitability.
- During a given year, the area that is effectively deforested is dependent on (1) the total rate of deforestation $D_{projectArea,baselineScenario,DF}(t)$, and (2) the remaining total forest cover. More specifically, the area that is effectively deforested equals the total rate of deforestation $D_{projectArea,baselineScenario,DF}(t)$ multiplied with the forest scarcity factor, which is a function of the remaining forest cover. Since deforestation is dependent on the remaining forest cover and the remaining forest cover changes as deforestation occurs, an iterative loop is necessary in which the remaining forest cover is updated as more and more forest is deforested. To begin the iterative loop, set $D_{projectArea,baselineScenario,DF,remaining}(t)$ to $D_{projectArea,baselineScenario,DF}(t)$ multiplied with the forest scarcity factor based on the remaining forest cover at the end of the previous year. Start deforesting cells (in order of highest to lowest deforestation probability). Every time a cell is deforested, update the remaining forest cover and the scarcity factor and re-calculate $D_{projectArea,baselineScenario,DF,remaining}(t)$ as $D_{projectArea,baselineScenario,DF}(t)$ minus the total amount of deforested cells and multiplied with the updated forest scarcity factor as a function of the remaining forest cover. Continue the loop until $D_{projectArea,baselineScenario,DF,remaining}(t)$ = 0.
- Calculate the suitability for a new non-forest LULC class on the cells that were selected for deforestation. Assign the LULC class with the highest suitability, according to the calibrated models in previous step.
- Repeat steps 1-4 for forest degradation on the forest cells that were not assigned for deforestation, and that are not in the forest strata or LULC class with the lowest carbon density. Degrade the cells selected for degradation by assigning them to the next-lower forest strata. The scarcity factor calculated based on remaining forest cover must be used for forest degradation. Note that degradation must be applied on the result of the deforestation, so that cells that were deforested that year cannot be subject to forest degradation as well.
- Using the maps developed in the previous steps, sum the areas for each transition

separately for (1) the project area excluding ANR and harvest ($\Delta area_{projectAreaEAH,baselineScenario}(t,i)$), (2) the areas with ANR ($\Delta area_{projectAreaWithANR,baselineScenario}(t,i)$) and (3) the areas with harvesting ($\Delta area_{projectAreaWithHarvest,baselineScenario}(t,i)$). This step will yield three transition matrices.

- For each of the three areas and three transition matrixes, calculate the regeneration transitions from one class or stratum ("CS1" in the equation below) to another class or stratum ("CS2" in the equation below) by multiplying the total area of the first class or stratum with the relative regeneration rate for transitions from one class or stratum to another, in the following formula noted as class or stratum 1 to 2. As explained in the summary, the baseline scenario includes not only projected degradation and deforestation, but also projected regeneration and reforestation in areas that were deforested. The equation below describes the carbon accounting for projected regeneration and reforestation under the baseline scenario.

$$\Delta area(t, CS1 \rightarrow CS2) = RFRGrate(CS1 \rightarrow CS2) \cdot area(t, CS1) \quad \text{[EQ41]}$$

where:

$\Delta area(t, CS1 \rightarrow CS2)$	=	Area of transition from class or stratum 1 to 2 from time t to $t+1$. [ha]
$RFRGrate(CS1 \rightarrow CS2)$	=	Relative annual regeneration rate for the transition from a class or stratum 1 to another, 2, from time t to $t+1$. [yr^{-1}]
$area(t, CS1)$	=	Total area of class or stratum 1 for time t of the crediting period. [ha]

Apply the regeneration area $\Delta area(t, CS1 \rightarrow CS2)$ to the appropriate LULC classes and forest strata obtained after step 5 (degradation) so that the areas of all LULC classes are updated. The resulting areas of LULC classes and forest strata represent all land use dynamics for year t for one of the three areas considered. Report the final areas of all LULC classes and forest strata for year t separately for each of the three areas introduced in step 7.

8.2 Project Emissions

One or more of the drivers of deforestation described in Section 8.1.3 must be mitigated through specific project activities. Some activities may focus on increasing the livelihood options of local communities or preventing leakage through, for example, increasing the land use intensity of already deforested land. Success of the implementation and on-going maintenance of these activities is critically dependent on the active involvement of all stakeholders in the planning and execution of these project activities. In particular, the local communities must be actively involved. Therefore, project management, advisory, oversight, and consultative structures must be developed to ensure the active involvement of all stakeholders.

A holistic approach should be taken to meet the various resource needs of local communities. For example, rather than excluding local communities from using any forest resources at all (and therefore necessarily forcing them to acquire these resources outside of the project area or purchase these in local or provincial markets, leading to leakage), a sustainable land management plan including key components of agriculture and forestry practices should be put in place to meet local wood and agricultural needs.

The *ex-ante* estimation of the deforestation and forest degradation rates is based on a breakdown of the effectiveness of every project activity (a) in decreasing any driver of deforestation (d) relative to that driver's contribution to deforestation and forest degradation, i.e. $effectiveness(a, d)$. For example, assume that the collection of fuelwood leads to a degradation of 200 Mg C per year, and the introduction of fuel-efficient woodstoves decreases emissions equivalent to 50 Mg C per year. Furthermore, assume that the development of biogas plants reduce emissions equivalent to 100 Mg C per year. The effectiveness of fuel-efficient woodstoves to decrease degradation from fuelwood collection, i.e. $effectiveness\left(fuel\text{-}efficient\ stoves, fuel\text{-}wood\ collection\right)$, is 25%, whereas the effectiveness of biogas plants to decrease degradation from fuelwood collection, i.e. $effectiveness\left(fuel\text{-}efficient\ stoves, fuel\text{-}wood\ collection\right)$, is 50%. Values of effectiveness factors must be estimated for every combination of project activity and driver of deforestation and forest degradation. Note that effectiveness values are only meant for *ex-ante* estimates of emission reductions/removals. E*x-post* emission reduction/removals are not quantified based on these values. The effectiveness values are often challenging to quantify, and depend on local conditions and the experience of the project proponent. However, estimation of the volume of emission reductions/removals that a project will generate depends on the ability of the project proponent to estimate the effectiveness values and refine these estimations throughout project monitoring.

The $effectiveness(a, d)$ factor represents the maximal effectiveness during the crediting period. This maximal effectiveness is adjusted over time using a rate factor, i.e., $rate(a, t)$, to reflect changes in the effectiveness due to gained experience, changes in funding levels, or on-going capacity building.

8.2.1 Identify Project Activities and Estimate the Effectiveness in Reducing Deforestation and Degradation Rates under the Project Scenario

A description of the REDD project activities that are included in this methodology, together with procedures to quantify the effectiveness for each project activity and each targeted driver follows.

8.2.1.1 Strengthening of Land-Tenure Status and Forest Governance

Legal agreements between the participating communities, landowners, project developers, and relevant government administrative levels are a necessary first step to secure land tenure and carbon rights. These agreements are particularly important when participating communities do not legally own the forest land, and the land-tenure status is unclear or obscured by a complex administrative hierarchy. The project proponent can assist local communities in securing their land tenure status. This can include developing legally binding community forestry agreements, purchasing or securing long-term conservation easements, or the revision of spatial plans and zoning laws. The expenses related to the establishment of these agreements can be covered by the revenue from REDD credit sales.

Strengthening the land-tenure status is essential for protecting land from encroachment by people other than participating communities and provide clarity on the allowed land use by the participating communities. However, legal tenure is insufficient for an effective protection of the forest resources. It must be complemented with on-the-ground protection measures such as social fencing or a patrolling system.

Table 10. Procedures to quantify the maximal effectiveness of strengthening land-tenure for target drivers.

Target driver	Maximal effectiveness quantification
Logging of timber for commercial on-sale	$effectiveness < 5\%$ [EQ42] Legal recognition of the land-tenure status will eliminate overlapping authority from different administrations and reduce the potential that logging concessions are granted without explicit permission of participating communities. In addition, it is a necessary (but insufficient) step to reduce illegal logging of timber for commercial on-sale. Note that strengthening land-tenure alone usually does not directly lead to a reduction in deforestation.
Conversion of forest land to cropland (by people other than participating communities)	$effectiveness < 5\%$ [EQ43] Legal recognition of the land tenure status will reduce the potential of conversion of forest land to cropland within the project area because it will provide clarity on the legal land uses. However, on-the-ground patrolling is necessary to effectively avoid conversion to cropland.
Conversion of forest land to settlements (by people other than participating communities)	$effectiveness < 5\%$ [EQ44] See previous driver
Conversion of forest land to infrastructure	$effectiveness < 5\%$ [EQ45] See previous driver

8.2.1.2 Support with the Development and Implementation of Sustainable Forest and Land Use Management Plans

Forest and land use management plans should be established in a participatory and democratic way. These plans can include the volumes of timber, fuelwood or NTFP each community can sustainably harvest, the areas for livestock grazing, or the area of forest land that can be converted into settlements or cropland and where the conversion must take place. The management plans must be based on the current and future need for forest products and land. Such plans will increase the efficiency of the current land use and avoid unplanned conversion of forest patches that can accelerate forest degradation. Plans must be integrated and compatible with the land tenure and usage rights and be long-term or permanent (where possible) in nature.

The management plan is only binding for participating communities and will not affect the drivers of deforestation for which the agents are not participating in the project. The following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 11. Procedure to quantify the maximal effectiveness of forest and land use plans for target drivers.

Target driver	Maximal effectiveness quantification
Conversion of forest land to cropland by participating communities	$$effectiveness = \left(1 - \frac{\Delta area_{cropland,allowed}}{\Delta area_{cropland,baseline}}\right)\%$$ [EQ46] Forest and land-use plans usually explicitly indicate how much land can be converted from forest to cropland. The baseline conversion rates must be estimated based on remote sensing analysis or social assessments when no remote sensing analysis is feasible.
Conversion of forest land to settlements by participating communities	$$effectiveness = \left(1 - \frac{\Delta area_{settlement,allowed}}{\Delta area_{settlement,baseline}}\right)\%$$ [EQ47] See previous driver
Logging of timber for commercial on-sale (commercial timber = CT)	$$effectiveness = \left(1 - \frac{CT_{allowed}}{CT_{baseline}}\right)\%$$ [EQ48] The baseline harvesting rate comes from (1) recent reports and studies within the project area, (2) peer-reviewed literature in regions similar to the reference region, (3) expert opinion.
Logging of timber for local and domestic use by participating communities (domestic timber = DT)	$$effectiveness = \left(1 - \frac{DT_{allowed}}{DT_{baseline}}\right)\%$$ [EQ49] See previous driver
Fuelwood collection for domestic and local energy needs (domestic fuelwood = DFW)	$$effectiveness = \left(1 - \frac{DFW_{allowed}}{DFW_{baseline}}\right)\%$$ [EQ50] See previous driver
Cattle grazing in forests (grazing = GR)	$$effectiveness = \left(1 - \frac{GR_{allowed}}{GR_{baseline}}\right)\%$$ [EQ51] See previous driver

Extraction of understory vegetation (vegetation = VG)	$$effectiveness = \left(1 - \frac{VG_{allowed}}{VG_{baseline}}\right)\%$$ [EQ52] See previous driver

Any variable with the subscript "allowed" represents the allowed quantity or amount under the project scenario within the project boundary. Analogously, variables with the subscript "baseline" refer to the quantity in the baseline scenario. At the start of the project, information on parameters for the baseline must come from the project area itself. During a baseline update, these values must come from the reference region and/or leakage belts.

8.2.1.3 Demarcating Forest, Tenure and Ownership Boundaries, and Areas of Forest Protection

The installation of fences, gates, boundary poles, and signage provides local communities a transparent, recognizable and fixed boundary of the project area. Because legal protection alone (project action 1, "Strengthening the land-tenure status") may be insufficient to prevent deforestation, often a physical boundary or signage is required to avoid deforestation and to support social fencing and patrolling. Once the boundaries are demarcated, they must be protected and patrolled. Often, the capacity of the law enforcing authorities is too limited to do this task, so communities commit to defend their own land-tenure and land use rights by engaging in regular patrolling of the forest area. It must be clarified with the local administration which types of actions can be undertaken in the case of illegal trespassing (e.g., confiscating chainsaws, alerting local law enforcers, etc.). This often results in improved synergies amongst local communities, law enforcement and other relevant agencies to support boundary protection. Other project actions can include the creation of logistical plans to protect boundaries, social fencing, and the acquisition of equipment (e.g., small motorized vehicles) for patrolling and enforcement. The following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 12. Procedures to quantify the maximal effectiveness of demarcating boundaries for target drivers.

Target driver	Maximal effectiveness quantification
Logging of timber for commercial on-sale	$$50\% < effectiveness < 100\%$$ [EQ53] Since legally sanctioned logging is already regulated under forest management plans, the main driver affected here is illegal logging for commercial on-sale. With a sound forest patrolling plan in place, it is assumed that illegal logging for commercial on-sale can be at least halved.
Conversion of forest land to cropland by people other than participating communities	$$effectiveness = 100\%$$ [EQ54] Boundary demarcation and forest protection can eliminate conversion of forest land to crop land in most instances.
Conversion of forest land to settlements by people other than	$$effectiveness = 100\%$$ [EQ55] See previous driver

participating communities	

8.2.1.4 Fire Prevention

If forest fires threaten the project's forest resources, specific fire prevention measures could be taken. These include (1) installation of fire breaks, (2) clearing the forest of dead wood that can act as fuel for fires, especially around regenerating and young secondary forests, (3) discouraging or eliminating (if possible) fire-based hunting techniques, and (4) social inclusion activities to ward off revenge related fires. Saplings and small trees are particularly vulnerable to forest fires. If fire prevention activities require cutting down trees, or removing dead wood, this loss of carbon should be accounted for. The following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 13. Procedures to quantify the maximal effectiveness of fire prevention for target drivers.

Target driver	Maximal effectiveness quantification
Forest fires	$40\% < effectiveness < 60\%$ [EQ56] Fire prevention measures such as fire breaks, together with education, can effectively reduce fire-related deforestation and forest degradation by 50%. Set the value of effectiveness between the thresholds above based on (1) pilot experiments in the project area, (2) peer-reviewed studies in an area similar to the project area or (3) advice from experts.

8.2.1.5 Reduce the Fuelwood Consumption by Increasing Energy Efficiency

The collection of fuelwood only leads to forest degradation if it is collected from live trees. A low-intensity collection of fuelwood from downed dead wood may, in fact, have a positive effect on forest regeneration by decreasing the potential for forest fires. In cases where the collection of fuelwood leads to forest degradation, the introduction of fuel-efficient woodstoves will decrease the need for local consumption of fuelwood (Top et al. 2004). Adoption rates of these alternatives need to be monitored, together with the potential on-sale of fuelwood on local markets, which can potentially annul the GHG benefits generated by the alternative stoves. Only fuelwood gathering for domestic use is allowed in project areas. No fuelwood gathering is allowed for commercial purposes. The carbon accounting related to a decrease in consumption of fuelwood is done by monitoring the changes in carbon stocks; the following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 14. Procedures to quantify the maximal effectiveness of energy efficiency for the target driver.

Target driver	Maximal effectiveness quantification
Fuelwood collection for domestic and local industrial energy needs	$$effectiveness = \sum (maximal\ adoption\ rate) \cdot (increase\ in\ efficiency\ of\ action)$$ [EQ57] Estimate the maximal adoption rate based on the willingness of project participants to change their practices as quantified (1) in social assessments, or (2) by expert opinion. Estimate the relative increase in efficiency of stoves from (1) field studies, (2) peer-reviewed literature, or (3) local experts.

8.2.1.6 Creation of Alternative Sources of Fuelwood

While the previous project action focuses on the *demand side* of energy, the set of project actions discussed in this section affects the *supply side* of energy. Activities can focus on creating alternative sources of fuelwood through agroforestry interventions, such as interplanting agricultural fields with trees that benefit agricultural yields, (as does Winterthorn, *Faidherbia albida*), but also provide some fuelwood to local farmers. Other examples include the creation of farm or village woodlots and woodlands on degraded land. Obviously, no forest may be cut to establish a woodlot or woodland. However, emissions related to the removal of biomass as part of a set of silvicultural interventions to maximize biomass growth, such as clearing of shrubs and weeds, are considered de minimis. Finally, renewable and non-fossil fuel based energy sources, such as solar or micro-hydro, can reduce the need for fuelwood by providing an alternative source of energy for cooking, heating or light.

Table 15. Procedures to quantify the maximal effectiveness of alternative fuelwood sources for target drivers.

Target driver	Maximal effectiveness quantification
Fuelwood collection for domestic and local industrial energy needs	$$effectiveness = \frac{DFW_{baseline} - DFW_{alternative}}{DFW_{baseline}}$$ [EQ58] Estimate the production of alternative fuelwood sources that would go to domestic uses. Calculate the fuelwood equivalent of solar and micro-hydro technologies, if applicable.
Wood collection for commercial on-sale	$$effectiveness = \frac{CFW_{baseline} - CFW_{alternative}}{CFW_{baseline}}$$ [EQ59] Estimate the production of alternative wood sources that would go to further on-sale. Calculate the fuelwood equivalent of solar and micro-hydro technologies, if applicable.

8.2.1.7 Sustainable Intensification of Agriculture on Existing Agricultural Land

Forest land is often deforested to make a place for subsistence farming or extensive grazing. Project activities that will increase productivity and agricultural yields on existing cropland and increase animal stocking rates on grazing lands minimize the need for further forest clearing. Such activities include increases in mechanization, installation of irrigation systems, the introduction of high-yielding crop varieties, increases in livestock stocking rates, conservation agriculture and agroforestry activities, and farm-wood lot management. Intensification of agriculture also provides alternative forest-based biomass resources. Only sustainable farming techniques should be promoted and any increases in GHG emissions due to these activities must be monitored, reported and accounted for. Agriculture can be intensified through (1) sponsoring pilot and demonstration studies on sustainable agriculture and agroforestry, (2) strengthening the relations with local agricultural extension services, colleges and universities and (3) establishing a system of small grants or micro-financing for local farmers to invest into agricultural equipment, infrastructure, seeds, or fertilizer.

Intensification measures must be done on land that was already under agricultural production, or on land that is sanctioned to become agricultural land given the land-use plans. The following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 16. Procedures to quantify the maximal effectiveness of agricultural intensification for target drivers.

Target driver	Maximal effectiveness quantification
Conversion of forest land to cropland by the project proponent	$effectiveness = (maximal\ adoption\ rate) \cdot (increase\ in\ yield\ per\ hectare)$ [EQ60] Estimate the maximal adoption rate based on the willingness of project participants to change their practices based on (1) quantified in social assessments, or (2) expert opinion. Estimate the relative increase in yield from (1) field studies, (2) peer-reviewed literature or (3) local agricultural extension experts. Latter options may only be used if former options are not available.
Cattle grazing	$0\% \leq effectiveness \leq 100\ \%$ [EQ61] See previous driver
Understory vegetation extraction	$0\% \leq effectiveness \leq 100\ \%$ [EQ62] See previous driver

8.2.1.8 Providing Alternative Livelihoods to the Agents of Deforestation

If agents of deforestation can engage in alternative livelihoods that are not based on deforestation, they can secure income without the need to further clear forests.

- As much as possible, planned project activities should be carried out by the local communities**.** Engaging communities in forest patrolling, biomass inventory, fire prevention activities, installation of fences and boundary poles, and assisted natural regeneration activities will provide employment and a greater financial return to the communities. In addition, the active involvement of the local communities will strengthen the project goals and decrease the risks of project failure.
- Part of the forest can be made accessible for sustainable eco-tourism, which will create jobs and increase revenue.
- The sustainable extraction of non-timber forest products can be further developed and commercialized. This includes the harvesting of honey, medicinal plants, fungi, and the extraction of resins. Clear harvesting plans need to be developed to ensure the sustainable extraction of these commodities.

It is assumed that people will shift automatically towards a livelihood alternative that has a sufficiently greater return than their current livelihood. Therefore, the total effectiveness is calculated by dividing the income from alternative livelihoods by the total value of forest products that are harvested from the forest and sold on local markets. It is further assumed that alternative livelihood options must be 25% more economically attractive before people will switch to these alternative livelihoods. The total effectiveness thus becomes $0.75 \cdot \frac{\sum income\ through\ alternative\ livelihood}{\sum total\ value\ of\ forest\ products}$. This total effectiveness is then divided into individual values for the effectiveness for each target driver by multiplying the respective relative financial contribution of the target driver with the total value of forest products. The following table outlines the procedure to quantify the maximal effectiveness for this driver.

Table 17. Procedures to quantify the maximal effectiveness of alternative livelihoods for target drivers.

Target driver	Maximal effectiveness quantification
• Conversion of forest land to cropland • Logging of timber for commercial on-sale • Logging of timber for local enterprises and domestic use • Collection of fuelwood and charcoal production for sale on markets • Cattle grazing	$effectiveness = 0.75 \cdot \frac{\sum income\ through\ alternative\ livelihood}{\sum total\ value\ of\ forest\ products}$ [EQ63]

8.2.2 Calculate Effectiveness of Project Activities in Reducing GHG Emissions

The effectiveness of project actions may change during the crediting period, due to the increased experience of project implementers or an increased allocation of funds during the crediting period. This time-dependent project activity rate is accounted for by integrating a factor $rate(a,t)$ for project activity a during year t. As was mentioned before, $effectiveness(a,d)$ represents the maximally attainable effectiveness given project conditions and capacity are optimal. As a consequence, $rate(a,t)$ must be 100% at least once during the crediting period. The relative reduction in deforestation can be estimated *ex-ante* by integrating the relative proportion of each driver of deforestation with the effectiveness coefficients and the estimated adoption rates for each project activity.

$$RelativeDriverImpact_{DF}(t,d) = \sum_{a=1}^{nrActivities} \left(rate(a,t) \cdot effectiveness(a,d) \cdot contribution_{DF}(d) \right) \quad \text{[EQ64]}$$

$$RelativeDriverImpact_{DG}(t,d) = \sum_{a=1}^{nrActivities} \left(rate(a,t) \cdot effectiveness(a,d) \cdot contribution_{DG}(d) \right) \quad \text{[EQ65]}$$

$$RelativeProjectImpact_{DF}(t) = \sum_{d=1}^{nrDrivers} RelativeDriverImpact_{DF}(t,d) \quad \text{[EQ66]}$$

$$RelativeProjectImpact_{DG}(t) = \sum_{d=1}^{nrDrivers} RelativeDriverImpact_{DF}(t,d) \quad \text{[EQ67]}$$

where:

$RelativeDriverImpact_{DF}(t,d)$ and $RelativeDriverImpact_{DG}(t,d)$	=	Relative impact of a driver d on deforestation and forest degradation, respectively for year t of the crediting period.[-]
$RelativeProjectImpact_{DF}(t)$ and $RelativeProjectImpact_{DG}(t)$	=	Impact of all project activities on deforestation and forest degradation respectively, relative to the baseline deforestation and forest degradation rates during year t. [-]
$nrActivities$	=	Total number of project activities. [-]
$nrDrivers$	=	Total number of drivers of deforestation. [-]

$rate(a,t)$	=	Adoption rate or relative degree of activity for activity a during year t. A value of 100% indicates that the activity cannot be more efficient in reducing deforestation or forest degradation. [-]
$effectiveness(a,d)$	=	The effectiveness of project action a to reduce driver of deforestation d. [-]
$contribution_{DF}(d)$ and $contribution_{DG}(d)$	=	The relative importance of driver d in deforestation and degradation to the total deforestation and degradation, respectively. [-]

The absolute rate of deforestation in hectares per year in the project region under the project scenario can be calculated by multiplying the relative project impact with the total deforestation and forest degradation rates in the project region under the baseline scenario.

$$D_{projectArea,projectScenario,DF}(t) = RelativeProjectImpact_{DF}(t) \cdot D_{projectArea,baselineScenario,DF}(t) \quad \text{[EQ68]}$$

$$D_{projectArea,projectScenario,DG}(t) = RelativeProjectImpact_{DG}(t) \cdot D_{projectArea,baselineScenario,DG}(t) \quad \text{[EQ69]}$$

Where:

$D_{projectArea,projectScenario,DF}(t)$ and $D_{projectArea,projectScenario,DG}(t)$	=	Rate of deforestation/degradation within the project area during year *t* under the project scenario. [ha yr^{-1}]
$RelativeProjectImpact_{DF}(t)$ and $RelativeProjectImpact_{DG}(t)$	=	Relative impact of all project activities on deforestation and forest degradation respectively during year t. [-]
$D_{projectArea,baselineScenario,DF}(t)$ and $D_{projectArea,baselineScenario,DG}(t)$	=	Baseline rate of deforestation/degradation within the project area during year *t.* [ha yr^{-1}]

8.2.3 Calculate Forest Strata-Specific Deforestation and Degradation Rates

Use the LULC model calibrated and validated in Section in 8.1.5 to divide the total *ex-ante* deforestation and forest degradation rates under the project scenario into individual rates for every forest stratum transition. The same statistical models may be used for calculating the stratum-specific rates under the project scenario. For every year of the crediting period, present a land transition table for the project areas under the project scenario.

8.2.4 Estimate GHG Emissions Sources from Firebreaks

The only project activity that may lead to an increase in emissions in the project is the clearing of trees to establish fire breaks or other fire prevention measures.[12] Increases in emissions from this activity must be duly accounted for and subtracted from the GHG emission reductions generated by the project activities. In case prescribed burning is used to remove woody biomass, all CH_4 emissions related to the burning must be included. The GHG emissions from fire breaks can be calculated by:

$$GHG_{fireBreaks} = \frac{44}{12} \cdot \sum_{i=1}^{nrFireClasses} area_{biomassLoss}(i) \cdot \left(C_{AGL}(i) + C_{AGD}(i) + C_{BG}(i)\right) + \sum_{i=1}^{nrStrata} area_{fireBiomassLoss}(i) \cdot \left(C_{AGL}(i) + C_{AGD}(i) + C_{BG}(i)\right) \cdot \frac{16}{12} \cdot GWP_{CH4} \cdot ER_{CH4} \quad \text{[EQ70]}$$

where:

$E_{fireBreaks}$	=	Annual GHG emissions from implementation of fire-preventing actions as REDD project activities. [$tCO_2e\ yr^{-1}$]
$nrFireClasses$	=	Number of forest strata in which fire breaks were installed. [-]
$area_{biomassLoss}(i)$	=	Total annual area of forest stratum i that was cleared for creating fire breaks. [$ha\ yr^{-1}$]
$C_{AGL}(i), C_{AGD}(i), C_{BG}(i)$	=	Carbon content in the aboveground live, aboveground dead, and belowground pools in forest stratum i. It is conservatively assumed that all biomass is removed. [$Mg\ C\ ha^{-1}\ yr^{-1}$].
$area_{fireBiomassLoss}(i)$	=	Annual area of forest stratum i that was cleared by prescribed burning. [$ha\ yr^{-1}$]
GWP_{CH4}	=	Global Warming Potential for CH_4 [-]
ER_{CH4}	=	Emission ratio for CH_4 (IPCC default value = 0.012). See Table 3A.1.15 in IPCC GPG-LULUCF (2003). [-]
$nrStrata$	=	Number of forest strata. [-]

12 Emissions from clearing herbaceous vegetation are insignificant.

Add annual values of $E_{fireBreaks}$ to the summary table of all GHG emissions due to project activities.

8.2.5 Estimate the Net GHG Sequestration from Assisted Natural Regeneration (ANR) Activities

8.2.5.1 Scope and Applicability

This methodology includes procedures to quantify the GHG removals generated from silvicultural activities aimed at restoring degraded forest. These ANR activities serve a triple goal: (1) increase the project area's overall GHG sink strength, (2) reduce activity-shifting, and (3) provide alternative livelihoods to local communities by employing local communities for executing the work.

See Section 4.2.1 for a list of applicability conditions related to ANR activities .Further specific requirements related to ANR activities are provided below.

Assisted natural regeneration must only be done by implementing one or more of the following measures:

- Removal of invasive understory species such as ferns or herbs to promote the growth of tree seedlings.
- Thinning of over-stocked and stagnated forest stands to promote radial growth.
- Removal of exotic and/or invasive tree species to promote the growth of native species.
- Stem removal on trees with multiple shoots to promote the growth of a single stem.
- Enrichment planting with trees of biodiversity or social value.

A detailed ANR management plan with a detailed description of all activities including their location must be included in the PD. An update to the management plan may be submitted at verification.

8.2.5.2 General Quantification

Since the general approach to quantify increases in biomass under the project scenario using remote sensing is not very sensitive to gradual changes in forest biomass, regeneration in the areas with ANR are better accounted for using forest biomass inventories only. As a consequence, the changes in carbon stocks in the ANR areas in the project scenario must be accounted for by directly measuring increases in forest biomass using forest biomass inventories. These forest biomass inventory plots must be established, which are re-measured periodically. The calculation of the GHG removals by sinks due to assisted natural regeneration activities follows the latest version of CDM methodology AR-ACM0001 by combining and annualizing equations (11) and (12) (equation numbers from AR-ACM0001). The activity-shifting leakage from ANR activities is already included in the total project's leakage, as explained in Section 8.3. The following equation must be used to calculate sequestration from ANR activities.

$$C_{ANR}(t) = \Delta C_{ANR}(t) - \Delta C_{ANR,BSL}(t) \quad \text{[EQ71]}$$

where:

$C_{ANR}(t)$	=	Net anthropogenic greenhouse gas removals due to biomass increase in assisted natural regeneration during year t. [tCO_2e]
$\Delta C_{ANR}(t)$	=	Annual change in carbon stocks in all selected carbon pools due to ANR during year t. [tCO_2e]
$\Delta C_{ANR,BSL}(t)$	=	Baseline GHG gas emissions or sources during year t. [tCO_2e]

The procedure for calculating $\Delta C_{ANR}(t)$ is explained in Section 8.2.5.3. The procedure for calculating $\Delta C_{ANR,BSL}(t)$ is explained in Section 8.2.5.4. Section 8.2.5.5 explains how to calculate $GHG_{sources,ANR}(t)$, the increase in CO_2 emissions from loss of existing woody biomass due to site-preparation (including burning), and/or to competition from forest (or other vegetation) planted as part of the ANR activities during year t.

8.2.5.3 Estimate Carbon Stock Increase

The procedure to calculate the carbon uptake by biomass in the areas where assisted natural regeneration activities are implemented follows the procedure described in the latest version of CDM-approved methodology AR-ACM0001.

$$\Delta C_{ANR}(t) = \frac{44}{12} \cdot \sum_{i=1}^{nrStrata} \Delta C(t,i) \cdot u_{inventory,ANR}(i) \quad \text{[EQ72]}$$

$$\Delta C(t,i) = area_{projectAreaWithANR,projectScenario}(t,i) \cdot \frac{C(t_2,i) - C(t_1,i)}{t_2 - t_1} \quad \text{[EQ73]}$$

where:

$\Delta C_{ANR}(t)$	=	Annual change in carbon stocks in all selected carbon pools due to ANR during year t of the crediting period. Corresponds to Equation (12) of AR-ACM0001excluding GHG_E, but converted to CO_2 equivalents. [tCO_2e]
$nrStrata$	=	Number of forest strata. [-]
$\Delta C(t,i)$	=	Carbon stock change for ANR stratum i during year t of the crediting period. [Mg C yr^{-1}]
$area_{projectAreaWithANR,projectScenario}(t,i)$	=	Amount of land on which ANR activities are planned under the project scenario during year t and in stratum i. [ha]

$C(t_2, i)$ and $C(t_1, i)$	=	Carbon stock density at time t_2 and t_1 respectively and in stratum i. [Mg C ha^{-1}]
$t_2 - t_1$	=	Duration between times 1 and 2. [year]

The larger of the two combined errors of the carbon stock density at time t_1 and t_2 must be used for uncertainty assessment in ANR areas using [EQ74].

$$CE_{inventory,ANR}(i) = max\left(CE_{inventory,ANR}(t_2, i), CE_{inventory,ANR}(t_1, i)\right) \quad \text{[EQ74]}$$

The discounting factor for uncertainty around biomass stock densities in the ANR area is estimated as :

$$u_{inventory,ANR}(i) = \begin{cases} 1 & \text{if } CE_{inventory,ANR}(i) \leq 0.15, \\ 1 - CE_{inventory,ANR}(t, i) & \text{if } 0.15 < CE_{inventory,ANR}(i) < 1, \\ 0 & \text{if } CE_{inventory,ANR}(i) \geq 1 \end{cases} \quad \text{[EQ75]}$$

Where:

$CE_{inventory,ANR}(t, i)$	=	Combined error in estimated biomass stock density at time period t (i.e., time t_1 or time t_2) within stratum i using equation EQ21. [-]
$CE_{inventory,ANR}(i)$	=	Combined error in estimated biomass stock density within stratum i. [-]
$HWCI(C(t_1, i))$ and $HWCI(C(t_2, i))$	=	Half-width of the 95% confidence interval around the mean carbon stock density of LULC classes of forest stratum i respectively at time t_1 and t_2. [tCO_2e ha^{-1}]
$u_{inventory,ANR}(i)$	=	Uncertainty discounting factor around biomass stock densities in transition stratum i within ANR areas during time t. [−]
$max\left(CE_{inventory,ANR}(t_2, i), CE_{inventory,ANR}(t_1, i)\right)$	=	Maximum of combined error in inventories that were carried out at time t_2 and t_1 in LULC class or forest stratum i.[-]

To ensure that any loss of biomass that occurs as part of ANR activities such as from site preparation is duly accounted for, in the first verification $C(t_1, i)$ are the carbon stocks at the starting date of the crediting period or the starting date of the crediting period of added instance and $C(t_2, i)$ are the carbon stocks at the time of verification in stratum i. In the successive verifications, $C(t_1, i)$ are the carbon stocks at the preceding verificaiton and $C(t_2, i)$ are the carbon stocks at the time of verification in stratum i.

Ex-ante, values for biomass densities in ANR areas must be based on pilot projects or data on biomass increases in regenerating forests from the literature. *Ex-post*, this quantity must be monitored for actual biomass according to a network of sampling plots according to the procedures within this document. Select a sampling design with a confidence level of 95%.

8.2.5.4 Calculate Baseline Emissions or Sinks on Land on which Assisted Natural Regeneration Activities are Planned

The baseline emissions or sinks on land with ANR are calculated similarly as to the land without ANR using [EQ76].

$$\Delta C_{ANR,BSL}(t) = -\sum_{i=1}^{nrFNFtransitions} \sum_{tt=1}^{t} \begin{pmatrix} u_{classification} \cdot u_{transition}(i) \\ \cdot \Delta area_{projectAreaWithANR,baselineScenario}(t,i) \\ \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right) \end{pmatrix} - \sum_{i=1}^{nrStrataTransitions} \sum_{tt=1}^{t} \begin{pmatrix} u_{stratification} \cdot u_{transition}(i) \\ \cdot \Delta area_{projectAreaWithANR,baselineScenario}(t,i) \\ \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right) \end{pmatrix} \quad \text{[EQ76]}$$

where:

$\Delta C_{ANR,BSL}(t)$	=	Baseline GHG gas emissions or sources during year t. [tCO_2e]
$u_{classification}$	=	Discounting factor for NERs from avoided deforestation, based on the accuracy of classification, i.e. dividing land into broad land use types. Section 8.1.2.7.
$u_{transition}(i)$	=	Discounting factor for all emission reductions, based on the uncertainty of biomass inventory related to transition i.
$\Delta area_{projectAreaWithANR,baselineScenario}(t,i)$	=	Hectares undergoing transition i within the ANR area under the baseline scenario during year t. [$ha\ yr^{-1}$]. Section 8.2.5.3
$EF_{AGL}(i), EF_{AGD}(i,t-tt), EF_{BG}(i,t-tt), EF_{SOM}(i,t-tt)$	=	Aboveground live, aboveground dead, belowground, and soil emission factor for transition i, and time after transition

		$t - tt$. Section 8.1.4.5
$u_{stratification}$	=	Discounting factor for NERs from avoided degradation, based on the accuracy of stratification, i.e. dividing forest into individual forest biomass classes. Section 8.1.2.7
$nrFNFtransitions$	=	Number of forest/non-forest transitions among land classes or forest strata, meaning transitions in which either the “from” or the “to” class are non-forests. Section 8.1.2.3
$nrStrataTransitions$	=	Number of transitions among forest strata. Section 8.1.2.38.1.2.3

8.2.5.5 Calculate Emission Sources from Assisted Natural Regeneration

The increase in GHG emissions as a result of the prescribed burning during the implementation of the proposed ANR activity, $GHG_{sources,ANR}(t)$ consists of CH_4 emissions from prescribed burning of woody biomass and is calculated as following:

$$GHG_{sources,ANR}(t) = \sum_{i=1}^{nrANRStrata} area_{fireBiomassLoss,ANR}(t,i) \cdot \left(C_{AGL}(i) + C_{AGD}(i) + C_{BG}(i)\right) \cdot \frac{16}{12} \cdot GWP_{CH4} \cdot ER_{CH4} \quad \text{[EQ77]}$$

where:

$GHG_{sources,ANR}(t)$	=	Increase in GHG emissions as a result ANR activity within the project boundary during year t. [tCO_2e]
$nrANRStrata$	=	Number of strata within the project area on which ANR activities are proposed. [-]
$area_{fireBiomassLoss,ANR}(t,i)$	=	Area of biomass removed within ANR stratum i using prescribed burning during year t. [ha]
$C_{AGL}(i), C_{AGD}(i), C_{BG}(i)$	=	Carbon content in aboveground live, aboveground dead and belowground pool in ANR stratum i. [Mg C ha^{-1}]
GWP_{CH4}	=	Global Warming Potential for CH_4 [-]
ER_{CH4}	=	Emission ratio for CH_4 (IPCC default value = 0.012). See Table 3A.1.15 in IPCC GPG-LULUCF (2003). [-]

8.2.6 Estimate the Net GHG Emissions Reductions from Cookstove and Fuel Efficiency Activities

8.2.6.1 Scope and Applicability

Cookstove and Fuel Efficiency (CFE) activities comprise improvements in the thermal application of non-renewable biomass. Examples of such activities include the introduction of high efficiency biomass-fired cookstoves, ovens and dryers, and improvement of energy efficiency of existing biomass-fired cookstoves, ovens and dryers. This methodology anticipates assisting the project proponent in reducing GHG emissions from degradation that can occur due to collection of fuelwood even if forest degradation is not included in the general quantification of GHG emissions reductions benefits. This methodology can be used to quantify GHG emissions reduction generated from reducing consumption of non-renewable biomass based on the procedures below.

See Section 4.2.2 for a list of applicability conditions related to CFE activities. Further specific requirements related to CFE activities are provided below.

8.2.6.2 General Quantification

The quantification approach assumes that, under the baseline scenario, the communities are collecting and consuming biomass fuel from the project area, directly causing deforestation and forest degradation. With the use of appliances with higher efficiency, the consumption of biomass is expected to decrease under the project scenario. The introduction of CFE activities reduces non-CO_2 from burning of fuelwood as well as CO_2 emissions from the loss of carbon stocks in the forest. When the degradation is included in the general quantification of GHG emissions reductions, emissions reductions from CFE activities arising from reducing CO_2 related emissions may have potential to be counted twice. In order to avoid double counting of emissions reductions generated from CFE activities are limited to those arising from non- CO_2 emissions reductions if degradation is included in the REDD project. On the other hand, when the degradation is excluded, GHG emissions emission reductions/removals from CFE activities include the non- CO_2 emissions and CO_2 related emissions. The CO_2 related emissions, however, exclude those related to deforestation activities.

Leakage related to the non-renewable biomass saved by the project activity must be assessed from surveys. Following method AMS.II.G. a leakage discount factor ($\mathrm{DF_{LeakageCFE}}$) of 0.95 can be applied to estimated emissions reduction benefits from CFE, in which are surveys are not required.

If the degradation is excluded:

$$ER_{CFE}(t) = DF_{LeakageCFE} \sum_{i=1}^{nrCFE} HH_{non-CFE}(i,t) \cdot U_{CFE}(t) \cdot Fuel(t) \cdot \left(1 - \frac{\eta_{old}}{\eta_{new}}\right) \cdot NCVfuel \cdot (EF_{non-CO2,fuel} + proportion_{DG,fuel} \cdot EF_{CO2,fuel}) \quad \text{[EQ78]}$$

If the degradation is included:

$$ER_{CFE}(t) = DF_{LeakageCFE} \sum_{i=1}^{nrCFE} HH_{non-CFE}(i,t) \cdot U_{CFE}(t) \cdot Fuel(t) \cdot \left(1 - \frac{\eta_{old}}{\eta_{new}}\right) \cdot NCVfuel \cdot EF_{non-CO2,fuel}$$

where:

$ER_{CFE}(t)$	=	Emission reduction from CFE activities during year t from cookstoves in the project area. [t CO2e]
$DF_{LeakageCFE}(t)$	=	Leakage discount factor [-]. A default factor from AMS.II.G of 0.95 can be used.
$U_{CFE}(t)$	=	Fraction of cumulative usage rate for technologies in project scenario in year t based on cumulative adoption rate and drop off rate revealed by usage surveys [-].
$Fuel(t)$	=	Average annual volume of biomass fuel consumed by households in the absence of the project activity at time t for cooking purpose. [Mg DM yr^{-1} HH^{-1}]
$HH_{non-CFE}(t,i)$	=	Total number of households in the project area that collect biomass fuel from the project area and use i number of efficient or alternative appliances under the project scenario and do not use CFE under the baseline at time t. [-]
i	=	Number of improved cookstoves and/or fuel efficient appliances from 1 to $nrCFE$ [-]
$nrCFE$	=	Total number of number of improved cookstoves and/or fuel efficient appliances [-]
η_{old}	=	Efficiency of the baseline cookstoves or appliances being replaced. [-]
η_{new}	=	Efficiency of the project CFE appliances deployed. [-]
$proportion_{DG}(fuelwood)$	=	The default proportion of degradation related carbon loss from fuelwood collection activities [-], (See Table 7)
NCV_{fuel}	=	Net calorific value of non-renewable biomass that is substituted. [TJ $(Mg\ DM)^{-1}$]
$EF_{non-CO2,fuel}$	=	Non--- CO_2 emission factor of the fuel that is reduced. [MgCO2 TJ^{-1}]
$EF_{CO2,fuel}$	=	Emission factor for the substitution of non-renewable biomass by similar consumers. [$MgCO_2$ TJ^{-1}]

8.2.7 Estimate GHG Emissions from Harvesting

This methodology allows (limited) harvesting of timber from the project area. Allowing harvesting activities (1) increases the attractiveness of a REDD project to participating communities by providing employment and/or controlled access to forest resources, (2) reduces activity-shifting and market leakage, and (3) ensures that harvesting occurs legally, controlled and in a sustainable fashion. An integrated forest management plan or a harvest plan must be developed and all harvesting activities must be carried out according to this plan. The plan must include boundary of areas within a REDD project where harvest activities take place, as well as details of the forest inventory, projected forest growth, projected removal and harvest schedules, harvest methods, and location of harvest activities. In addition, forest management as well as silvicultural activities that aim at enhancing the growth and vigor of the forests inside the harvested areas must be described in the plan. The integrated forest management plan must be submitted at validation or during a verification event and may be updated at a verification event. If a specific area on which ANR activities are done or were done in the past but on which harvesting activities are planned at any point in the future, this area must be considered under this section and not in the section on ANR so to avoid overlap in areas. The quantification of the carbon stock density in harvest areas ($C_{harvest}(t,i)$) must be made from sample plots established in the harvest areas.

See Section 4.2.3 for a list of applicability conditions regarding harvesting. Further specific requirements related to harvesting are provided below.

The harvest plan description in PD must include the following information:

- Description of harvest areas in terms of location, size, forest inventory and topography.
- A description of all silvicultural activities that will be applied in the areas where harvesting will be carried out. This description must include number of trees removed and number of trees retained, in case of individual tree selection cut methods. For clear-cut methods or group selection cut methods, maximum opening size must also be described.
- The harvesting methods, i.e. mechanized vs. manual, as well as all processes such as felling, bunching, skidding/ forwarding, loading, and unloading. All machinery and equipment must be described.
- The harvest frequency (years between harvests) and volume of harvest at each time period.
- Regeneration assumptions and description of site indexes for dominant species in the strata. The harvest plan must include the expected tree density that will be maintained in the project area. Additionally, growth estimates for harvest areas in terms of total biomass as well as biomass stock density per unit area must be described and all assumptions and validity of any growth estimates must be justified. If any software based models have been used, proper justification of the suitability of such models used must also be described in the harvest plan.
- Activities that are practiced to protect soil, water, site and residual trees in the

harvest area.

- Documentation on presence/absence of any threatened or endangered species and/or habitat on site, potential impacts on species and mitigation measures, presence/absence of natural heritage areas, and potential impacts on natural heritage areas and mitigation measures.
- A map of the harvest site including the following:
    - Plot locations.
    - Harvest area boundary within the project area boundary.
    - Slope classes.
    - Streams/rivers/roads (if present).
    - Wetlands (if present).
    - Stream side management zones or river buffer (if applicable).
    - Planned skid trails (if applicable).
    - Landing sites/areas (if applicable).

8.2.7.1 Determining Long-term Average Carbon Stock

The long-term average carbon stock represents the maximum carbon stock that can be attained in harvest areas. GHG benefits must be calculated using a carbon stock that never exceeds the long-term average carbon stock in the areas where harvest activities take place. The long-term average must be quantified based on an appropriate minimal time period which must include at least one full harvest/cutting cycle. The minimal time period must be established as following:

- If the harvest plan concentrates harvest activities in smaller blocks and continuously moves harvesting activities from one block to the next throughout the forest until all the areas are harvested within one harvesting cycle (as practiced in clear-cut or group-selection cut methods), the minimal time period must end at the first year after the end of the crediting period during which all forest blocks have undergone a similar number of harvesting cycles. For example, if the crediting period is 30 years and the duration for all blocks to be harvested once is 12 years, the minimal time period must be 36 years even though project crediting period is only 30 years.
- If the harvest plan intends to target individual trees for harvest throughout the crediting period and the harvest can take place anywhere in a specified are within the forest (as practiced in individual tree selection cut methods), then the established time period over which the long-term average is calculated must be the length of the project crediting period. For example, if the crediting period is 30 years and harvesting of individual trees are carried out throughout the forest during the project crediting period, then the long-term average must be estimated based on the project crediting period.

- After determining the time period for estimating the long-term average, the long-term average carbon stock density must be calculated using [EQ79].

$$LTAC_{harvest} = \frac{\sum_{t=0}^{T}\sum_{i=1}^{nrStrata} C_{harvest}(t,i) \cdot u_{inventory,harvest}(i)}{T} \quad \text{[EQ79]}$$

where:

$LTAC_{harvest}$	=	Long-term average Carbon stock density contained in harvested areas. [tCO_{2e} ha-1]
$nrStrata$	=	Number of forest strata. [-]
$C_{harvest}(t,i)$	=	Biomass carbon stock density at time t in stratum i in harvested areas. [tCO_2 ha^{-1}]
$u_{inventory,harvest}(i)$	=	Discounting factor for the uncertainty in biomass estimation in harvested areas in stratum i in harvest areas. The most recent $u_{inventory,harvest}(t,i)$ value must for used for discounting the estimate for future years. [-]
T	=	Minimal time period for estimating long term average. [yr].

The ex-ante estimation of the $LTAC_{harvest}$ must use biomass carbon stock density $C_{harvest}(t,i)$ values that are estimated using a projection model such as a computer simulation model or a growth table. All projection models must be properly calibrated using field measurements and must estimate the removal of biomass from the harvest areas using the harvest management plan. After the start of the project, the projection model must be re-calibrated using actual harvesting and biomass growth data and the $LTAC_{harvest}$ must be re-calculated at every verification. Any projection model used must have the following characteristics:

- The used models have been prescribed or recommended by designation forest department or related agencies in the country/jurisdiction. For example, growth models or yield project tables listed in forest act/regulations can be used. Alternatively, models that have been found in peer reviewed literature and are from the same region as of the project area can be used. However, such models must be parameterized for the specific conditions of the project area.
- The used models must be clearly documented with respect to the scope of the model, assumptions, known limitations, embedded hypotheses, assessment of uncertainties, and sources for equations, data sets, factors or parameters.
- Simulation software must be based on local data or calibrated for use in the project area. CO2FIX is an example of a simple ready-to-use model that can be easily applied globally. FVS, a different simulation model, has more functionality but requires calibration for use outside of the US (and Canada).

- When no individual simulation model is available, a simple spreadsheet model using IPCC biomass growth estimates or growth estimates based on expert opinion corroborated by local studies and historical practice for the project area can be used. The IPCC biomass tables provide estimate of annual growth and total biomass as a function of different forest types, age-group, and time. When biomass removal is tracked along with the annual growth, biomass remaining in forest can be estimated. Note that this approach gives only linear growth.

8.2.7.2 Calculate Emissions or Sinks on Land on which Harvesting Activities are Implemented

The emissions reductions or removals on the land with harvest activities are calculated using [EQ80].

$$\Delta C_{areaWithHarvest}(t) = \sum_{i=1}^{nrStrata} area_{projectAreaWithHarvest,projectScenario}(t,i) \cdot \left(\frac{C_{harvest}(t_2,i) - C_{harvest}(t_1,i)}{t_2 - t_1}\right) \cdot u_{inventory,harvest}(i) - \sum_{i=1}^{nrFNFtransitions} \sum_{tt=1}^{t} \left(u_{classification} \cdot u_{transition}(i) \cdot \Delta area_{projectAreaWithHarvet,baselineScenario}(t,i) \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right)\right) - \sum_{i=1}^{nrStrataTransitions} \sum_{tt=1}^{t} \left(u_{stratification} \cdot u_{transition}(i) \cdot \Delta area_{projectAreaWitHarvest,baselineScenario}(t,i) \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-\mathrm{tt}) + EF_{SOM}(i,t-tt)\right)\right) \quad \text{[EQ80]}$$

In the first verification, $C_{harvest}(t_1,i)$ are the carbon stocks at the starting date of the crediting period and $C_{harvest}(t_2,i)$ are the carbon stocks at the time of verification in stratum i . In the successive verifications, $C_{harvest}(t_1,i)$ are the carbon stocks at the preceding verification event and $C_{harvest}(t_2,i)$ are the carbon stocks at the time of verification in stratum i . Furthermore, when a new instance is included in the project area, in the first verification of the added instance, $C_{harvest}(t_1,i)$are the carbon stock at the time of that instance addition. $u_{inventory,harvest}\ (i)$ must be estimated using procedure described in 8.2.5.

where:

$\Delta C_{areaWithHarvest}(t)$	=	Net greenhouse gas emissions or removals in project area with harvest activities during year t. [tCO_2e]
$area_{projectAreaWithHarvest,projectScenario}(t,i)$	=	Size of strata i within the project area with harvest activities during year t under the project scenario. [-]
$C_{harvest}(t,i)$	=	Biomass carbon stock density at time t in stratum i in harvested areas. [$tCO_2\ ha^{-1}$]

$u_{inventory,harvest}(i)$ = Discounting factor for the uncertainty in biomass estimation in harvested areas in stratum i in harvest areas. The most recent $u_{inventory,harvest}(t,i)$ value must for used for discounting the estimate for future years. [-]

$\Delta area_{projectAreaWithHarvet,baselineScenario}(t,i)$ = Hectares undergoing transition i within the project area in the harvest area, under the baseline scenario during year t. [ha yr^{-1}].

$nrStrataTransitions$ = Number of transitions among forest strata. Section 8.1.2.3

$nrFNFtransitions$ = Number of forest/non-forest transitions among land classes or forest strata, meaning transitions in which either the “from” or the “to” class are non-forests. Section 8.1.2.3

$EF_{AGL}(i)$, $EF_{AGD}(i,t-tt)$, $EF_{BG}(i,t-tt)$, and $EF_{SOM}(i,t-tt)$ = Aboveground live, aboveground dead, belowground, and soil emission factor for transition i, and time after transition $t-tt$. Section 8.1.4.5

$u_{stratification}$ = Discounting factor for NERs from avoided degradation, based on the accuracy of stratification, i.e. dividing forest into individual forest biomass classes. Section 8.1.2.7

$u_{classification}$ = Discounting factor for NERs from avoided deforestation, based on the accuracy of classification, i.e. dividing land into broad land use types. Section 8.1.2.7

$u_{transition}(i)$ = Discounting factor for all emission reductions, based on the uncertainty of biomass inventory related to transition i.

8.2.7.3 Quantification of Emissions from Harvesting

The fossil fuel emissions from forest harvesting activities are likely to be less than 5% of the total GHG emissions reductions benefits generated by the project. Considering that emissions from deforestation and forest degradation will be much higher than those associate to timber harvesting, the emissions from fossil fuel during transport and machinery can be considered *de-minimis*. In addition, according to VCS *AFOLU Requirements* Section 4.3.3.fossil fuel emissions from transport and machinery use in the REDD project activities can be considered *de minimis*. Therefore, emissions from harvesting, $GHG_{sources,harvest}(t)$, are considered “0”.

8.3 Leakage

8.3.1 Leakage Categories Included in this Methodology.

Under this methodology, leakage is estimated *ex-ante*, but actual NERs are based on actual leakage calculated with project monitoring data. Leakage does not only occur on forest land outside of the project area, but also on non-forest land, such as woodlands or grassland.

The market leakage assessment only has to be included when illegal logging activities that supply timber to national or international markets as an identified driver. Stopping illegal logging to supply timber products to local communities is going to shift pressures to forested areas close to the project area. As a consequence, emissions due to market-effect leakage will be detected by the monitoring for activity shifting leakage.

However, if the illegal logging activities supply timber products to regional, national or global markets, there is high likelihood of market leakage beyond the detection boundaries of the activity-shifting leakage. Therefore, market leakage $GHG_{marketLeakage}(t)$ from reducing logging activities that supply timber products to regional, national or global markets must be quantified by applying appropriate market leakage discount factor to the total GHG emissions reductions/removals benefits derived from avoiding the deforestation and/or degradation activities that supply timber would otherwise supply timber products to regional, national or global markets in the baseline. The market leakage discount factor must be derived by using procedures for the market leakage discount factors for IFM projects set out in VCS *AFOLU Requirement*.

The procedure to quantify leakage differs between drivers that are geographically constrained and geographically unconstrained drivers (see Table 18).

- *Ex-ante* activity-shifting leakage from the geographically constrained drivers uses a factor-approach based on rural appraisals and expert knowledge; *ex-post* leakage from these drivers is based on the remotely sensed deforestation/degradation rates in the leakage area.
- *Ex-ante* activity-shifting leakage from the geographically unconstrained drivers is based on a factor-approach based on rural appraisals and expert knowledge. *Ex-post* activity shifting leakage is based on a factor-approach using conservative assumptions.

Table 18. Distinction between geographically constrained and geographically unconstrained drivers.

Geographically constrained driver categories	Geographically unconstrained driver categories
• Conversion of forest land to cropland for subsistence farming by local communities • Conversion of forest land to settlements	• Conversion of forest land to cropland for subsistence farming by migrants • Conversion of forest land to

by local communities • Logging of timber for local enterprises and domestic use • Fuelwood collection or domestic and local industrial energy needs • Cattle grazing in forests • Extraction of understory vegetation • Forest fires not part of natural ecosystem dynamics[13]	settlements by migrants • Logging of timber for commercial on-sale • Wood collection for commercial on-sale of fuelwood and charcoal production

8.3.2 Estimate Leakage from Geographically Constrained Drivers

Leakage from geographically constrained drivers is estimated *ex-ante* by calculating deforestation and forest degradation rates in the area adjacent to the project area subject to leakage, i.e. the leakage belts.

- First, calculate the leakage induced increase in deforestation/degradation due to project activities.
- Subsequently, demarcate the location and the size of the leakage belts using a GIS analysis.
- Next, estimate forest strata-specific deforestation and forest degradation rates in the leakage belts. Calculate first the total deforestation and degradation rates in the leakage belts by adding the leakage-induced increases in deforestation/degradation to the baseline deforestation/ degradation rates in the leakage belts. Estimate then forest strata-specific deforestation and forest degradation rates using the land use model previously calibrated (Section 8.1.5) for every time t of the crediting period.

8.3.2.1 Calculate the Leakage-Induced Increase in Deforestation and Forest Degradation Rates

$$\Delta D_{LK,DF}(t) = RelativeLeakageImpact_{DF}(t) \cdot D_{projectArea,baselineScenario,DF}(t) \quad \text{[EQ81]}$$

$$\Delta D_{LK,DG}(t) = RelativeLeakageImpact_{DG}(t) \cdot D_{projectArea,baselineScenario,DG}(t) \quad \text{[EQ82]}$$

13 Not all forest fires are a source of leakage, only the forest fires caused by displaced agents such as hunters or beekeepers. The cause of the fire is not specified in the name of the leakage source, however, since, in practice, it is impossible to determine the source of fire. Any statistically significant increase in fire occurrence relative to a 10-yr baseline period must be considered as leakage.

where:

$\Delta D_{LK,DF}(t)$ and $\Delta D_{LK,DG}(t)$	=	Leakage induced increase in deforestation and forest degradation rates during year t of the crediting period. [ha yr^{-1}]
$RelativeLeakageImpact_{DF}(t)$ and $RelativeLeakageImpact_{DG}(t)$	=	Total relative impact of leakage on the decrease in GHG emissions due to project activities for deforestation and forest degradation respectively for year t of the crediting period. [-]
$D_{projectArea,baselineScenario,DF}(t)$, and $D_{projectArea,baselineScenario,DG}(t)$	=	Baseline rate of deforestation/degradation within the project area during year t of the crediting period. [ha yr^{-1}]

The relative impact of leakage is quantified by *ex-ante* leakage cancellation factors, which express the driver-specific relative amount of leakage for the amount of deforestation or degradation that is avoided. This quantity describes the proportion of the (expected) gross emission reductions inside the project area that are lost again due to leakage outside of the project area. Only changes that are directly attributed to project activities must be included in the cancellation rate. For example, if preventing illegal encroachment within the project area by patrolling saves 500 ha of forest per year, but directly leads to an increased deforestation outside of the project area of 300 ha, the achieved GHG emissions reductions benefits are cancelled due to leakage. The cancellation of GHG emissions reductions benefit is 60%. Once the leakage cancellation rates $leakage(d)$ are fixed for every driver d, the $RelativeLeakageImpact$ can be calculated as following:

$$RelativeLeakageImpact_{DF}(t) = \sum_{d=1}^{nrCDrivers} leakage_{constrained}(d) \cdot RelativeDriverImpact_{DF}(t,d) \quad \text{[EQ83]}$$

$$RelativeLeakageImpact_{DG}(t) = \sum_{d=1}^{nrCDrivers} leakage_{constrained}(d) \cdot RelativeDriverImpact_{DG}(t,d) \quad \text{[EQ84]}$$

where:

$RelativeLeakageImpact_{DF}(t)$ and $RelativeLeakageImpact_{DG}(t)$	=	Total relative impact of leakage on the decrease in GHG emissions due to project activities for deforestation and forest degradation respectively at time t. [-]
$nrCDrivers$	=	Number of geographically constrained drivers. [-]

$leakage_{constrained}(d)$	=	Leakage cancellation rate for avoiding deforestation/degradation of geographically constrained driver d. [-]
$RelativeDriverImpact_{DF}(t,d)$ and $RelativeDriverImpact_{DG}(t,d)$	=	Relative impact of a driver d on deforestation and forest degradation, respectively at time t of the crediting period. [-]

Every driver is assigned a leakage cancellation rate based expert knowledge, social assessments and past project experience. Summarize all cancellation rates for each driver in a separate table for avoided deforestation or avoided forest degradation. Any variable with subscript "allowed" indicates that the amount contained in that variable is allowed under the project. Similarly, variables with subscript "project" and "baseline" respectively indicate amount demanded under project and baseline. For example, as part of the REDD project strategy, measures can be put in place to reduce the allowed extraction of certain forest products and reduce the demand for these forest products. Any demand for forest products which cannot be eliminated and cannot be met by the allowed production can cause leakage. Leakage must be calculated as a function of baseline demand, project demand and project supply. If the project intervention does not expect any reduction in demand under the project scenario, any parameter with subscript "project" must be equal to corresponding parameters with subscript "baseline". Similarly, if no deforestation and/or degradation parameter is allowed/expected under project scenario then parameter with subscript "allowed' must be set to "0" in these calculations.

8.3.2.1.1 Leakage Cancellation Rate for Conversion of Forest Land to Cropland for Subsistence Farming by Participating Communities

$$leakage_{constrained}(cropland\ conversion\ by\ participating\ communities) = \frac{\Delta area_{cropLand,project} - \Delta area_{cropLand,allowed}}{\Delta area_{cropLand,baseline} - \Delta area_{cropLand,allowed}} \quad \text{[EQ85]}$$

Where:

$leakage(cropland\ conversion)$	=	Leakage cancellation rate for avoiding deforestation/degradation due to conversion of forest land to settlements. [-]
$\Delta area_{cropLand,baseline}$	=	Area that would be converted to cropland by participating communities under the baseline scenario. [ha yr^{-1}]
$\Delta area_{cropLand,project}$	=	Area that will be converted to cropland by participating communities under the project scenario after reduction in demand for cropland conversion. [ha yr^{-1}]

$\Delta area_{cropLand,allowed}$	=	Area that will be converted to cropland within the project area under the project scenario as defined in the management plan or project document. [ha yr^{-1}]

If the data are missing to calculate $leakage(cropland\ conversion)$, use a conservative rate of 100%. This is allowed because no *ex-post* NERs are dependent on this rate estimated. If the project does not anticipate or allow any conversion after the project start date then, $\Delta area_{cropLand,allowed}$ must be "0".

8.3.2.1.2 Leakage Cancellation Rate for Conversion of Forest Land to Settlements by Local Communities

$$leakage_{constrained}(settlement\ conversion) = \frac{\Delta area_{settlement,project} - \Delta area_{settlement,allowed}}{\Delta area_{settlement,baseline} - \Delta area_{settlement,allowed}} \quad \text{[EQ86]}$$

where:

$leakage_{constrained}(settlement\ conversion)$	=	Leakage cancellation rate for avoiding deforestation/degradation due to conversion of forest land to settlements. [-]
$\Delta area_{settlement,baseline}$	=	Area that would be converted to settlements by participating communities under the baseline scenario. [ha yr^{-1}]
$\Delta area_{settlement,project}$	=	Area that will be converted to settlements by participating communities under the project scenario after reduction in demand for settlement to conversion. If reduction in demand is not applicable, then this must be equal to $area_{settlement,baseline}$. This area is required by communities. [ha yr^{-1}]
$\Delta area_{settlement,allowed}$	=	Area that will be converted to settlements within the project area under the project scenario as defined in management plan/project document. [ha yr^{-1}]

If the data are missing to calculate $leakage(settlement\ conversion)$, use a conservative rate of 0.9. This is allowed because no *ex-post* NERs are dependent on this rate estimated.

8.3.2.1.3 Leakage Cancellation Rate for Conversion of Forest Land to Infrastructure

$$leakage_{constrained}(infrastucture\ conversion) = \frac{\Delta area_{infrastucture\ ,project} - \Delta area_{infrastucture\ ,allowed}}{\Delta area_{infrastucture\ ,baseline} - \Delta area_{infrastucture\ ,allowed}} \quad [EQ87]$$

where:

$leakage_{constrained}(infrastucture\ conversion)$	=	Leakage cancellation rate for avoiding deforestation/degradation due to conversion of forest land to infrastructure. [-]
$\Delta area_{infrastucture\ ,baseline}$	=	Area that would be converted to infrastructure under the baseline scenario. [ha yr^{-1}]
$\Delta area_{infrastucture\ ,project}$	=	Area that will be converted to infrastructure under the project scenario after reduction in demand for infrastructure development. If reduction in demand is not applicable, then this must be equal to $\Delta area_{infrastructure,baseline}$. [ha yr^{-1}]
$\Delta area_{infrastucture\ ,allowed}$	=	Area that will be converted to infrastructure within the project area under the project scenario as defined in management plan/project document. [ha yr^{-1}]

If the data tocalculate $leakage(infrastructure\ conversion)$ is not available, use a conservative rate of 100 %. If the similar project activities have proven to achieve 100% reduction in demand for infrastructure development elsewhere in the reference region or in areas similar to reference region in the same jurisdiction as the location of project area, then $leakage(infrastructure\ conversion)$ can be set to 0%. If the project does not anticipate or allow any conversion for infrastructure after the project start date then, $\Delta area_{infrastructure,allowed}$ must be “0”.

8.3.2.1.4 Leakage Cancellation Rate for Logging of Timber for Local Enterprises and Domestic Use.

The timber needed for local and domestic use is non-elastic. If the project activities allows extraction of timber from forest, then the leakage is “0” and if the project activities does not allow extraction of timber for such uses, then the leakage cancellation rate is 100%. For any value less than 100%, sufficient proof must be provided to justify lower leakage rate and must be assessed by the validation/verification body. In order to justify a lower leakage, the project proponent must be able to demonstrate a lower demand for timber products or supply from the sources that are not causing deforestation within the country boundary such as managed forest lots.

$$leakage_{constrained}(domestic\ timber) = 0 - \ 100\% \quad \text{[EQ88]}$$

8.3.2.1.5 Leakage Cancellation Rate for Fuelwood Collection for Domestic and Local Industrial Energy Needs

Estimate the leakage cancellation rate as:

$$leakage_{constrained}(fuel\text{-}wood) = \frac{DFW_{project} - DFW_{allowed}}{DFW_{baseline} - DFW_{allowed}} \quad \text{[EQ89]}$$

where:

$leakage_{constrained}(fuel\text{-}wood)$	=	Leakage cancellation rate for avoiding deforestation/degradation of fuelwood collection for domestic and local energy needs. [%]
$DFW_{baseline}$	=	Biomass (dry matter) of fuelwood collected by project participants under the baseline scenario. [$m^3\ yr^{-1}$]
$DFW_{project}$	=	Biomass (dry matter) of fuelwood collected by project participants under the project scenario after any adjustments to demand. [$m^3\ yr^{-1}$]
$DFW_{allowed}$	=	Biomass (dry matter) of allowed fuelwood collection in the project area under the project scenario as defined in a management plan/project document. [$m^3\ yr^{-1}$]

An example of applying this equation is given here for illustration. Assuming that collection of fuel-wood for domestic uses is one of the drivers of deforestation and under the baseline, the demand for fuel-wood within participating communities is equivalent to 100 arbitrary units ($DFW_{baseline} = 100$). As part of project activities, a forest management plan and land use planning will be in place. These plans streamline the extraction and limit the amount of wood that can be harvested from the forest. When it is allowed to harvest only 80 units of fuel-wood (as part of project activity) in the REDD project area ($DFW_{allowed} = 80$) without implementing any energy efficiency measures, the demand will remain constant under the project scenario ($DFW_{project} = 100$), causing a leakage of 20 units or 100%, because:

$$leakage_{constrained}(fuel\text{-}wood) = \frac{100 - 80}{100 - 80} = 100\%$$

However, when the project implementation reduces the demand for forest products itself, such as by increasing the efficiency and reducing the demand from 100 to only 90 units, $DFW_{project} = 90$), then there is leakage of 10 units or 50%, since:

$$leakage_{constrained}(fuel\text{-}wood) = \frac{90-80}{100-80} = 50\%$$

A number of project activities may be implemented to decrease the need for the resource either directly (e.g., the introduction of fuel-efficient woodstoves) or indirectly by providing alternative sources for the resource (e.g., solar stoves instead of woodstoves) must be used. Estimate $B_{projectScenario}$ as:

$$DFW_{project} = \sum_{i=1}^{nrfuelWoodReductionActions} adoption(i) \cdot \big(1 - efficiency(i)\big) \cdot DFW_{baseline} \quad \text{[EQ90]}$$

where:

$nrfuelWoodReductionActions$	=	The number of project activities that reduce the need for fuelwood. E.g., introduction of fuel-efficient woodstoves, biogas plants. [-]
$adoption(i)$	=	Adoption rate of project activity i which reduces fuelwood consumption. [-]
$efficiency(i)$	=	Rate at which project activity i reduces fuelwood consumption. [-]
$DW_{baseline}$	=	Biomass (dry matter) of fuelwood collected in the project area in the baseline scenario. [Mg DM yr^{-1}]

8.3.2.1.6 Leakage Cancellation Rate for Cattle Grazing in Forests.

Cattle grazing will be reduced or avoided as part of project activities by replacing in-forest grazing activities with stall feeding. Livestock feeds will be supplied by intensification of agricultural activities and farm woodlot management. When stall feeding is used and there is no displacement of grazing activities, there is no leakage from grazing. The leakage from displacement of grazing activities must be estimated using the latest version of the CDM A/R Methodological Tool *Estimation of GHG emissions related to displacement of grazing activities in A/R CDM project activity*.

$$leakage_{constrained}(grazing) = 0 - 100\% \quad \text{[EQ91]}$$

8.3.2.1.7 Leakage Cancellation Rate for Extraction of Understory Vegetation.

Understory vegetation extraction that is required by communities for purposes such as roofing, livestock bedding and poles needs to be quantified and alternatives should be provided. Non-biomass alternatives for roofs could help defray the displacement of biomass extraction in leakage belts. Similarly, intensification of agriculture and farm wood management can provide alternatives to understory vegetation extraction.

$$leakage_{constrained}(VG) = \frac{VG_{project} - VG_{allowed}}{VG_{baseline} - VG_{allowed}} \quad \text{[EQ92]}$$

where:

$leakage_{constrained}(VG)$	=	Leakage cancellation rate for avoiding deforestation/degradation of understory vegetation extraction. [-]
$VG_{baseline}$	=	Biomass (dry matter) of understory vegetation extraction by project participants under the baseline scenario. [Mg DM yr^{-1}]
$VG_{project}$	=	Biomass (dry matter) of understory vegetation extraction by project participants under the project scenario. [Mg DM yr^{-1}]
$VG_{allowed}$	=	Biomass (dry matter) allowed as understory vegetation extraction under the project scenario. This amount is typically fixed in a management plan. [Mg DM yr^{-1}]

A number of project activities may be implemented to decrease the demand of understory vegetation (e.g., the introduction of alternative roofing material, biomass from intensification of agriculture). Estimate $VG_{project}$ as:

$$VG_{project} = \sum_{i=1}^{nrVGReductionActions} adoption(i) \cdot \left(1 - efficiency(i)\right) \cdot VG_{baseline} \quad \text{[EQ93]}$$

where:

$nrVGReductionActions$	=	The number of project activities that reduce the need for understory vegetation extraction. [-]
$adoption(i)$	=	Adoption rate of project activity i which reduces understory vegetation extraction.[-]
$efficiency(i)$	=	Rate at which project activity i reduces fuelwood consumption. [-]
$VG_{baseline}$	=	Biomass (dry matter) of understory vegetation extraction. [Mg DM yr^{-1}]

8.3.2.1.8 Leakage Cancellation Rate for Forest Fires Not Part of Natural Ecosystem Dynamics.

Most forest fires that are avoided through fire prevention activities and education will not lead to increased occurrence of forest fires outside of the project area. Select a conservative leakage cancellation rate between 0-100%. For example, fires induced by hunters or beekeepers may be partially or fully displaced by patrolling the project areas. Substantiate the selected rate based on rational arguments, field observations and scientific literature.

$$leakage_{constrained}(forest\ fires\ by\ participating\ communities) = 0 - 100\% \qquad [EQ94]$$

8.3.2.2 Demarcate the Leakage Belts

Leakage from drivers that are geographically constrained will remain close to the project areas. Leakage from these drivers is monitored in an *ex-ante* fixed geographical region around each discrete project area parcel (a leakage belt). Note that the leakage areas must contain both forest and non-forest land. The leakage belts are identical for all geographically constrained drivers (see Table 18). A correct *ex-ante* demarcation of each leakage belt is crucial to accurately account for the GHG benefits of the REDD project since the leakage belt is the area where leakage from geographically constrained drivers will be monitored and deducted from the actual NERs. The size and location[14] of the leakage belts is determined using a cost-of-transportation-based GIS approach and social assessments. Use the following steps:

- Determine the average “cost” to move across an LULC class, forest stratum, or road/track. The relative costs must be calculated by reciprocating the maximal speed for every class or road category and relevant mode of transportation, and therefore represent the fastest time it takes to cross a set distance. The speeds were analyzed in Section 8.1.3.3.
- Using a GIS, generate a raster map of the reference region in which every pixel contains the cost to cross this pixel, based on the class or roads/tracks on this pixel. The cost to cross areas that are not accessible to agents of deforestation must be set to an arbitrary large value. Examples of inaccessible areas include protected areas, national parks, economic land concessions, and large plantations. These must have been excluded already from the reference region.
- This map must have an identical resolution as the remote sensing images of the historical reference period.
- Using the cost map, generate a cost-distance map of the reference region in which every pixel contains the cost (time) to reach the nearest point of the project area.
- For every agent of deforestation/degradation, estimate the extra time this agent is willing to take to move its deforestation activities from the project area to the nearest accessible forest. Determine this value using social assessments by asking what the extra time is that a single household would have to spend if the project area is not accessible anymore.
- Select the area in the cost-distance map that is accessible from the boundary of the project area within the maximal time determined in the previous step multiplied by a

14 Note that the leakage belt encompasses both forest land and non-forest land.

factor 1.5.[15] This area must contain both forest and non-forest land. Therefore, when different agents and drivers of deforestation are active, the most mobile agent of deforestation must determine the size of a leakage belt. Note that the leakage area should be fully encompassed within the reference region. Increase the size of the reference region, if necessary, to accommodate the defined leakage belts.

8.3.2.3 Calculate the Forest Strata-specific Deforestation and Degradation Rates in the Leakage Belts

Once the leakage area is demarcated, the total deforestation/ degradation rates in the leakage belts are calculated using:

$$D_{leakageArea,baselineScenario,DF}(t) = D_{projectArea,baselineScenario,DF}(t)\frac{size_{leakageArea}}{size_{projectArea}} \quad \text{[EQ95]}$$

$$D_{leakageArea,baselineScenario,DG}(t) = D_{projectArea,baselineScenario,DG}(t)\frac{size_{leakageArea}}{size_{projectArea}} \quad \text{[EQ96]}$$

$$D_{leakageArea,projectScenario,DF}(t) = \Delta D_{LK,DF}(t) + D_{leakageArea,baselineScenario,DF}(t) \quad \text{[EQ97]}$$

$$D_{leakageArea,projectScenario,DG}(t) = \Delta D_{LK,DG}(t) + D_{leakageArea,baselineScenario,DG}(t) \quad \text{[EQ98]}$$

where:

$D_{leakageArea,baselineScenario,DF}(t)$ and $D_{leakageArea,baselineScenario,DG}(t)$	=	Baseline rate of deforestation/degradation within the leakage area at time t of the crediting period. [ha yr^{-1}]
$D_{projectArea,baselineScenario,DF}(t)$ and $D_{projectArea,baselineScenario,DG}(t)$	=	Baseline rate of deforestation/degradation within the project area at time t of the crediting period. [ha yr^{-1}]
$size_{leakageArea}$	=	Size of the leakage area. [ha]
$size_{projectArea}$	=	Size of the project area. [ha]
$D_{leakageArea,projectScenario,DF}(t)$ and $D_{leakageArea,projectScenario,DG}(t)$	=	Rate of deforestation/degradation within the leakage area under the project scenario at time t of the crediting period. [ha yr^{-1}]
$\Delta D_{LK,DF}(t)$ and $\Delta D_{LK,DG}(t)$	=	Leakage induced increase in deforestation and forest degradation rates during year t of the crediting period. [ha yr^{-1}]

[15] The factor of 1.5 takes into account that an agent of deforestation that is living close to the project area and who used to rely on the project area for certain activities may shift the activities to a forest in the opposite direction of the project area. However, this effect will gradually decrease. With a factor of 1.5, 95% of all potential leakage is captured.

- The total deforestation and forest degradation rates in the leakage area are calculated by adding the leakage-induced increase in deforestation/degradation rates to the baseline deforestation/ degradation rates. The baseline deforestation and forest degradation rates are calculated by taking the size-wise proportion of the deforestation/degradation rates in the project area under the baseline scenario. Add the total deforestation and forest degradation rates in the leakage area in two separate tables such as Table 15.
- Subsequently, estimate the forest strata-specific deforestation and forest degradation rates for every year of the crediting period using the land use model previously calibrated (Section 8.1.5).

8.3.3 Estimate Leakage from Geographically Unconstrained Drivers

Activity-shifting leakage from geographically unconstrained drivers is quantified using a factor approach in both the *ex-ante* and *ex-post* cases. All leakage from reducing logging of timber for commercial on-sale or wood collection for commercial on-sale of fuelwood and charcoal production is considered through the 'market leakage evaluations' mechanism from the VCS *AFOLU Requirements* document. The only other geographically unconstrained drivers are conversion of forests by migrants to either cropland or settlements outside of the leakage belts. Conversion of forest land to cropland or settlements by migrants or other people outside of the participating communities must be minimized with leakage prevention activities[16] such as the creation of alternative livelihoods and the intensification of land-use. The emissions from leakage are calculated by first quantifying the area of the leakage by multiplying the area of deforestation and degradation that is avoided with a leakage factor. Next, this area of leakage is multiplied with an average emission factor (EF_{forest}), a representative emission factor for the entire forest strata within the project area (i.e. average emission factor excluding non-forest strata) to calculate emissions from leakage by unconstrained drivers. This approach is fully conservative: in contrast to the deforestation by geographically constrained agents, it is not possible to predict in which forests the deforestation through leakage from unconstrained drivers will take place.

The following equation is to be used:

$$GHG_{\mathrm{otherLeakageSources}}(t) =$$

$$+EF_{forest} \cdot D_{projectArea,baselinScenario,DF} \cdot \sum_{d=1}^{nrUDrivers} leakage_{unconstrained}(d) \cdot RelativeDriverImpact_{DF}(t,d)$$

$$+EF_{forest} \cdot D_{projectArea,baselinScenario,DG} \cdot \sum_{d=1}^{nrUDrivers} leakage_{unconstrained}(d) \cdot RelativeDriverImpact_{DG}(t,d)$$

[EQ99]

16 A list of the allowed leakage prevention activities and the associated applicability criteria can be found in Step 12, section 8.3.4.

where:

$GHG_{otherLeakageSources}(t)$	=	GHG emissions from leakage due to unconstrained geographic drivers during year t of the crediting period. [tCO_2e]
EF_{forest}	=	Emission factor related to leakage. If comprehensive national-level statistics on biomass densities are available, EF_{forest} must be calculated based on the average biomass of the country, if local data is not available. Sources of the data allowed are (1) academic research papers and (2) studies and reports published by the forestry administration or other organizations, including the FAO's Forest Resource Assessment reports, (3) the upper range of biomass in the GPG-LULUCF (2003) Table 3A.1.2. [tCO_2e]
$D_{projectArea,baselinScenario,DF}$ and $D_{projectArea,baselinScenario,DG}$	=	Baseline rate of deforestation and forest degradation respectively within the project area during year t of the crediting period. [ha yr^{-1}]
$nrUDrivers$	=	Number of geographically unconstrained drivers that are not covered by market leakage, i.e., "Conversion of forest land to cropland for subsistence farming by migrants" and "Conversion of forest land to settlements by migrants"
$leakage_{unconstrained}(d)$	=	Leakage cancellation rate for avoiding deforestation/degradation from geographically unconstrained drivers such as area of cropland conversion displaced beyond the leakage belts relative to the area of cropland conversion avoided within the project area. Unless a lower rate can be justified, a default rate of 100% must be used. The burden of proof lies with the project developer[17]. Valid sources to substantiate a smaller leakage rate include social assessments, scientific literature, and reports from civil society or governments. Sources have to be reliable and based on scientific methods and a good statistical design.

[17] For example, REDD Project participants can demonstrate that different measures to reduce leakage in the country are effective. Evidence from other areas could be used to substantiate a smaller leakage rate after it is demonstrated that the circumstances are similar.

$RelativeDriverImpact_{DF}(t,d)$ and $RelativeDriverImpact_{DG}(t,cd)$	=	Relative impact of the geographically unconstrained driver d at time t of the crediting period. [-]

Calculate values for $GHG_{otherLeakageSources}(t)$ for every year of the project crediting period and report in the overview table.

8.3.4 Estimate Applicability of and Emission sources from Leakage Prevention Activities

Leakage can be minimized by implementing a number of leakage prevention activities. Under this methodology, a number of potential leakage prevention activities are allowed. Note that the implementation of potential leakage prevention activities is optional. However, if leakage prevention activities are implemented, they must follow the relevant applicability criteria detailed in Section 4.2 as well as the requirements specified below.

Any significant increase in GHG emissions due to the implementation of leakage prevention activities ($E_{sources,leakagePrevention}(t)$) must be subtracted from the project's overall GHG emissions according to the procedures included within this Section. In addition, as part of the validation, the validation/verification body must analyze that no other significant emissions exist originating from any measure associated with the project and intended to prevent leakage.

The following sources of GHG emissions from leakage prevention activities are included in this methodology:

$$GHG_{sources,leakagePrevention}(t) = \Delta E_{flooded\ rice}(t) + \Delta E_{livestock}(t) \quad \text{[EQ100]}$$

where:

$GHG_{sources,leakagePrevention}(t)$	=	Emission sources from leakage prevention activities during time t of the crediting period. [tCO_2e]
$\Delta E_{flooded\ rice}(t)$	=	Annual difference in GHG emissions due to increased use of flooded rice production systems as agricultural intensification measures during year t of the crediting period. [tCO_2e]
$\Delta E_{livestock}(t)$	=	Annual difference in GHG emissions by enteric fermentation and manure management from increased animal stocking rates as an agricultural intensification measure during year t of the crediting period. [tCO_2e]

The significance of these and other emissions is tested according to the procedures provided in CDM EB31, Appendix 16 to determine whether it must be included. If an emission source is found insignificant, it must be omitted.

8.3.4.1 Check Conditions and Quantify Emissions from Intensification of Annual Cropping Systems

See Section 4.2.4 for a list of applicability conditions related to intensification of annual crop production systems. In addition, intensification of annual crop production systems must only be done by implementing one or more of the following measures:

- Increasing synthetic or organic N inputs.
- The use of fallow crops or shrubs.
- Replacing subsistence crops by cash crops.
- Replacing low-yielding crop varieties by higher-yielding, or less pest-sensitive crop varieties.
- Introduction of irrigation systems, except for flooded rice production systems.

The emissions from intensification of annual cropping systems are considered negligible and considered ‘0’.

8.3.4.2 Check Conditions and Quantify Emissions from Introduction of Flooded Rice Production

8.3.4.2.1 Scope and Applicability

See Section 4.2.5 for a list of applicability conditions when introducing flooded rice production

8.3.4.2.2 Emissions

A simple yet conservative estimate of the CH_4 emissions from flooded rice fields is used to discount emission reductions. Emissions are calculated based on a maximal daily emission rate multiplied with the maximal length of the growing season determined by PRAs. Equation 5.1 of Chapter 5, Volume 4 of IPCC sets out the calculation for estimating total CH_4 emissions from flooded rice fields for a given year. The change in CH4 emissions due to agricultural intensification in flooded rice production systems is estimated by quantifying the annual expansion of flooded rice harvest area. Therefore annual difference in GHG emissions due to increased use of flooded rice production systems must be estimated as:

$$\Delta E_{flooded\ rice}(t) = GWP_{CH4} \cdot \Delta A_{rice}(t) \cdot t_{flooded,max} \cdot EF_{rice,max} \cdot 10^{-6} \quad \text{[EQ101]}$$

where:

t	=	Time after project start. [yr]
$\Delta E_{flooded\ rice}(t)$	=	Annual difference in GHG emissions due to increased use of flooded rice production systems as agricultural intensification measures during year t of the crediting period. [tCO_2e]
GWP_{CH4}	=	Global Warming Potential for CH_4 [-]
$\Delta A_{rice}(t)$	=	Total and cumulative increase in harvested area of rice due to leakage prevention measures since the start of the project and until year t. The increase in area of rice cultivation must be quantified using social assessments [ha yr^{-1}].
$t_{flooded,max}$	=	Maximal period of time a field is flooded [days yr^{-1}]
$EF_{rice,max}$	=	Maximal emission rate for methane. By default, an emission rate of 36 kg CH4 ha^{-1} day^{-1} must be used, which is 25% greater than the maximal value found in a review study comparing 25 studies of CH4 fluxes in rice fields (Le Mer and Roger, 2001). The project proponent may use a smaller emission rate if it can be demonstrate that the rate remains conservative for the project conditions. [kg CH_4 ha^{-1} day^{-1}]

Add annual values of $\Delta E_{flooded\ rice}(t)$ to the summary table of all GHG emissions due to project activities.

8.3.4.3 Estimate GHG Emissions from Increased Livestock Stocking Rates, $\Delta E_{livestock}$

8.3.4.3.1 Scope and Applicability

See Section 4.2.6 for a list of applicability conditions when increasing livestock stocking rates. Livestock stocking rates must be increased through either or both of the following measures:

- Increasing the stocking density of livestock on existing grazing land.
- Moving of cattle to a zero-grazing system, defined as a system of feeding cattle or other livestock in which forage is brought to animals that are permanently housed instead of being allowed to graze.

8.3.4.3.2 Quantification and Monitoring of Emissions from Increased Stocking rates

Use the leakage procedures provided in the latest version of approved CDM methodology AR-AM0006 and as well as the latest version of CDM A/R Tool *Estimation of GHG emissions related to displacement of grazing activities in A/R CDM project activity* to determine the CH_4 and N_2O emissions from livestock, [18]. The sum of variable $LK_{FFL,t}$ within the latest version of CDM methodology AR-AM0006 and the variable $LK_{Displacement,t}$ (minus $LK_{Deforestation,t}$ and $LK_{N2O-Displacement,t}$ which are already accounted in the carbon stock change assessment) within the CDM A/R tool is equivalent to $\Delta E_{livestock}(t)$ within this methodology. Add annual values of $\Delta E_{livestock}(t)$ to the summary table of all GHG emissions due to project activities.

Use the variables list of default parameters and parameters to be monitored from the latest versions of AR-AM0006 and the CDM tool for displacement of grazing activities. Livestock population increases must be quantified using social assessments or peer-reviewed literature, and re-evaluated after every baseline update. Livestock population increases must be monitored using social assessments or peer-reviewed literature.

8.4 Summary of GHG Emission Reduction and/or Removals

8.4.1 Estimate Change in Carbon Stocks in the Long-Lived Wood Product Pool

This methodology considers the carbon in long-lived wood products sequestered for over 100 year as permanently sequestered carbon. First, the carbon in harvested wood products must be calculated for the project and baseline scenarios. Then, the carbon in long-lived wood products must be calculated for the project and baseline scenarios. The net change in carbon in long-lived wood products is then calculated by subtracting the carbon in long-lived wood products under the baseline scenario and the project scenario.

8.4.1.1 Calculate Carbon in Harvested Wood Products.

The carbon in harvested wood products is calculating based on the volume of timber extracted within the project area in both the baseline scenario and the project scenario.

$$C_{HWP,project}(ty,t) = \sum_{h=1}^{H_{PS}} \sum_{j=1}^{S_{PS}} \left(\left(DT_{project}(h,j,ty,t) + CT_{project}(h,j,ty,t) \right) \cdot \rho_{wood,J} \cdot CF \right) \quad \text{[EQ102]}$$

[18] This tool has been approved for A/R CDM projects, but is applicable to REDD projects. All references to “A/R CDM” within this tool should be interpreted as “REDD”.

$$C_{HWP,baseline}(ty,t) = \sum_{h=1}^{H_{PS}} \sum_{j=1}^{S_{PS}} \left(\left(DT_{baseline}(h,j,ty,t) + CT_{baseline}(h,j,ty,t) \right) \cdot \rho_{wood,J} \cdot CF \right)$$

where:

$C_{HWP,project}(ty,t)$ and $C_{HWP,baseline}(ty,t)$	=	Total carbon stock in long-lived wood products within the project boundary for class ty during time t of wood product ty in the project and baseline scenario, respectively [Mg C]
$DT_{project}(h,j,ty,t)$, $DT_{baseline}(h,j,ty,t)$, $CT_{project}(h,j,ty,t)$ $CT_{baseline}(h,j,ty,t)$	=	The volume of timber extracted from within the project boundary during harvest h by species j and wood product class ty during year t in the project and baseline scenario, respectively. DT = domestic timber; CT = commercial timber [m^3].
$\rho_{wood,j}$	=	Wood density of harvested species or species group j [Mg DM m^{-3}]
h	=	1, 2, 3, …, H_{PS} number of harvests [-]
j	=	1, 2, 3, …, S_{PS} harvested tree species [-]
ty	=	Wood product class – defined here as sawn wood (sw), wood-based panels (wp), other industrial round wood (oir), and paper and paper board (ppb).
CF	=	Carbon fraction of wood [Mg C (Mg DM)$^{-1}$] (default value = 0.5)

- Under the baseline scenario $DT_{baseline}$ and $CT_{baseline}$ must be calculated using Section 8.1.3.2 and Table 8. The uncertainty around the estimates of $DT_{baseline}$ and $CT_{baseline}$ must be estimated and/or justified with appropriate methods, such as reported uncertainties from scientific literature, or calculated uncertainties when social assessments are used. In situations when uncertainty cannot be estimated, the most conservative estimate must be used.
- For the *ex-ante* project case, $DT_{project}$ and $CT_{project}$ must be calculated using the procedures in Section 8.2.1.
- *Ex-post*, $DT_{project}$ and $CT_{project}$ must be monitored and quantified using forest operation records (i.e., log books kept as part of forest management plan). The uncertainty around the monitored volume of timber must be explicitly reported.

In case the uncertainty, as quantified by the half-width of the confidence interval, is less than 15% of the volume of timber extracted, no adjustment for uncertainty must be applied. If, however, the uncertainty is greater than 15% of the volume of timber extracted, $C_{HWP,baseline}(ty,t)$ must be adjusted upwards with its associated uncertainty and $C_{HWP,project}(ty,t)$ must be adjusted downwards with its associated uncertainty.

8.4.1.2 Calculate the Carbon in Long-Lived Wood Products

Carbon in long-lived wood products is defined as being sequestered for at least 100 years. Instead of tracking annual emissions through retirement, burning and decomposition, the methodology calculates the proportion of wood products that have not been emitted to the atmosphere 100 years after harvest and assumes that this proportion is permanently sequestered. All factors are derived from Winjum et al. (1998).

$$C_{LWP,project}(t) = \sum_{s,wp,ppb,oir}^{ty} C_{HWP,project}(ty,t) \cdot \left(1 - wwf(ty)\right)\left(1 - slp(ty)\right)\left(1 - fo(ty)\right)$$
$$C_{LWP,baseline}(t) = \sum_{s,wp,ppb,oir}^{ty} C_{HWP,baseline}(ty,t) \cdot \left(1 - wwf(ty)\right)\left(1 - slp(ty)\right)\left(1 - fo(ty)\right) \quad \text{[EQ103]}$$

where:

$C_{LWP,project}(t)$ and $C_{LWP,baseline}(t)$	=	Carbon stock of long-lived wood products at time *t* in the project and baseline scenario, respectively. [Mg C]
$C_{HWP,project}(ty,t)$ and $C_{HWP,baseline}(ty,t)$	=	Total biomass carbon harvested within the project boundary by wood class ty during year t in the project and baseline scenario, respectively [Mg C]
$wwf(ty)$		Fraction of carbon in harvested wood products that is emitted immediately because of mill inefficiency for wood class ty. This can be estimated by multiplying the applicable fraction to the total amount of carbon in different harvested wood product category. The default applicable fraction is 24% and 19% respectively for developing and developed countries (Winjum et al. 1998).
$slp(ty)$	=	Proportion of short lived products. These fractions are 0.2, 0.1, 0.4 and 0.3 respectively for wood class ty, i.e., sawnwood, wood-based panel, paper and paper boards and other industrial round woods as described in Winjum et al. (1998). The methodology assumes that all other classes of wood products are emitted within 5 years.
$fo(ty)$	=	Fraction of carbon that will be emitted to the atmosphere between 5 and 100 years of harvest for wood class ty. See Table 19. [-]
t	=	*1, 2, 3….. t* years elapsed since the start of the project. [yr]
ty	=	Wood product class – defined here as sawnwood (sw), wood-based panels (wp), other industrial round wood (oir),

and paper and paper board (ppb)

Table 19. Proportion of remaining wood products oxidized between 5 and 100 years after initial harvest by wood product class and forest region

Wood product category	Forest region		
	Boreal	Temperate	Tropical
Sawnwood	0.378	0.613	0.850
Wood base panel	0.613	0.850	0.977
Other industrial round wood	0.850	0.977	0.999
Paper and paperboard	0.378	0.613	0.999

Source: Winjum et al. 1998

8.4.1.3 Calculate Net Change in Carbon in Long-Lived Wood Products

The net change in carbon in long-lived wood products is then calculated by subtracting the carbon in long-lived wood products under the baseline scenario and the project scenario.

$$\Delta C_{LWP}(t) = C_{LWP,project}(t) - C_{LWP,baseline}(t) \quad \text{[EQ104]}$$

where:

$\Delta C_{LWP,t}$ = Net carbon stock change in long-lived wood products during year *t* [Mg C]

$C_{LWP,project}(t)$ = Carbon stock in long-lived wood products under the baseline scenario during year *t* [Mg C]

$C_{LWP,baseline}(t)$ = Carbon stock in long-lived wood products under the project scenario during year *t* [Mg C]

8.4.2 Summarize the Projected Land Use Change

- Present a table with the total deforestation and degradation rates under the baseline and project scenarios for the project area and leakage area for every year of the project duration.
- Present tables with the LULC class and forest-strata specific land transitions for the project and leakage area under the baseline and project scenarios.
- Subtract the land transition changes under the baseline scenario from the changes under the project scenario, and multiply with the difference of the appropriate emission factor and baseline net annual increment. Apply all applicable uncertainty discounting factors.
- Calculate values for $GHG_{otherLeakageSources}(t)$ from the procedure in 8.3.3.
- Calculate the net GHG benefits from ANR without taking emission sources into account for every year t of the crediting period.

- Calculate the net GHG benefits from harvested wood products pool.
- Calculate the net GHG benefits from fuel-efficiency activities only if the degradation is not included in the REDD project.
- Calculate the net GHG benefits from areas subject of harvest activities.

8.4.3 Test the Significance of GHG Emissions

In this step, the significance of emission sources is determined. This test has to be carried out at validation for for each of the first ten years of the project crediting period, and the procedure has to be repeated at every baseline update. All insignificant emissions can be omitted from the *ex-ante* calculation of the NERs. The CDM *Tool for testing significance of GHG emissions in A/R CDM project activities* from EB31 appendix 16 should be used to test the significance of GHG emissions.

The sum of increases in emissions that may be excluded must be less than 5% of the emission reductions. If it is determined that a specific GHG emission source will never reach this threshold and will never become significant, it may be omitted from the monitoring plan.

8.4.4 Estimate *Ex-ante* NERs

Use Equation [EQ105] to estimate the *ex-ante* NERs; only use the significant GHG sources as determined in the step above. Prepare a table with all the individual terms of Equation [EQ105]. Calculate the *ex-ante* NERs for every year of the crediting period. After NERs are calculated, use Equation [EQ106] to calculate the VCUs.

Cumulative emissions reductions/removals from ANR activities must account for less than 50% of the cumulative emissions reductions/removals generated by the project. For every year of the crediting period, divide the total emissions reduction from ANR by the total NERs in the overview table, and confirm that the result is less than 50%. Note that *ex-ante* NERs are are calculated and reported for the entire project crediting period but the estimates must be re-validated at every baseline update. (i.e., every ten years.

Net Emission Reductions(NERs)	=		
		ΔGHG from avoided deforestation excluding ANR and harvest areas	❶
		+ ΔGHG from deforestation due to leakage	❷
		+ ΔGHG from avoided degradation	❸
		+ ΔGHG from degradation due to leakage	❹
		+ΔGHG from leakage by unconstrained geographic drivers	❺
		+ ΔGHG from assisted natural regeneration	❻
		+ ΔGHG from changes in long-lived wood products	❼
		+ ΔGHG from improved cookstoves	❽
		+ ΔGHG from other and secondary sources	❾

+ΔGHG from avoided deforestation from areas under harvest ❿

[EQ105]

$$\text{Verified Carbon Units} = \text{NERs} - buffer \cdot (❶ + ❸ + ❻ + ❼ + ❿)$$ [EQ106]

where:

Note that i and tt are simple indices to the summations and do not have any further meaning; t is the year for which the emissions and removals are calculated.

ΔGHG from avoided deforestation:

$$❶ = \sum_{i=1}^{nrFNFtransitions} \sum_{tt=1}^{t} u_{classification} \cdot u_{transition}(i) \cdot \begin{pmatrix} +\Delta area_{projectAreaEAH,projectScenario}(t,i) \\ -\Delta area_{projectAreaEAH,baselineScenario}(t,i) \end{pmatrix} \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right)$$ [EQ107]

ΔGHG from deforestation due to leakage:

$$❷ = \sum_{i=1}^{nrFNFtransitions} \sum_{tt=1}^{t} u_{classification} \cdot u_{transition}(i) \cdot \begin{pmatrix} +\Delta area_{leakageArea,projectScenario}(t,i) \\ -\Delta area_{leakageArea,baselineScenario}(t,i) \end{pmatrix} \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right)$$ [EQ108]

ΔGHG from avoided degradation:

$$❸ = \sum_{i=1}^{nrStrataTransitions} \sum_{tt=1}^{t} u_{stratification} \cdot u_{transition}(i) \cdot \begin{pmatrix} +\Delta area_{projectAreaEAH,projectScenario}(t,i) \\ -\Delta area_{projectAreaEAH,baselineScenario}(t,i) \end{pmatrix} \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right)$$ [EQ109]

ΔGHG from degradation due to leakage: [EQ110]

$$❹ = \sum_{i=1}^{nrStrataTransitions} \sum_{tt=1}^{t} u_{stratification} \cdot u_{transition}(i) \cdot \begin{pmatrix} +\Delta area_{leakageArea,projectScenario}(t,i) \\ -\Delta area_{leakageArea,baselineScenario}(t,i) \end{pmatrix} \cdot \left(EF_{AGL}(i) + EF_{AGD}(i,t-tt) + EF_{BG}(i,t-tt) + EF_{SOM}(i,t-tt)\right)$$

ΔGHG from leakage by unconstrained geographic drivers:

$$❺ = -GHG_{otherLeakageSources}(t) - GHG_{marketLeakage}(t) \quad \text{[EQ111]}$$

ΔGHG from assisted natural regeneration:

$$❻ = C_{ANR}(t) \quad \text{[EQ112]}$$

ΔGHG from changes in long-lived wood products:

$$❼ = \frac{44}{12} \cdot \left(C_{LWP,project}(t) - C_{LWP,baseline}(t)\right) \quad \text{[EQ113]}$$

ΔGHG from GHG Emissions Reduction from Cookstove and Fuel Efficiency (CFE):

$$❽ = ER_{CFE}(t) \quad \text{[EQ114]}$$

ΔGHG from other and secondary sources:

$$❾ = -GHG_{fireBreaks}(t) - GHG_{sources,leakagePrevention}(t) - GHG_{sources,ANR}(t) \quad \text{[EQ115]}$$

ΔGHG from avoided deforestation and degradation from areas under harvest [EQ116]

In case:

$$\sum_{i}^{t} \Delta C_{areaWithHarvest}(i) \geq \sum_{i=1}^{nrStrata} area_{projectAreaWithHarvest,projectScenario}(t,i) \cdot LTAC_{Harvest}$$

$$❿ = 0$$

In case the inequality above does not hold, (10) must be:

$$❿ = \Delta C_{areaWithHarvest}(t) \quad \text{[EQ117]}$$

Positive leakage is not allowed. Therefore, values for equations [EQ108] and [EQ110] must be set to “0” if they are found to be greater than 0. In order to avoid over compensation for leakage, the leakage from avoided deforestation and forest degradation i.e., [EQ108], [EQ110], and [EQ111] must be set to ‘0’ if GHG emissions from leakage exceed the total GHG emissions reductions from avoided deforestation and/or forest degradation for each crediting period.

Variable	Explanation
$NERs(t)$	Net emission reductions during time t. Section 8.4.4. [tCO_{2e}]
$VCUs(t)$	Verified Carbon Units generated during year t. [tCO_{2e}]

$buffer$	Buffer withholding percentage according to the latest version of the VCSA*FOLU Non-Permanence Risk Tool* analysis and buffer determination. [-]
$nrFNFtransitions$	Number of forest/non-forest transitions among land classes or forest strata, meaning transitions in which either the “from” or the “to” class are non-forests. Section 8.1.2.3
$nrStrataTransitions$	Number of transitions among forest strata. Section 8.1.2.3
$nrStrata$	Number of strata within the ANR area. Section 8.1.2.3
$\Delta area_{projectAreaEAH,projectScenario}(t,i)$	Hectares undergoing transition i within the project area, excluding ANR and harvest areas, under the project scenario during year t. [ha yr^{-1}]. Section 8.2.3
$\Delta area_{projectAreaEAH,baselineScenario}(t,i)$	Hectares undergoing transition i within the project area, excluding the ANR area and harvest areas, under the baseline scenario during year t. [ha yr^{-1}]. Section 8.1.5.4
$C_{ANR}(t)$	Net anthropogenic greenhouse gas removals due to biomass increase in assisted natural regeneration during year t. [tCO_2e]. Section 8.2.5.2.
$\Delta area_{leakageArea,projectScenario}(t,i)$	Hectares undergoing transition i within the leakage area under the project scenario during year t. [ha yr^{-1}]. Section 8.3.2.3
$\Delta area_{leakageArea,baselineScenario}(t,i)$	Hectares undergoing transition i within the leakage area under the baseline scenario during year t. [ha yr^{-1}]. Section 8.1.5.4
$GHG_{otherLeakageSources}(t)$	GHG emissions from leakage by unconstrained geographic drivers during year ***t***. [$tCO_2e\ yr^{-1}$]
$GHG_{marketLeakage}(t)$	GHG emissions from market leakage during time t. [tCO_{2e}].Section 8.3.1.
$EF_{AGL}(i)$, $EF_{AGD}(i,t-tt)$, $EF_{BG}(i,t-tt)$, and $EF_{SOM}(i,t-tt)$	Aboveground live, aboveground dead, belowground, and soil emission factor for transition i, and time after transition $t-tt$. Section 8.1.4.5
CF	Carbon fraction of wood (use 0.5 by default).
$area_{projectAreaWithHarvest,projectScenario}(t$	Size of strata i within the project area with harvest activities during year t under the project scenario.

$u_{stratification}$	Discounting factor for NERs from avoided degradation, based on the accuracy of stratification, i.e. dividing forest into individual forest biomass classes. Section 8.1.2.7
$u_{classification}$	Discounting factor for NERs from avoided deforestation, based on the accuracy of classification, i.e. dividing land into broad land use types. Section 8.1.2.7
$u_{transition}(i)$	Discounting factor for all emission reductions, based on the uncertainty of biomass inventory related to transition i.
$\Delta C_{\text{ANR}}(t)$	Annual change in carbon stock in all selected carbon pools for forest stratum during year t. Section 8.2.5.3 [EQ72]. [$tCO_2e\ yr^{-1}$]
$u_{inventory,ANR}(i)$	Uncertainty discounting factor around biomass stock densities in transition stratum i within ANR areas. $[-]$
$GHG_{sources,projectArea}(t)$	Annual GHG emissions from implementation of fire-preventing actions as REDD project activities. Section 8.2.4. [$tCO_2e\ yr^{-1}$]
$GHG_{sources,leakagePrevention}(t)$	Emissions from sources of methane, nitrous oxide or fuel-CO_2 from leakage prevention activities during year t. Emission sources within the leakage area are included in Table 1. Section 8.3.4. [$tCO_2e\ yr^{-1}$]
$GHG_{sources,ANR}(t)$	Emissions of sources of methane, nitrous oxide or fuel-CO_2 from assisted natural regeneration activities during year t. Section 8.2.5.5. [$tCO_2e\ yr^{-1}$]
$ER_{CFE}(t)$	Emission reductions from reducing biomass use through high efficiency cookstoves and fuel efficiency activities during year t when degradation is not included in general quantification i.e. [EQ78]. [$tCO_2e\ yr^{-1}$]
$C_{LWPbaseline}(t)$	GHG sink in long-lived wood product in baseline scenario at year ***t*** [Mg C]
$C_{LWPProject}(t)$	GHG sink in long-lived wood product in project scenario at year ***t*** [Mg C]
$CreditingPeriod$	Project crediting period. [year]
$C_{harvest}(t,i)$	Carbon stock density in harvested areas in stratum i at year t. [tCO_2 ha-1]
$LTAC_{Harvest}$	Long term average carbon stock density in harvest areas. [tCO_{2e} ha-1]

$u_{inventory,harvest}(i)$	Uncertainty in estimated carbon stock density in harvest areas in stratum i . [-]
$\Delta C_{areaWithHarvest}(i)$	Net greenhouse gas emissions or removals in project area with harvest activities during year t. [tCO_2e]

9 MONITORING

9.1 Data and Parameters Available at Validation

The following data and parameters are defined for standalone projects. For projects that are nested within a jurisdictional REDD+ program, at the time of validation the project will identify any data or parameters in the project document, if any, that will be adopted from the jurisdictional REDD+ program.

Data/parameter [EA1]:	CF
Data unit:	[Mg C (Mg DM)$^{-1}$]
Description:	Carbon fraction of dry matter in wood
Sources of data:	Default value of 0.5 (IPCC GPG-LULUCF 2003)
Measurement procedures:	
Any comment:	

Data/parameter [EA2]:	E
Data unit:	[-]
Description:	Average combustion efficiency of the aboveground tree biomass
Sources of data (*):	The project proponent must use project-specific measurements where available . Where such measurements are not available, the following data sources may be used in the order described below. • Regionally valid estimates from recognized, peer reviewed sources • Estimates from Table 3.A.14 of IPCC GPG LULUCF • If no appropriate combustion efficiency can be used, use the IPCC default of 0.5
Measurement procedures:	
Any comment:	

Data/parameter [EA3]:	P
Data unit:	[-]

Description:	Average proportion of mass burned from the aboveground tree biomass.
Sources of data:	GPG-LULUCF Table 3A.1.13
Measurement procedures:	
Any comment:	

Data/parameter [EA4]:	GWP_{CH4}
Data unit:	[-]
Description:	Global Warming Potential for CH_4
Sources of data:	GWP values shall be derived from sources specified by the VCS rules
Measurement procedures:	
Any comment:	

Data/parameter [EA5]:	ER_{CH4}
Data unit:	Proportion
Description:	Emission ratios for CH_4
Sources of data:	Table 3A.1.15 in IPCC GPG-LULUCF 2003
Measurement procedures:	IPCC default value of 0.012
Any comment:	

Data/parameter [EA6]:	sc_1
Data unit:	[-]
Description:	First shape factor for the forest scarcity equation; steepness of the decrease in deforestation rate (greater is steeper).
Sources of data:	Statistical fitting procedure. Using remotely sensed forest cover data in heavily deforested areas close to the project area such as neighboring provinces, states or countries
Measurement procedures:	Use procedure from Section 8.1.5.4
Any comment:	

Data/parameter [EA7]:	sc_2
Data unit:	[-]
Description:	Second shape factor for the forest scarcity equation; relative deforested area at which the deforestation rate will be 50% of the initial deforestation rate.

Sources of data:	Statistical fitting procedure. Using remotely sensed forest cover data in heavily deforested areas close to the project area such as neighboring provinces, states or countries
Measurement procedures:	Use procedure from Section 8.1.5.4
Any comment:	

Data/parameter [EA8]:	$wwf(ty)$
Data unit:	[-]
Description:	Fraction of carbon in harvested wood products that are emitted immediately because of mill inefficiency for wood class ty. This can be estimated by multiplying the applicable fraction to the total amount of carbon in different harvested wood product category.
Sources of data:	The default applicable fraction is 24% and 19% respectively for developing and developed countries (Winjum et al. 1998).
Measurement procedures:	
Any comment:	Any new updates from locally generated results can be used instead of the default values.

Data/parameter [EA9]:	$slp(ty)$
Data unit:	[-]
Description:	Proportion of short lived products
Sources of data:	Default values are 0.2, 0.1, 0.4 and 0.3 respectively for wood class ty, i.e., sawnwood, wood-based panel, paper and paper boards and other industrial round woods as described in Winjum et al. (1998).
Measurement procedures:	
Any comment:	Any new updates from locally generated results can be used instead of the default values. The methodology assumes that all other classes of wood products are emitted within 5 years.

Data/parameter [EA10]:	$fo(ty)$
Data unit:	[-]
Description:	Fraction of carbon that will be emitted to the atmosphere between 5 and 100 years of harvest for wood class ty.
Sources of data:	See Table 19 Winjum et al. 1998)
Measurement procedures:	
Any comment:	Any new updates from locally generated results can be used instead

	of the default values.

Data/parameter [EA11]:	$\rho_{wood,j}$
Data unit:	[Mg DM m^{-3}]
Description:	Average basic wood density of species or species group j
Sources of data:	GPG-LULUCF Table 3A.1.9. or published data/literature.
Measurement procedures:	
Any comment:	When no species-specific or species-group specific densities are available, an average representative density may be used for all species or species groups.

Data/parameter [EA12]:	BEF_2
Data unit:	[-]
Description:	Biomass expansion factor for converting volumes of extracted round wood to total aboveground biomass (including bark).
Sources of data:	IPCC GPG LULUCF Table 3A.1.10 or published data from scientific peer reviewed literature
Measurement procedures:	
Any comment:	

Data/parameter [EA13]:	$EF_{rice,max}$
Data unit:	[kg CH_4 ha^{-1} day^{-1}]
Description:	Maximal emission factor for methane
Sources of data:	By default, an emission rate of 36 kg CH_4 ha^{-1} day^{-1} must be used, which is 25% greater than the maximal value found in a review study comparing 23 studies of CH4 fluxes in rice fields (Le Mer and Roger, 2001). The project proponent may use a smaller emission rate if it can be demonstrated from empirical data or other supporting information such as published data that the rate remains conservative for the project conditions.
Measurement procedures:	
Any comment:	Only to be included if rice production is increased as a leakage prevention measure.

Data/parameter [EA14]:	$NCV_{biomass}$
Data unit:	[TJ (Mg DM) $^{-1}$]
Description:	Net calorific value of non-renewable biomass that is substituted.

Sources of data:	0.015 TJ (Mg DM) $^{-1}$ IPCC default value.
Measurement procedures:	
Any comment:	

9.2 Data and Parameters Monitored

Where multiple sources of data are provided, the project proponent must use the higher-ranked data sources where available.

9.2.1 Sizes, areas, and transitions

Data/parameter [MN1]:	$size_{projectArea}$, $size_{leakageArea}$. $size_{referenceregion}$, $size_{referenceForest}$
Data unit:	[ha]
Description:	Size of project area, leakage area, reference region, and forest area in the reference region
Sources of data:	Project design
Measurement procedures:	
Frequency of monitoring:	$size_{projectArea}$ and $size_{leakageArea}$ may be adjusted during crediting period per the rules for grouped projects and updated at verification, but only for the additional instances that were added after the project start date..
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN2]:	$\Delta area_{projectAreaEAH,projectScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the project area, excluding ANR and harvest areas, under the project scenario during year t. [ha yr^{-1}]. Section 8.2.3
Sources of data:	Remote sensing analysis
Measurement procedures:	Follow the procedures described in Section 8.2.3
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN3]:	$\Delta area_{projectAreaEAH,baselineScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the project area, excluding the ANR area, and harvest areas, under the baseline scenario for year t.
Sources of data:	Land-use change modeling
Measurement procedures:	Follow the procedures described in Section 8.1.5.4
Frequency of monitoring:	At least once before every baseline. For added instances, may be recalculated at verification.
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN4]:	$\Delta area_{projectAreaWithANR,baselineScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the leakage area under the project scenario for year t.
Sources of data:	Land-use change modeling
Measurement procedures:	Follow the procedures described in Section 8.1.5.4
Frequency of monitoring:	At least once before every baseline update. For added instances, may be recalculated at verification.
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN5]:	$\Delta area_{leakageArea,projectScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the leakage area under the project scenario for year t
Sources of data:	Remote sensing analysis
Measurement procedures:	Follow the procedures described in Section 8.1.2.4. In case emissions reductions/removals from avoided degradation are included, this parameter will provide the data required to calculate the activity data to estimate the emissions from both deforestation and forest degradation.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be	

applied:	
Any comment:	

Data/parameter [MN6]:	$\Delta area_{leakageArea,baselineScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the leakage area under the baseline scenario during year t
Sources of data:	Land-use change modeling
Measurement procedures:	Follow the procedures described in Section 8.1.5.4
Frequency of monitoring:	Once every baseline update. May also be updated at the time of instance inclusion that requires new leakage area.
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN7]:	$\Delta area_{historical}(CS_1 \rightarrow CS_2, t_1 \rightarrow t_2)$
Data unit:	[ha yr^{-1}]
Description:	Area of transition from LULC class or forest stratum 1 to 2 from time 1 to 2 during the historical reference period
Sources of data:	Remote sensing analysis
Measurement procedures:	Calculate based on the remote sensing-based classification and stratification procedures detailed in Section 8.1.2
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN8]:	$RFRGrate(CS_1 \rightarrow CS_2)$
Data unit:	[yr^{-1}]
Description:	Relative annual forest cover increase and regeneration factor for the transition from class or stratum 1 to 2.
Sources of data:	Remote sensing analysis
Measurement procedures:	Calculate based on the remote sensing-based classification and stratification procedures detailed in Section 8.1.2. Multiply with 100 to obtain a forest cover increase and regeneration rate in percentage per year.
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	

Any comment:	It can be used for producing baseline transition matrix for new instances to be added into the project area.

Data/parameter [MN9]:	$area_{historical}(CS_1, t_1)$
Data unit:	[ha]
Description:	Total area of LULC class or forest stratum 1 at time 1
Sources of data:	Remote sensing analysis
Measurement procedures:	Calculate based on the remote sensing-based classification and stratification procedures detailed in Section 8.1.2
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN10]:	$area_{biomassLoss}(i)$
Data unit:	[ha yr^{-1}]
Description:	Total annual area of LULC class i that was cleared for creating firebreaks
Sources of data:	Records of implemented activities or management plan
Measurement procedures:	
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN11]:	$area_{fireBiomassLoss}(i)$
Data unit:	[ha yr^{-1}]
Description:	Annual area of forest stratum i that was cleared by using prescribed burning
Sources of data:	Records of implemented activities or management plan
Measurement procedures:	
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN12]:	$area_{fireBiomassLoss,ANR}(t, i)$

Data unit:	[ha]
Description:	Area of biomass removed by prescribed burning within ANR stratum i during year t
Sources of data:	Records of implemented activities
Measurement procedures:	Only to be included if ANR activities are implemented.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN13]:	$area_{projectAreaWithANR,projectScenario}(t,i)$
Data unit:	[ha]
Description:	Amount of land on which ANR activities are planned under the project scenario for year t and in stratum i
Sources of data:	Records of implemented activities
Measurement procedures:	Only to be included if ANR activities are implemented.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN14]:	$area_{harvest}(t,i)$
Data unit:	[ha]
Description:	Area of forest in harvest stratum i that is harvested at time t.
Sources of data:	Project Description or Forest/Harvest Management Plan
Measurement procedures:	
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN15]:	$area_{projectAreaWithHarvest,projectScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Size of strata i within the project area with harvest activities during year t under the project scenario.
Sources of data:	Remote sensing analysis

Measurement procedures:	Follow the procedures described in Section 8.1.5.4
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN16]:	$\Delta area_{projectAreaWithHarvest,baselineScenario}(t,i)$
Data unit:	[ha yr^{-1}]
Description:	Hectares undergoing transition i within the harvest areas under under the baseline scenario during year t.
Sources of data:	Land-use change modeling
Measurement procedures:	Follow the procedures described in Section 8.1.5.4
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN17]:	$BetaReg_{DF}(t)$and $BetaReg_{DG}(t)$
Data unit:	[ha yr^{-1}]
Description:	Beta regression model describing the relationship between time and deforestation/degradation rate in the reference region during the historical reference period.
Sources of data:	Historic forest degradation and deforestation modeling
Measurement procedures:	Procedure described in Section 8.1.5.1 or similar approach from peer-reviewed scientific literature.
Frequency of monitoring:	At least once every baseline update
QA/QC procedures to be applied:	
Any comment:	

9.2.2 Locations, Descriptions, Qualitative, and Social Data

Data/parameter [MN18]:	Area under agricultural intensification
Data unit:	[ha]
Description:	Size of the area of agricultural intensification separated for each agricultural intensification measure
Sources of data:	Participatory rural appraisals
Measurement procedures:	Calculate based on areas of cropland in the leakage and project areas

	Only to be included if agricultural intensification activities are implemented.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN19]:	Yields under agricultural intensification
Data unit:	[Mg ha^{-1}]
Description:	Harvested yield for agricultural intensification practices
Sources of data:	Participatory rural appraisals
Measurement procedures:	Only to be included if agricultural intensification activities are implemented.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

9.2.3 Data on Drivers and Actions

Data/parameter [MN20]:	$CFW_{baseline}$
Data unit:	[m^3 yr^{-1}]
Description:	Annual volume of fuelwood gathering for commercial sale and charcoal production in the baseline scenario
Sources of data (*):	1. Participatory rural appraisals 2. Recent (<10 yr) literature in the reference region 3. Recent (<10 yr) literature in an area similar to the reference region
Measurement procedures:	If emission reductions from avoided degradation were excluded due to insufficient accuracy, in which case $u_{classification} = 0$, and emission reductions from fuel-efficient woodstoves are included, $CFW_{baseline}$ may only be measured using the first option, social assessments.
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN21]:	$DFW_{baseline}$

Data unit:	[m^3 yr^{-1}]
Description:	Annual volume of fuelwood gathered for domestic and local energy in the baseline scenario
Sources of data (*):	• Participatory rural appraisals • Recent (<10 yr) literature in the reference region • Recent (<10 yr) literature in an area similar to the reference region
Measurement procedures:	If emission reductions from avoided degradation were excluded due to insufficient accuracy, in which case $u_{classification} = 0$, and emission reductions from fuel-efficient woodstoves are included, $DFW_{baseline}$ may only be measured using the first option, social assessments.
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN22]:	$DFW_{project}$
Data unit:	[m^3 yr^{-1}]
Description:	Biomass (dry matter) of fuelwood collected by project participants under the project scenario.
Sources of data (*):	1. Participatory rural appraisals 2. Recent (<10 yr) literature in the reference region 3. Recent (<10 yr) literature in an area similar to the reference region
Measurement procedures:	If emission reductions from avoided degradation were excluded due to insufficient accuracy, in which case $u_{classification} = 0$, and emission reductions from fuel-efficient woodstoves are included, $DW_{baseline}$ may only be measured using the first option, social assessments.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN23]:	$DFW_{allowed}$
Data unit:	[m^3 yr^{-1}]
Description:	Biomass (dry matter) of allowed fuelwood collection in the project area under the project scenario. This amount is typically fixed in a management plan. [m3 yr-1]
Sources of data (*):	Forest management plan

Measurement procedures:	
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN24]:	$VG_{baseline}$
Data unit:	[m^3 yr^{-1}]
Description:	Biomass (dry matter) of understory vegetation extraction by project participants under the baseline scenario. [Mg DM yr-1]
Sources of data (*):	1. Participatory rural appraisals 2. Recent (<10 yr) literature in the reference region 3. Recent (<10 yr) literature in an area similar to the reference region
Measurement procedures:	Calculate by multiplying the number of households involved in extraction of vegetation with the average annual extraction rate by household for different vegetation types
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN25]:	$VG_{project}$
Data unit:	[Mg DM yr-1]
Description:	Biomass (dry matter) of understory vegetation extraction by project participants under the project scenario.
Sources of data (*):	1. Participatory rural appraisals 2. Recent (<10 yr) literature in the reference region 3. Recent (<10 yr) literature in an area similar to the reference region
Measurement procedures:	Calculate by multiplying the number of households involved in extraction of vegetation with the average annual extraction rate by household for different vegetation types
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN26]:	$VG_{allowed}$
Data unit:	[Mg DM yr-1]
Description:	Biomass (dry matter) of allowed as understory vegetation extraction under the project scenario. This amount is typically fixed in a management plan
Sources of data (*):	Forest management plan
Measurement procedures:	
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN27]:	$CT_{baseline}(h, j, ty, t)$
Data unit:	[m^3 yr^{-1}]
Description:	Annually extracted volume of harvested timber round-wood for commercial on-sale under the baseline scenario during harvest h by species j and wood product class ty during year t
Sources of data (*):	1. Participatory rural appraisals conducted by the project proponent. 2. Recent (<10 yr) literature in the reference region 3. Recent (<10 yr) literature in an area similar to the reference region 4. Recent (<10 yr) non peer-reviewed reports by local organizations
Measurement procedures:	
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN28]:	$CT_{allowed}$
Data unit:	[m^3 yr^{-1}]
Description:	Annually allowed volume of harvested timber round-wood for commercial on-sale under the project scenario
Sources of data (*):	Project document and/or management plan
Measurement procedures:	
Frequency of monitoring:	At least once before every baseline update

QA/QC procedures to be applied:	

Data/parameter [MN33]:	$contribution_{DF}(d)$ and $contribution_{DG}(d)$
Data unit:	[-]
Description:	Relative contribution of driver i respectively to total deforestation and forest degradation.
Sources of data:	Calculated using procedure described in 8.1.3.
Measurement procedures:	
Frequency of monitoring:	At least once before baseline update.
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN34]:	$RelativeDriverImpact_{DF}(t, d)$ and $RelativeDriverImpact_{DG}(t, d)$
Data unit:	[-]
Description:	Relative impact of the geographically unconstrained driver d at time t of the crediting period respectively on deforestation and forest degradation.
Sources of data:	Calculated using procedure described in 8.2.2.
Measurement procedures:	
Frequency of monitoring:	At least once before baseline update.

QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN35]:	$leakage_{unconstrained}(d)$
Data unit:	[-]
Description:	Leakage cancellation rate for avoiding deforestation/degradation from geographically unconstrained drivers.
Sources of data:	Valid sources to substantiate a smaller leakage rate include social assessments, scientific literature, and reports from civil society or governments. Sources have to be reliable and based on scientific methods and a good statistical design.
Measurement procedures:	
Frequency of monitoring:	At least once before baseline update.
QA/QC procedures to be applied:	
Any comment:	Unless a lower rate can be justified, a default rate of 100% must be used.

Data/parameter [MN36]:	$effectiveness(a, d)$
Data unit:	[-]
Description:	Effectiveness of every project activity a in decreasing any driver of deforestation d relative to that driver's contribution to deforestation and forest degradation,
Sources of data:	Relevant academic literature or documented expert opinion.
Measurement procedures:	
Frequency of monitoring:	At least once before baseline update.
QA/QC procedures to be applied:	
Any comment:	The $effectiveness(a, d)$ factor represents the maximal effectiveness during the crediting period.

Data/parameter [MN37]:	$\Delta A_{rice}(t)$
Data unit:	[ha]
Description:	Annual increase in harvested area of rice due to leakage prevention measures.
Sources of data:	Project design decision
Measurement procedures:	Only to be included if rice production is increased as a leakage prevention measure.

Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN38]:	$t_{flooded,max}$
Data unit:	[days yr^{-1}]
Description:	Maximal period of time a field is flooded
Sources of data:	Participatory rural appraisals or expert opinion
Measurement procedures:	Only to be included if rice production is increased as a leakage prevention measure.
Frequency of monitoring:	At least once before baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN39]:	$GR_{baseline}$
Data unit:	[-]
Description:	Number of grazing animals of type g within the project boundary baseline
Sources of data:	1. Local agricultural records 2. Social assessments conducted by the project proponent
Measurement procedures:	Calculate by multiplying the number of animals taking into account different types of grazing animals.
Frequency of monitoring:	At least once before baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN40]:	$GR_{allowed}$
Data unit:	[-]
Description:	Number of grazing animals of type g allowed for grazing within the project boundary in the project scenario

Any comment:	

Data/parameter [MN41]:	$Fuelwood(t)$, $Fuel(t)$
Data unit:	$[m^3\ yr^{-1}\ HH^{-1}]$
Description:	Average annual volume of biomass fuel consumed by households in the absence of the project activity in year t for cooking purpose.
Sources of data:	Social assessments results or wood energy statistics applicable to the project
Measurement procedures:	
Frequency of monitoring:	At least once every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN42]:	$HH_{non-CFE}(t)$
Data unit:	[-]
Description:	Total number of household in the project area that collect biomass fuel from the project area and do not use CFE in year t.
Sources of data:	Social assessments results or wood energy statistics applicable to the project
Measurement procedures:	*Ex-post,* this value must be obtained from socio-economic survey.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN43]:	η_{old}
Data unit:	[-]
Description:	Efficiency of the project cookstoves or appliances.
Sources of data:	Default value of 0.10 for three stone stove or conventional stove that lacks improved combustion air supply mechanism and flue gas ventilation systems i.e., without a grate as well as a chimney; for rest of the systems 0.2 default value may be used.
Measurement procedures:	Measured using representative sampling method or based on referenced literature values. Use weighted average values if more than one type of systems are used. If measured, the procedure must comply with the Water Boiling Test (WBT) based on VITA 1985 - the 'International Standards'.
Frequency of monitoring:	At least once every baseline update
QA/QC procedures to be	

applied:	
Any comment:	

Data/parameter [MN44]:	η_{new}
Data unit:	[-]
Description:	Efficiency of the baseline cookstoves or appliances.
Sources of data:	1. Values obtained from the manufacturer of the stove. 2. Calculated from field testing using ISO standards.
Measurement procedures:	Measured using representative sampling method or based on referenced literature values. Use weighted average values if more than one type of systems is used.
Frequency of monitoring:	• If the stoves used are manufactured by a recognized company that is still in business and provides a warranty for the stoves stated life, then the monitoring must be done during every baseline update. • If the manufacturer does not provide any warranty or the manufacturer of the stove is no longer in the business, then the efficiency must be monitored annually using the water boiling test (WBT) protocol carried out in accordance with national standards (if available) or international standards or guidelines as specified in the latest version of Approved CDM Methodology – AMS.II.G. *Energy efficiency measures in thermal applicants of non-renewable biomass*. Biennial monitoring (i.e. monitoring once every two years) may be chosen, if the project proponent are able to demonstrate that the efficiency of the cookstove does not drop significantly as compared to the initial efficiency of the new device, over a time period of two years of typical usage. • Finally, if the conservativeness of the used efficiency can be demonstrated, the monitoring frequency can be once every baseline update. Demonstration of the conservativeness must be based on historical efficiency data for the type of stoves showing how efficiency declines from the initial efficiency level through the life of the stoves and the lowest efficiency value must be used for that type of stove.
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN45]:	$U_{CFE}(t)$
Data unit:	[-]
Description:	Fraction of cumulative usage rate for technologies in project scenario in year t.

	[-]
Sources of data:	Social assessments or wood energy statistics applicable to the project
Measurement procedures:	Cumulative adoption rate and drop off rate revealed by usage surveys [-].
Frequency of monitoring:	Annual
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN46]:	$DF_{LeakageCFE}(t)$
Data unit:	[-]
Description:	Leakage discount factor applicable to GHG emissions reduction benefits from CFE activities [-]
Sources of data:	1. Social assessments or wood energy statistics applicable to the project. 2. Default value of 0.95 following AMS.II.G CDM methodology.
Measurement procedures:	Leakage related to the non-renewable biomass saved by the project activity must be assessed based on surveys of users and the areas from which woody biomass saved under the project by non-project households that previously used renewable energy or efficient appliances must be considered. If this leakage assessment quantifies an increase in the use of non-renewable biomass, that is attributable to the project activity, then biomass used in the baseline must be adjusted by a factor ($DF_{LeakageCFE}$) to account for the leakage.
Frequency of monitoring:	Annual
QA/QC procedures to be applied:	
Any comment:	If the default value of 0.95 is used, no survey is required.

Data/parameter [MN47]:	$EF_{non-CO2,fuel}$, $EF_{CO2,fuel}$
Data unit:	[t CO_2 TJ^{-1}]
Description:	Respectively, non--CO2 emission factor of the fuel that is reduced and CO2 emission factor for the substitution of non-renewable biomass by similar consumers.
Sources of data:	Social assessments or wood energy statistics applicable to the project
Measurement procedures:	Emission factor can include a combination of emission factors from fuel production, transport, and use. Both CO_2 and Non-CO2 of the fuel such as emissions factors for charcoal can be estimated from project specific monitoring or alternatively by researching a conservative wood to charcoal production ratio (from IPCC, credible

	published literature, project-relevant measurement reports, or project-specific monitoring) and multiplying this value by the pertinent emission factor of wood.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN48]:	EF_{forest}
Data unit:	[t CO_2e]
Description:	Emission factor related to leakage.
Sources of data:	1. If comprehensive national-level statistics on biomass densities are available, EF_{forest} must be calculated based on the average biomass of the country. 2. If local data is not available. Sources of the data allowed are (1) academic research papers and (2) studies and reports published by the forestry administration or other organizations, including the FAO's Forest Resource Assessment reports, (3) the upper range of biomass in the GPG-LULUCF (2003) Table 3A.1.2.
Measurement procedures:	
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

9.2.4 Data on Organic Matter and Carbon Densities

Data/parameter [MN49]:	$OM_o(i)$
Data unit:	[Mg DM ha-1]
Description:	Plant-derived organic matter of LULC class or forest stratum i in pool o. [Mg DM ha-1]
Sources of data:	Field measurements using sampling plots in forest strata or LULC classes.
Measurement procedures:	The average biomass stock density in applicable organic matter pools: aboveground tree - $OM_{AGT}(i)$, aboveground non-tree - $OM_{AGNT}(i)$, lying dead wood - $OM_{LDW}(i)$, standing dead wood $OM_{SDW}(i)$, belowground $OM_{BG}(i)$, and soil organic matter $OM_{SOM}(i)$
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be	Follow uncertainty deduction procedures described in methodology.

applied:	Re-measure plots by independent teams.
Any comment:	Summed across multiple pools and divided into $OM_{plant}(i)$ and $OM_{soil}(i)$

Data/parameter [MN50]:	$proportion_{DF}(d)$ and $proportion_{DG}(\mathrm{d})$
Data unit:	[-]
Description:	Proportion of the gradual carbon loss that leads to deforestation or forest degradation, respectively, due to driver d
Sources of data:	Estimate using the procedure detailed in Table 9.
Measurement procedures:	
Frequency of monitoring:	At least once before every baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN51]:	$C(t,i)$
Data unit:	[Mg C ha^{-1} yr^{-1}]
Description:	Carbon stock density at time □ in stratum □.
Sources of data:	Estimate within the biomass inventory plots
Measurement procedures:	
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	Used in estimating change in carbon stock density such as in ANR areas.

Data/parameter [MN52]:	$f_{allometric}(y)$
Data unit:	Equation
Description:	Allometric relationship to convert a tree metric such as DBH or tree height into biomass
Sources of data (*):	1. Allometric equations developed by the project proponent 2. Allometric equations developed locally by groups other than the project proponent **3.** Allometric equations developed for forest types that are similar to the ones in the project as found in found in Tables 4.A.1. and 4.A.2. of the GPG LULUCF
Measurement procedures:	

Frequency of monitoring:	May be updated at baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN53]:	$f_{belowground}(y)$
Data unit:	Equation
Description:	Relationship between aboveground and belowground biomass, such as a root-to-shoot ratio
Sources of data (*):	1. A relationship calculated from destructive sampling data obtained within the project area 2. A relationship obtained from the local/national studies that closely reflect the conditions of the project activity 3. Standard root-to-shoot ratios as found in Table 4.4 of the IPCC GPG-LULUCF 2003
Measurement procedures:	
Frequency of monitoring:	May be updated at baseline update
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN54]:	$C_{Harvest}(t,i)$
Data unit:	Mg C ha-1
Description:	Biomass carbon stock density at time t in stratum i in harvested areas.
Sources of data:	Field inventory
Measurement procedures:	Generic procedure is described in Section 8.1.4.4. Estimate must be made from plots located areas where harvesting takes place.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	Carbon stocks in harvested strata must come from sampling. It may be necessary to include additional plots in harvested strata for a precise estimation of carbon stocks. The exact measurement of aboveground and below tree carbon must follow international standards and follow IPCC GPG LULUCF 2003. These measurements are explained in detail in CDM approved methodology AR-AM0002 *Restoration of degraded lands through afforestation/reforestation*.

Data/parameter [MN55]:	$CE_{inventory,harvest(t,i)}$
Data unit:	[-]
Description:	Combined error in estimate of average biomass stock density in harvest areas in stratum i at time t.
Sources of data (*):	Field inventory
Measurement procedures:	Generic procedure is described in Section 8.1.4.4. Estimate must be made from plot located in areas where harvesting takes place.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	Uncertainty estimate in carbon stocks in harvested strata must come from sampling of plots in harvested areas.

Data/parameter [MN56]:	$CE_{inventory,ANR(t,i)}$
Data unit:	[-]
Description:	Combined error in estimate of average biomass stock density in ANR areas in stratum i at time t.
Sources of data (*):	Field inventory
Measurement procedures:	Procedure is described in Section 8.2.5.3.
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	Uncertainty estimate in carbon stocks in harvested strata must come from sampling of plots in ANR areas.

Data/parameter [MN57]:	$u_{classification}$
Data unit:	[-]
Description:	Discounting factor for NERs from avoided deforestation, based on the accuracy of classification, i.e. dividing land into broad land use types.
Sources of data:	
Measurement procedures:	Section 8.1.2.7
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN58]:	$u_{stratification}$
Data unit:	[-]

Description:	Discounting factor for NERs from avoided degradation, based on the accuracy of stratification, i.e. dividing forest into individual forest biomass classes. Section 8.1.2.7
Sources of data:	
Measurement procedures:	Section 8.1.2.7
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

Data/parameter [MN59]:	$u_{transition}(i)$
Data unit:	[-]
Description:	Discounting factor for the emission factor for the transition from LULC class or forest stratum 1 to class 2 according to the uncertainty of the biomass inventory.
Sources of data:	
Measurement procedures:	Section 8.1.2.4.3
Frequency of monitoring:	At least once before verification
QA/QC procedures to be applied:	
Any comment:	

9.3 Description of the Monitoring Procedures

This methodology requires the following monitoring components for calculating actual NERs:

- Monitoring of drivers of deforestation, project activities and emission sources related to REDD project activities inside and outside of the project area.
- Monitoring LULC class and forest strata transitions in the project area, leakage area, and reference region using remote-sensing technologies, and validated with ground-truthing data.
- Monitoring carbon stock densities in LULC classes and forest strata.
- Monitoring carbon stock increases in the area on which ANR are performed.
- Monitoring of carbon stock in long-lived wood products.
- Monitoring of natural disturbances.
- Monitoring of cookstoves and fuel efficiency activities.
- Monitoring of harvesting activities.

A monitoring report is produced which contains all of the information above, and which outlines the calculations for actual NERs generated. At each monitoring event, the project proponent must confirm that there are GHG projects in the project area and a formal statement to that effect must be included in the monitoring report.

Given that any natural disturbance is fully accounted as part of the on-going monitoring during the crediting period, any loss of biomass during the credited period must also accounted for and reported in the monitoring report regardless of the cause of the loss. However, where an event that qualifies as a loss event occurs and VCUs have previously been issued, project proponent must follow the applicable VCS rules.

The project proponent must follow the requirements below for monitoring project activities.

9.3.1 Calculation of *Ex-post* Actual Net GHG Emission Reductions

A monitoring report must contain the *ex-post* values of the actual net GHG emission reductions. Actual net NERs must be based on Equation [EQ105]; actual VCUs must be based on Equation [EQ106].

9.3.2 Calculation of *Ex-post* GHG Emissions and Changes in Sinks Under the Project Scenario Inside the Project Area

The changes in carbon sinks under the project scenario in the project area must be calculated based on remote sensing change analysis and field measurements. Carbon stock densities must be re-measured at least once before every baseline update using ground-based biomass inventories, as described in Section 8.1.4.4. However, carbon stock densities may be measured more frequently. For the calculation of the NERs, the most recent values of the carbon stock densities must be used. Therefore, if new carbon stock densities are available, values for the emission factors must be updated and the new values must be reported in the monitoring report based on the procedure in Section 8.1.4.

- Acquire (a) remote sensing image(s) between validation or the last verification and the current date, and use the same procedure as used for the baseline to produce (a) land use, land cover, and forest cover map(s). As explained in Section 8.1.2.5, if any part of the project area is covered in clouds or cloud shadows, its GHG accounting should be postponed on that portion of the project area in this monitoring period until cloud-free imagery in this portion of the project area is available. The postponed NERs may be added to the NERs generated in the subsequent monitoring period. Note that if a different remote sensing data source is used than for the historical baseline analysis, the provisions in Section 9.3.9 must be followed.

- Execute an image classification on the acquired image according to the procedures in Section 8.1.2.4. If emissions reductions/removals from avoided degradation are included, apply exactly the same stratification model as the one used for validation. Perform an accuracy assessment of the LULC classification as described in Section 8.1.2.4 using data from field sampling and independent remote sensing data. Ensure that the accuracy of the LULC classification is equal or greater to the average accuracy achieved for the historical remote sensing. The same $u_{classification}$ used for ex-ante calculations must be used ex-post until the next baseline update. When additional biomass plots were measured, update $u_{stratification}(i)$, all relevant emission factors as well as $u_{transition}(CS1 \rightarrow CS2)$.

- Compare the changes in between consecutive map(s) since the last time the project was verified and until the current map of land use, land cover, and forest cover. For the project area where no ANR or harvesting activities were performed, produce (a) land transition matrix/matrices between the consecutive map(s) since the last verification.

- Annualize the land transition matrix/matrices by dividing the land transition rates by the duration in between the two states represented by the maps. The annual rates of land transition changes for the project area on which no ANR activities are planned is $\Delta area_{projectAreaEAH,projectScenario}(t,i)$.

- For the ANR and harvesting areas, in which increases in forest biomass are quantified using biomass inventories, follow the procedures in Sections 8.2.5 and 8.2.7, respectively.

- The project proponent may choose to increase the number of sampling plots during the crediting period or replace previous plots when the biomass plots are located on land that has been deforested or lost through some other cause.

9.3.3 Calculation of *Ex-post* GHG Emissions and Changes in Sinks Under the Project Scenario

Outside the Project Area (Leakage)

Similar to Section 8.3.1, a distinction is made between the calculation of leakage from geographically constrained drivers and leakage from geographically unconstrained drivers. See Section 8.3.1 for a distinction between these two categories.

9.3.3.1 Calculation of Ex-post Leakage from Geographically Constrained Drivers

The land-use and land cover changes[19] in the leakage belts and leakage area must be calculated using exactly the same remote sensing change analysis as for the project area:

- Acquire (a) remote sensing image(s) between validation or the last verification and the current date, and use a similar procedure as used for the baseline to produce (a) land use, land cover, and forest cover map(s) in the leakage belts.

---

19 These land-use and land cover (LULC) changes do not only include deforestation and forest degradation, but also LULC changes on non-forest land such as the conversion of woodlands to grasslands due to fuelwood collection.

- Compare the changes in between consecutive map(s) since the last time the project was verified and until the current map of land use, land cover, and forest cover. Produce (a) land transition matrix/matrices between the consecutive map(s) since the last verification for the leakage area.
- Annualize the land transition matrix/matrices by dividing the land transition rates by the duration in between the two states represented by the maps. The annual rates of land transition changes for the leakage area is $\Delta area_{leakageArea,projectScenario}(t,i)$.

However, in case the project proponent can justify in the monitoring report that observed change in deforestation and/or forest degradation in the leakage area compared to deforestation and/forest degradation in baseline in the leakage area is not caused by project activities, but rather through some external factor, the project proponent are allowed to adjust the baseline rate of deforestation and forest degradation within the leakage area as explained in this paragraph. This justification may include the case when in the monitoring period the deforestation and/or forest degradation rate in the reference region is higher than the monitored rate of deforestation and forest degradation within the leakage area. Under this case, the project proponent may adjust the baseline rate of deforestation and/forest degradation rate in the leakage area before calculating the geographically constrained leakage. The rate of deforestation and/or forest degradation within the leakage area under the baseline is adjusted by first estimating the rate of deforestation and/or forest degradation in the reference region through remote sensing, and then using this rate as the total rate of deforestation (and/or forest degradation) in estimating the adjusted baseline rate of deforestation and forest degradation for the monitoring period within the leakage areas following the procedures described in Section 8.1.5.4. All other variables and inputs to the procedure in Section 8.1.5.4 must remain the same as the values used at validation or last baseline update.

Once the project proponent elects to adjust the baseline rate of deforestation and/or forest degradation in the leakage area, the project proponent must continue to demonstrate that the adjusted rate is valid for the next monitoring period, or readjust the baseline rate of deforestation and/or forest degradation in leakage areas relevant to that monitoring period until the next baseline update.

9.3.3.2 Calculation of Ex-post Leakage from Geographically Unconstrained Drivers

Activity-shifting leakage from geographically unconstrained drivers must be quantified *ex-post* using a factor approach in which the leakage cancellation factors, set at validation following the procedure in Section 8.3.3, are used.

9.3.3.3 Calculation of Ex-post Emission Sources from Leakage Prevention Activities

Actual emissions from sources from leakage prevention activities, $GHG_{sources,leakagePrevention}(t)$, must be calculated using the equations in Section 8.3.4, but with monitored data.

9.3.4 Monitoring of CFE Activities

Any CFE appliances that have been brought from outside the project boundary does not qualify for emission removals/reductions as this can cause potential leakage. Similarly, non-operational appliances must be excluded. If the baseline appliances still continue to operate on the top of project cookstoves (i.e. CFE appliances are secondary), the project proponent must ensure that the fuelwood consumption of those stoves is excluded from the estimation of baseline emissions.

The GHG emissions reductions benefits from CFE activities must also be excluded once the project site is no longer threatened by the fuel-wood collection activities. This can happen either as a result of effective implementation of the REDD projects or as a result of reduced household energy needs. The following are indicators of such shifts and must be monitored periodically.

- Trend showing decrease in the time spent or distance travelled by users (or drivers of deforestation and degradation or fuel-wood suppliers) for gathering fuelwood.
- Survey results, national or local statistics, studies, maps or other sources of information such as remote sensing data that show that carbon stock are not depleting in the project area and leakage belt i.e. when fraction of non-renewable biomass (f_{NRB}) is 0.
- Decreasing trend in fuel-wood price indicating abundance of fuelwood.

9.3.5 Monitoring of Long-Term Average Carbon Stock in Harvest Areas

- The long term average carbons stock density, i.e., $LTAC_{Harvest}$, in the harvest areas must be updated at least once every verification period and at every baseline update using the most recent forest inventory carried out in the harvest areas. The procedure to estimate $C_{harvest}(i)$ and $u_{inventory\ ,harvest}(i)$ is as described in Section 8.1.4.4 but the estimates are based on only the plots located in harvest areas.
- The project proponent must use the log-book for timber product harvest in the project area. When the actual harvest differs from the estimated harvest by more than 15% then $LTAC_{Harvest}$ must be updated and NERs adjusted accordingly i.e., to safeguard from over issuance of emissions reductions/removals have occurred due to the change in $LTAC_{Harvest}$.
- The harvest plan/description in PD must be updated with any changes in the harvest plan.

9.3.6 Monitoring Grouping of Project Area Parcels

Where new project area parcels are added subsequent to project validation, information on the new project area parcels must be included in the monitoring report as per VCS rules on grouping. In addition, the following conditions must be met and documented in the monitoring report.

The following conditions must be met before a new project area parcel can be added to an existing project:

- If the new project area and leakage area are located entirely within the existing reference region boundary and the size of the total new project area (ie, cumulative since the beginning of the project) is less than half of the size of the reference region, that area can be added to the existing project area without the need to update the reference region and the baseline. However, if a new project area is not inside the existing reference region boundary, or the size of the total new project area is greater than half the size of the reference region, a new reference region must be created. This must only be done when the baseline is updated.
- The new project area must pass the similarity to the reference region test outlined in Table 3. The similarity must be demonstrated for the new project area as a whole and not for each individual parcel.
- Leakage must be re-assessed for all new project instances, including activity-shifting, market leakage and ecological leakage assessments. The boundaries of existing leakage belts can be expanded or new leakage belts can be demarcated around the new project area parcels. The new leakage belts must remain located within the boundary of the reference region. If new project parcels are added within the leakage belts, the boundaries of existing leakage belt must be reassessed.

9.3.7 Monitoring Addition of New Project Activities

Despite the implementation of REDD activities, it is possible that some deforestation may still occur in the project area during the project crediting period. This deforestation can be either a catastrophic or non-catastrophic reversal as defined by the VCS. In case a reversal event occurs within the project area after the start of the crediting period, the project proponent must follow the VCS *AFOLU Requirements* for treatment of areas that suffer losses of forest cover . However, this methodology allows addition of new ANR activities (see 8.2.5) on deforested or degraded forest areas to incentivize good forest management, accelerate forest re-growth, and enable the project proponent to recuperate part of the suffered losses under the following conditions.

Where ANR activities are added in existing project areas after the project is validated, the new ANR activities must be described in the monitoring report and the following requirements must be met and demonstrated in the monitoring report.

- Only areas that were forest at the start of the project but become deforested or degraded after the start of the project are eligible regardless of whether the reversal occurred due to anthropogenic or non-anthropogenic reasons such as a natural disaster.

9.3.8 Update of the Sampling Design of Biomass Inventory Plots

If the project proponent have set-up permanent sampling plots in the project area, it is likely that during the crediting period, permanent forest sampling plots will have to be abandoned due to unforeseen deforestation or natural disasters. Similarly, with continuous increases in forest carbon stocks, additional sample plots must be required to accurately account for forest carbon stocks. In such cases, new permanent sampling plots must be established, or the sampling procedure must be switched to temporary sampling plots and measured following the procedure in this methodology. Ex-post emission reductions/removals must be calculated using the most recent emission factors that are calculated using the most up-to-date set of biomass inventories.

9.3.9 Updates to Baseline Net GHG Removals by Sinks

Once the baseline (calculated *ex-ante*) is validated, it is fixed for ten years and must be re-assessed and updated every ten years. The updated baseline must be validated at the subsequent verification as per VCS *AFOLU Requirements*.

Baseline updates must follow the procedures in Section 8, using updated values for all variables indicated as such in the monitoring table. The following exceptions to the procedures of Section 8 must be followed:

- The baseline must be re-calculated for the entirety of the crediting period, meaning from the start of the crediting period until the end of the crediting period. However, only the *ex-ante* NERs and baseline calculations until the next baseline update will be validated. Note that the re-calculation of previous years is necessary to understand the baseline state in the project area at the time of the baseline update.
- The new historical reference period used for the baseline update extends from the original start date of the historical reference period to the time at which the baseline update event is scheduled. In other words, all intermediate values for deforestation and forest degradation rates from the beginning of the historical reference period until the current time must be included. During the crediting period, the graphs of deforestation and forest degradation rates versus time will contain an increasing number of points.
- In addition, after the start of the crediting period, the reference region must exclude project areas and leakage belts. If after project start, new areas within the reference region become protected, these must be excluded from the updated reference region. Protected areas include:
    - National parks that are effectively protected.
    - Areas under conservation that are effectively protected.
    - Areas under a logging or economic land concession where access is effectively being restricted.
    - Large plantations that are effectively protected.
- Allometric equations used for biomass stock density calculations may be revised during a baseline update.

- The project proponent must use the same remote sensing data sources and analysis procedures as were used for project design or in the previous baseline update. However, if improved (i.e., spectral resolution of minimally 20% higher) data sources and remote sensing data analysis procedures become available to the project participants during the crediting period, or if the sensors used for the previous *ex-ante* baseline calculations become unavailable, changing the procedures previously used is allowed under the following conditions:
- Any change in data sources and analysis procedures must be duly explained and recorded. The Standard Operations Procedure for remote sensing analyses must be updated when a new sensor is used and the baseline is updated.
- Similar spectral bands (e.g., Red, Green, Blue, NIR, SWIR, MIR, etc.) used for classification from the original sensor must be present in the alternative sensor. A formal comparison of the sensors must be added to the baseline update Section within the monitoring report.
- If a new sensor is used and the baseline is not updated, the spectral resolution must be down-sampled to the spectral resolution of the original sensor, so that the same remote sensing procedure used during the baseline calculation can be used. Demonstrate that the classification results of the images from the previous sensor and the new sensor are comparable.
- Full resolution may only be used forward-looking after a baseline update and if sufficient historical images of the higher resolution are available to calculate the baseline, according to the procedures in Table 5. As a consequence, the inclusion of forest degradation based on higher-resolution data may only occur during a baseline update.
- The discounting factors $u_{stratification}$ and $u_{classification}$ must be updated during the baseline update period based on the classification and stratification accuracies for the period until the baseline update.
- The relative forest cover increase and regeneration rates may only be updated using data that is less than 10 years old.
- Summarize all updated baseline land transitions. Update the *ex-ante* NERs using the updated baseline estimates, and present an updated version of the overview table in the monitoring report.

Similarly, all requirements for biomass inventories, social surveys, etc. that were included in Section 8 must be followed.

9.3.10 Procedures for Verification of Allometric Equations

Every time one or more new $f_{allometric}$ equations are proposed, the proposed equation(s) must be verified according to the following criteria:

- The proposed equation(s) must have an r^2 value of greater than 0.5 (50%) and a p-value that is significant at 95% confidence level as reported in the source publications.

- The proposed equation(s) was developed from trees where the largest and smallest DBH (or any other tree metric used in the equation) of the trees fall within the range of the metric of the trees within the project areas.
- If the proposed equation(s) was/were derived from data solely from within the reference region then such equations can be used. If the proposed equation(s) was/were derived outside of the reference region, the project proponent must justify the similarity in climatic, edaphic, geographical and species composition between the project area and the location from where the equations were derived. The source publication must include an estimate of the uncertainty or sufficient data to estimate the uncertainty. If this uncertainty is within ±15% of the mean values and is not biased in a non-conservative manner (i.e., the equation(s) do(es) not systematically overestimate the project net anthropogenic removals by sinks), the equation(s) may be used.
- For any other equations that do not satisfy criteria (d) or if new equations or equations which do not have estimate of uncertainty are to be used, then one of the following two steps must be carried out:
- Step 1:Destructive Sampling
    - Selecting at least 5 trees covering the range of DBH (or any other tree metric used in the allometric equation) existing in the project area, and felling and weighing the aboveground biomass to determine the total (green) weight of the stem an branch components
    - Extracting and immediately weighing subsamples from each of the green stems and branch component, followed by oven drying at 105°C to determine dry biomass.
    - Determine the total dry weight of each tree from the green weights and the averaged ratios of wet and dry weights of the stem and branch components.
- Step 2: Limited Measurements.
    - Select at least 10 trees per species or species group distributed across the project area.
    - Calculate volume of tree from basal and top diameters and tree height. Multiply by species-specific density to gain biomass of bole. Add an additional 20 percentage of weight to approximately cover the biomass of branches.

If the biomass of the measured trees is within ±15% of the mean values predicted by the selected default allometric equation, and is not biased – or if biased towards the conservative side (i.e., equation underestimates of the project net anthropogenic removals by sinks), then mean values from the equation may be used. However, if the biomass of the measured trees is not within ±15% of the mean values predicted by the selected default allometric equation, estimated biomass must be further discounted with the relative average half-width of the confidence interval of the model.

Note – The project proponent must follow the remote sensing procedures provided in

Section 8.1.4.1 and should refer to guidance provided in Appendix 1 for procedures with regard to conducting social assessments, , QA/QC procedures and on verification of allometric equations.

APPENDIX 1: ADDITIONAL GUIDANCE

1.1 Guidance for Social Assessments

Social assessments must be conducted to collect social information regarding project conditions. For most data items that are to be collected within the methodology, personal interviews with individual households are preferred; these are referred to as "household surveys". However, for data items that are more challenging to quantify such as forest fires and forest encroachment, semi-structured focus group discussions with representative community members are more appropriate; these are referred to as "participatory rural appraisals". The sample size for household surveys can be based on a comparatively small proportion of the target population (UN 2008). The required number of household surveys must be selected so that a minimal confidence level of 95%. The exact number of surveys can be determined using the formula in Krejcie and Morgan (1970). In case of semi-structured interviews in participatory rural appraisals; at least 10 focus group discussions must be conducted. Further guidelines for carrying out these appraisals can be found in Cochran (1977), Freudenberger (1994), Top et al. (2004) and UN (2008). The following steps should be followed for designing and conducting surveys.

- Assemble all information that must be collected and determine the goals of the questionnaire. Identify all information that is required by the methodology.
- Determine the target group of the questionnaire, and sub-divide the group into different strata. Strata should be defined according to geography, household size, age, gender, etc. Take proper care to avoid the selection of a biased target group.
- Determine the total sample size and the number of samples required in each stratum. Identify the population in each of the strata categories defined in the previous step. Set quotas, a minimal number of surveys from each of the sample strata. Surveys must be collected until the quotas have been reached.
- Create your questionnaire. Transform the required data into neutral, simple and systematic questions. If possible and relevant, generate a set of expected answers. Include partially redundant questions to ensure consistency of data. Include space for some sketch mapping, if relevant. Expected answers could be complemented with graphs, figures, maps and pictures. Allow a "not applicable" or "uncertain" category. Group questions logically according to their contents and leave difficult or sensitive questions until near the end of a survey.
- Choose interviewing methodology and develop a standard operations procedure for interviewing. Include QA/QC procedures such as re-sampling a randomly selected sub-group by different experts, and the requirement to take geo-tagged pictures. All surveys must contain date, time, location, and name of the expert who conducted the survey. In addition, include a Section on how to introduce the purpose of the questionnaires to the interviewees.
- Pre-test the questionnaire and methodology, and adjust the questionnaire and its methodology, if necessary. More specifically, if questions are multiple choices (discrete), ensure that all potential answers are included.

- Train experts for conducting interviews. Through instruction, role playing exercises, and test sessions followed by immediate feedback, train experts to conduct interviews. Experts should be properly trained in explaining the broader scope of the social assessments.
- Conduct interviews and enter data. Make sure a copy is made of all surveys and put in a secure archive. Furthermore, all surveys should be scanned and stored electronically to avoid loss of data. Surveys should be immediately evaluated and if systematic problems arise, the survey must be adjusted or experts conducting the interviews should be re-trained. Make sure that experts are accompanied by an experienced supervisor for at least 10% of the interviews throughout the surveying campaign, and not only in the beginning of the campaign.
- Analyze the data.
- Produce reports.

1.2 Guidance for Quality Assurance and Quality Control

To ensure the precise, verifiable and transparent calculation of net NERs, a quality assurance and quality control (QA/QC) procedure must be implemented. The stipulations in the *IPCC 2003 Good Practice Guidance for Land Use, Land-Use Change and Forestry* on quality assurance/quality control (QA/QC) were followed within this methodology, and should be followed by the project proponent when designing a QA/QC plan.

1.2.1 QA/QC for Field Measurements

QA/QC should be conducted as follows:

- Persons involving in the field measurement work should be fully trained in the field data collection and data analyses.
- List all names of the field teams and the project leader and the dates of the training sessions.
- Record which teams have measured each sampling plot. Record that was responsible for each task.
- Develop Standard Operating Procedures (SOPs) for each step of the field measurements and adhere to these at all times, both *ex-ante* and *ex-post.*
- Put a mechanism in place to correct potential errors or inadequacies in the SOPs by a qualified person.
- Verify that plots have been installed and measured correctly, by having approximately 10% of all plots re-measured by an independent team. If the deviation between measurement and re-measurement is larger than 5%, investigate the source of the error, record and correct.

1.2.2 QA/QC for Data Entry, Documentation and Analyses

QA/QC should be conducted as follows:

- Review the entry of data into the data analyses spreadsheets by an independent source.
- Archived all original data sheets safely. Electronic data must be backed up adequately on durable media.
- Ensure that all files are named appropriately. Ensure that all database fields, spreadsheet headings or cells are adequately documented in such a way that it can be verified independently.
- Verify calculations for trivial errors such as unit conversion errors.
- If parameters are common between analyses (e.g., emission factors), ensure that consistent values are used.
- Check for consistency among time series data. Identify outliers as soon after the actual measurement as possible. Investigate the cause of the outlying observation, and correct if needed.
- Compare estimates from field measurements or social appraisals with literature values.
- An SOP for non-biomass monitoring must be developed and adhered to at all times.

1.2.3 QA/QC for Remote Sensing Analyses

QA/QC should be conducted as follows:

- Develop Standard Operating Procedures (SOPs) for each step of the remote sensing analyses and adhere to these at all times, both *ex-ante* and *ex-post*.
- Use ground-truthing data to validate the LULC classification and forest stratification. Use confusion matrices and accuracy indices to analyze and quantify the accuracy of the classification.
- Use visual interpretation of high-resolution satellite imagery to complement the medium resolution imagery.
- Check for consistency among time series data. If outliers are present (e.g., in deforestation quantities), analyze the cause and correct if errors were made.
- Compare estimates of deforestation and forest degradation rates with relevant estimates from the literature.

1.2.4 QA/QC for Land Use Change Modeling

QA/QC should be conducted as follows:

- Split the available data in 2/3 for calibration purposes, and 1/3 for validation purposes. Never use the same data for calibration and validation.
- Report a measure for the accuracy of the land use change model.

APPENDIX 3: DOCUMENT HISTORY

Version	Date	Comment
v1.0	3 Dec 2010	Initial version released
v2.0	21 Oct 2013	• Revisions were made to accommodate a wider range of drivers of deforestation and degradation as well as a wider range of project activities. • Simplifications were made in the procedures to determine historical LULC transition rates and the area of the reference region. • Quantification of carbon in above ground non-tree pools and soil carbon pools have been incorporated. • The decay of carbon in belowground biomass and soil carbon pools have been quantified such that immediate release of carbon is not assumed.
v2.1	24 Jan 2014	• A procedure to determine a leakage cancellation rate for the conversion of forest land to infrastructure has been incorporated. • Revisions were made to align all market leakage procedures with the discount factor approach set out in *AFOLU Requirements v3.4.*
v2.2	17 Mar 2017	• Incorporated 10 December 2014 errata which removed unnecessary applicability conditions related to data requirements for determining the baseline scenario (Section 4.1.1) • Clarified that GWP values shall be derived from sources specified by the VCS rules (Sections 8.2.4, 8.2.5.5, 8.3.4.2.2, 9.1)

VCS Methodology

VM0007

REDD+ Methodology Framework (REDD-MF)

Version 1.5

9 March 2015

Sectoral Scope 14

Methodology developed by:

Table of Contents

1 SOURCES

This methodology is comprised of a number of modules and tools each of which has been assigned an abbreviated title (eg, *CP-AB*) which are referenced throughout the modules and tools. This methodology uses the latest versions of the following methodologies, modules and tools:

Methodologies:

- CDM methodology *AR-ACM0003 Afforestation and reforestation of lands except wetlands*

Carbon pool modules:

- *VMD0001 Estimation of carbon stocks in the above- and belowground biomass in live tree and non-tree pools (CP-AB)*
- *VMD0002 Estimation of carbon stocks in the dead-wood pool (CP-D)*
- *VMD0003 Estimation of carbon stocks in the litter pool (CP-L)*
- *VMD0004 Estimation of carbon stocks in the soil organic carbon pool (mineral soils) (CP-S)*
- *VMD0005 Estimation of carbon stocks in the long-term wood products pool (CP-W)*

Baseline modules:

- *VMD0006 Estimation of baseline carbon stock changes and greenhouse gas emissions from planned deforestation and planned degradation (BL-PL)*
- *VMD0007 Estimation of baseline carbon stock changes and greenhouse gas emissions from unplanned deforestation (BL-UP)*
- *VMD0008 Estimation of baseline emission from forest degradation caused by extraction of wood for fuel (BL-DFW)*
- *VMD0041 Estimation of baseline carbon stock changes and greenhouse gas emissions in ARR project activities on peat and mineral soil (BL-ARR)*
- *VMD0042 Estimation of baseline soil carbon stock changes and greenhouse gas emissions in peatland rewetting and conservation project activities (BL-PEAT)*

Leakage modules:

- *VMD0009 Estimation of emissions from activity shifting for avoiding planned deforestation and planned degradation (LK-ASP)*
- *VMD0010 Estimation of emissions from activity shifting for avoiding unplanned deforestation (LK-ASU)*
- *VMD0011 Estimation of emissions from market-effects (LK-ME)*
- *VMD0012 Estimation of emissions from displacement of fuelwood extraction (LK-DFW)*

- *VMD0043 Estimation of emissions from displacement of pre-project agricultural activities (LK-ARR)*
- *VMD0044 Estimation of emissions from ecological leakage (LK-ECO)*

Emissions modules (applicable to baseline, project scenario and leakage):

- *VMD0013 Estimation of greenhouse gas emissions from biomass and peat burning (E–BPB)*
- *VMD0014 Estimation of emissions from fossil fuel combustion (E-FFC)*
- CDM tool *Estimation of direct N_2O emissions from nitrogen application (E-NA)*

Monitoring modules:

- *VMD0015 Methods for monitoring of greenhouse gas emissions and removals in REDD project activities (M-REDD)*
- *VMD0045 Methods for monitoring greenhouse gas emissions and removals in ARR project activities on peat and mineral soil (M-ARR)*
- *VMD0046 Methods for monitoring of soil carbon stock changes and greenhouse gas emissions and removals in peatland rewetting and conservation project activities (M-PEAT)*

Miscellaneous modules:

- *VMD0016 Methods for stratification of the project area (X-STR)*
- *VMD0017 Estimation of uncertainty for REDD+ project activities (X-UNC)*

Tools:

- CDM *Tool for testing significance of GHG emissions in A/R CDM project activities (T-SIG)*
- CDM *Combined tool to identify the baseline scenario and demonstrate additionality in A/R CDM project activities (T-ADD)*
- VCS *AFOLU Non-Permanence Risk Tool* (T-BAR)

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

Additionality and Crediting Method	
Additionality	Project Method
Crediting Baseline	Project Method

This REDD+ Methodology Framework document is the basic structure of a modular REDD+ methodology. It provides the generic functionality of the methodology, which frames pre-defined modules and tools that perform a specific function. It constitutes, together with the modules and tools it calls upon, a complete REDD+ baseline and monitoring methodology.

The modules and tools called upon in this document are applicable to project activities that reduce emissions from planned (APD) and unplanned (AUDD) deforestation, for activities that reduce emissions from forest degradation, for afforestation, reforestation and revegetation activities (ARR), or combinations of these, as well as to any of these activities when they occur on peatland and are combined with peatland rewetting or conservation (being sub-categories of wetland restoration and conservation - WRC). Hereafter in this module and all other modules in methodology VM0007 applied to avoiding planned deforestation projects, “planned deforestation” refers to both planned deforestation and planned degradation.

The reference to this methodology and the modules used to construct the project-specific methodology must be given in the project description (PD).

Identification of the Most Plausible VCS-eligible Activity(s)

To identify the type of VCS-eligible REDD+ project activity use the following decision tree. The decision tree must be used to provide a broad indication of likely baseline type and applicability. Ultimately the relevant baseline modules (*BL-UP* – avoiding unplanned deforestation; *BL-PL* – avoiding planned deforestation and planned degradation; *BL-DFW* – avoiding forest degradation (fuelwood/charcoal); *BL-ARR* - degraded land suited for ARR; and, where applicable, *BL-PEAT* – peatland) must be applied with relevant applicability conditions and criteria.

Provide all the necessary evidence to demonstrate the type of eligible activity as given in each module.

A project can include areas subject to different eligible activities (eg, Area A = avoiding planned deforestation; Area B = avoiding unplanned deforestation; Area C = avoiding degradation; Area D = reforestation; Area E = peatland rewetting and reforestation). In such cases the areas that are eligible for different categories must be captured by different strata and clearly delineated, and the procedures outlined below applied to each of them separately. Projects may combine WRC with REDD or WRC with ARR in a single area, in which case they must apply concomitantly the procedures for both categories.

The demonstration of eligibility must be reported in the PD.

Tables 1 below provides a decision tree for identifying the types of REDD+ and ARR project activities eligible under this methodology.

Table 1: Decision Tree for Determining REDD Project Activity Type and ARR Suitability

<table>
<tr><td colspan="4">Is the forest land expected to be converted to non-forest land in the baseline case, or expected to be subject to authorized conversion to a managed tree plantation in the baseline case?</td></tr>
<tr><td colspan="2">YES[1]</td><td colspan="2">NO</td></tr>
<tr><td colspan="2">Is the land legally authorized and documented to be converted to non-forest or a managed tree plantation?</td><td colspan="2">Is the forest in the baseline expected to degrade by fuelwood extraction or charcoal production?</td></tr>
<tr><td>YES[2]</td><td>NO</td><td>YES</td><td>NO</td></tr>
<tr><td>Avoiding planned deforestation/planned degradation</td><td>Avoiding unplanned deforestation</td><td>Avoiding forest degradation</td><td>Proposed project is not a VCS REDD[3] activity currently covered by the</td></tr>
<tr><td colspan="4">Is part of the land non-forest land or with degraded forest?</td></tr>
<tr><td colspan="2">YES</td><td colspan="2">NO</td></tr>
<tr><td colspan="2">Suitable for ARR</td><td colspan="2">No additional activity</td></tr>
</table>

If the project area includes peatland already drained or that would be drained in the baseline case, project must combine the project activities identified above with the WRC category, as set out in Table 2 below.

Table 2: Determination of WRC Combined Categories

<table>
<tr><th colspan="2">Baseline Scenario</th><th rowspan="2">Project Activity</th><th rowspan="2">Combined Categories</th></tr>
<tr><th>Pre-Project Condition</th><th>Land Use</th></tr>
<tr><td rowspan="2">Drained peatland</td><td>Non-forest</td><td>Rewetting and conversion to forest/revegetation</td><td>WRC+ARR</td></tr>
<tr><td>Forest with deforestation/degradation</td><td>Rewetting and avoiding deforestation/degradation</td><td>WRC+REDD</td></tr>
<tr><td>Undrained peatland</td><td>Forest with deforestation/degradation</td><td>Avoiding drainage and deforestation/degradation</td><td>WRC+REDD[4]</td></tr>
</table>

REDD+ projects under the methodology are divided between the following activity types: avoiding unplanned deforestation/degradation due to collection of wood for fuel and production of charcoal (AUDD), avoiding planned deforestation (APD), forest rehabilitation (ARR), and peatland

[1] If the answer is "yes", evidence must be provided based on the application of the appropriate baseline module (BL-PL for APD and BL-UP for AUDD).
[2] If the answer is "yes", evidence must be provided based on the application of the BL-PL module. Project are required to show legal permissibility to deforest, suitability of project area for conversion and intent to deforest.
[3] If degradation is occurring through legal or sanctioned timber production then this is an eligible IFM activity.
[4] Includes Avoiding Unplanned Wetland Degradation and Avoiding Planned Wetland Degradation.

rewetting and conservation (RWE). Projects can be REDD, REDD+ARR, WRC+ARR, WRC+REDD+ARR. Improved forest management (IFM) is not covered by this methodology.

In Table 3 below the modules and tools are listed and it is indicated when use of modules/tools is mandatory under each activity type. Where any of these project activities take place on peatland, the project must adhere to both the respective project category modules and the relevant WRC modules, unless the expected emissions from the soil organic carbon pool or change in the soil organic carbon pool in the project scenario is deemed below *de minimis*. The tool T-SIG must be used to justify the omission of carbon pools and emission sources.

Table 3: Determination of When Module/Tool Use is Mandatory (M) or Optional (O)

	Module	Avoiding Unplanned Deforestation/ Degradation	Avoiding Planned Deforestation	Avoiding Degradation (Fuelwood / Charcoal)	ARR	REDD or ARR on Peatland
Always Mandatory	**REDD-MF**	M	M	M	M	M
	M-REDD	M	M	M	-	←

M Modules marked with an M are fully mandatory: the indicated modules and tools must be used

O Modules marked with an O are fully optional: the indicated pools and sources can be included or excluded as decided by the project but if included in the baseline they must also be included in the project scenario

X Modules marked with an X are excluded

(m)[1] Mandatory where the process of deforestation involves timber harvesting for commercial markets

(m)[2] Mandatory where fuelwood or charcoal is harvested for commercial markets

(m)[3] Mandatory if this carbon pool is greater in baseline (post-deforestation/degradation) than project scenario and significant; otherwise can be conservatively omitted

(m)[4] Mandatory where leakage prevention activities include increases in the use of fertilizers

* VCS requirements and the tool T-SIG must be used to justify the omission of carbon pools and emission sources

** Procedures provided in M-ARR.

*** Procedures provided in BL-ARR and M-ARR.

**** Procedures provided in BL-PEAT and M-PEAT.

3 DEFINITIONS

In addition to the definitions set out in VCS document *Program Definitions*, the following definitions apply to this methodology:

Baseline Period
The period of time with a fixed baseline (10 years), applicable to REDD and WRC baselines

Expert Judgment
Judgment on methodological choice and choice of input data and to fill gaps in the available data, to select data from a range of possible values or on uncertainty ranges as established in the *IPCC 2006 Good Practice Guidance*. Obtaining well-informed judgments from domain experts regarding best estimates and uncertainties of inputs to the quantification of emission reductions is an important aspect in various procedures throughout this methodology. The guidance provided

in Chapter 2, Volume 1 (Approaches to Data Collection) must be used, in particular, Section 2.2 and Annex 2A.1 of the *IPCC 2006 Guidelines for National Greenhouse Gas Inventories*.

Historical Reference Period

The historical period prior to the project start date that serves as the source of data for defining the baseline

4 APPLICABILITY CONDITIONS

This REDD+ Methodology Framework is a compilation of modules and tools that together define the project activity and necessary methodological steps. By choosing the appropriate modules, a project-specific methodology can be constructed. The justification of the choice of modules and why they are applicable to the proposed project activity must be given in the PD.

Specific applicability conditions exist for each module and must be met for the module to be used.

This methodology includes forest degradation caused only by extraction of wood for fuel. No modules are included for activities to reduce emissions from forest degradation caused by illegal harvesting of trees for timber.[5]

Use of this methodology is subject to the following applicability conditions, noting the project must also comply with the applicability conditions of the applied modules and tools:

4.1 General

All land areas registered under the CDM or under any other GHG program (both voluntary and compliance-oriented) must be transparently reported and excluded from the project area. The exclusion of land in the project area from any other GHG program must be monitored over time and reported in the monitoring reports.

4.2 REDD

4.2.1 All REDD Activity Types

REDD activity types applicable under the following conditions:

- Land in the project area has qualified as forest (following the definition used by VCS) at least 10 years before the project start date.
- If land within the project area is peatland and emissions from the soil carbon pool are deemed significant, the relevant WRC modules (see Table 1) must be applied alongside other relevant modules.
- Baseline deforestation and forest degradation in the project area fall within one or more of the following categories:

[5] Illegal timber harvest may be occurring in the project area in the baseline but conservatively no benefit can be calculated for preventing timber harvests, and any emissions arising from timber harvests in the project case must be monitored and deducted from calculated project net emission reductions.

- Unplanned deforestation (VCS category AUDD);
- Planned deforestation/degradation (VCS category APD);
- Degradation through extraction of wood for fuel (fuelwood and charcoal production) (VCS category AUDD).

- Leakage avoidance activities must not include:
  - Agricultural lands that are flooded to increase production (eg, paddy rice);
  - Intensifying livestock production through use of feed-lots[6] and/or manure lagoons.[7]

4.2.2 Unplanned Deforestation

Unplanned deforestation activities are applicable under the following conditions:

- Baseline agents of deforestation must: (i) clear the land for settlements, crop production (agriculturalist) or ranching, where such clearing for crop production or ranching does not amount to large scale industrial agriculture activities[8]; (ii) have no documented and uncontested legal right to deforest the land for these purposes; and (iii) be either residents in the Reference Region for Deforestation (cf. section 1 below) or immigrants. Under any other condition this methodology must not be used.
- If, in the baseline scenario of avoiding unplanned deforestation project activities, post-deforestation land use constitutes reforestation, this methodology may not be used.

4.2.3 Planned Deforestation/Degradation

Unplanned deforestation/degradation activities are applicable under the following condition:

- Conversion of forest lands to a deforested condition must be legally permitted.

4.2.4 Degradation (Fuelwood/Charcoal)

Degradation activities are applicable under the following conditions:

- Fuelwood collection and charcoal production must be non-renewable[9] in the baseline period.
- If degradation is caused by either illegal or legal tree extraction for timber, this methodology cannot be used.

[6] Feedlots are defined as areas in which naturally grazing animals are confined to an area which produces no feed and are fed on stored feeds.
[7] Anaerobic lagoons that function as receptacles for animal waste flushed from animal pens. Anaerobic organisms present in the manure and the environment decompose the waste in the lagoon.
[8] Small-scale / large-scale agriculture to be defined and justified by the project.
[9] As defined in Module BL-DFW

4.3 ARR

ARR activities are applicable under the following conditions:

- The project area is non-forest land or land with degraded forest.
- The project scenario does not involve the harvesting of trees. Therefore, procedures for the estimation of long-term average carbon stocks are not provided.
- The project scenario does not involve the application of nitrogen fertilizers.

Note, where project activities on wetlands are excluded by the applicability conditions of applied modules or tools, these can be disregarded for the purpose of their use within this methodology, as quantification procedures for the peat soil are provided in modules *BL-PEAT* and *M-PEAT*.

4.4 WRC

WRC activities are applicable under the following conditions:

- This methodology is applicable to rewetting drained peatland (RDP) and conservation of undrained and partially drained peatland (CUPP) activities on project areas that meet the VCS definition for peatland[10]. The scope of this methodology is limited to domed peatlands in the tropical climate zone.
- Fire reduction projects on peatland that exclude rewetting as part of the project activity are not eligible.
- Rewetting of drained peatland and conservation of undrained or partially drained peatland may be implemented in combination with REDD project activities. REDD project activities on peatland must not increase drainage.
- Rewetting of drained peatland may be implemented as a separate activity or in combination with ARR project activities. ARR activities must not enhance peat oxidation and therefore this activity requires at least some degree of rewetting.

5 PROJECT BOUNDARY

The following categories of boundaries must be defined:

1) The geographic boundaries relevant to the project activity;
2) The temporal boundaries;
3) The carbon pools that the project will consider;
4) The sources and associated types of greenhouse gas emissions that the project will affect.

[10] RDP (Rewetting of Drained Peatland) and CUPP (Conservation of Undrained or Partially Drained Peatland) project activities are both sub-categories of Restoration of Wetland Ecosystems (RWE) and Conservation of Intact Wetlands (CIW) of the Wetlands Restoration and Conservation (WRC) project category.

5.1 Geographical Boundaries

5.1.1 General

The spatial boundaries of a project must clearly be defined, so as to facilitate accurate measuring, monitoring, accounting, and verifying of the project's emissions reductions and removals. The REDD project activity may contain more than one discrete area of land. When describing physical project boundaries, the following information must be provided per discrete area:

- Name of the project area (eg, compartment number, allotment number, local name); Unique ID for each discrete parcel of land;
- Map(s) of the area (preferably in digital format);
- Geographic coordinates of each polygon vertex along with the documentation of their accuracy (from a geo-referenced digital map – data must be provided in the format specified / required by the VCS).
- Total land area; and
- Details of land holder and user rights.

The geographical boundaries of a project are fixed (*ex-ante*) and cannot change over the project lifetime (*ex-post*). Where multiple baselines exist (eg, planned deforestation, unplanned deforestation, forest degradation, degraded land) there must be no overlap in boundaries between areas appropriate to each of the baselines. Thus two project types cannot occur on the same piece of land, other than those including a WRC component (ie, combined REDD+WRC, ARR+WRC).

5.1.2 REDD

The boundary of the REDD activity must be clearly delineated and defined and include only land qualifying as forest for a minimum of 10 years prior to the project start date.

In REDD project activities, various kinds of boundaries must be distinguished, depending on the REDD category (planned or unplanned deforestation, forest degradation), ie, in case of:

- Avoiding planned deforestation: project area and proxy area(s). Refer to module *BL-PL* for the detailed procedures to define these boundaries.
- Avoiding unplanned deforestation: project area, reference regions for deforestation, and leakage belt area. Refer to module *BL-UP* for definitions and the detailed procedures to define these boundaries.
- Avoiding forest degradation: Refer to module *BL-DFW* (for degradation due to removals for wood fuel or charcoal) for the detailed procedures to define these boundaries.

Methods for establishing the boundaries of areas subject to leakage from activity shifting are provided in the following modules:

- For avoiding planned deforestation/degradation: module *LK-ASP*
- For avoiding unplanned deforestation: module *BL-UP*

5.1.3 ARR

The project area must not have been not cleared of native ecosystems to create GHG emissions reductions/removals. Such proof is not required where such clearing took place prior to the 10-year period prior to the project start date. Areas that do not meet this requirement must be excluded from the project area.

5.1.4 WRC

The project area must not have been not drained or converted to create GHG emissions reductions/removals. Such proof is not required where such draining or conversion took place prior to 1 January 2008. Areas that do not meet this requirement must be excluded from the project boundary.

The maximum eligible quantity of GHG emission reductions in WRC project activities on peatland is limited to the difference between the remaining peat carbon stock in the project and baseline scenarios after 100 years. If a significant difference at the 100-years mark cannot be demonstrated, the project area is not eligible for carbon crediting. The assessment must be executed ex ante using conservative parameters. Procedures are provided in module *X-STR*.

5.2 Temporal Boundaries

The following temporal boundaries must be specified:

5.2.1 Start Date and End Date of the Historical Reference Period

REDD

The historical reference period is the temporal domain from which information on historical deforestation is extracted, analyzed and projected into the future. A historical reference period must be defined for all eligible REDD categories. The starting date of this period must be between 9 and 12 years in the past and the end date must be within two years of project start date.

WRC

While developing WRC baselines, project must reference a period of at least 10 years for modeling a spatial trend in drainage, taking into account the long-term (20-year) average climate variables, for which procedures are provided in module *BL-PEAT*.

5.2.2 Start Date and End Date of the Project Crediting Period

General

The project crediting period is the period of time for which GHG emissions reductions or removals generated by the project are eligible for crediting with the VCS Program. The project must have a robust operating plan covering this period.

The project crediting period for REDD+ projects must be between 20 and 100 years. The duration of the project activity/crediting period must be reported in the PD.

<u>REDD</u>

Projections of baseline emissions must be presented in the PD for the first 10-year period after the project start date. Emission reductions/removals can only be claimed for 10-year periods for which the baseline is fixed and a monitoring plan has been implemented.

<u>WRC</u>

Projections of baseline emissions from peatland must be presented in the PD for the first 10-year period after the start of the project. Emission reductions/removals can only be claimed for 10-year periods for which the baseline is fixed and a monitoring plan has been implemented.

Peat Depletion Time (PDT)

Peat depletion may be accelerated by peat fires and is attained if the peat has disappeared or if a stable water table inhibits further oxidation of the peat. The PDT for a stratum in the baseline scenario equals the period during which the project can claim emission reductions from rewetting. Procedures for determining the PDT are provided in module *X-STR*.

Since the PDT is part of the baseline assessment, it must be reassessed every 10 years.

5.2.3 Duration of the Monitoring Periods

The minimum duration of a monitoring period is one year and the maximum duration is 10 years.

Baseline projections must be annual and be available for each proposed future verification date.

Data on baseline deforestation and degradation rates, as well as on the hydrological layout and climatic variables in the peatland areas, must be presented as well as data collection for future baseline revision.

5.3 Carbon Pools

5.3.1 General

Any significant decreases in carbon stock in the project scenario and any significant increases in carbon stock in the baseline scenario must be accounted for. In addition, decreases in the baseline scenario and increases in the project scenario can be accounted for. Where ARR or REDD activities take place on peatland, the project must account for expected emissions from the soil organic carbon pool or change in the soil organic carbon pool in the project scenario, unless they are is deemed *de minimis*. The significance of this pool may be determined by using the tool *T-SIG*.

Selection of carbon pools and the appropriate justification must be presented in PD.

5.3.2 REDD

The carbon pools (and corresponding methodology modules) included in or excluded from the boundary of REDD project activities are shown in Table 3.

Harvested wood products and dead-wood must be included when they increase more or decrease less in the baseline than in the project scenario. In all other cases only aboveground biomass is mandatory. If a carbon pool is included in the baseline accounting, it must also be included in project scenario and leakage accounting.

Where the carbon pool in harvested wood products and dead-wood increases more or decreases less in the baseline case than in the project case, the tool *T-SIG* must be used to determine whether significant. Insignificant pools can always be ignored.

5.3.3 ARR

The carbon pools included in or excluded from the boundary of the ARR component are shown in Table 4 below. The selection of carbon pools and the appropriate justification must be provided in the PD.

Table 4: Carbon Pools in Baseline and Project Scenario of ARR Project Activities

Carbon pool	Included?	Justification / Explanation
Aboveground tree biomass	Included	Mandatory pool in ARR project activities
Aboveground non-tree biomass	Included	Carbon stock in this pool may increase in the baseline scenario and may increase or decrease due to the implementation of the project activity
Belowground biomass	Included	Carbon stock in this pool may increase in the baseline scenario and is expected to increase due to the implementation of the project activity
Litter		
On mineral soil	Optional	Given the applicability conditions that the project area for ARR is non-forest land or land with degraded forest and that the project scenario does not involve the harvesting of trees, the litter carbon pool will increase due to project implementation. It is therefore conservative not to include litter. If included, litter must be accounted for using procedures in modules *CP-L*, *BL-ARR* and *M-ARR*.

On peatland	Optional	This pool is not mandatory on peatland but may be included. Given the applicability conditions that the project area for ARR is non-forest land or land with degraded forest and that the project scenario does not involve the harvesting of trees, the litter carbon pool will increase due to project implementation. It is therefore conservative not to include litter. If included, litter must be accounted for using procedures in modules *CP-L*, *BL-ARR* and *M-ARR*.
Dead wood		
On mineral soil	Optional	Given the applicability conditions that the project area for ARR is non-forest land or land with degraded forest and that the project scenario does not involve the harvesting of trees, the dead wood carbon pool will increase due to project implementation. It is therefore conservative not to include dead wood. If included, dead wood must be accounted for using procedures in modules *CP-D*, *BL-ARR* and *M-ARR*.
On peatland	Optional	This pool is not mandatory on peatland but may be included. Given the applicability conditions that the project area for ARR is non-forest land or land with degraded forest and that the project scenario does not involve the harvesting of trees, the dead wood carbon pool will increase due to project implementation. It is therefore conservative not to include dead wood. If included, dead wood must be accounted for using procedures in modules *CP-D*, *BL-ARR* and *M-ARR*.
Soil		
On mineral soil	Included	Carbon stock in this pool may increase due to the implementation of the project activity and this increase can be assessed as a carbon stock change.
On peatland	Included	Carbon stock in this pool may increase due to the implementation of the project activity but this increase is not accounted for; emissions from soil organic carbon are estimated in modules *BL-ARR* and *M-ARR*.
Wood products	Excluded	This pool is optional as per VCS rules.

5.3.4 WRC

The carbon pools included in or excluded from the boundary of the WRC component are shown in Table 5 below. The selection of carbon pools and the appropriate justification must be provided in the PD.

Table 5: Carbon Pools in Baseline and Project Scenario of WRC Project Activities

Carbon pool	Included?	Justification / Explanation
Aboveground tree biomass	Excluded	Covered under REDD or ARR
Aboveground non-tree biomass	Excluded	Covered under REDD or ARR
Belowground biomass	Included	This pool is not distinguished from the soil pool in WRC procedures
Litter	Excluded	Covered under REDD or ARR
Dead wood	Excluded	Covered under REDD or ARR
Soil	Included	The WRC procedures account for emissions from the soil pool based on proxies and default factors.
Wood products	Excluded	Covered under REDD or ARR

5.4 Sources of GHG Emissions

5.4.1 General

The project must account for any significant increases in emissions of carbon dioxide (CO_2), nitrous oxide (N_2O) and methane (CH_4) relative to the baseline that are reasonably attributable to the project activity, with additional guidance provided in Tables 6, 7 and 8.

T-SIG may be used to determine whether an emissions source is significant. If a source is included in the estimation of baseline emissions[11], it must also be included in the calculation of project and leakage emissions.

5.4.2 REDD

The GHG emission sources included in or excluded from the boundary of the REDD project activity are shown in Table 6 below. The selection of sources and the appropriate justification must be provided in the PD.

Table 6: GHG Sources Included In or Excluded From the REDD Project Boundary

Sources	Gas	Included?	Justification / Explanation
Biomass burning	CO_2	Excluded	However, carbon stock decreases due to burning are accounted as a carbon stock change

[11] Eg, CH_4 or N_2O emission from agriculture that results from deforestation or fire to clear forest land.

	CH_4	Included	Non-CO_2 gases emitted from woody biomass burning - it is conservative to exclude in the baseline but must be included in the project case if fire occurs.
	N_2O	Included	
Combustion of fossil fuels	CO_2	Included	Can be neglected if excluded from baseline accounting.
	CH_4	Excluded	Potential emissions are negligible
	N_2O	Excluded	Potential emissions are negligible
Use of fertilizers	CO_2	Excluded	Potential emissions are negligible
	CH_4	Excluded	Potential emissions are negligible
	N_2O	Included	Can be excluded if excluded from baseline accounting except in the situation where fertilizer use is enhanced as a leakage avoidance mechanism.

5.4.3 ARR

The GHG emission sources included in or excluded from the boundary of the ARR component are shown in Table 7 below. The selection of sources and the appropriate justification must be provided in the PD.

Table 7: GHG Sources Included In or Excluded From the ARR Project Boundary

Sources	Gas	Included?	Justification / Explanation of choice
Burning of woody biomass	CO_2	Excluded	However, carbon stock decreases due to burning are accounted as a carbon stock change
	CH_4	Included	Burning of woody biomass for the purpose of site preparation, or as part of forest management, is allowed
	N_2O	Included	Burning of woody biomass for the purpose of site preparation, or as part of forest management, is allowed

Table 7 with the selection of sources and the appropriate justification must be presented in the PD.

5.4.4 WRC

The GHG emission sources included in or excluded from the boundary of the WRC component are shown in Table 8 below. The selection of sources and the appropriate justification must be provided in the PD.

Table 8: GHG Sources Included In or Excluded From the WRC Project Boundary

Sources	Gas	Included?	Justification / Explanation
Oxidation of drained peat	CO_2	Included	Considered under carbon pools
	CH_4	Included	Required unless *de minimis* or conservatively omitted
	N_2O	Excluded	Excluded as per applicability condition in module *BL-PEAT*
Peat combustion	CO_2	Included	Procedures provided in module *E-BPB*
	CH_4	Included	Procedures provided in module *E-BPB*
	N_2O	Included	Procedures provided in module *E-BPB*
Combustion of fossil fuels	CO_2	Excluded	Deemed *de minimis* in VCS *AFOLU Requirements*
	CH_4	Excluded	Deemed *de minimis* in VCS *AFOLU Requirements*
	N_2O	Excluded	Deemed *de minimis* in VCS *AFOLU Requirements*

6 BASELINE SCENARIO

6.1 Determination of the Most Plausible Baseline Scenario

For each of the included project activities, the most plausible baseline scenario must be determined using *T-ADD*, listed in Section 2 above. The tool has been designed for A/R CDM project activities, but is used by this methodology applying the notes provided in Table 9 below.

Table 9: Translation between VCS and CDM Terminology

Where the tool refers to:	It must be understood as referring to:
A/R, afforestation, reforestation, or forestation	REDD, ARR or WRC project activity
Net greenhouse gas removals by sinks	Net greenhouse gas emission reductions
CDM	VCS
DOE	VVB
tCERs, lCERs	VCUs

Footnotes 1 and 3 included in T-ADD can be disregarded. In case there is a conflict between the CDM tool requirements and the VCS rules, the VCS rules must be followed (as set out in VCS *AFOLU Guidance: Additional guidance for VCS Afforestation, Reforestation and Revegetation projects using CDM Afforestation/Reforestation Methodologies*, available on the VCS website.

6.2 Re-assessing the Baseline Scenario

The project baseline must be revised at the following frequencies:

- For planned deforestation projects, the baseline must be revised every 10 years for ongoing planned deforestation.
- For unplanned deforestation, the project baseline must be revised every 10 years from the project start date.
- For degradation, the baseline must be revised every 10 years.
- For WRC areas, the project must, for the duration of the project, reassess the baseline every 10 years and have this validated at the same time as the subsequent verification.

The date of the next scheduled revision must be specified. The starting point for the baseline revision of the project will be forest cover projected to exist at the end of the baseline period. Projections for each baseline revision will be subject to independent verification.

Reassessments must capture changes in the drivers and/or behavior of agents that cause the change in land use and/or land management practices and changes in carbon stocks. The new baseline scenario must be incorporated into revised estimates of baseline emissions. This baseline reassessment must include the evaluation of the validity of proxies for GHG emissions.

For REDD and WRC project activities, *ex-ante* baseline projections beyond a 10-year period are not required. For this assessment the historic reference period is extended to include the original reference period and all subsequent monitoring periods up to the beginning of the current monitoring period.

7 ADDITIONALITY

T-ADD must be used to identify credible alternative land use scenarios and evaluate both the alternatives and the proposed project scenarios and to demonstrate the additionality of the project.

The assessment and demonstration of additionality must be presented in the PD.

Default factors and standards used to ascertain GHG emission data and any supporting data for demonstrating additionality must be publicly available from a recognized, credible source, such as *IPCC 2006 Guidelines for National GHG Inventories* or the *IPCC 2003 Good Practice Guidelines for Land Use, Land-Use Change and Forestry*.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

8.1.1 General

Each activity type included in the project must estimate an individual baseline following the provisions and specific modules mentioned below. Combined activities (ie, ARR or REDD with a WRC component) must develop a unique baseline considering peat as the soil carbon pool and incorporating the resulting emission estimates to the calculation of emissions and carbon stock changes of the ARR and/or REDD activities.

The same procedure must be followed *ex ante* and *ex post*. For parameters that will be monitored subsequent to project initiation, guidance is given in the parameter tables of the relevant modules for the values that must be used in *ex-ante* calculations.

8.1.2 REDD

The baseline of the REDD project activity is estimated *ex ante*. It can be monitored in a reference area (unplanned deforestation) or proxy area (planned deforestation) for the purpose of periodically adjusting the baseline. *Ex-ante* baseline estimations are therefore used in both the *ex-ante* and *ex-post* estimation of net carbon stock changes and greenhouse gas emission reductions.

Methods for estimating net baseline carbon stock changes and greenhouse gas emissions are provided in the following modules:

- For planned deforestation/degradation: module *BL-PL*
- For unplanned deforestation: module *BL-UP*
- For forest degradation from extraction of wood for fuel: module *BL-DFW*

8.1.3 ARR

The baseline net GHG removals must be estimated using module *BL-ARR*.

8.1.4 WRC

Baseline net emissions from the soil (peat) carbon pool in combined projects must be estimated using module *BL-PEAT*.

8.2 Project Emissions

For emissions and removals in the project scenario the following modules must be used:

- For REDD project activities: module *M-REDD*
- For ARR project activities: module *M-ARR*
- For WRC project activities module *M-PEAT*

8.2.1 General

The same procedure must be followed *ex ante* and *ex post*. For parameters that will be monitored subsequent to project initiation, guidance is given in the parameter tables of the relevant modules for the values that must be used in *ex-ante* calculations.

8.2.2 REDD

Methods for estimating net carbon stock changes and GHG emissions in the project scenario are provided in module *M-REDD*.

8.2.3 ARR

The net GHG removals in the project scenario must be estimated using module *M-ARR*.

8.2.4 WRC

Net GHG emissions from the soil (peat) carbon pool in the project scenario in combined projects must be estimated using module *M-PEAT*.

8.3 Leakage

Leakage must be considered for all activities using the following leakage modules:

- For planned deforestation/degradation: module *LK-ASP*
- For unplanned deforestation: module *LK-ASU*
- For fuel-wood/charcoal collection: module *LK-DFW*
- For pre-project agricultural activities: module *LK-ARR*

For WRC project activities that are not combined with REDD or ARR, where pre-project activities may be displaced to undrained or partially drained peatland areas, the procedures provided for activity shifting to peatland areas in module LK-ASP (planned drainage of peatland) or module LK-ASU (unplanned drainage of peatland) must be used.

For WRC projects activities, the following module must be used:

- For ecological leakage: module *LK-ECO*

The significance of leakage and the significance of carbon pools may be determined using *T-SIG*.

Where applicable, leakage due to market effects must be considered using module *LK-ME*. Market effects must be considered where the project leads to a decrease in the production of timber, fuelwood, or charcoal.

Where, pre-project, unsustainable fuelwood collection is occurring within the project boundary, modules *BL-DFW* and *LK-DFW* must be used to determine potential leakage.

Where leakage prevention activities include tree planting, aquacultural intensification, agricultural intensification, fertilization, fodder production, other measures to enhance cropland and/or grazing land areas, leakage management zones or a combination of these, then any significant increase in GHG emissions associated with these activities must be accounted for, unless deemed *de minimis*, as determined using *T-SIG*.

Leakage prevention activities may lead to the increase in combustion of fossil fuels, however, any increase in emissions is considered insignificant.

Where leakage prevention leads to a significant increase in the use of fertilizers, module *E-NA* must be used. *T-SIG* can be used to determine significance.

As per the applicability conditions, leakage prevention may not include the flooding of agricultural lands (eg, for new rice paddies) nor the creation of livestock feedlots and/or manure lagoons. Leakage prevention may also not include the drainage of peatland.

The list of leakage sources with appropriate justification must be presented.

Positive leakage may not be accounted for.

8.4 Summary of GHG Emission Reduction and/or Removals

8.4.1 General

The total net greenhouse gas emissions reductions of the project are calculated as:

$$NER_{REDD+} = NER_{REDD} + NGR_{ARR} + NER_{WRC} \quad (1)$$

Where:

NER_{REDD+}	Total net GHG emission reductions of the REDD+ project activity up to year t^* (t CO_2e)
NER_{REDD}	Total net GHG emission reductions of the REDD project activity up to year t^* (t CO_2e)
NGR_{ARR}	Total net GHG removals of the ARR project activity up to year t^* (t CO_2e)
NER_{WRC}	Total net GHG emission reductions of the WRC project activity up to year t^* (t CO_2e)

Project must present conservative *ex-ante* estimations of the total net GHG emissions reductions of the project activity.

For *ex-ante* estimation for specific parameters project must refer to the parameter tables in the appropriate modules.

8.4.2 REDD

The total net greenhouse gas emissions reductions of the REDD project activity are calculated as follows:

$$NER_{REDD} = \Delta C_{BSL-REDD} - \Delta C_{WPS-REDD} - \Delta C_{LK-REDD} \quad (2)$$

Where:

NER_{REDD}	Total net GHG emission reductions of the REDD project activity up to year *t** ($t\ CO_2e$)
$\Delta C_{BSL\text{-}REDD}$	Net GHG emissions in the REDD baseline scenario up to year *t** ($t\ CO_2e$)
$\Delta C_{WPS\text{-}REDD}$	Net GHG emissions in the REDD project scenario up to year *t** ($t\ CO_2e$)
$\Delta C_{LK\text{-}REDD}$	Net GHG emissions due to leakage from the REDD project activity up to year *t** ($t\ CO_2e$)

$$\Delta C_{BSL,REDD} = \Delta C_{BSL,planned} + \Delta C_{BSL,unplanned} + \Delta C_{BSL,\deg rad-FW/C} \tag{3}$$

Where:

$\Delta C_{BSL\text{-}REDD}$	Net GHG emissions under the REDD baseline scenario up to year *t** ($t\ CO_2e$)
$\Delta C_{BSL,planned}$	Net GHG emissions in the baseline scenario from planned deforestation up to year *t** ($t\ CO_2e$)
$\Delta C_{BSL,unplanned}$	Net GHG emissions in the baseline scenario from unplanned deforestation up to year *t* ($t\ CO_2e$)
$\Delta C_{BSL,degrad\text{-}FW/C}$	Net GHG emissions in the baseline scenario from degradation caused by fuelwood collection and charcoal making up to year *t** ($t\ CO_2e$)

$$\Delta C_{LK-REDD} = \Delta C_{LK-AS,planned} + \Delta C_{LK-AS,unplanned} + \Delta C_{LK-AS,\deg rad-FW/C} + \Delta C_{LK-ME} \tag{4}$$

Where:

$\Delta C_{LK\text{-}REDD}$	Net GHG emissions due to leakage from the REDD project activity up to year *t** ($t\ CO_2e$)
$\Delta C_{LK\text{-}AS,planned}$	Net GHG emissions due to activity shifting leakage for projects preventing planned deforestation up to year *t** ($t\ CO_2e$)
$\Delta C_{LK\text{-}AS,unplanned}$	Net GHG emissions due to activity shifting leakage for projects preventing unplanned deforestation up to year *t** ($t\ CO_2e$)
$\Delta C_{LK\text{-}ME}$	Net GHG emissions due to market-effects leakage up to year *t** ($t\ CO_2e$)
$\Delta C_{LK\text{-}AS,degrad\text{-}FW/C}$	Net GHG emissions due to activity shifting leakage for degradation caused by extraction of wood for fuel up to year *t** ($t\ CO_2e$)

8.4.3 ARR

The total net greenhouse gas removals of the ARR project activity are calculated as follows:

$$NGR_{ARR,t} = \Delta C_{WPS\text{-}ARR} - \Delta C_{BSL\text{-}ARR} - \Delta C_{LK\text{-}ARR} \tag{5}$$

Where:

NGR_{ARR}	Total net GHG removals of the ARR project activity up to year *t** ($t\ CO_2e$)
$\Delta C_{BSL\text{-}ARR}$	Net GHG removals in the ARR baseline scenario up to year *t** ($t\ CO_2e$)
$\Delta C_{WPS\text{-}ARR}$	Net GHG emissions in the ARR project scenario up to year *t** ($t\ CO_2e$)

$\Delta C_{LK\text{-}ARR}$	Net GHG emissions due to leakage from the ARR project activity up to year *t** (t CO_2e)

8.4.4 WRC

The total net GHG emission reduction of the WRC project activity is calculated as follows:

$$NER_{WRC} = GHG_{BSL\text{-}WRC} - GHG_{WPS\text{-}WRC} + Fire\ Reduction\ Premium - GHG_{LK\text{-}ECO} \quad (6)$$

Where:

NER_{WRC}	Total net GHG emission reductions in the WRC project up to year *t** (t CO_2e)
$GHG_{BSL\text{-}WRC}$	Net GHG emissions in the WRC baseline scenario up to year *t** (t CO_2e)
$GHG_{WPS\text{-}WRC}$	Net GHG emissions in the WRC project scenario up to year *t** (t CO_2e)
Fire Reduction Premium	Greenhouse gas emission reduction from peat combustion due to rewetting and fire management up to year *t** (t CO_2e)
$GHG_{LK\text{-}ECO}$	Net GHG emissions due to ecological leakage from the WRC project activity up to year *t** (t CO_2e)

8.4.5 Calculation of VCS Buffer

The number of credits to be held in the AFOLU pooled buffer account is determined as a percentage of the total carbon stock benefits. For REDD project activities, this is equal to the net emissions in the baseline minus emissions from fossil fuel use and fertilizer use minus the net emissions in the project case minus emissions from fossil fuels and fertilizer use. Leakage emissions do not factor into the buffer calculations.

For REDD projects, the calculation of the net change in carbon stocks applied in this methodology includes an adjustment for emissions from fossil fuel combustion and direct N_2O emissions and excludes emissions from biomass burning. Besides other GHG fluxes, biomass burning involves a carbon stock change. The procedure, therefore, provides a conservative (larger) estimate of the buffer withholding.

For WRC project activities – where carbon stock changes are not estimated – the proxy for the net change in carbon stocks applied in this methodology is NER_{WRC}. As this proxy includes all net GHG emissions reductions it provides a conservative (larger) estimate of the buffer.

Since GHG emission reductions from ARR are unlikely to differ greatly from the net change in carbon stocks, the proxy for the net change in carbon stocks applied in this methodology is NGR_{ARR}. As this proxy includes all GHG emissions reductions and removals it provides a conservative (larger) estimate of the buffer withholding.

$$Buffer_{Total} = Buffer_{Planned} + Buffer_{Unplanned} + Buffer_{Degrad-FW/C} + Buffer_{WRC} + Buffer_{ARR} \quad (7)$$

$$Buffer_{Planned} = \left(\left(\Delta C_{BSL,Planned} - \sum_{t=1}^{t^*_{BSL}} \sum_{i=1}^{M_{Planned}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) - \left(\Delta C_{P,Planned} - \sum_{t=1}^{t^*_{P}} \sum_{i=1}^{M_{Planned}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) \right) \times Buffer\% \quad (8)$$

$$Buffer_{Unplanned} = \left(\left(\Delta C_{BSL,Unplanned} - \sum_{t=1}^{t^*_{BSL}} \sum_{i=1}^{M_{Unplanned}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) - \left(\Delta C_{P,Unplanned} - \sum_{t=1}^{t^*_{P}} \sum_{i=1}^{M_{Unplanned}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) \right) \times Buffer\% \quad (9)$$

$$Buffer_{Degrad-FW/C} = \left(\left(\Delta C_{BSL,Degrad-FW/C} - \sum_{t=1}^{t^*_{BSL}} \sum_{i=1}^{M_{Degrad-FW/C}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) - \left(\Delta C_{P,Degrad-FW/C} - \sum_{t=1}^{t^*_{P}} \sum_{i=1}^{M_{Degrad-FW/C}} \left(E_{FC,i,t} + N_2O_{direct,i,t} \right) \right) \right) \times Buffer\% \quad (10)$$

$$Buffer_{ARR} = NGR_{ARR} \times Buffer\% \quad (11)$$

$$Buffer_{WRC} = NER_{WRC} \times Buffer\% \quad (12)$$

Where:

$Buffer_{Total}$	Total permanence risk buffer withholding (t CO_2e)
$Buffer_{Planned}$	Buffer withholding for avoiding planned deforestation project activities (t CO_2e)
$Buffer_{Unplanned}$	Buffer withholding for avoiding unplanned deforestation project activities (t CO_2e)
$Buffer_{Degrad-FW/C}$	Buffer withholding for avoiding degradation through extraction of fuelwood project areas (t CO_2e)
$Buffer_{ARR}$	Buffer withholding for ARR project activities (t CO_2e)
$Buffer_{WRC}$	Buffer withholding for WRC project activities (t CO_2e)
$\Delta C_{BSL,Planned}$	Net GHG emissions in the baseline from planned deforestation (t CO_2e)
$\Delta C_{BSL,Unplanned}$	Net GHG emissions in the baseline from unplanned deforestation (t CO_2e)
$\Delta C_{BSL,Degrad-FW/C}$	Net GHG emissions in the baseline from degradation caused by fuelwood collection and charcoal making (t CO_2e)

ΔC_P	Net GHG emissions within the project area under the project scenario[12] (t CO_2e)
$E_{FC,i,t}$	Emission from fossil fuel combustion in stratum *i* in year *t* (t CO_2e)
$N_2O_{direct\text{-}N,i,t}$	Direct N_2O emission as a result of nitrogen application on the alternative land use within the project boundary in stratum *i* in year *t* (t CO_2e)
Buffer%	Buffer withholding percentage[13] (percent)
NER_{WRC}	Total net GHG emission reductions in the WRC project up to year *t** (t CO_2e)
NGR_{ARR}	Total net GHG removals of the ARR project activity up to year *t** (t CO_2e)
i	1, 2, 3, …*M* strata (unitless)
t	1, 2, 3, …t^* time elapsed since the start of the REDD+ project activity (years)

8.4.6 Uncertainty Analysis

Project must use module *X-UNC* to combine uncertainty information and conservative estimates and produce an overall uncertainty estimate of the total net GHG emission reductions. The estimated cumulative net anthropogenic GHG emission reductions must be adjusted at each point in time to account for uncertainty as indicated in module *X-UNC*[14]. *X-UNC* calculates an adjusted value for NER_{REDD+} for any point in time. This adjusted $Adjusted\_NER_{REDD+}$ must be the basis of calculations at each point in time in equation 13.

8.4.7 Calculation of Verified Carbon Units

To estimate the number of Verified Carbon Units (VCUs) for the monitoring period *T* = *t2-t1*, this methodology uses the following equation:

$$VCU_t = \left(Adjusted\_NER_{REDD+,t_2} - Adjusted\_NER_{REDD+,t_1}\right) - Buffer_{Total} \quad (13)$$

Where:

VCU_t	Number of Verified Carbon Units at year $t = t_2 - t_1$ (VCU)
$Adjusted\_NER_{REDD+,t2}$	Total net GHG emission reductions of the REDD+ project activity up to year t_2 adjusted to account for uncertainty (t CO_2e)
$Adjusted\_NER_{REDD+,t1}$	Total net GHG emission reductions of the REDD+ project activity up to year t_1 adjusted to account for uncertainty (t CO_2e)

[12] The project emissions must be divided between the emissions arising from the respective project areas for planned and unplanned deforestation and degradation through fuelwood extraction/charcoal production.

[13] Buffer withholding percentages are based on the project's overall risk classification, the percentage of carbon credits generated by the approved project activity that must be deposited into the AFOLU pooled buffer account to cover non-permanence related project risks. Buffer withholding percentage must be calculated using T-BAR. Different percentages will likely be calculated for each of the baseline types as relevant.

[14] The allowable uncertainty under this methodology is +/- 15% of NER_{REDD+} at the 95% confidence level. Where this precision level is met then no deduction should result for uncertainty. Where uncertainty exceeds 15% of NER_{REDD+} at the 95% confidence level then the deduction must be equal to the amount that the uncertainty exceeds the allowable level.

$Buffer_{Total}$	Total permanence risk buffer withholding ($t\ CO_2e$)

The adjusted value for NER_{REDD+} to account for uncertainty must be calculated as:

$$Adjusted\_NER_{REDD+} = NGR_{ARR} + (NER_{REDD} + NER_{WRC}) \times (100\% - NER_{(REDD+ERROR)} + 15\%) + 15\%) + 15\%)$$

Where:

$Adjusted\_NER_{REDD+}$	Total net GHG emission reductions of the REDD+ project activities up to year *t** adjusted to account for uncertainty ($t\ CO_2e$)
NER_{REDD}	Total net GHG emission reductions of the REDD project activity up to year *t** ($t\ CO_2e$)
NER_{WRC}	Total net GHG emission reductions of the WRC project activity up to year *t** ($t\ CO_2e$)
NER_{REDD+_ERROR}	Cumulative uncertainty for the REDD+ (REDD and WRC) project activities up to year *t** (percent)
NGR_{ARR}	Total net GHG removals of the ARR project activity up to year *t** ($t\ CO_2e$)

For details see module *X-UNC*.

9.3 Description of the Monitoring Plan

9.3.1 Development of Monitoring Plan

General

The monitoring plan must address the following monitoring tasks, which must be included in the monitoring plan:

- Monitoring of project implementation
- Monitoring of actual carbon stock changes and greenhouse gas emissions
- Monitoring of leakage carbon stock changes and greenhouse gas emissions
- Estimation of *ex-post* net carbon stock changes and greenhouse gas emissions.

For each of these tasks, the monitoring plan must include the following information:

a. Technical description of the monitoring task.
b. Data to be collected. The list of data and parameters to be collected must be given in PD.
c. Overview of data collection procedures.
d. Quality control and quality assurance procedure.
e. Data archiving.
f. Organisation and responsibilities of the parties involved in all the above.

Uncertainty and Quality Management

Quality management procedures are required for the management of data and information, including the assessment of uncertainty, relevant to the project and baseline scenarios. As far as practical, uncertainties related to the quantification of GHG emission reductions and removals by sinks should be reduced.

To help reduce uncertainties in the accounting of emissions and removals, this methodology uses whenever possible the proven methods from the latest available IPCC guidance documents (GPG-LULUCF and Reporting Guidelines) and peer-reviewed literature. Despite this, potential uncertainties still arise from the choice of parameters to be used. Uncertainties arising from input parameters would result in uncertainties in the estimation of both baseline net GHG emissions and project net GHG emissions – especially when global default factors are used. The project must identify key parameters that would significantly influence the accuracy of estimates. Local values that are specific to the project circumstances must then be obtained for these key parameters, whenever possible. These values should be based on:

- Data from well-referenced peer-reviewed literature or other well-established published sources[15]; or,

- National inventory data or default factors from IPCC literature that has, whenever possible and necessary, been checked for consistency against available local data specific to the project circumstances; or

- In the absence of the above sources of information, expert opinion may be used to assist with data selection. Experts will often provide a range of data, as well as a most probable value for the data. The rationale for selecting a particular data value must be briefly noted.

For any data provided by experts, documentation must also record the expert's name, affiliation, and principal qualification as an expert as well as a 1-page summary CV for each expert consulted, included in an annex.

In choosing key parameters, or making important assumptions based on information that is not specific to the project circumstances, such as in use of default factors, project must select values that will lead to an accurate estimation of net GHG emission reductions, taking into account uncertainties.

If uncertainty is significant, project must choose data such that it indisputably tends to under-estimate, rather than over-estimate, net GHG project benefits.

To ensure that GHG fluxes are estimated in a way that is accurate, verifiable, transparent, and consistent across measurement periods, the project must establish and document clear standard operating procedures and procedures for ensuring data quality. At a minimum, these procedures must include:

- Comprehensive documentation of all field measurements carried out in the project area. This document must be detailed enough to allow replication of sampling in the event of staff turnover between monitoring periods.
- Training procedures for all persons involved in field measurement or data analysis. The scope and date of all training must be documented.
- A protocol for assessing the accuracy of plot measurements using a check cruise and a

[15] Typically, citations for sources of data used should include: the report or paper title, publisher, page numbers, publication date etc. (or a detailed web address). If web-based reports are cited, hardcopies should be included as annexes in the PD if there is any likelihood such reports may not be permanently available.

plan for correcting the inventory if errors are discovered.

- Protocols for assessing data for outliers, transcription errors, and consistency across measurement periods.
- Data sheets must be safely archived for the life of the project. Data stored in electronic formats must be backed up.

Monitoring of Project Implementation

Information must be provided, and recorded, to establish that:

1) The geographic position of the project boundary is recorded for all areas of land. The geographic coordinates of the project boundary (and any stratification or buffer zones inside the boundary) are established, recorded and archived. This can be achieved by field survey (eg, using GPS), or by using georeferenced spatial data (eg, maps, GIS datasets, orthorectified aerial photography or georeferenced remote sensing images).

   The above also applies to the recording of strata, including strata resulting from peatland fires in the project scenario.

2) Commonly accepted principles of land use inventory and management are implemented.

   - Standard operating procedures (SOPs) and quality control/quality assurance (QA/QC) procedures for inventories including field data collection and data management must be applied. Use or adaptation of SOPs already applied in national land use monitoring, or available from published handbooks, or from the latest IPCC guidance documents (GPG–LULUCF, Reporting Guidelines, is recommended;
   - Apply SOPs, especially, for actions likely to cause peat disturbances;
   - The project plan, together with a record of the plan as actually implemented during the project must be available for validation or verification, as appropriate.

REDD

For monitoring changes in forest cover and carbon stock changes, the monitoring plan must use the methods given in module *M-REDD*. All relevant parameters from the modules are to be included in the monitoring plan.

ARR

For monitoring carbon stock changes, the monitoring plan must use the methods given in module M-ARR. All relevant parameters from the modules are to be included in the monitoring plan.

WRC

For monitoring GHG emissions from peatland, the monitoring plan must use the methods given in module *M-PEAT*. All relevant parameters from the modules are to be included as the soil carbon pool in the monitoring plan.

9.3.2 MONITORING

Ex-post monitoring must have two key aspects:

TASK 1. Monitoring according to monitoring plan

TASK 2. Revising the baseline for future project crediting periods

TASK 1: Monitoring According to the Monitoring Plan

Monitoring of Key Baseline Variables

<u>REDD</u>

Information required to periodically reassess the project baseline must be collected during the entire project crediting period. Key variables to be measured are:

- Changes in forest cover in the Reference Regions for Deforestation (RRD) (at a minimum of every 10 years) as specified in module *M-REDD* and where relevant in module *BL-UP*.
- Spatial variable datasets used to model the location of deforestation, as specified in module BL-UP. As a minimum, the variables used in the first baseline assessment must be monitored at the time of the re-assessment to determine if they have changed.
- Where required, carbon stock data as specified in module *M-REDD*.

<u>WRC</u>

In projects with a WRC component, the information required to periodically reassess the project baseline must include changes in the drainage layout and climate variables, as specified in module M-PEAT and, where relevant, module *BL-PEAT*.

Monitoring of Actual Carbon Stock Changes and GHG Emissions

<u>REDD</u>

Changes in forest cover in the project area (and leakage belt for unplanned deforestation), must be measured before each verification as part of the monitoring. Methods must be consistent with the methodology given in module *M-REDD* and any technical guidance specified in the monitoring plan.

Carbon stocks in most cases will not have to be monitored during the baseline period, except in the following cases:

- Where there is an increased accuracy and precision of the *ex-ante* carbon stock estimates, which are also used for *ex-post* calculations. Verifiable evidence must be provided to VCS verifiers that the accuracy and precision of the carbon stock estimates has improved compared to previous estimates. Any change in carbon stock densities will be subject to validation.

- Where emissions reductions/removals are claimed for avoiding forest degradation caused by extraction of wood for fuel or charcoal or carbon sequestration in forest land that would have been deforested in the baseline case. In such cases, the methods described in module *M-REDD*.

Carbon stocks must be reassessed at every baseline revision.

Where emissions are included in the baseline, they must be monitored in the project case, following the methodological procedures described in the emission modules (*E-BPB*, *E-FFC*, and *E-NA*).

The calculations of actual carbon stock changes and greenhouse gas emissions must be reported using transparent procedures.

<u>ARR</u>

Changes in woody biomass carbon stocks in the project area must be measured before each verification as part of the monitoring. Methods must be consistent with the methodology given in module *M-ARR* and any technical guidance specified in the monitoring plan.

<u>WRC</u>

Changes in water depths in the project area (and leakage belt for unplanned deforestation), must be measured before each verification as part of the monitoring. Methods must be consistent with the methodology given in module *M-PEAT* and any technical guidance specified in the monitoring plan.

Monitoring of Leakage

All significant sources of leakage identified are subject to monitoring, following the procedures outlined in the monitoring plan. Such procedures must be consistent with the applicable leakage modules (*LK-ASP*, *LK-ASU*, *LK-ME*, *LK-DFW*, *LK-ARR* and *LK-ECO*). All relevant parameters in the leakage modules must be included in the monitoring plan.

The calculations of leakage carbon stock changes and greenhouse gas emissions must be reported.

TASK 2: Revising the Baseline for Future Project Crediting Periods

Baselines must be revised over time because agents, drivers and underlying causes of deforestation as well as drainage layouts and climate variables change dynamically. The methodological procedure used to update the baseline must be the same as used in the first estimation.

DOCUMENT HISTORY

Version	Date	Comment
v1.0	3 Dec 2010	Initial version
v1.1	7 Sept 2011	The REDD Methodology Framework was updated to limit the reassessment of the unplanned baseline scenario to every ten years. The methodology was also incremented to reflect a revision to the module for estimation of baseline carbon stock changes and greenhouse gas emission from unplanned deforestation (BL-UP), v2.0, which was approved under the VCS Program on 7 September 2011.
v1.2	31 July 2012	Table 2 was removed to avoid confusion with Table 1. Table 1 is now the exclusive source in the methodology for determining included/excluded pools.
v1.3	20 Nov 2012	The REDD Methodology Framework was updated to include avoided planned degradation as an allowable activity: • Removed the applicability condition "where post-deforestation land use constitutes reforestation this module must not be used" • Renamed "planned deforestation" to "planned deforestation and planned degradation" • Added the text "hereafter in this module, "deforestation" refers to both deforestation and planned degradation" A correction made to equation 8 to appropriately calculate the total VCUs available for issuance.
v1.4	3 May 2013	Applicability condition for unplanned deforestation "where post-deforestation land use constitutes reforestation this module must not be used" was removed. Equations 4, 5 and 6 were revised to appropriately account for the buffer.
v1.5	9 March 2015	Updated to include REDD+ project activities on peatlands as well as activities that include ARR. Methodology now includes six new modules: *VMD0041 BL-ARR*, *VMD0042 BL-PEAT*, *VMD0043 LK-ARR*, *VMD0044 LK-ECO*, *VMD0045 M-ARR*, and *VMD0046 M-PEAT*.

A Global Benchmark for Carbon

Approved VCS Methodology VM0008

Version 1.1

Sectoral Scope 3

Weatherization of Single Family and Multi-Family Buildings

Scope

This methodology provides a procedure to determine net CO_2 emission reductions associated with grouped projects that focus on energy efficiency activities for existing residential dwellings within a set geographic area and building stock.

Methodology Developer

The methodology was developed by the Maine State Housing Authority (MaineHousing) in collaboration with Lucille Van Hook, Lee International, and Climate Focus.

1 SOURCES

The methodology complies with the principles of:

- ISO 14064: Part 2, "Specification with guidance at the project level for the quantification, monitoring and reporting of greenhouse gas emission reductions and removal enhancements: 2006

The methodology also draws on ideas from the latest version of the following approved CDM tools and standards:

- CDM *Tool for the Demonstration and Assessment of Additionality*
- CDM *Tool to calculate the emission factor for an electricity system*

The methodology also references or draws on ideas, data, and definitions from the following sources:

- ASHRAE building standard 90.1-2004
- IAF Guidance on the Application of ISO/IEC Guide 66 Issue 4 IAF GD:2006
- Marrakesh Accords, Article 48 (c), 2001
- National Manufactured Housing Construction and Safety Standards Act of 1974 section 603
- Nationally recognized weatherization best practice standards, e.g., training curricula, core competencies, and example best practice standards for Weatherization activities offered by Department of Energy Weatherization Assistance Program and the Building Performance Institute
- US Environmental Protection Agency Refrigerants Global Warming Potentials
- US Department of Energy Buildings Energy Data Book

The methodology provides an overview of performance in the sector based on the following sources:

- American Council for an Energy Efficient Economy, *What Have We Learned from Energy Efficiency Financing Programs?*, 2011
- Gigaton Throwdown, *Redefining What's Possible for Clean Energy by 2020,* 2009
- International Energy Agency, *Worldwide trends in Energy Use and Energy Efficiency*, 2008
- McKinsey & Company, *Unlocking Energy Efficiency Potential in the U.S.*, 2009
- US Department of Energy, *Building Energy Data Book*, 2010

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology covers Weatherization of Dwellings, that is, energy efficiency measures directed at reducing the consumption of energy within a Dwelling. Examples include, but are not limited to, adding/improving insulation, air sealing, and replacing Appliances and central heating/cooling components.

Table 1: Additionality and Crediting Baseline Methods

Additionality	Performance Method: Categories A, B, and C Project Method: Category D
Crediting Baseline	Project Method: Categories A, B, C, and D

3 DEFINITIONS

Appliance means a major or minor household Appliance, which includes, but is not necessarily limited to, a refrigerator, microwave, dishwasher, clothes washer or dryer, space heater, and water heater. It does not include heating/cooling systems. An Appliance runs on electricity or another fuel source and is a discreet unit. It must be contained within the Building Envelope to be included in the Project activity.

Building Envelope means the exterior thermal boundary of the physical structure of an individual building. Thermal boundary typically includes the ceiling/roof, wall, floor, attic floor, window, or door that separates the habitable, occupiable, and conditioned spaces from the outdoor weather.

Cooling Degree Days (CDD) measure the cumulative degree difference between the warmer outside temperature and the base temperature of the conditioned space on a daily basis during the cooling season. CDD are determined by summing the daily degree days, which are calculated as the average daily temperature minus the base temperature. The average daily temperature is calculated by summing the daily high temperature and the daily low temperature and dividing by two. The average daily temperature can also be calculated by averaging the daily temperature over shorter time intervals, rather than just the high and low temperature. CDD reported by weather stations are often reported in sixty or thirty minute time intervals. In the US, the cooling base temperature is 78° F.

Dwelling means a single family house, including a mobile home[1], or an apartment within a multi-family building. The following are eligible under the methodology as long as the eligibility requirements in 1.3 are met: single family residential homes, including mobile homes; and multi-family residential homes.[2]

Energy Load means the sum of the heat load, cooling load and the electricity demand per Dwelling. Heat load means the total fuel consumed, including electricity (in BTUs, GJ or kWh) to provide comfort in a conditioned space in a given year. Cooling load means the total electricity, or other fuel type in the case of central cooling systems, consumed (in BTUs, GJ or kWh) necessary to remove heat from the conditioned space to provide comfort in a given year.

Heating Degree Days (HDD) measure the cumulative degree difference between the colder outside temperature and the base temperature of the conditioned space on a daily basis during the heating season. HDD are determined by summing the daily degree days, which are calculated as the base temperature minus the average daily temperature.[3] The average daily temperature is calculated by summing the daily high temperature and the daily low temperature and dividing by two. The average daily temperature can also be calculated by averaging the daily temperature over shorter time intervals, rather than just the high and low temperature. HDD reported by weather stations are often reported in sixty or thirty minute time intervals. In the US, the base temperature is 65° F. In the UK, the base temperature is 15° C.

R-value means a measurement of thermal resistance as expressed by a recognized authority, such as the U.S. Department of Energy, or the American Society of Heating, Refrigerating and Air-

[1] In the United States, mobile homes built later than 1976 are referred to as “manufactured homes” as defined in section 603 of the National Manufactured Housing Construction and Safety Standards Act of 1974. In this methodology, the term “mobile home” also refers to and includes a “manufactured home” when the replacement home is a manufactured home that can be transported and is permanently affixed to a steel chassis.

[2] In the United States, multi-family buildings that are over three stories above grade are considered commercial under the ASHRAE building standard 90.1-2004. These are also covered by the methodology.

[3] For example, a winter day (24 hours) has a low daily temperature of 20°F and a high daily temperature of 35°F. The total HDD for that day are calculated as: 65°F (base temperature) – ((35°F+20°F)/2). The HDD for that day are 37.5. If, the next day is slightly warmer and the daily low is 30°F and the daily high is 38°F, then the HDD for that day are 31. The cumulative HDD for the two days are 68.5. HDD for the heating season are cumulative.

conditioning Engineers (ASHRAE). The R-value of insulation in the floor, walls, ceiling, skirting or any other element will depend on the thickness and specific material of the installed insulation.

Same Building Stock means Dwellings 1) in the same state, province, or region, 2) in the same category (single family or multi-family), and 3) inhabited by the same income group (low-income, middle-income or high-income) as defined by a recognized authority.[4]

U-value means the thermal conductance of a material or, in other words, the total heat transmission in GJ per square meter per hour with a 1°C temperature difference between the inside and the outside. The U-value of the window is the inverse of the R-value or 1/R. The U-value for the make and model of a window can often be found on a window manufacturer's specification sheet included with the window.

Weatherization means energy efficiency measures in Dwellings. Weatherizing shall refer to the act of installing energy efficiency measures in Dwellings.

4 APPLICABILITY CONDITIONS

4.1 Any Dwelling or measures included in a Project shall meet the following conditions:

The condition of the Dwelling shall be and remain adequate for Project activities according to nationally recognized Weatherization best practice standards.[5] Project activities may not result in a violation of health and safety, environmental, or other relevant regulations.

The replacement Appliances and mobile homes must replace functioning Appliances, and/or occupied homes.

The Dwelling must be occupied. Vacancy is permitted on an intermittent basis for up to three months, or if the Dwelling is occupied seasonally on an annual basis.

The capacity of any replacement Appliance or replacement component of a central heating/cooling system shall satisfy the post-retrofit heat load, cooling load and electricity demand ("Energy Load") within the Dwelling.

In the case of heating/cooling systems that serve multiple Dwellings, all residential Dwellings connected to the system shall be included in the Project.

The Project activity must not be mandated, or required by local, state or federal law or regulation.

The Dwelling must meet or exceed the performance benchmark as calculated for the Same Building Stock. As evidenced by data, dwellings exceeding this performance benchmark would, with 90% certainty, not have happened without the intervention created by the Project.

[4] In the US, The Department of Health and Human Services issues guidelines that define the term "low-income" as a multiple of the income level defined as poverty level on an annual basis. For example, the 2009 poverty level was $10,400 for a single person, and $21,200 for a family of four. Households are considered low income if their household income is no more than 200% of poverty level.

[5] For example, in the United States, the Department of Energy Weatherization Assistance Program and the Building Performance Institute provide training curricula, core competencies, and example best practice standards for Weatherization activities, which are available at: http://www.waptac.org/sp.asp?mc=training_resources and http://www.bpi.org/standards.aspx.

4.2 The methodology is applicable to Weatherizing whole buildings, replacing mobile homes or implementing individual energy efficiency measures within existing Dwellings. Applicable interventions fall into one of the following categories:

Category A--All energy retrofit: A combination of energy efficiency measures directed at the Building Envelope (i.e. air infiltration, insulation), improving the efficiency of the central heating and/or cooling system and reducing energy consumption of Appliances (i.e. replacement of refrigerators, air conditioning units, lamps, showerheads).

Category B--Efficiency enhancement of the Building Envelope and central heating and/or cooling system only.

Category C--Replacement of Appliances currently in service.

Category D--Replacement of a mobile home currently occupied.

4.3 The methodology does not cover fuel switching.

4.4 In the case of "replacement" of a mobile home, the word "retrofit" shall be read to mean replacement throughout the methodology.

4.5 The methodology may be applied in any geographic region, provided appropriate data exist to establish the level of the performance benchmark for the Same Building Stock of a Project's geographic region.

4.6 When sampling, the minimum number of Dwellings or Appliances to be sampled shall be the square root of the total number of Dwellings i, or Appliances included in the Project. Statistically sound sampling approaches shall be used. When the control group approach (Approach 3 in Part C. Emission Reductions and Monitoring Parameters) is utilized, the size of the control group shall be the square root of the total number of Dwellings in the Project, but need not exceed 100 Dwellings. In any sampling approach, the following conditions must be met:

1) The sample shall be statistically valid, and may be one of the following:
    a. Simple random sample
    b. Systematic sampling
    c. Stratified sampling within the Same Building Stock
    d. Cluster sampling.
2) The sample must be representative of the population.
3) The data must come from an approved source, i.e. a certified energy auditor, or a nationally recognized data source.
4) Actions that may bias the sample shall be avoided. Sampling shall include Dwellings that are dispersed geographically. For each defined Building Stock included in the Project activity, sampling shall occur. Criteria include region, Dwelling type, and income.

5 PROJECT BOUNDARY

The Project boundary is the Building Envelope of the Dwelling(s) and its heating/cooling equipment.

Table 2: Greenhouse Gas Sources Included and Exclude in the Baseline and Project

The following greenhouse gas sources are included and excluded in the baseline and the Project:

Source		Gas	Included?	Justification/Explanation
Baseline	Grid electricity consumption by cooling systems or other electric Appliances	CO_2	Included	Only CO_2 emissions from grid connected electricity generation shall be accounted for.
		CH_4	Excluded	
		N_2O	Excluded	
		Other	Excluded	
	Fossil fuel consumption by heating systems	CO_2	Included	Only CO_2 emissions from fossil fuel combustion shall be accounted for.
		CH_4	Excluded	
		N_2O	Excluded	
		Other	Excluded	
	Emissions from wood combustion for heat	CO_2	Excluded	Excluded for simplification and to be conservative.
		CH_4		
		N_2O		
		Other		
Project	Grid electricity consumption by cooling systems or other electric Appliances heat	CO_2	Included	Only CO_2 emissions from grid connected electricity generation shall be accounted for.
		CH_4	Excluded	
		N_2O	Excluded	
		Other	Excluded	
	Fossil fuel consumption by heating systems Emissions from wood combustion for	CO_2	Included	Only CO_2 emissions from fossil fuel combustion shall be accounted for.
		CH_4	Excluded	
		N_2O	Excluded	
		Other	Excluded	
	Grid electricity consumption by cooling systems or other electric Appliances	CO_2	Excluded	Excluded for simplification and to be conservative.
		CH_4		
		N_2O		
		Other		
Leakage	Emissions from improper disposal of Appliances (e.g. refrigerators)	CO_2	Included	When the Appliance is not disposed of according to applicable laws and regulations there will be leakage from continued operation. The leakage emissions shall be calculated and excluded from emission reductions as described in the methodology.
		HFC	Included	
		CH_4	Excluded	
		N_2O	Excluded	
		Other	Excluded	

Leakage

Appliances, heating/cooling equipment and/or mobile homes that are replaced shall be properly disposed of and their disposal shall be documented. The disposal documentation shall confirm that: 1) the Appliances have been disposed of in a manner that prevents operation of the Appliance, and 2) the disposal procedure complies with applicable law and regulations. If not documented, CO_2 emissions from continued operation of replaced Appliances, heating/cooling equipment and/or mobile homes and HFC emissions from refrigerators or air conditioners shall be accounted for as leakage.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

The baseline scenario represents the conditions most likely to occur in the absence of the Project.

Category A--All energy retrofit: the baseline scenario consists of fossil fuel and electricity consumed to satisfy the heat and cooling load and the Appliance plug load prior to Project implementation.

Category B--Efficiency enhancement of the Building Envelope and/or central heating/cooling system: the baseline scenario consists of fossil fuel consumed to satisfy the heat and cooling load prior to Project implementation. Electricity shall only be included when it is a heating or cooling source within the Dwelling. Appliances and their corresponding electricity consumption shall not be included.

Category C--Replacement of Appliances: the baseline scenario consists of electricity consumed by the Appliances to be replaced prior to Project implementation.

Category D--Replacement of a mobile home: the baseline scenario consists of fossil fuel and electricity consumed to satisfy the heat and cooling load and the Appliance plug load of the mobile home to be replaced prior to Project implementation.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

7.1 A Project shall demonstrate additionality for project activities in category A, B, or C using the Performance Method that incorporates the performance benchmark set forth in section 1.3 below. A Project shall demonstrate additionality for project activities in category D using the Project Method.

7.2 The Project Method:

For demonstration of additionality for project activities under category D, the latest version of the CDM “Tool for the Demonstration and Assessment of Additionality” shall be applied, noting the following:

1) The project proponent may choose to complete an investment analysis or a barrier analysis or both.

2) Where the barrier analysis is used, sub-steps 3a and 3b of the above-referenced Tool shall be applied. The Project may rely on any of the barriers listed in the Tool as well as the barriers described below. When a barrier analysis is used, the following guidance applies:

   - Investment barrier: The Project may demonstrate it faces an investment barrier that the VCU revenue stream may help overcome. Such a barrier may be present when activities similar to those proposed in the Project: face a lack of available private capital due to real or perceived risks with the program or process or can only be implemented with the aid of grants, tax incentives, subsidies or non-commercial finance terms. A lack of private capital is defined as a lack of investors or a lack of access to financing at the local, state, provincial or regional level for activities similar to those proposed in the Project.

- Technological barrier: The Project may demonstrate it faces a technological barrier that the VCU revenue stream may help overcome. Such a barrier may result from a less technologically advanced alternative to the technology proposed for the Project activity including an alternative that would lead to higher emissions. The barrier could be due to the performance uncertainty or low market share of the new technology adopted for the Project activity and/or the less technologically advanced alternative would have led to higher emissions: examples a Project may use to demonstrate a technological barrier include, but are not limited to, non-availability of human capacity to operate and maintain the new technology, lack of infrastructure to utilize the new technology, unavailability of the new technology or a high level of technology risk.

- Institutional barrier: The Project may demonstrate it faces financial, organizational, cultural or social barriers that the VCU revenue stream can help overcome. Such a barrier may be based on prevailing practices, institutional resistance to change, lack of adequate funds to offer effective incentives to engage in the Project activity or other factors that impede more effective Project implementation, monitoring or maintenance. Examples a Project may use to demonstrate an institutional barrier include, but are not limited to, absence of an existing trained and qualified workforce, absence of a strong central organization to manage the Project and/or perform the Project activities, absence of suitable tools for monitoring carbon emissions, absence of incentives that can be shown to help to stimulate the Project activity.

7.3. The Performance Method provides as follows:

Category A--All energy retrofit: The percent savings in the pre- and post-retrofit Energy Load of each Dwelling in the Project shall be equal to or greater than the performance benchmark. The performance benchmark is a value above average performance that represents a percent savings in energy consumption that Dwellings are not likely to reach with 90% certainty in the absence of the Project. The average performance is the annual average percent savings in weather normalized energy consumption in Dwellings from the Same Building Stock over the three most recent years for which data are available[6]. Dwellings weatherized as part of the Project may be excluded.

Category B--Efficiency enhancement of the Building Envelope and/or central heating/cooling system: The percent savings in the pre- and post-retrofit Energy Load of each Dwelling in the Project shall be equal to or greater than the performance benchmark. The performance benchmark is the same as defined in Category A. Although Category B comprises measures to the Building Envelope only, the same performance benchmark can be used if the percent savings is calculated for the entire energy consumption of the Dwelling and not just for the consumption of heating and cooling energy. This way, savings achieved under the Project are comparable to overall trends. By broadening the base, savings from the Project are diluted. They would be higher if calculated for the savings in heat and cooling energy alone.

[6] Energy Load shall be used to determine whether the dwelling is additional because the Energy load is established during the energy audit. Energy consumption is used to calculate the mean percent savings within the Same Building Stock because that is the data available. Energy Load and energy consumption may be used in conjunction because energy consumption may be projected based on Energy Load.

The performance benchmark for Category A and Category B, *x*, shall be calculated as follows[7]:

For data following a normal distribution:

The performance benchmark is based on the standard deviation of the sample.

Equation 1

$$x = a + 1.85\sigma$$

Where:
x = Performance benchmark
a = Average performance[8]
σ = Standard deviation (sigma) of the percent savings in the Same Building Stock Energy Load

For data not following a normal distribution:

The performance benchmark is equal to the 90th percentile value within the numerically ordered sample. To calculate the 90th percentile the sample data point values ($v_1, v_{2 \ldots} v_N$) must be ordered from least to greatest. The 90th percentile value is equal to the value of the data point with the rank at which 90% of the data falls below.

Equation 2

a. $$n = (NP_{90}/100) + 0.05$$

b. *x*= the value of the data point at rank n calculated in equation 2a.

Where:
x = Performance benchmark
n = Rank of the ordered data point falling at the 90th percentile
N = Total number of data points included in the sample
P_{90} = *90th percentile*

To be additional, Dwellings must satisfy the following condition:

Equation 3

$$\frac{EL_{\Pr e,i} - EL_{post,i}}{EL_{\Pr e,i}} * 100 \geq x$$

---

[7] Under a normal bell curve distribution, the mean plus or minus 2σ encompasses 95% of the statistical sample. Therefore 97.5% of the data falls below the value *x*, if *x* is calculated as the mean plus 2σ. A 90% likelihood of the data falling below the value *x* is calculated as the mean plus 1.85 σ.

[8] To correct for any potential increase in electricity consumption due to an increase in electric appliances, the statewide percent increase in electricity consumption, as reported by the U.S. Department of Energy or other recognized authority, will be added to the value of the average performance to make the performance benchmark even more rigorous and conservative if such electricity data are reasonably available and it is feasible to do so. For example, in the US the value of the increase in regional electricity consumption may be obtained from the following website: http://apps1.eere.energy.gov/states/state_information.cfm

Where:
$EL_{pre,\,i}$= Pre-retrofit energy load of Dwelling *i*
$EL_{post,\,i}$= Post-retrofit energy load of Dwelling *i*

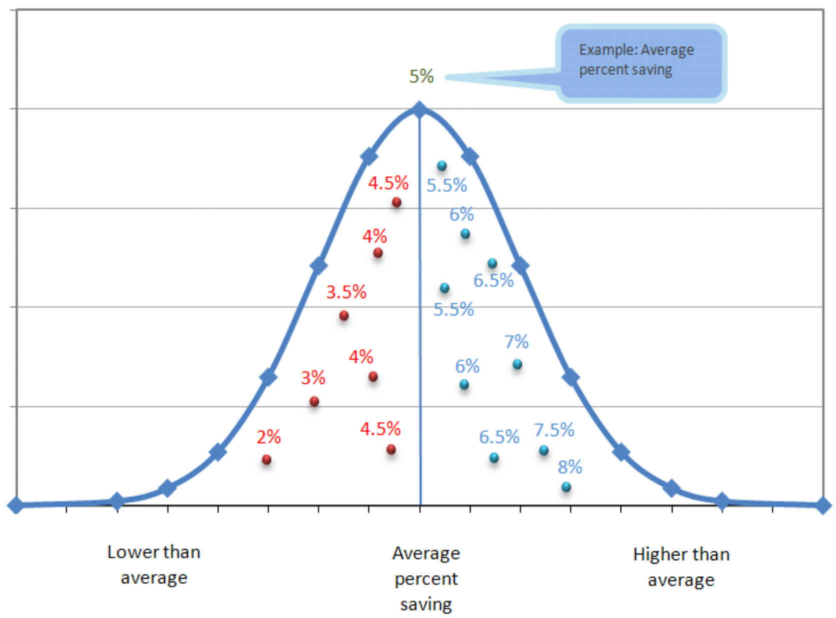

Figure 1. This graph shows the percent savings in energy consumption of buildings and Dwellings within the Same Building Stock. The percent savings is calculated from the change in weather normalized energy consumption in Dwellings from the Same Building Stock over at least the three most recent years for which data are available. The average performance, on which the performance benchmark is based, is calculated from these data. Dwellings with a high percent savings in energy consumption will fall to the right of the average performance, and Dwellings with a low percent savings in energy consumption will fall to the left of the average performance.

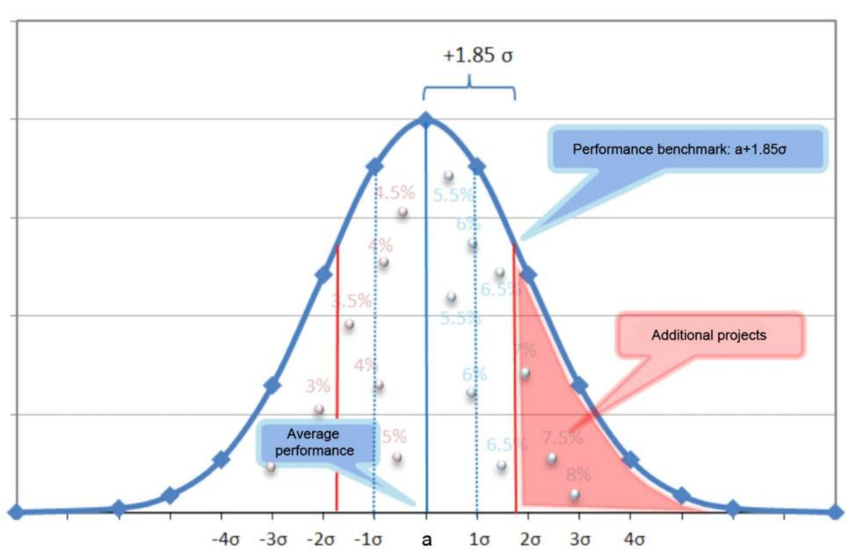

Figure 2. This graph shows how the performance benchmark (vertical red line to the right) is calculated by determining the average performance (vertical solid blue line), defined as the annual average of the percent savings in weather normalized energy consumption in the Same Building Stock over the past three years, and adding 1.85σ . The standard deviation (σ) is calculated from the actual data obtained from the Same Building Stock within the past three years. The numbers along the horizontal axis represent the number of standard deviations from the average value (average performance). For example, the data point 7% falls in line with 2σ, which means that 7% is 2 standard deviations away from the average performance, meaning that 95% of all buildings do not reach a 7% savings in energy consumption or higher .

The parameters to be monitored for calculating the average performance and standard deviation for Category A and Category B are listed in Section 9.

Category C--Replacement of Appliances: the energy consumption of the replacement Appliance shall meet or fall below the performance benchmark. The performance benchmark is a value below the average performance that represents a level of energy consumption per Appliance that Appliances are not likely to reach with 90% certainty in the absence of the Project. The average performance is the annual average energy consumption by existing Appliances of the same Appliance type, as defined by the particular make and model of the Appliance. Appliances replaced as part of the Project may be excluded. National Appliance data may be used due to the uniformity of Appliances available in the market. Data may be further differentiated (i.e. by income class) as appropriate data are available.

The performance benchmark for Category C, *x*, shall be calculated as follows:

For data following a normal distribution:

The performance benchmark is based on the standard deviation of the sample.

Equation 4

$$x = a - 1.85\sigma$$

Where:
x = Performance benchmark
a = Average performance
σ = Standard deviation (sigma) of the annual energy consumption of existing Appliances in operation.

For data not following a normal distribution:

The performance benchmark is equal to the 90th percentile value within the numerically ordered sample. To calculate the 90th percentile the sample data point values ($v_{1,}$ $v_{2...}v_N$) must be ordered from greatest to least. The 90th percentile value is equal to the value of the data point with the rank at which 90% of the data fall below.

Equation 5

a. $n = (NP_{90}/100) + 0.05$

b. x= the value of the data point at rank n calculated in equation 5a.

Where:
x = Performance benchmark
n = Rank of the ordered data point falling at the 90th percentile
N = Total number of data points included in the sample
P90 = 90th percentile

To be additional, Dwellings must satisfy the following condition:

$$a_{rc,\,k} \leq x$$

Where:
x = Performance benchmark
arc, k = Annual energy consumption per appliance of the replacement Appliance, type k

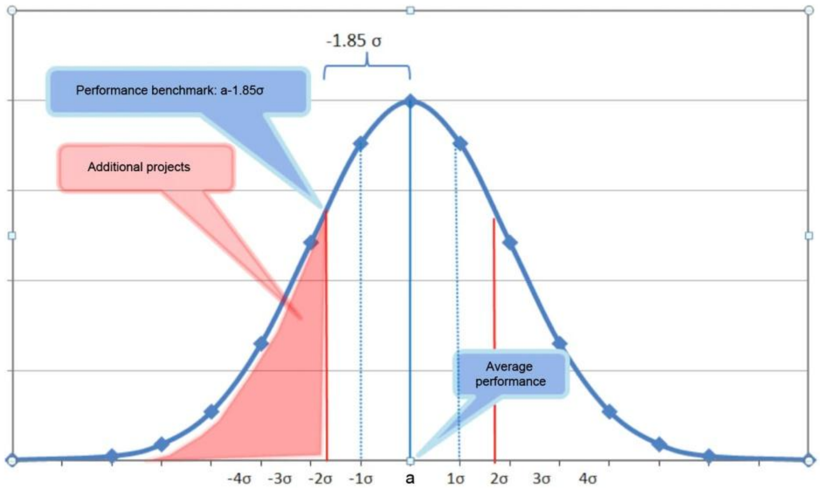

Figure 3. This graph shows how the performance benchmark (vertical red line to the left) is calculated by determining the average performance (vertical solid blue line), defined as the annual average energy consumption by existing Appliances of the same Appliance type and subtracting 1.85σ. The standard deviation (σ) is calculated from the existing Appliance data obtained from the population. The numbers along the horizontal axis represent the number of standard deviations from the average value (average performance). The shaded red section represents replacement Appliances with an annual energy consumption values that fall below the performance benchmark, and are considered additional.

The parameters to be monitored for calculating the average performance and standard deviation for Category C are listed in Section 9.

Category D--Replacement of a mobile home: No performance benchmark is defined.

Performance Benchmark Level

The level of the performance benchmark established using the performance method is based on the rigorous requirement that with 90% certainty, dwellings deemed additional under the methodology would not have reached the improvement in energy efficiency on their own. This is evidenced by performance data of dwellings from the Same Building Stock as defined in the methodology. The methodology formulates a universally applicable approach. The actual value of the performance benchmark (i.e., the 90^{th} percentile of percentage improvement in energy efficiency over the 3 most recent years) then has to be calculated for the specific project area where the methodology is applied. Hence, the same rigour applies wherever the methodology is used. Example case data from the US shows that only a tiny fraction of houses have undergone weatherization in recent years and that on average, energy use is still on the rise, making substantial energy efficiency improvements not a likely occurrence on their own.

The choice of 90% as confidence level for the performance method aligns with or exceeds similar requirements set forth in guidance pertaining to the CDM:

- The Marrakech Accords of the UNFCCC foresee three optional approaches to additionality of CDM projects of which one consists in the formulation of a benchmark. Article 48 (c) defines the benchmark as “The average emissions of similar project activities undertaken in the previous five years in similar social, economic, environmental and technological circumstances, and whose performance is among the top 20 per cent of their category”. The proposed top 10 percent in VM0008 is a more conservative approach.

- VM0008 provides for significant rigour in applying the performance method, far exceeding previous cases of methodologies that were not accepted. For example, a new CDM methodology, 302 “CDM methodology for cement and clinker production facilities based on benchmarking”, was proposed using the top 20 percent performing installations as a performance benchmark for additionality. This methodology has not been accepted by the CDM EB (as time of writing) on several grounds. We chose to be far more stringent in VM0008.

Distribution of Performance in the Sector

There is an abundance of data showing that energy use in existing U.S. buildings is inefficient and increasing over time, and that there are significant barriers to increased penetration of energy efficiency measures. Studies show that the trends in energy use and efficiency are largely similar across the world, although there are some programs (e.g., the United Kingdom Green Deal under the Energy Act of 2011) which target economy-wide energy efficiency program implementation on a large scale.

It is important to note that the level of the performance benchmark is dictated by the performance in a particular geographic area as defined by the Same Building Stock. Therefore, even though there may be programs in different geographic areas that promote residential energy efficiency measures, projects in those locations would still need to exceed the locally applicable performance benchmark.

By extension, in geographic locations where programs exist to promote energy efficiency measures, the performance benchmark can be expected to represent a level of savings that is more stringent than in locations where no such programs exist. The performance method is designed to ensure that the level of the performance benchmark automatically becomes more stringent in geographic locations with increasing levels of residential energy efficiency activities.

The following status quo description for residential buildings in the US serves solely to provide examples of relevant data for the establishment of a Same Building Stock and its particular performance benchmark. The following example case information does not limit the applicability of the performance method to the US. Each performance benchmark must be calculated relative to each Same Building Stock and its particular geographical boundary.

Relative to the US, studies show:

- In 2005, the U.S. housing stock was found to be comprised of dwellings classified by household type as follows: single family (71.7%), multi-family (22.0%) and mobile homes (6.2%). (DOE Building Energy Data Book 2010, Table 2.2.2)
- In 2005, the following average energy intensities were found in each building stock: single family, 106.6 million Btu per household; multi-family, 64.1 million Btu per household; mobile homes, 70.4 million Btu per household. (DOE Building Energy Data Book 2010, Table 2.1.11)
- In 2008, the breakdown in energy use in U.S. residential buildings was approximately: Natural Gas, 35%; Petroleum, 6%, Coal, 35%, Renewables, 8%; and Nuclear, 14%. Projected values are not expected to vary by more than +/- 5% from 2008 to 2035. (DOE Building Energy Data Book 2010, Table 2.1.2)
- There are “significant and persistent barriers” to implementing energy efficiency measures in the U.S. including structural, behavioral, and availability barriers. (McKinsey 2009)
- Rates of U.S. residential energy efficiency program penetration range broadly from 16% to 0.5% or less (American Council for an Energy Efficiency Economy, 2011). On average, less than 5% of homes in the U.S. have undergone an energy-efficiency retrofit. (Gigaton Throwdown 2009)
- Residential sector energy use is projected to increase at 0.4% per year under a business-as-usual scenario between 2008 and 2020. (McKinsey 2009)
- A typical residence uses up to 40% more energy than it needs to operate economically. (Gigaton Throwdown 2009)
- Worldwide residential energy use increased 19% between 1990 and 2005. (International Energy Agency 2008)
- Only weatherization measures that systematically address the thermal envelope or significantly improve the efficiency of end-use appliances are likely to enable a project to exceed a performance benchmark;
  - Evaluations of physical weatherization measures in residential dwellings demonstrate savings of around 20-30%. See, for example: Oak Ridge National Laboratories, ORNL/CON-493, 2005; and Cadmus Group, Efficiency Maine Trust Home Energy Savings Program Final Evaluation Report, 2011.
  - By comparison, evaluations of behavior change programs (e.g., providing information to encourage occupants to turn off unneeded lighting and equipment) demonstrate levels of energy savings ranging from levels not statistically different than 0 to energy savings levels of up to about 3%. See, for example: Navigant, Evaluation Report: OPOWER SMUD Pilot Year 2, 2011; and Energy Center of Wisconsin, Focus on Power-PowerCost Monitor Study, 2010.

Evaluation of the Tradeoff between False Negatives and False Positives

The level of the performance benchmark was determined after careful consideration of the tradeoff between false negatives and false positives.

False negatives, in the context of the methodology, are dwellings that have been excluded by the performance method (found not to be additional) even though the efficiency upgrades to these dwellings would not have occurred in the absence of the Project. False positives are dwellings that are included in the project even though their efficiency upgrades would have happened anyway. The latter can be considered free-riders.

In elaborating the performance method, the team originally intended to develop a performance benchmark value for efficiency that dwellings would have to attain in order to be considered additional, in the form kWh / m2 or a comparable metric. This metric however was shown to create a risk of producing an unacceptable number of false negatives. During stakeholder consultations, Joel Eisenberg, Weatherization Evaluation Consultant for the U.S. Department of Energy acting as Program Manager at Oak Ridge National Laboratory, pointed out that weatherization efforts directed at low income houses typically target the most energy inefficient houses. While the impact of weatherization is large, both in terms of energy savings compared to the baseline and in social impact, these dwellings are unlikely to meet a high energy efficiency standard even after weatherization. To avoid unnecessary and inappropriate disqualification of low income dwellings, the decision was made to elaborate the performance method based on a percentage change rather than an absolute performance level.

In setting the performance benchmark, the 90th percentile was deemed a sufficiently rigorous requirement for exclusion of free-riders. If the performance benchmark were to be established using a higher level, e.g. 95% or even 99%, there would be a significant risk that the level of energy efficiency enhancement to be exceeded by dwellings in the Project would be determined by singular and random occurrences rather than a systematic trend in the population. For instance, there are households which undertake energy efficiency improvements based on personal environmental consciousness, or because residents are particularly handy and can do the work themselves, or because houses are so drafty that air sealing is necessary to improve living comfort. Special cases with high energy efficiency gains are not and should not be considered the norm. To consider these the norm would lead to the perverse result of disqualifying many weatherization projects.

In choosing a benchmark value of 90% that is more rigorous than comparable CDM guidance yet does not allow for rare occurrences to set the performance benchmark, and by focusing on percentage changes in efficiency enhancements rather than absolute levels of efficiency, VM0008 seeks to minimize and optimally balance the tradeoff between false positives and false negatives.

Geographic Scope

When using a performance benchmark for Category A, Category B, or Category C activities, project proponents shall calculate the performance benchmark for each Same Building Stock identified in the project description. While the methodology does not set out a geographic limitation on project location, this requirement restricts each performance benchmark to a specific geographic area defined in a project description (e.g., a state, province or region).

Data Selection and Use

In developing a performance benchmark, project proponents must select and use data sources that meet the following requirements of Section 4.5.6 of the VCS Standard Version 3.3) as modified for the methodology:

1) Data collected directly from primary sources shall comply with relevant and appropriate standards, where available, for data collection and analysis, and be audited at an appropriate frequency by an appropriately qualified, independent organization.
2) Data collected from secondary sources shall be available from a recognized, credible source and must be reviewed for publication by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.

3) Where sampling is applied in data collection, the project proponent shall demonstrate that sampling results provide an unbiased and reliable estimate of the true mean value (i.e., the sampling does not systematically underestimate or overestimate the true mean value). Project proponents may choose to demonstrate the appropriateness of sampling results based on a qualitative description of data sources and methods, where appropriate.
4) Data shall be publicly available, where appropriate (not confidential). Proprietary data (e.g., data pertaining to individual facilities) may be aggregated, and therefore not made individually publicly available, as there are demonstrable confidentiality considerations. However, sufficient data shall be publicly available to provide transparency and credibility to the dataset.
5) All data shall be made available, under appropriate confidentiality agreements as necessary, to the VCSA and each of the validation/verification bodies assessing the proposed performance benchmark, to allow them to reproduce the determination of the performance benchmark. Data shall be presented in a manner that enables them to independently assess the presented data.
6) All reasonable efforts shall be undertaken to collect sufficient data and the use of expert judgment as a substitute for data shall only be permitted where it can be demonstrated that there is a paucity of data. Expert judgment may be applied in interpreting data. Where expert judgment is used, good practice methods for eliciting expert judgment shall be used (e.g., IPCC 2006 Guidelines for National GHG Inventories).
7) Where data must be maintained in a central repository on an on-going basis (e.g., in a database that holds sector data for use by project proponents in establishing specific performance benchmarks for their projects), there shall be clear and robust custody arrangements for the data and defined roles and responsibilities with respect to the central repository.

Data Maintenance

Project proponents must maintain data used to establish any performance benchmark in a manner that meets the following requirements of Section 4.5.7 of the VCS Standard version 3.3 as modified for the methodology:

The dataset may be documented and contained within the project description, or may be maintained in a separate repository that is referenced by the project description. Datasets documented and contained within the project description are static datasets, where all project activities use the level of the relevant performance benchmark that is specified in the project description. The following applies with respect to datasets maintained in a separate repository:

1) The dataset may be static or dynamic (ie, may or may not be periodically updated).
2) The project description shall establish criteria and procedures for the use of the dataset and for establishing a specific performance benchmark for each Same Building Stock
3) The project description may specify that projects use the level of the performance benchmark metric available at project validation for the duration of their project crediting periods, or may specify that projects use an updated level of the performance benchmark at each verification event. The frequency that data is updated within the dataset shall be determined by the project proponent.
4) It shall be demonstrated that procedures are in place to maintain the dataset in accordance with the applicable requirements set out in Section 7.3, “Data Selection and Use”.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

This section presents five approaches to calculating emission reductions and related monitoring parameters. They are: 1) the adjusted consumption approach, 2) the pre-and post retrofit audit approach,

3) the control group approach, 4) the deemed savings approach, and 5) the mobile homes approach. Equations required to calculate emission reductions under each approach and monitoring parameters applicable to each approach are listed in this section.

Emission reductions are calculated directly under each approach; in other words, baseline and project emissions are not calculated separately under the methodology. This method results in a simplified and accurate estimation of project emissions normalized for weather and electricity correction factors. Leakage is calculated separately under each approach.

Category A--All energy retrofits: calculation of the emission reductions and monitoring shall be based on either:

1. The adjusted consumption approach;
2. The pre- and post-retrofit audit approach; or
3. The control group approach.

Category B--Efficiency enhancements of the Building Envelope and central heating/cooling: calculation of the emission reductions and monitoring shall be based on either:

1. The adjusted consumption approach;
2. The pre- and post-retrofit audit approach; or
3. The control group approach.

In Category B, electricity shall only be included in the calculation of emission reductions when it is a heating or cooling source within the building or Dwelling.

Category C--Appliance replacement: calculation of the emission reductions and monitoring shall be based on:

4. The deemed savings approach.

Category D--Replacement of a mobile home: calculation of the emission reductions and monitoring shall be based on either:

1. The adjusted consumption approach;
3. The control group approach; or
5. The mobile homes approach.

1. Adjusted consumption approach

In the adjusted consumption approach, measured energy consumption pre-retrofit, the baseline consumption, shall be corrected for changes in electricity demand over time and adjusted for Heating/Cooling Degree Days using an Electricity Correction Factor ("ECF") and Heating/Cooling Degree Day Correction Factors ("HDDCF" or "CDDCF" as applicable). A sample may be used to measure energy consumption pre-retrofit. Project consumption of fuel and electricity shall be subtracted from the adjusted baseline consumption. The result shall be multiplied by an emission factor for the fuel or electricity used in the baseline. A control group of non-weatherized, or non-retrofitted, Dwellings shall be monitored as a quality assurance measure.

1.1 Emission reductions in the adjusted consumption approach shall be calculated as follows:

Equation 6

$$ER_y = \sum_{i=1}^{I}(Elec_{b,i} * ECF_y * CDDCF_y - Elec_{p,y,i}) * Elec_{CO2} + \sum_{i,j=1}^{I,J}(F_{b,i,j} * HDDCF_y - F_{p,y,i,j}) * Cal_j * F_{CO2j} - L_y$$

Where:

ER_y = Emission Reduction in year *y* in metric tons ("t") CO_2e/yr

i = Dwelling
$Elec_{b,i}$ = Electricity consumed in the year prior to Project implementation for Dwelling i in kWh (baseline consumption)[9]
$Elec_{p,y,i}$ = Electricity consumed by the Project in year y for Dwelling i in kWh (Project consumption)
ECF_y = Electricity correction factor for year y to be applied to the baseline
$CDDCF_y$ = Cooling degree days correction factor for year y
$HDDCF_y$ = Heating degree days correction factor[10] for year y
$F_{b,i,j}$ = Fuel type j consumed in the year prior to Project implementation for Dwelling i in the appropriate mass, or volume unit (baseline consumption)
$F_{p,y,i,j}$ = Fuel type j consumed by the Project in year y for Dwelling i in the appropriate mass, or volume unit (Project consumption)
Cal_j = Calorific value of fuel type j in GJ/mass or volume
$Elec_{CO2}$ = Grid emission factor in tCO_2e/kWh
$F_{CO2,j}$ = The CO2 emission factor per unit of energy of fuel type j expressed in tCO_2e / GJ
L_y = Leakage in year y
I = Number of Dwellings
J = Number of fuel types
j = Fuel type
y = Any consecutive twelve months during the Project's crediting period, and shall be defined with an integer from 1 on in a consecutive manner

Leakage, L_y, shall be calculated as follows:

Equation 7

$$L_y = L_{CO2,y} + L_{HFC,y}$$

Leakage from continued operation of Appliances, $L_{CO2,y}$, shall be calculated as follows:

Equation 8

$$L_{CO2,y,} = \sum_{k=1}^{K} (a_{np,k,y} * h_k * E_{dem,pre,k}) * Elec_{CO_2} + \sum_{t=1}^{T-1} L_{(y-t),CO2}$$

Where:
$a_{np,k,y}$ = Appliance not properly disposed of Appliance type k in year y
K = Number of Appliance types
$E_{dem,pre,k}$ = Electricity demand of Appliance type k before replacement
h_k = Annual working hours of Appliance type k
$Elec_{CO2}$ = Grid emission factor in tCO2e/kWh
T = Years from beginning of project crediting period

Leakage from improper disposal of refrigerators or air conditioners, $L_{HFC,y}$ shall be calculated as follows:

[9] If multiple dwellings within a single building are served by a single meter, the electricity consumption unit shall change to kWh/m2 and the equation shall be multiplied by the area of each individual dwelling. Consequently, the area of each dwelling shall be recorded and included in the monitoring parameters.

[10] When fossil fuel is the cooling source the CDDCF shall replace the HDDCF in the equation. Conversely, when electricity is the heating source the HDDCF shall replace the CDDCF in the equation.

Equation 9

$$L_{HFC,y} = \sum_{k=1}^{K} a_{np,k,y} * RCC_a * GWP_R * \frac{1t}{1{,}000{,}000g}$$

Where:

RCC_a = Charge capacity of refrigerant gas of replaced cooling Appliance a in grams
GWP_R = Global Warming Potential of refrigerant gas R used in Appliance in tons CO_2equivalent per ton of R

Table 1: GWP for common refrigerant types

Refrigerant Type	**HFC-23**	**HFC-32**	**HFC-125**	**HFC-134a**	**HFC-143a**	**HFC-152a**
GWP 100yr (IPCC 1996)	11700	650	2800	1300	3800	140

Refrigeration equipment often uses blends of HFC refrigerant gases. The GWP of these blends should be calculated based on the proportion of different refrigerants used[11].

1.2 The grid emission factor ($Elec_{CO2}$) shall be calculated in a transparent and conservative manner based on one of the following approaches:

A combined margin, consisting of the combination of operating margin and build margin according to the procedures prescribed in the most recent CDM 'Tool to calculate the emission factor for an electricity system'. The grid emission factor shall be monitored following either the *Ex ante* option or the *Ex post* option within the CDM Tool.

Or

The weighted average emissions (in tCO2e/kWh) of the current generation mix obtained from a regulated source. The data from the most recent year for which data are available shall be used. The grid emission factor shall be monitored annually, and updated as the regulated source publishes data. If the grid emission factor is published later than year *y*, the emission factor from an earlier year, up to three years prior (*y-3*), may be used.

1.3 The ECF represents the trend in electricity demand based on average electricity consumption within a region or state over a period of at least ten years. Historical data from a recognized national authority may be used to determine the ECF. Projected trends in changes in the rate of electricity demand reported by a national authority may also be used as the ECF[12]. The ECF shall be stated as a multiplier. For example, 0.98 represents an electricity consumption growth rate of -2%.

The Electricity Correction Factor ("ECF") is used to update the baseline electricity consumption based on decreases in electricity demand over time. The ECF shall only be applied when it is less than 1 to maintain conservativeness in the emission reduction calculation. This factor shall be applied to the calculation of the emission reductions after Project implementation because electricity consumption in the baseline may not remain the same (see Figure 3). The factor shall be determined from local, regional or national electricity household consumption data from a

[11] Examples of the available compositions of refrigerant blends are available at the U.S. Environmental Protection Agency website: http://www.epa.gov/Ozone/snap/refrigerants/refblend.html
[12] Examples of reported values that may be used as an ECF are available at the Department of Energy website: http://apps1.eere.energy.gov/states/electricity.cfm/state=ME.

government agency, a public utility or regulatory agency, or a recognized energy research organization.

In a situation where overall electricity consumption decreases, the Electricity Correction Factor ensures against over-estimation of emission reductions (see Figure 4).

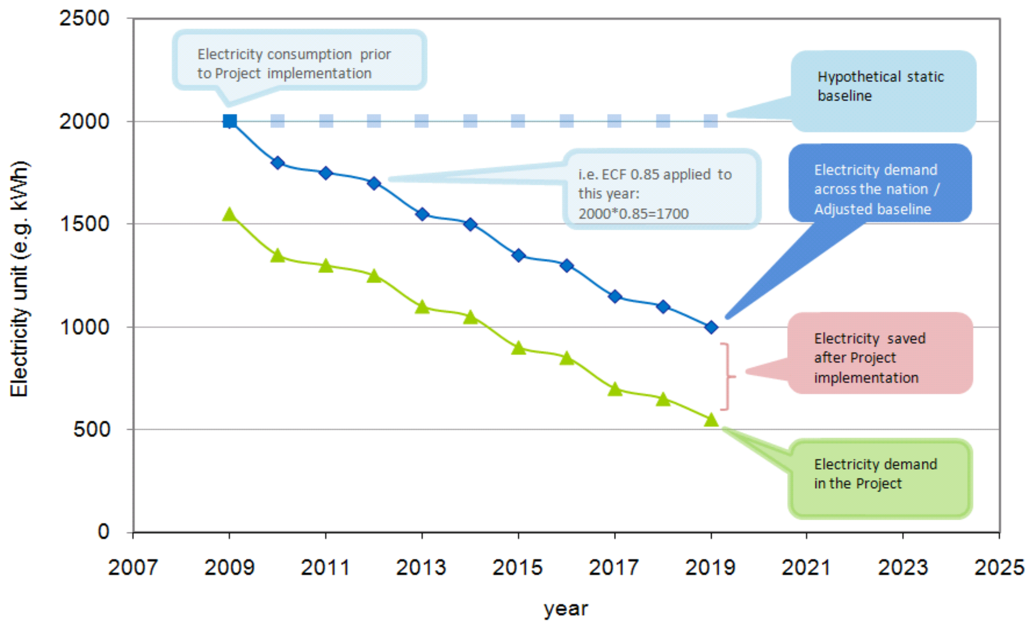

Figure 4 : This graph shows how the adjusted consumption approach takes into account a reduction in electricity consumption over time. Failure to adjust for decreasing consumption over time would result in an over-estimation of emission reductions.

1.4 The Heating/Cooling Degree Day Correction Factors (HDDCF and CDDCF) are used to update the baseline energy consumption annually based on changes in temperature. These factors account for changes in heating/cooling degree days and associated changes in heating and cooling loads (see Figure 3). The factors shall be determined based on data from reputable regional or national meteorological organizations[13].

The Heating Degree Day Correction Factor shall be calculated as follows:

Equation 10

$$HDDCF_y = \frac{HDD_y}{HDD_b}$$

The Cooling Degree Day Correction Factor shall be calculated as follows:

Equation 11

$$CDDCF_y = \frac{CDD_y}{CDD_b}$$

Where:

HDD_y = Heating degree days for year *y* after the retrofit

[13] An example of such organization is the National Oceanic and Atmospheric Administration (NOAA) in the United States.

HDD_b = Heating degree days for one year before the retrofit
CDD_y = Cooling degree days for year *y* after the retrofit
CDD_b = Cooling degree days for one year before the retrofit

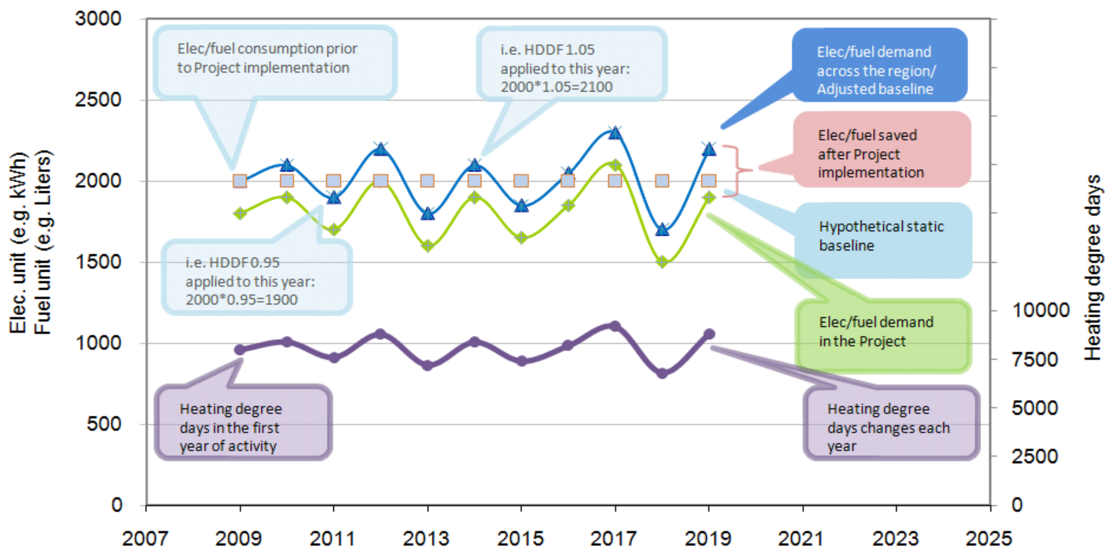

Figure 5: This graph shows how heating degree days affect fuel/electricity consumption over time. Failure to adjust the baseline based on changes in temperature would result in inaccurate calculation of emission reductions.

Quality Assurance

1.5 When using the adjusted consumption approach, a sample group of Dwellings Weatherized as part of the Project shall be monitored to ensure the reduction in energy consumption and resulting reduction in emissions is real. The sample group shall measure the emission reductions resulting from the change in energy consumption. In case of a significant discrepancy between emission reductions calculated according to the approach and emission reductions calculated from the sample group, the adjusted baseline consumption approach shall be calibrated accordingly. The sample size of the sample group shall be established by multiplying 0.6 by the square root of the total number of Dwellings, *i*, or Appliances, included in the Project[14]. Monitoring of the sample group for quality assurance shall occur for two years and shall consist of collecting electricity and fuels bills that represent a twelve month period.

When the data come from two different processes, such as the adjusted consumption calculation and the measurements from the sample group, significant discrepancy is defined on the basis of an independent 2-sample t-test for equality of two means. If the value T of the above statistic obtained from a t-value table or calculation is greater than the corresponding value of the t-distribution for a 95% confidence level and degrees of freedom given by 2n-2, then the null hypothesis of equal means is rejected and the observed discrepancy is concluded to be significant.

A t-test is a standard statistical tool and readily available. One of the t-tests set forth below shall be applied. The particular test shall be determined by the type of samples, samples sizes and assumptions made on the underlying population variances.

[14] The equation for determining the minimum sample size number for quality assurance purposes was taken from the surveillance requirements in the IAF Guidance on the Application of ISO/IEC Guide 66 Issue 4 IAF GD: 2006.

1. An independent 2-sample t-test for samples of equal sizes and equal variances shall be used when the number of observations (data points) in both samples is equal and it can reasonably be assumed that the population variance of both samples is the same.

2. An independent 2-sample t-test for unequal sample sizes and equal variances shall be used when the number of observations (data points) in both samples is not equal and it can reasonably be assumed that the population variance of both samples is the same.

3. An independent 2-sample t-test for unequal sample sizes and unequal variances shall be used when the two data samples are of unequal size and it can be reasonably assumed that the population variance is different. This test is referred to as Welch's t-test.

1.6 The parameters to be monitored in the adjusted consumption approach are listed in Section 9.

2. Pre- and post-retrofit audit approach

Monitoring emission reductions shall be based on the data generated by a pre- and post- retrofit energy audit for a sample of the Dwellings. A pre-retrofit audit shall take place once before Project implementation for every Dwelling and a post-retrofit audit shall take place once after the retrofit has been completed for a sample of the Dwellings. In every multi-family building, a representative sample of the Dwellings shall undergo a pre- and post-retrofit audit. The pre-retrofit audit shall determine the electricity demand and heat load in the baseline. The pre-retrofit electricity demand and heat load shall then be compared to the post-retrofit electricity demand and heat load. This comparison shall provide the Electricity Demand Reduction Factor and the Heat Load Reduction Factor, which shall be used to calculate emission reductions created by the Project.

2.1 To calculate emission reductions, the reduction factors obtained from the pre- and post- energy audit shall be applied to the baseline consumption of electricity and fuel. The result shall then be multiplied by the emission factor of the fuel type. Emission reductions shall be adjusted for changes in electricity demand over time and adjusted for heating/cooling degree days during the project crediting period.

2.2 Energy auditors must be certified by a public authority or a private certification program recognized by a public authority. Energy audits shall be conducted using industry best-practices, cover both fuel and electricity consumption, include diagnostic tests (such as a blower door test, pressure pan test or thermal imaging) and use energy modeling software, or appropriate calculations[15].

2.3 The Electricity Demand Reduction Factor ("EDF") shall be calculated for a sample of the Dwellings as follows:

Equation 12

$$EDF = 1 - \frac{\sum_{s=1}^{S} E_{dem,post,s}}{\sum_{s=1}^{S} E_{dem,pre,s}}$$

[15] In the United States there are several established energy auditing programs that are credible and accepted as industry best practice. Examples include, but are not limited to RESNET HERS rating, Building Performance Institute Audit, Home Performance with Energy Star, Maine Certified Energy Audit. The certification process is a substitute for a single industry standard.

The Heat Load Reduction Factor (HLF) shall be calculated for a sample of the Dwellings as follows:

Equation 13

$$HLF = 1 - \frac{\sum_{s=1}^{S} H_{load,post,s}}{\sum_{s=1}^{S} H_{load,pre,s}}$$

Where:

EDF	= Electricity demand reduction factor (no unit)
$E_{dem,post,s}$	= Electricity demand post-retrofit for Dwelling *s*, kW
$E_{dem,pre,s}$	= Electricity demand pre-retrofit for Dwelling *s*, kW
HLF	= Heat load reduction factor (no unit)
$H_{load,post,s}$	= Heat load post-retrofit for Dwelling *s*, kWh/m^2
$H_{load,pre,s}$	= Heat load pre-retrofit for Dwelling *s*, kWh/m^2
S	= Number of sample Dwellings
s	= sample Dwelling undergoing post retrofit audit

2.4 Emission reductions shall be calculated as follows:

Equation 14

$$ER_y = \sum_{i=1}^{I} Elec_{b,i} * EDF * ECF_y * CDDCF_y * Elec_{CO2} + \sum_{i,j=1}^{I,J} F_{b,i,j} * HLF * HDDCF_y * Cal_j * F_{CO2} - L_y$$

Leakage, L_y, shall be calculated using Equation 7.

Quality Assurance

2.5 When using the pre- and post-audit approach, energy bills based on direct metering of consumption shall be collected for one year pre-retrofit and compared with post-retrofit energy bills based on direct metering of consumption in a sample of Dwellings. When dealing with non-regulated fuels, an acceptable alternative measure shall be compared to that same measure as shown in the post-retrofit audit to ensure the energy savings were achieved. The sample size for quality assurance samples shall be established by multiplying the 0.6 by square root of the total number of Dwellings, *i*, or Appliances, included in the Project. The reduction in demand as calculated in Equation 12 and Equation 13, shall be compared to the reduction in consumption based on directly metered electricity or natural gas consumption data, or in the case of non-regulated fuels an acceptable alternative measure. The sample group shall be tested for a significant discrepancy between the calculated reduction in energy demand as shown in the post-retrofit audit and actual reduction in consumption calculated from directly metered energy bills. When dealing with non-regulated fuels an acceptable alternative measure shall be used, as noted above. If the discrepancy between the two mean values is found to be significant, the mean energy consumption from the directly metered value shall be used to calculate the HLF or EDF.

When the two data samples come from the same Dwelling, significant discrepancy is defined on the basis of a dependent 2-sample t-test for equality of two means. If the t-value of the above statistic obtained from a t-value table or calculation is greater than the corresponding value of the t-distribution for a 95% confidence level and degrees of freedom given by n-1, then the null hypothesis of equal means is rejected and the observed discrepancy is concluded to be significant.

A dependent 2-sample t-test shall be applied to test for the difference of the two means. The two means to be compared shall be from the sample group of weatherized Dwellings, and shall be the mean of the energy demand determined by the post-retrofit audit and the mean of the directly metered energy bill in the case of electricity and natural gas. However, in the case of non-regulated fuels, the two means compared shall be based on an acceptable alternative measure, such as blower door test value as shown in the post-retrofit audit, and the blower door test value recorded one year post-retrofit.

2.6 The parameters to be monitored in the pre-and post-retrofit audit approach are listed in Section 9.

3. Control group approach

In this approach a control group and a sample group shall be defined. The control group shall be comprised of Dwellings from the Same Building Stock that are not, and shall not be Weatherized[16]. The sample group shall be comprised of Dwellings to be Weatherized, or, in the case of mobile homes, replaced. Electricity and fuel bills shall be collected for both groups annually throughout the project crediting period. The control group shall consist of Dwellings that have not been weatherized as part of the Project. The Project shall not prevent or deny Weatherization to any homeowner, or individual for the purpose of maintaining the control group. Instead, as the population of Weatherized Dwellings increases, the control group sample may include different Dwellings as long as the control group contains only non-Weatherized Dwellings.

3.1 The difference in the energy consumption between the control group and the sample group each year will constitute the fuel and electricity savings for all Dwellings in the Project for that year and shall serve as the basis for calculating emission reductions[17].

The sample group shall come from Dwellings included in the Project activity. The control group shall be selected from Dwellings not included in the Project activity and shall have the following requirements in addition to the requirements established in section 1.9 Part A:

1) Participants shall not have the ability to “opt-in” to the control group.
2) Once selected, homeowners shall be required to make their fuel and electricity bills available to the Project. Where appropriate, the homeowner will be requested to sign a waiver granting the Project proponent electronic access to directly metered electricity and gas bills.
3) Dwellings shall be in the Same Building Stock.

3.2 Emission reductions shall be calculated as follows:

[16] The control group sample size must be large enough to be statistically valid. When approaching complete saturation of Weatherized homes, the control group will diminish in size as the number of non-Weatherized homes diminishes. This is a risk that must be weighed when choosing the control group approach. One option for addressing the diminishing control group is to use the control group approach for as long as possible and then switch to the adjusted consumption approach. The control group monitoring will be able to be used as the baseline in the adjusted consumption approach.

[17] Since the energy consumed by retrofitted dwellings shall be directly compared to the energy consumed by non-retrofitted Dwellings within the Same Building Stock and the same year, there is no need to apply the Electricity and Heating/Cooling Degree Day Correction Factors.

Equation 15

$$ER_y = \sum_{b=1}^{B} \{ \{(Elec_{CG,y,b} - Elec_{SG,y,b}) * Elec_{CO2}\} + \sum_{j=1}^{J} \{(F_{CG,y,j,b} - F_{SG,y,j,b}) * Cal_j * F_{CO2j}\} \} * I_b - L_{y,b}$$

Leakage, $L_{y,b}$, shall be calculated for each Building Stock using Equation 7.

Where:

$Elec_{SG,y,b}$ = Mean electricity consumed by sample group Dwellings in Building Stock *b* in year *y*
$Elec_{CG,y,b}$ = Mean electricity consumed by control group Dwellings in Building Stock *b* in year *y*
$F_{SG,y,j.b}$ = Mean fuel type *j* consumed by sample group Dwellings in Building Stock *b* year *y*
$F_{CG,y,j,b}$ = Mean fuel type *j* consumed by control group Dwellings in Building Stock *b* in year *y*
I_b = Number of Dwellings in Building Stock *b*
$L_{y,b}$, = Leakage in Building Stock *b* in year *y*

To ensure conservativeness in the emission reduction calculation approach, a 95% confidence interval, with an alpha value equal to 5% (α =0.05) shall be applied to the fuel and/or electricity consumption within the control group and the sample group, denoted by $Elec_{SG,y,b}$, $Elec_{CG,y,b}$, $F_{SG,y,j,b}$, $F_{CG,y,j,b}$ above. The lower bound of the confidence interval of the control group, and the upper bound of the confidence interval of the sample group shall be the values compared to determine the emission reductions resulting from Project activity.

The 95% confidence interval shall be calculated as follows:

$$\bar{x} - Z_{0.025}(SE) < \mu < \bar{x} + Z_{0.025}(SE)$$

$$SE = \hat{\sigma} / \sqrt{n} \quad \text{and} \quad \hat{\sigma} = s * \sqrt{n/(n-1)}$$

Where:

$\bar{x}$ = the mean energy consumption calculated from the sample
$Z_{0.025}$ = 1.960, established standard value
s = the standard deviation calculated from the sample
n = the sample size
n-1 = the sample size minus one
μ = the mean of the population. This value is not actually calculated, instead it is contained within the upper and lower bounds of the equation.
SE = standard error
$\hat{\sigma}$ = standard deviation that approximates the standard deviation of the population, used to calculate the standard error.

3.3 The parameters to be monitored in the control group approach are listed in Section 9.

4. The deemed savings approach

4.1 Emission reductions for the replacement of Appliances shall be calculated as follows:

4.1.1 The electricity demand (rated capacity) of both the Appliance to be replaced and of the replacement Appliance shall be determined from the nameplate, manufacturer's specification sheet, or direct metering;

4.1.2 The typical annual hours of operation of the Appliance to be replaced in the Project area shall be recorded;

4.1.3 The emission reductions from an individual Appliance shall be calculated by comparing the electricity demand of the replacement Appliance with that of the replaced Appliance, multiplied by annual hours of operation and by the grid emission factor. To account for failed operation of Appliances a correction factor shall be applied.

4.1.4 Emission reductions shall be calculated as follows:

Equation 16

$$ER_y = \sum_{k=1}^{K} a_k (E_{dem.pre,k} - E_{dem.post,k}) * h_k * Elec_{CO2} * Corr_k - L_y$$

Leakage, L_y, shall be calculated using Equation 7.

Where:

$E_{dem,pre,k}$	=Electricity demand of Appliance type *k* before the replacement takes place
$E_{dem.post,,k}$	=Electricity demand of Appliance type *k* after the replacement
h_k	=Annual working hours of the Appliance type *k*
$Corr_k$	=Correction factor for failed operation of each Appliance type *k*
a_k	=Number of Appliances of each Appliance type *k*
K	=Number of Appliance types
k	= Appliance type

4.2 Monitoring shall consist of verifying the operation of a sample of the Appliances within the first year of installation and in three year intervals thereafter.

The parameters to be monitored in the deemed savings approach are listed in Section 9.

5. The mobile homes approach

5.1 Emission reductions for the replacement of mobile homes shall be calculated as follows:

5.1.1 The heat load of both the mobile home to be replaced and of the replacement home shall be determined from best practice heat load modelling. In the case of the home to be replaced, the heat load may be calculated by applying a heat load formula that applies a default energy consumption value determined from statistically significant fuel consumption records[18]. In the case of the replacement home, the heat load shall be modelled taking into account the building specifications. The building specifications may include but are not

[18] The heat load formula shall be based on best practice energy modeling software that takes into account the number of rooms, the metric size of the rooms, the energy load per meter, and the degree days of the region. In the United States, for example, the design heat load calculation that is used to determine fuel award amounts in the national Low Income Home Energy Assistance Program may be used. That equation is: number of rooms multiplied by the square feet per room, multiplied by the BTU consumption per square foot per degree day multiplied by degree days, all divided by 1,000,000 BTUs to yield the MBTU needed to heat/cool the space. In metric the equation would be: number of rooms multiplied by the square meters per room, multiplied by the KJ consumption per square meter per degree day multiplied by degree days, all divided by 1,000,000 KJ to determine the GJ needed to heat/cool the space.

limited to; R-value of insulation in the floor, walls and ceiling, U-value and size of the windows, and the R-value of the skirting.

5.1.2 Emission reductions shall be based on the difference between pre- and post-replacement heat load[19] and pre-and post-replacement size of the mobile home, multiplied by the annual heating/cooling degree days, and both the calorific value and the emission factor of the fuel consumed within the Dwelling[20].

5.1.3 If Appliances are replaced at the same time the mobile home is replaced, the calculation of emission reductions from Appliance replacement shall follow the deemed savings approach. Total emission reductions shall be the sum of emission reductions from the replacement of the mobile home plus the emission reductions from replacement of the Appliances, minus leakage.

5.1.4 Emission reductions shall be calculated as follows:

Equation 17

$$ER_y = \sum_{i=1}^{I}((H_{load,pre,i} * S_{pre,i} - H_{load,post,i} * S_{post,i}) * HDD_y * F_{CO2j}) + ER_{ARy}$$

Note* In a region with a predominantly hot climate, the equation can be changed to incorporate cooling load $C_{load,pre,j}$ and Cooling Degree Days CDD_y, which would replace $H_{load,pre,j}$ and Heating Degree Days HDD_y respectively.

Where:

$H_{load,pre,i}$	= Heat load of mobile Dwelling *i* to be replaced
$H_{load,post,i}$	= Heat load of replacement Dwelling *i*
HDD_y/CDD_y	= Heating/cooling degree days
$S_{pre,i}$	= Size of Dwelling *i* to be replaced in m^2
$S_{post,i}$	= Size of replacement Dwelling *i* in m^2
ER_{ARy}	= Emission reductions from Appliance replacement
I	= Number of Dwellings

Emission reductions from Appliance replacement, ER_{ARy}, shall be calculated using Equation 16.

5.2 The parameters to be monitored in the mobile homes approach are listed in Section 9.

[19] The heat load of a Dwelling shall include cooling load when both heating and cooling are provided by one central system.
[20] When electricity is the central heating/cooling source, the grid electricity factor shall replace both the fuel calorific value (Cal_j) and the fuel emission factor ($F_{CO2,j}$). In this case, the heat load shall be expressed in kWh per square meter per degree day.

9 MONITORING

9.1 Data and Parameters Available at Validation

Table 3. Monitoring parameters for the performance benchmark for Category A and B

Parameter Description	Parameter	Unit	Source	Frequency
Average performance, defined as the annual average percent savings in weather normalized energy consumption in Dwellings within the Same Building Stock.	*a*	Percent	Calculated from regional or national statistics for at least the three most recent 12 month periods for which data are available from Dwellings within the Same Building Stock. A sample of the Dwellings may be used. Percent savings are calculated by comparing year 1 to year 2 and year 2 to year 3[21].	Once per project crediting period
Standard Deviation of the annual percent savings.	σ	-	Calculated from regional or national statistics used to calculate the average performance.	Once per project crediting period

Table 4. Monitoring parameters for the performance benchmark for Category C

Parameter Description	Parameter	Unit	Source	Frequency
Average performance, defined as the annual average electricity consumption by existing Appliances, of the same Appliance type.	*a*	kWh/appliance	Calculated from regional or national statistics for at least the recent 12 month period for which data are available. A sample of the Dwellings may be used.	Once per project crediting period
Standard Deviation of the annual energy consumption of	σ	-	Calculated from regional or national statistics used to	Once per project crediting

[21] Year 1, year 2 and year 3 may have gaps of time in between the years. For example: Year 1 data may cover 2001, year 2 data may cover 2005, and year 3 may cover 2009.

existing Appliances.			calculate the average performance.	period

Table 5. Monitoring parameters for the adjusted consumption approach, pre- and post-retrofit audit approach, control group approach, and mobile homes approach

Parameter Description	Parameter	Unit	Source	Frequency
Grid emission factor for the regional electricity source	$Elec_{CO2}$	tCO_2e/kWh	Obtained from a recognized authority; or calculated by the Project proponent based on raw data obtained from a local, or national electric utility.	As per approach listed in Part C, section 1.2; this parameter could be available at validation or it could change throughout the project crediting period
Calorific value of fuel type *j*	Cal_j	GJ/mass or GJ/volume	Local, regional or national data. If unavailable, IPCC default values may be used.	Once per project crediting period
CO2 emission factor for fuel type *j* (baseline fuel)	F_{CO2j}	tCO_2e / GJ	Local, regional or national data. If unavailable, IPCC default emission factors may be used.	Once per project crediting period

Table 6. Monitoring parameters for replacement of Appliances

Parameter Description	Parameter	Unit	Source	Frequency
Grid emission factor for the regional electricity source	$Elec_{CO2}$	tCO_2e/kWh	Obtained from a recognized authority; or calculated by the Project based on raw data obtained from a local, or national electric utility.	As per approach listed in Part C, section 1.2; this parameter could be available at validation or it could change throughout the project crediting period

9.2 Data and Parameters Monitored

Table 7. Monitoring parameters for the performance benchmark for Category A and B

Parameter Description	Parameter	Unit	Source	Frequency
Pre-retrofit energy load of Dwelling i	$EL_{pre,\ i}$	BTU/m^2	Energy audit	Once
Post-retrofit energy load of Dwelling i	$EL_{post,\ i}$	BTU/m^2	Energy audit	Once

Electricity demand of Appliance *k* before replacement	$E_{dem.pre,k}$	kW	Nameplate, or manufacturer's specification sheet, or direct metering of	Once pre-replacement

[22] Fuel consumption shall be based on fuel purchased as reflected in the billing. Some households may store some fuel, or refill the tank before it is empty. However, the fuel storage level will become inconsequential over time as any fuel purchased to fill the fuel tank above the storage level will be consumed and therefore reflected in the billing upon refueling. Any remaining differences in the filling level, before Project implementation and at the end of the Project lifetime, of individual households will cancel each other out over the entire sample of Dwellings.

[23] In the case where consumed energy for each household cannot be measured separately or in the case of district heating, the temperature in/out and water discharge (flow rate) of the heating system shall be monitored. Fuel consumption monitoring shall take place using the utility company fuel inventory for that specific district heating system.

			the Appliance	
Annual working hours of Appliance *k*	h_k	Hours	Sampling, consumer surveys, or common practice based on local, regional or national data[24]	Once, may be updated

Sectoral Scope 14

Methodology for Avoided Ecosystem Conversion

This methodology was developed by Wildlife Works and ecoPartners.

About Wildlife Works

Wildlife Works Carbon LLC, one of the world's leading REDD project development companies, was originally established to help local landowners in the developing world to monetize their forest and biodiversity assets, whether they are governments, communities, ownership groups or private individuals.

Wildlife Works pioneered a novel business model that uses the marketplace to bring innovative economic solutions to wildlife conservation, reduce human/wildlife conflict and protect forests in the developing world.

The company's first project at Rukinga, Kenya has been operating for over a decade protecting wildlife and forests. This history has enabled Wildlife Works to launch the Kasigau Corridor REDD project, through which the company has expanded the area under protection to over 500,000 acres. Wildlife Works continues to bring the benefits of direct carbon financing to Kenyan communities, while simultaneously securing a contiguous wildlife migration corridor between Tsavo East and West National Parks.

Building on this successful model, Wildlife Works plans to leverage its experience in Southeastern Kenya to future REDD projects around the globe, with a goal to protect 5 million hectares from deforestation. Wildlife Works is committed to protecting wildlife, forests and biodiversity, with a direct, hands-on approach to creating alternative livelihoods.

Contributing Authors: Jeremy Freund, Mike Korchinsky, Simon C. Bird, Gordon Smith

About ecoPartners

ecoPartners works with project developers, forest owners and verification bodies to build successful forest carbon offset projects. ecoPartners specializes in the technical aspects of project design, planning and development: remote sensing, biometrics and accounting methodologies, with significant experience validating and verifying projects under the Climate Action Reserve (CAR) Standard, Verified Carbon Standard (VCS), and Climate Community & Biodiversity (CCB) Standard. We help our clients navigate methodologies, mitigate risk, build long-term capacity and generate credits.

Contributing Authors: Kyle Holland, Ben Caldwell, Ryan S. Anderson, Wilson Salls, Melanie Jonas, Zach Barbane, Paz Lozano

Table of Equations

Equations are in Appendices A-F:

1 SOURCES

This methodology was developed based on the requirements in the following documents:

- VCS Standard, v3.4
- AFOLU Requirements, v3.4
- Program Definitions, v3.5

This methodology uses the latest version of the following tools:

- VT0001 Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities
- CDM tool *Estimation of direct and indirect (eg, leaching and runoff) nitrous oxide emission from nitrogen fertilization*
- CDM tool *Tool for testing significance of GHG emissions in A/R CDM project activities*

2 SUMMARY

Additionality and Crediting Method	
Additionality	Project Method
Crediting Baseline	Project Method

This methodology provides a means to quantify net GHG emission reductions and removals (NERs) from project activities that prevent conversion of forest to non-forest and of native grassland and shrubland to a non-native state. The methodology accounts for emissions from all allowable pools specified by the VCS *AFOLU Requirements* for the REDD and ACoGS project categories, with the exception of peat soils and litter. This methodology can be applied to account for avoided emissions from planned deforestation and degradation (APD), unplanned deforestation and degradation (AUDD), planned conversion (APC), and unplanned conversion (AUC) baseline scenarios. It uses a project method to determine additionality (see section 7).

This methodology differentiates between eight baseline types based on the proximate agent of conversion, the drivers of conversion, whether the specific agent of conversion can be identified, and the progression of conversion (see Figure 2, Section 6.3). A single project may include one or more baseline types. The addition (in this version 3.0) of ACoGS baseline types for native grassland ecosystems means that the applicability of this methodology has been dramatically expanded, and now can be used to address both planned and unplanned conversion in both forest and native grassland ecosystems. For the five baseline types associated with conversion of forest to non-forest, the agent of conversion can include a primary agent and secondary agents, which contribute to a cascade of degradation ultimately leading to a non-forest state.

Under this methodology, project proponents implement project activities in the project area and surrounding region that address the agents and drivers of conversion. When the agents of conversion are not known, they can be identified using expert knowledge or a participatory rural appraisal, which is a type of community survey. In some cases related to planned conversion, the specific agent of conversion may be known. Identifying the agents and drivers of conversion is essential to designing effective project activities to mitigate conversion of forest and native grassland.

The baseline scenario for a project is defined by at least one baseline type (See Figure 3, Section 6.3). Once the agents and drivers of conversion are known, this information can be used to identify baseline types (section 6.3). Each baseline type is characterized by baseline emissions models that are applied to a project accounting area. All project accounting areas must meet either the definition for *forest project accounting area* or *grassland project accounting area*. Parameters to these models are partially determined using a reference area. Descriptions of parameterization methods are described in section 2.1.1, and vary by baseline type. The intent of these models is to provide simplified and unified accounting with clear and user-friendly implementation. This approach dramatically reduces the number of parameters and equations in the methodology relative to prior versions.

Leakage is quantified using an activity-shifting leakage area(s) and a market leakage area(s), which may or may not overlap with the reference area. Like the reference area, the activity-shifting leakage area is defined by the agents and drivers of conversion for each identified baseline type in the baseline scenario. However, unlike the reference area, the activity-shifting leakage area(s) is also defined by proximity to the project area and anticipated directional shifts in conversion activities. The activity-shifting leakage area is more purposeful than a belt or an arbitrary buffer around the project area. The market leakage area is defined when long-lived wood products or agricultural products exist in the baseline scenario, and is used to estimate leakage resulting from a change in the supply of domestic long-lived wood products or agricultural products as a result of illegal or legal-sanctioned logging or agricultural production.

Residual biomass in the baseline scenario is quantified for each baseline type using a proxy area. The proxy area is distinct from the leakage areas, and may or may not overlap the reference area. For example, the reference area must be similar to the project accounting area in regards to various conditions (see section 6) and must be the same size or greater than the project accounting area, whereas the proxy area may be an area smaller than the project accounting area located inside or outside of the reference area. The proxy area(s) characterizes the carbon stocks associated with the end land uses that are non-forest or converted native grassland in the baseline scenario. Some examples of these end land uses may be pasture, subsistence agriculture or mechanized agriculture. The project proponent measures biomass for selected carbon pools in the proxy area. The proxy area must have the same landscape configuration as the project accounting area before conversion and be large enough to accommodate an adequate (per Appendix B and D) sample of measurement plots, but the proxy area need not be as large as the project area. Because the proxy area allows project proponents to include baseline types with end land uses that have significant biomass, such as swidden agriculture, the accounting is complex.

Compared to approaches taken by other REDD and ACoGS methodologies, the approaches used in this methodology deviate significantly in three regards. First, the baseline emissions models predict cumulative emissions over time rather than an aerial rate of ecosystem conversion in hectares per year. Second, important parameters to the baseline emissions models are fit using simple point observations of land use conversion over a historic reference period rather than requiring a series of complex Land Use Land Cover (LULC) classifications of full-coverage satellite imagery. Third, accounting for the various sources of emissions from biomass is dramatically simplified by rolling all sources of potential emissions into a single model and parameterizing the model based on easily understood baseline types (section 6.3).

These approaches make the baseline emissions models particularly attractive to project proponents for several reasons. First, the time required to build the models is relatively short. Almost any type of historical imagery can be used to build the model, including grey-scale aerial, color aerial, panchromatic, satellite, SAR or even Landsat 7 SLC-OFF imagery (despite its failed sensor). Second, despite the fact that cloud contamination may result in limited coverage of the reference area, all collected imagery can be used to build the models in lieu of cloud cover within individual images. Once the imagery is imported into a geographic information system (GIS), data collection for model fitting is performed using simple, heads-up interpretation of point samples from the imagery. As of the publication of this methodology, Wildlife Works maintains an ArcMap GIS extension to automate point interpretation and compute weights (see section 6.8.6), thus further facilitating the use of the baseline emissions models. For all of these reasons, thematic land cover classifications of complete sets of images for each date in the reference period are not necessarily required.

In addition to the relative simplicity and robustness of the baseline emissions models, this methodology differentiates among carbon pools, and thus project proponents will find it particularly attractive. For example, both standing dead wood and lying dead wood are components of the dead wood pool, but standing dead wood is measured using a plot, while lying dead wood is measured using a line transect. Because the dead wood pool is optional, project proponents may choose to conservatively omit lying dead wood. This avoids the added complexity of sampling line transects while still including the optional standing dead wood pool. Such an approach may be preferable to project proponents as measurements of standing dead wood can easily be made at the same time as measurements of aboveground live trees on the same plot.

This methodology monitors carbon stocks using a sample of fixed area plots in the project accounting area(s) and proxy area(s). Lying dead wood is estimated using a line intersect sample, and soil organic carbon (SOC) is estimated using samples removed from soil cores or pits located within the plots used for biomass estimation. This methodology also differentiates between merchantable trees and non-merchantable trees. In addition to improving sampling techniques, this differentiation allows project proponents to characterize the emissions from biomass as a result of logging in the baseline scenario. Additionally, if any livestock are being grazed within the project area, the emissions from these livestock are quantified and if they are found not to be *de minimis,* they will be included in the calculation of project emissions.

Because this methodology uniquely differentiates among carbon pools, each major accounting section is purposely organized by carbon pool to facilitate ease of use; the baseline scenario, baseline emissions and monitoring sections are subdivided by carbon pool. In this way, project proponents may first select carbon pools to include in the project boundary and then easily trace the accounting sections to find the appropriate methods. This is a departure from other methodologies, which typically attempt to account for all pools simultaneously despite the fact that some pools might not be selected for some projects.

Lastly, project proponents will find that this methodology provides cohesive transitions between the concepts that guide accounting while also providing necessary and important details of the accounting procedures themselves. To unify the text and tone of the methodology, complex equations and variables have been omitted from the body and placed in separate appendices. Equations are placed in Appendix F, and many equations are reused and applied in different sections of the methodology. Project proponents should use these appendices side-by-side with the body of the methodology during project development and reporting.

Background information is provided in Appendix A in order to facilitate understanding of the accounting concepts without affecting usability. Appendix B provides methods for estimating carbon stocks which can be used during monitoring of the project accounting area(s), activity-shifting leakage area(s) and proxy area(s). Appendix C provides methods to account for long-lived wood products under the baseline scenario and from project activities.

Appendix F is a comprehensive list of equations, literature sources, assumptions and comments by equation number, and Appendicies G and H include a list of variables, variable descriptions and units. All equations cited in the body of the methodology are hyperlinked by equation number and all equations are hyperlinked by section number back to the sections where they are used. Many defined terms and abbreviations in the text are hyperlinked to their definitions.

Project proponents considering this methodology for their project are encouraged to contact Wildlife Works for resources and technical assistance.

2.1 Core Concepts in Accounting

Accounting is underpinned by observing specially-defined areas and by specifying the baseline emissions models using time-lag shifts. The baseline emissions models are parameterized for, and applied to, project accounting areas within the project area, each having a unique baseline type. All projects must have at least one project accounting area and therefore at least one set of baseline emissions models. Projects may have more than one project accounting area, and likewise, multiple sets of baseline emissions models.

2.1.1 Emissions Models

The underlying mechanics of this methodology utilize four types of emissions models. The first two relate to the baseline scenario and are referred to as the baseline emissions models. The baseline emissions models include the Biomass Emissions Model (BEM) and Soil Emissions Model (SEM) that characterize the baseline scenario for each accounting area to estimate avoided baseline emissions from forest degradation, land-use conversion and subsequent soil carbon loss. These baseline emissions models may appear complex, but their parameterization and implementation are fairly straightforward. Depending on the baseline type, model parameters are selected from defaults or estimated from data.

The BEM and SEM do not account for carbon stored in long-lived wood products or the decay of carbon in dead wood, below-ground biomass or soil. These emissions are accounted for using Appendix C and the Decay Emissions Model (DEM). The fourth model is the Leakage Emissions Model (LEM) which accounts for emissions from activity-shifting leakage. Project emissions are accounted for separately from the models to determine gross credit generation. Net credit generation is determined by subtracting deductions for contributions to the AFOLU Pooled Buffer Account.

To aid modeling, parameters must match the time scale of the data from which they are derived. For example, if data were collected on a specific day – such as a Landsat image – that specific date must be used. If data is collected on a longer time scale (eg, monthly or annually), that time scale must also be used consistently. See section 6.7.1 for further explanation on how to convert large time scales to a specific day for the purposes of modeling emissions. From a vintage perspective, it is desirable to use a number of days to determine the proportion of emissions reductions or removals that occur in part of a calendar year when monitoring periods are not defined by the first of the year.

2.1.2 Areas

The concept of an area is to specify a location where emissions are characterized or measured. This methodology uses six types of areas (see Table 1). The project area is the area under control of the project proponent and is where the project activities may be implemented to address the agents and drivers of conversion, thus preventing emissions from the project accounting area(s).

The project accounting area is an area within the project area that is subject to conversion under the baseline scenario and is associated with a baseline type. All project accounting areas must meet the definition for either *forest project accounting area* or *grassland project accounting area*. In some cases where there exists multiple baseline types for one project area, there will be multiple project accounting areas within a single project area (see Figure 1). In this methodology, the general term *project accounting area* is used when instructions or requirements cover both forest project accounting areas and grassland project accounting areas. The terms *forest project* *accounting area* or *grassland project accounting area* are used when instructions or requirements specifically apply to only forested or native grassland baseline types.

Associated with each project accounting area is a reference area that is located in the same region as the project area and where historical conversion is observed. The reference area is similar to the project accounting area in most respects, and represents what would have happened to the project accounting area in the baseline scenario over time. The baseline scenario is further characterized using proxy areas, and one proxy area must be defined for each identified baseline type. The proxy area is defined in much the same way as the reference area. Like the project accounting area, the carbon pools in the proxy area are measured through monitoring to establish the residual carbon stocks after conversion.

Finally, emissions from leakage are measured using an activity-shifting leakage area and a market leakage area. A market leakage area is required only when the baseline scenario includes commercial logging. The activity-shifting leakage area is defined similarly to the reference and proxy areas, but also relative to the proximity of agents of conversion. An activity-shifting leakage area is associated with each project accounting area. The definition of the market leakage area is similar, but must be selected based on where baseline logging entities could shift their production. If the baseline scenario includes illegal or legally-sanctioned commercial logging, there will be no more than one market leakage area.

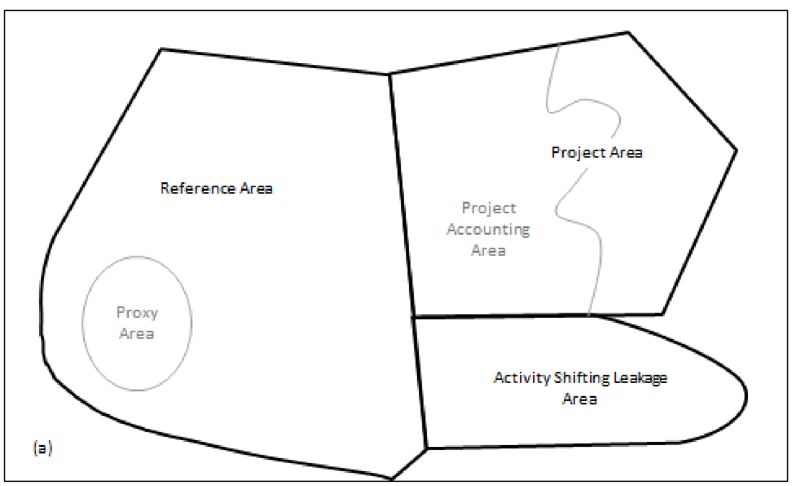
Table 1: Description of carbon accounting areas. For exact definitions, please see section 3.

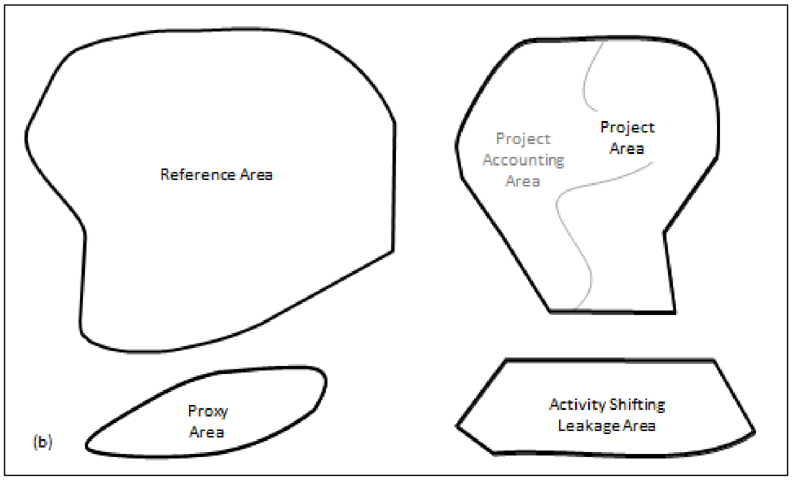
Area	Description	Quantity	Size relative to project area
Project area	The area under control of the project proponent which contains at least one project accounting area.	Only one	Equal
Project accounting area	The area to which the *baseline emissions models* are applied. A forest or native grassland area within the project area that is subject to conversion in the *baseline scenario* as delineated by section 6.2.	One for each identified baseline type	Less than or equal
Reference area	An area in the same region as the project area that is similar to the project area in regards to acting agents of conversion, acting drivers of conversion, socio-economic conditions, cultural	One for each identified baseline type	Greater than or equal

	conditions and landscape configuration.		
Proxy area	The area where residual carbon stocks (after conversion, the end state) are estimated for each baseline type.	One for each identified baseline type	No prescribed size
Activity-shifting leakage area	The area where *leakage* resulting from the activities of the agent of conversion would likely occur due to the *project activity* (ies).	One for each identified baseline type	No prescribed size
Market leakage area	The area where *leakage* would likely occur resulting from a change in the supply of wood products due to the *project activity* (ies).	One if the baseline scenario includes commercial logging	No prescribed size

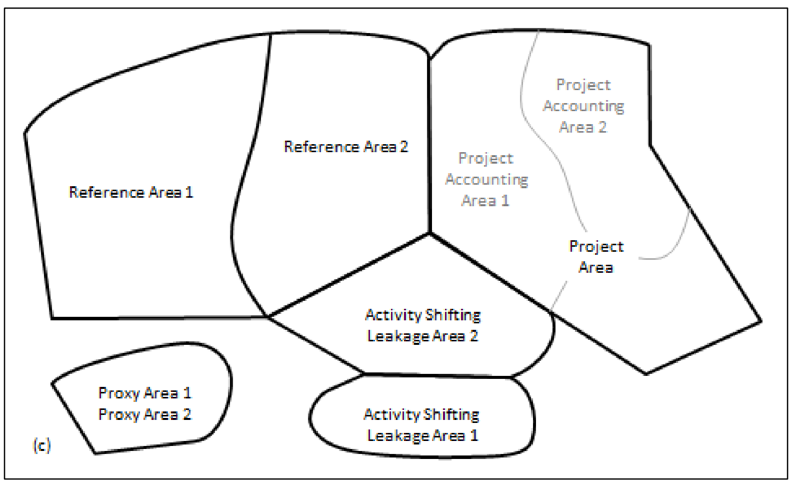
Figure 1: Three example configurations of areas for a single project instance (see section 3.1 for abbreviations).

(a-b) A project area containing one project accounting area, one associated reference area, proxy area and activity-shifting leakage area.





(c) A project area containing two project accounting areas, and an associated reference area, proxy area and activity-shifting leakage area for each project accounting area. The proxy areas happen to be identical.



2.1.3 Shifts

The concept of a shift is to account for temporal differences in the onset of degradation and conversion in the baseline scenario relative to historic observations in the reference area. A shift could also account for the delay between the beginning of degradation and ultimately conversion. Shifts are mathematical expressions or parameters that adjust terms of the baseline emissions models so that the parameterized models reflect a defensible baseline scenario.

Although not always explicitly defined as shifts in the text, several shifts are employed in this methodology depending on the baseline type for a particular project accounting area. For most projects, the baseline emissions models are affected by a shift to apply historic observations made in the reference area to the project accounting area after the project start date. Another shift is associated with emissions from soil relative to degradation because these emissions are assumed to occur after conversion.

2.2 Notation

The notation used in this methodology is intended to clearly communicate the variables and mathematical processes intended for quantifying carbon stock and project greenhouse gas benefits. The notation adopted differs in some ways from that seen in other forest carbon methodologies. These deviations improve the clarity and readability of this document.

2.2.1 Equations

Equations in this methodology are numbered and bracketed (eg, [F.7]). The equations themselves are located in Appendix F and are referenced in the text by number. The intent is that Appendix F will be printed and used as a separate document in conjunction with the text of the methodology. Equations in Appendix F contain additional information including citations, literature sources and comments.

In some instances, similar operations are performed on different variables in multiple places. For example, estimating above-ground carbon stock in the merchantable tree, non-merchantable tree, and non-tree biomass pools involve summing plot level measurements, dividing by plot area, summing across plots in a stratum, and multiplying by stratum area. A generic equation is given to estimate each pool and the relevant variable or equation can be substituted for x as indicated by the methodology.

2.2.2 Variables

Variables in this methodology and their units are enumerated in the list of variables in Appendix G and H. The intent is that Appendix G and H will be printed and used as a separate document in conjunction with the text of the methodology. For most of these variables, their units are in tonnes of carbon dioxide equivalents. The variables x and y (with and without subscripts) are sometimes used as placeholder variables — they may stand in for another variable or the results of an equation as indicated by the methodology text. The variables x and y are also used to indicate geographic coordinates in the development of the conversion and soil carbon loss models in the baseline scenario section (see section 6). The meaning of these variables should be clear based on the context provided in the methodology text.

2.2.3 Summations

Summations use set notation. Sets of variables are indicated using script notation. For example, $\mathcal{S}$ represents the set of all strata in the project area, while $\mathcal{P}_k$ represents the set of all plots in stratum k. Set notation greatly reduces the number of variables used in the methodology as well as the complexity of summations.

2.2.4 Elements

Elements of a set are denoted using subscript notation. A sum over the elements of a set is indicated by the notation $\sum_{k \in \mathcal{S}} A_k$. This particular example sum indicates the sum of the area of all strata, where A_k indicates the area of stratum k. The number of elements in a set is indicated by functional notation $\#(\mathcal{S})$ where the pound sign stands for “count of”.

2.2.5 Standard Deviations and Variances

Standard deviation is indicated by the σ symbol, with subscripts used to indicate the quantity for which it is estimated. Variance is indicated by the σ^2 symbol and is the square of standard deviation. Standard deviations may not be in units tCO2e.

2.2.6 Standard Errors

Estimated standard error is indicated by the U symbol, with additional subscripts used to indicate the quantity for which the uncertainty is estimated. Standard errors are always in units tCO2e.

2.2.7 Theoretical Parameters and Parameterized Models

Parameters to model are denoted by variables, such as the project shift parameter γ. When such parameters have a “hat” on them – such as the parameter $\hat{\gamma}$ – they refer to a value rather than a theoretical, unknown quantity.

2.2.8 Monitoring Periods

Monitoring periods are notated using bracketed superscripts $[m]$. The first monitoring period is denoted by $[m = 1]$, the second monitoring period $[m = 2]$ and so forth. The superscript [m=0] is used to indicate the value of carbon pools at project start. These values remain constant throughout the project crediting period. In the case where project validation and the first verification event fall on the same date, then [*m=0*] parameters will be equal to [*m=1*] parameters. These superscripts should not be confused with references to equation numbers, as equation numbers are never in superscript. Nor should they be confused with powers of numbers which are not enclosed in brackets. Also see the definition for monitoring period. A monitoring event is the reporting and verification of NERs claimed for a monitoring period.

2.2.9 Baseline, Project and Leakage Estimates

Estimates related to emissions, emissions reductions, emissions removals, and carbon stocks for the baseline, project, and leakage are specifically denoted with B, P and L in the subscripts of variables, respectively.

2.2.10 Averages for Carbon Pools

Average carbon (measured by tCO2e/ha) to which accounting is applied is denoted by a lower-case c, with subscripts to differentiate between carbon pools as indicated in the list of variables. For example, $c_{P\ AGMT}^{[m]}$ indicates the average carbon stock in above-ground merchantable trees in the project area in monitoring period $[m]$. Subscripts from carbon pools are acronyms listed in section 3.1.

2.2.11 Totals for Carbon Pools

Total carbon (measured by tCO2e) to which accounting is applied is denoted by a capital C, with subscripts to differentiate between carbon pools as indicated in the list of variables. For example, $C_{AGMT}^{[m]}$ indicates the total carbon stock in above-ground merchantable trees in monitoring period $[m]$. Subscripts from carbon pools are acronyms listed in section 3.1.

2.2.12 Emissions for Carbon Pools and Decay Sources

Total emissions (measured by tCO2e) from accounting are denoted by a capital E, with subscripts to differentiate between carbon pools as indicated in the list of variables. For example, $E_{B\ AGMT}^{[m]}$ indicates the total emissions from above-ground merchantable trees at monitoring period $[m]$ in the baseline scenario. Subscripts from carbon pools are acronyms listed in section 3.1.

2.2.13 Quantified Uncertainties

Uncertainties in major carbon pools are expressed as standard error SE (measured by tCO2e) and are denoted using a capital letter U. For example, $U_{P}^{[m]}$ is used to indicate the uncertainty in estimated total carbon stocks for selected carbon pools in the project accounting area at monitoring period $[m]$.

2.2.14 Vectors

Vectors are indicated using bold face; for example $\boldsymbol{\theta}$ is the vector of covariate parameters to the logistic function of conversion are described in section 6.8. This vector may include numerous elements such as the numeric effects of population density, road density or per-capita household income on predicted conversion.

2.2.15 Matrices

Matrices are intentionally not used in this methodology to avoid complexity and confusion.

2.3 Application Overview

This methodology may be applied in multiple ways and at different stages of project development. For the purposes of project validation, when monitoring data are not yet available, literature estimates for carbon stocks in selected carbon pools may be used (see section 8.4.7). If validation and the first verification occur simultaneously, measurements from monitoring may be used to estimate carbon stocks. During subsequent monitoring events, direct measurements from the various areas must be used to calculate NERs.

Upon the first application of the methodology to a project, project proponents must identify the project area per section 5, and the baseline scenario per section 6. The process will result in at least one project accounting area and one associated reference area. For many project proponents, the project area will be the area to which the project proponent has legal title to the carbon stocks in the selected carbon pools. For REDD and ACoGS projects, the boundaries of the project area may be protected as a project activity.

The baseline scenario may be identified using expert knowledge or a PRA (see Appendix E). Depending on the identified agents and drivers of conversion, the baseline scenario may contain several baseline types. For instance, a portion of the project area may be subject to legally-sanctioned commercial logging which ultimately results in non-forest while a different portion of the project area may be subject to land use conversion caused by charcoal production. Because the agents and drivers are different, the project proponent must define two baseline types in the project's baseline scenario. In this example, one baseline type is F-P1.a and the other may be type F-U1.

For each identified baseline type, project proponents must delineate project accounting areas within the greater project area (see section 6.2). Likewise, the project proponent must delineate a reference area to parameterize the baseline emissions models (see section 6.8.1), a proxy area to estimate residual carbon stocks in the baseline scenario (see section 6.4), and an activity shifting leakage area (see section 8.3.2.1) for each identified baseline type. For most projects, there will be only one baseline type and hence one project accounting area, reference area, proxy area and activity shifting leakage area. For some projects, the project accounting area may encompass the entire project area.

Once baseline types and areas have been defined, the baseline emissions models must be parameterized. For validation purposes, a small sample size of 300 interpretation points in each reference area may be used to estimate the conversion parameters, while for verification purposes a larger sample size should be used (see section 6.8). If a small sample size is selected to estimate the conversion parameters for verification purposes, the calculation of NERs may be reduced as a result of a confidence deduction (see section 8.4.1.1). Likewise, for the estimation of carbon stocks in the project accounting areas and the proxy areas, a small sample size of measurement plots may result in a confidence deduction. The confidence deduction is an incentive for project proponents to invest adequate amount of time and money into model parameterization and carbon stock monitoring without prescribing absolute requirements on sample sizes.

For validation and verification purposes, the project proponent must document the project design and calculated NERs using the Project Description Requirements (PD Requirements) and the Monitoring Requirements. Demonstration of these requirements may be presented in a document(s) referenced from the PD or monitoring reports, or in the PD or monitoring reports themselves. Demonstration of these requirements along with completed, VCS-approved templates must be provided to the Validation/Verification Body (VVB). Project proponents must note that in addition to the Project Description Requirements and the Monitoring Requirements, projects must adhere to all VCS rules when applying this methodology (ie, the PDRs and MRs cover all the requirements of this methodology, but they do not necessarily cover each and every VCS requirements relevant to the project).

Once the baseline emissions models have been validated, the project proponent need only monitor carbon stocks in the project accounting areas and proxy areas, and monitor degradation in the activity shifting leakage areas. The project proponent may choose to monitor log production as a result of project activities in the project area to determine carbon stored in wood products. The project proponent may also choose to monitor the burning of biomass as a result of project activities. However, most project emissions will be captured in the re-measurement of plots in the project accounting areas even if there is a natural disturbance event or logging after the project start date.

3 DEFINITIONS

3.1 Definitions

In addition to the definitions set out in VCS document *Program Definitions*, the following definitions and acronyms apply to this methodology:

Activity-Shifting Leakage Area
The area where leakage resulting from the activities of the agent of conversion would likely occur due to the project activity(ies).

Agent of Conversion
People, groups of people or organizations responsible for degradation and deforestation or native grassland conversion.

Allometric Equation
A statistical model used to predict biomass given the measurement of closely related attributes of a tree or shrub, such as diameter (DBH) or stem count.

Baseline Type
One of five types that address the AFOLU Requirements for planned, unplanned mosaic and unplanned frontier conversion.

Baseline Emissions
For any monitoring period, baseline emissions $E_{B\,\Delta}^{[m]}$ are a sum of estimated emissions over selected carbon pools and time between monitoring events.

Baseline Emissions Models
The Biomass Emissions Model and Soil Emissions Model that characterize the baseline scenario.

Baseline Reevaluation
Revision of the baseline scenario which occurs at least every 10 years (see section 6.20).

Biomass Emissions Model (BEM)
A model that characterizes the emissions from biomass in the baseline scenario.

Carbon Fraction
The proportion of biomass that is carbon, which may vary by species.

Cascade of Degradation
A primary agent and secondary agent(s), and their associated drivers, that eventually degrade the forest to a non-forest state. The secondary agents are ultimately responsible for deforestation.

Class of Agents
A group of agents of conversion that share the same driver of conversion.

Conversion
The removal or replacement of vegetation and/or disturbance of soil.

Conversion Parameters
the parameters of the baseline emissions models that describe the behavior of degradation and conversion over time.

Covariate
A variable possibly predictive of the outcome under study; in this case quantifiable social, economic, or political factors that may improve model fit.

Decay Emissions Model (DEM)
A model that characterizes the exponential decay of certain carbon pools in the baseline scenario or as result of project activity (ies).

Degradation
Please see current VCS definition. In addition, degradation can include any intermediate state of conversion.

Drivers of Conversion
Geographic, climatic or other physical, social and/or economic conditions that cause conversion.

Emissions Model
One of the four emissions models (Biomass Emissions Model, Soil Emissions Model, Decay Emissions Model or Leakage Emissions Model).

End Land Use
The utility of a discrete piece of land that is on average over its area non-forest (eg, pasture land, grazing land, open pit mines, urban living space, subsistence agriculture or mechanized agriculture).

Foreign Agents
Groups originating outside the region in which the project resides (eg, a group of settlers that emigrates a far distance inland from the coast).

Forested Project Accounting Area
A project accounting area that meets the definition of forest as of the project start date and for at least 10 years prior to the project start date.

Forested
Meets the definition of forest on average across the area to which it is applied.

Grassland Conversion
The conversion of grassland in its natural state to one of anthropogenic use (eg, agriculture, development (including housing) or other anthropogenic land-use discernable from remotely sensed imagery). Conversion to grazing lands and/or pasture is excluded from this definition.

Grassland Project Accounting Area
A project accounting area that meets the definition of *native grassland* or *shrubland* as of the project start date and for at least 10 years prior to the project start date.

Imminent Conversion
The risk of land use change in a portion of the project accounting area and within 10 years of the project start date by the agents of conversion.

Leakage Emissions Model
A model that characterizes the emissions from leakage under conditions that would have occurred in the activity-shifting leakage area had the project activity (ies) not been implemented.

Log Production
The carbon in logs removed from a logging unit onto a landing which is subsequently processed and a portion turned into long-lived wood products.

Long-Lived Wood Products
Products derived from the harvested wood of a merchantable tree such as sawn timber and plywood that are assumed to remain or decay during the project crediting period.

Market Leakage Area
The area where leakage would likely occur resulting from a change in the supply of wood products due to the project activity(ies).

Merchantable Tree
A tree containing wood of commercial value, size, and desirable quality.

Monitoring Period
An interval of time following the project start date and project crediting period start date designated for systematically verifying project claims of GHG emissions reductions and/or removals and project additionality. Specifically, an interval of time from $t^{[m-1]}$ to $t^{[m]}$ where

$t^{[m-1]} \geq 0$ (the project crediting period start date) and $t^{[m-1]} < t^{[m]}$. The length of the monitoring period is $t^{[m]} - t^{[m-1]}$ where m denotes the number of any single monitoring period and t the number of days after the project crediting period start date that is the end of the monitoring period. The length of each monitoring period must be less than or equal to five years.

Native Ecosystem

Please see current VCS definition. A native ecosystem must include indigenous species, but does not need to be exclusively indigenous.

Native Grassland

A grassland which includes indigenous grass species, and may include some density of trees too low to be defined as forest (such as a woodland). There may exist some patches of forest which meet the definition of forest, but an area defined as native grassland does not meet the definition of forest, on average, across the area.

Native Shrubland

A shrubland which includes indigenous shrub and woody species, and may include some density of trees too low to be defined as forest. There may exist some patches of forest which meet the definition of forest, but an area defined as native shrubland does not meet the definition of forest, on average, across the area.

Net GHG Emission Reductions and Removals (NERs)

Tonnes of carbon dioxide equivalent (tCO_2e) emissions that are reduced or removed from the atmosphere due to project activities during the project crediting period.

Non-Decay Pool

A carbon pool that does not decay over time.

Non-Forest

Not meeting the country-specific definition of forest.

Non-Merchantable Tree

All other trees that do not meet the definition of a merchantable tree.

Non-Tree Biomass

Biomass that includes grasses, sedges, herbaceous plants and non-tree woody biomass.

Non-Tree Woody Biomass

Biomass that includes woody shrubs and any trees too small for carbon stock estimation using the allometric equation derived or selected for trees.

Participatory Rural Appraisal
A voluntary survey of the populace surrounding the project area that can be used to identify the agents and drivers of conversion, delineate the reference area, and identify strategies to mitigate conversion in the project area.

Peat Soil
See current VCS definition for peatland.

Permanent Plot
A plot with fixed area and location used to repeatedly measure change in carbon stocks over time.

Planned Commercial Deforestation
A deforestation scenario where the immediate agent of deforestation is known and there is commercial harvest in the baseline scenario (baseline type F-P1.a and F-P1.b).

Planned Non-Commercial Conversion
A conversion scenario where the immediate agent of conversion is known and there is no commercial harvest of wood products in the baseline scenario (baseline type F-P2 and G-P2).

Primary Agent
An agent of conversion that initiates cascade of degradation ultimately leading to conversion. Without the primary agent, conversion would not occur.

Project Accounting Area
An area within the project area that meets the definition of forest or native grassland and is subject to conversion in the baseline scenario. All project accounting areas will meet the definition of either a forest project accounting area or grassland project accounting area.

Project Area
The area controlled by the project proponent where project activities may be implemented.

Project End Date
The date of the end of the last monitoring period and the conclusion of the Project Crediting Period.

Project Emissions
Emissions for any monitoring period $[m]$ as estimated by the events of woody biomass consumption.

Project Shift Period
The period of time between conversion observed in the reference area and the project start date, denoted by γ.

Project Performance
A comparison of ex-post credit generation to ex-ante estimates over time.

Proxy Area
The area where residual carbon stocks (after conversion, the end state) are estimated for each baseline type.

Reference Area
An area in the same region as the project area that is similar to the project accounting area in regards to acting agents of conversion, acting drivers of conversion, socio-economic conditions, cultural conditions and landscape configuration. This area is used to estimate the conversion parameters (see section 6.8.1).

Reference Period
A historic period of time in the same region as the project that is similar in acting agents of conversion, acting drivers of , socio-economic conditions, cultural conditions and landscape configuration to the project area.

Secondary Agent
An agent of conversion that follows after the primary agent in the cascade of degradation ultimately leading to conversion. A secondary agent may not be present for conversion to occur.

Shrubland Conversion
The conversion of shrubland in its natural state to one of anthropogenic use (eg, agriculture, development (including housing) or other anthropogenic land-use discernable from remotely sensed imagery). Conversion to grazing lands and/or pasture is excluded from this definition.

Soil Emissions Model (SEM)
A model that characterizes the emissions from SOC in the baseline scenario.

Specific Agent of Conversion
An agent of conversion that can be identified by name and that resides in a known area, and that is directly responsible for conversion or the beginning of cascade of degradation.

Stratification
The process of grouping homogenous subgroups of a given population to reduce sampling measurement error.

Temporal Project Boundary
The period of time when conversion is mitigated in the project area as a result of project activities, the boundaries of which are defined by the project start date and project end date.

Threatened Perimeter
The perimeter of the project area that is vulnerable to conversion by being accessible to the local agents of conversion.

Type of Agent
Either a primary agent or a secondary agent.

Unplanned Conversion
A conversion scenario where the immediate agent of conversion is unknown (baseline type F-U1, G-U1, F-U2, G-U2 and F-U3).

Woody Biomass
Biomass resulting from secondary growth.

3.2 Acronyms

ACoGS	Avoided Conversion of Grasslands and Shrublands
AGMT	Above-ground merchantable tree (see merchantable tree)
AGOT	Above-ground other tree (see non-merchantable tree)
AGNT	Above-ground non-tree
AFOLU	Agriculture, Forestry and Other Land Use
APC	Avoided Planned Conversion
APD	Avoided Planned Deforestation
AS	Activity-shifting
AUC	Avoided Unplanned Conversion
AUDD	Avoided Unplanned Deforestation and Degradation
B	Baseline
BA	Buffer account
BE	Baseline emissions
BEM	Biomass Emissions Model
BGB	Below-ground biomass

BGMT	Below-ground merchantable tree
BGOT	Below-ground other tree
BGNT	Below-ground non-tree
BR	Baseline reevaluation
BRN	Burning of biomass
CF	Carbon fraction
CON	Conversion
D	Decay
DBH	Diameter at breast height
DEG	Degradation
DEM	Decay Emissions Model
DF	Deforestation
DMD	Demand
DOM	Domestic
DNA	Designated National Authority
DW	Dead wood
EM	Emissions models
F	Forest
FAO	Food and Agriculture Organization
G	Grassland
GERs	Gross Emission Reductions
GHG	Greenhouse gas
GIS	Geographic Information System
GLB	Global

IPCC	Intergovernmental Panel on Climate Change
IRLS	Iteratively Reweighted Least Square
ISO	International Organization for Standardization
L	Emissions from leakage
LD	Lying dead wood
LEM	Leakage Emissions Model
LS	Livestock
LTR	Litter
MC	Moisture content
ME	Market leakage
MR	Monitoring requirement
NERs	Net GHG Emission Reductions and/or Removals
P	Project
PA	Primary Agent
PD	Project Description
PDR	Project description requirement
PE	Project emissions
PX	Proxy area
RA	Reference area
REDD	Reduced Emissions from Deforestation and Degradation
RMSE	Root Mean-Squared Error
PA	Project area
PAA	Project accounting area
PAI	Project activity instance

PRA	Participatory Rural Appraisal
RS	Root-to-shoot ratio
SEM	Soil Emissions Model
SA	Secondary agent
SD	Standing dead wood
SE	Standard error
SF	Synthetic fertilizer
SL	Slash
SP	Spatial algorithm
SPC	Species
SOC	Soil organic carbon
SUP	Supply
UNFCCC	United Nations Framework Convention on Climate Change
VVB	Validation/Verification Body
VCS	Verified Carbon Standard
VCSA	Verified Carbon Standard Association
VCU	Verified Carbon Unit
WP	Long-lived wood products

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that prevent conversion of forest to non-forest and of native grassland to a non-native state.

This methodology is applicable under the following conditions:

1. The drivers and agents of conversion in the baseline scenario must be consistent with those described in section 6 of this methodology, and the end land use in the baseline scenario is non-forest (in the case of REDD project activities) or converted native

grassland (in the case of ACoGS project activities). Accordingly, the project activity must be APD or AUDD for forested project accounting areas and APC or AUC for grassland project accounting areas.

2. All project accounting areas must have been in an unconverted state (ie, forest or native grassland) for at least 10 years prior to the project start date, according to the following:
    a. Land in all forested project accounting areas has qualified as forest, on average, across the project accounting areas, as defined by FAO 2010 or by the residing designated national authority (DNA) for the project country for a minimum of 10 years prior to the project start date.
    b. Land in all grassland project accounting areas has qualified as native grassland or shrubland for a minimum of 10 years prior to the project start date.
3. For project accounting areas with an unplanned baseline type, a conversion threat must exist for each project accounting area as demonstrated by one of the following two options:
    a. Imminent conversion (see definition) must be predicted by a survey, where more than 60% of respondents predict the end land use identified in the baseline scenario. The survey must meet the requirements of Appendix E.

       OR
    b. As of the project start date, some point within 2 kilometers of the perimeter of the project accounting area has been converted to the end land use identified in the baseline scenario[1].
4. In the case of baseline type F-U1, at least 25% of the project area boundary is within 120 meters of deforestation and at least 25% of the project area boundary is adjacent to the reference area (see section 6.3).
5. In the case of baseline type G-U1, at least 25% of the project area boundary is adjacent to the reference area (see section 6.3).
6. In the case of baseline type F-U2, at least 25% of the project area boundary is within 120 meters of deforestation (see section 6.3).
7. The project accounting area(s) must not contain peat soil.
8. For each project accounting area, a reference area can be delineated for each baseline type in the baseline scenario that meets the requirements, including the minimum size requirement, of section 6.8.1 of this methodology.
9. As of the project start date, historic imagery of the reference area(s) exists with sufficient coverage to meet the requirements of section 6.8.4 of this methodology.

[1] The appropriateness of the 2 kilometer proximity is described in Broadbent et al., 2008.

10. Project activities are planned or implemented to mitigate ecosystem conversion by addressing the agents and drivers of conversion as described in section 8.3.1 of this methodology.

11. The project proponent has access to the activity-shifting leakage area(s) and proxy area(s) to implement monitoring (see sections 8.3.2.1 and 6.4), or has access to monitoring data from these areas for every monitoring event.

12. If logging is included in the baseline scenario and a market leakage area is required as per section 8.3, then the project proponent has access to (or monitoring data from) the market leakage area if measurement is needed (see section 8.3.3).

13. This methodology is applicable to all geographies. However, if SOC is a selected carbon pool and the default value from section 6.19.2 is selected, then the project must be located in a tropical ecosystem.

14. If livestock are being grazed within the project area in the project scenario, there must be no manure management taking place, as emissions from N_2O as a result of manure management are not quantified or addressed in this methodology.

15. For ACoGS project types, project activities must not result in significant GHG emissions. All GHG emissions from project activities must be shown to be *de minimis* (see section 8.3.1).

PD Requirements: Applicability Conditions
The project description must include the following: **PDR.1** For each applicability condition, a statement of whether it applies to the project. If the applicability condition does not apply to the project, justification for this conclusion. **PDR.2** Where applicability conditions apply, credible evidence in the forms of analysis, documentation or third-party reports to satisfy the condition. **PDR.3** Definition of forest used by the project proponent and its source.

5 PROJECT BOUNDARIES

The physical and temporal constraints of the project as well as the greenhouse gases and carbon pools must be clearly delineated and defined by the project proponent. Bounds must conform to the latest VCS requirements and this methodology, and must be clearly and objectively defined to facilitate monitoring and evaluation per the requirements in this section.

5.1 Delineating the Spatial Boundaries

The project area may be a combination of forest, non-forest, native grassland, or converted native grassland. However the baseline emissions models can only be applied to the forest or native grassland areas subject to conversion in the baseline scenario (see section 6.2). Project accounting areas, on average over their entirety, must meet the definition of forest or native grassland given in section 3 (this means that not every stratum must meet the definition of forest or native grassland). The project area may consist of multiple contiguous or non-contiguous parcels.

The geographic or physical boundaries of the project area must be clearly delineated using, at minimum, the following:

- Name of the project area (compartment or allotment number, local name)
- Digital maps of the area, including geographic coordinates of vertices
- Total land area
- Details of ownership, including user rights and/or land tenure information
- Topography
- Roads
- Major rivers and perennial streams
- Land use/vegetation type classification

The size of the project area cannot increase after the end of the first monitoring period.

PD Requirements: Spatial Project Boundaries
The project description must include the following: **PDR.4** A digital (GIS-based) map of the project area with at least the above minimum requirements for delineation of the geographic boundaries. **PDR.5** Credible documentation demonstrating control of the project area.

Monitoring Requirements: Spatial Project Boundaries
The monitoring report must include the following: **MR.1** A digital (GIS-based) map of the project area with at least the above minimum requirements for delineation of the geographic boundaries.

5.2 Defining the Temporal Boundaries

Temporal boundaries define the period of time when degradation, deforestation and conversion in the project area are mitigated by project activities.

The following temporal boundaries must be defined:

- The project start date.
- The project crediting period (projects may use an historical crediting period under specific circumstances, consistent with current VCS rules).
- The length of the project crediting period.
- The dates and periodicity of baseline reevaluation and monitoring periods. A baseline reevaluation after the project start date and monitoring must conform to the current VCS requirements.

The project crediting period start date may occur after the project start date. If the project crediting period start date is more than 10 years after the project start date, then as of the project crediting period start date, a baseline reevaluation must occur prior to the end of the first monitoring period (see section 6.20).

PD Requirements: Temporal Project Boundaries	
The project description must include the following:	
PDR.6	The project start date.
PDR.7	The project crediting period start date and length.
PDR.8	The dates for mandatory baseline reevaluation after the project start date.
PDR.9	A timeline including the first anticipated monitoring period showing when project activities will be implemented.
PDR.10	A timeline for anticipated subsequent monitoring periods.

Monitoring Requirements: Temporal Project Boundaries	
The monitoring report must include the following:	
MR.2	The project start date.
MR.3	The project crediting period start date, end date and length.

5.3 Gases

Project proponents must account for significant sources of the following included greenhouse gases as specified in Table 2.

Table 2: Included GHG Sources

Gas	Sources	Inclusion	Justification
CO_2 (Carbon Dioxide)	Flux in carbon pools	Yes	Major pool considered in the project scenario
CH_4 (Methane)	Burning of biomass	No	Conservatively excluded
	Livestock	Yes	A required source when emissions from grazing are not *de minimis*
N_2O (Nitrous Oxide)	Burning of biomass	No	Conservatively excluded
	Livestock	No	Excluded on the basis of applicability condition 14.
	Synthetic fertilizer	Yes	Included if not *de minimis*

5.4 Selecting Carbon Pools

Project proponents must account for the required carbon pools and may additionally select from the optional pools listed in Table 3 for forested project accounting areas and Table 4 for grassland project accounting areas.

Table 2: Required and Pptional Carbon Pools for Forested Project Accounting Areas and Justifications.

Pool		Required	Justification
AGMT	Above-ground merchantable tree	Yes, if baseline scenario or project activity (ies) include the harvest of long-lived wood products. Otherwise, accounting for this carbon pool is not required.	Major pool considered when accounting for emissions from long-lived wood products
AGOT	Above-ground other (non-merchantable) tree	Yes	Major pool considered

AGNT	Above-ground non-tree	Yes, if the baseline scenario includes perennial tree crops. Otherwise, accounting for this carbon pool is optional.	May be conservatively excluded, though it is not conservative to exclude if the baseline scenario includes perennial tree crops
BGMT	Below-ground merchantable tree	Optional	May be conservatively excluded
BGOT	Below-ground other (non-merchantable) tree	Optional	May be conservatively excluded
BGNT	Below-ground non-tree	Optional	May be conservatively excluded
LTR	Litter	No	Always conservatively excluded
DW	Dead wood	Yes, if AGMT is selected	May be a significant reservoir from slash under the baseline scenario
SD	Standing dead wood	Optional	May be conservatively excluded
LD	Lying dead wood	Optional	May be conservatively excluded
SOC	Soil organic carbon	Optional	May be conservatively excluded
WP	Long-lived wood products	Yes, if AGMT is selected	May be a significant reservoir under the baseline scenario

Table 3: Required and optional carbon pools for grassland project accounting areas and justifications.

Pool		Required	Justification
AGMT	Above-ground merchantable tree*	Yes, if baseline includes perennial crops. Otherwise, accounting for this carbon pool is optional	May be conservatively excluded
AGOT	Above-ground other (non-merchantable) tree*	Yes, if baseline includes perennial crops. Otherwise,	May be conservatively excluded

		accounting for this carbon pool is optional	
AGNT	Above-ground non-tree*	Yes, if baseline includes perennial crops. Otherwise, accounting for this carbon pool is optional	May be conservatively excluded
BGMT	Below-ground merchantable tree*	Optional	May be conservatively excluded
BGOT	Below-ground other (non-merchantable) tree*	Optional	May be conservatively excluded
BGNT	Below-ground non-tree*	Optional	May be conservatively excluded
LTR	Litter	No	Always conservatively excluded
DW	Dead wood*	Optional	May be conservatively excluded
SD	Standing dead wood*	Optional	May be conservatively excluded
LD	Lying dead wood*	Optional	May be conservatively excluded
SOC	Soil organic carbon	Optional	May be conservatively excluded
WP	Long-lived wood products	No	De minimis

*To avoid confusion, this methodology uses the term "tree" and "non-tree" throughout for both REDD and ACoGS carbon pools. For ACoGS carbon pools, this should be read as "woody" and "non-woody" respectively, as set out in the *AFOLU Requirements*.

Optional pools may be excluded if it can be demonstrated that it is conservative to do so (ie, exclusion of the pool will lead to fewer emission reductions). The project proponent must use *ex-ante* estimates (see section 8.4.7) to demonstrate conservative exclusion of optional pools. Conservative exclusions must always meet current VCS requirements.

Merchantable trees containing biomass in AGMT and BGMT are differentiated from non-merchantable trees containing biomass in AGOT and BGOT. For accounting, the important distinction between these classes of trees is that, under the baseline scenario and as a result of project activities that include logging, carbon stored in long-lived wood products must be considered (see sections 8.1.6 and 8.2.3). Merchantable trees must be defined by expert knowledge, the PRA or third-party publications.

Required and optionally selected carbon pools are referred to as the set of selected carbon pools denoted by $\mathcal{C}$ (see section 2.2 for notation).

PD Requirements: Carbon Pools	
The project description must include the following:	
PDR.11	A list of the greenhouse gases considered.
PDR.12	A list of the selected carbon pools and evidence for the conservative exclusion of any optional pools.
PDR.13	The definition and evidence to support the definition of a merchantable tree if the baseline scenario or project activities include logging.

5.5 Grouped Projects

Grouped projects are allowed, where each project activity instance is treated as a project accounting area in a single project area. All project activity instances that are grouped must be in the same region and must each meet all the applicability conditions of this methodology, including applicability conditions related to the baseline scenario (see sections 4 and 6).

All project activity instances must be exactly the same with regard to common reference areas, baseline scenarios, proxy areas, activity-shifting leakage areas and market leakage areas as described in the project description (see reporting requirements in sections 6, 6.8.1 and 8.3.3). Project documentation may vary with respect to carbon stock estimation, as stratification and plot location will vary by project activity instance (see reporting requirements in section 9), and project emissions (see reporting requirements in section 8.2).

Each project activity instance must have a project activity instance start date and those project activity instances sharing the same project activity instance start date and baseline type must be grouped into a single project accounting area.

PD Requirements: Grouped Projects	
If grouped projects are developed, then the project description must include the following:	
PDR.14	A list and descriptions of all enrolled project activity instances in the group at the time of validation.

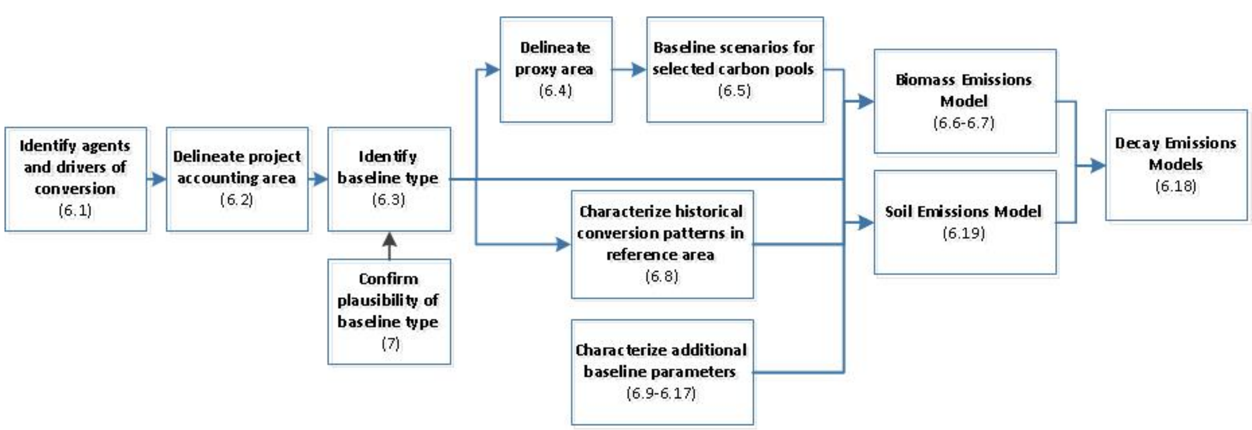
PDR.15	A map of the designated geographic area within which all project activity instances in the group will be located, indicating that all instances are in the same region.
PDR.16	A map of the common reference area, proxy area, activity-shifting leakage area, and market leakage area.

Monitoring Requirements: Grouped Projects
The monitoring report must include the following: **MR.4** A list and descriptions of all instances in the group. **MR.5** A map of the locations or boundaries of all instances in the group indicating that all instances are in the same region.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

The baseline scenario in this methodology hinges on the identification of the agents and drivers of conversion and an understanding of how, when and where they might have acted in the project area. Upon determining the baseline type (Section 6.3), the end land use in the baseline scenario (Sections 6.4 and 6.5), and historical patterns of conversion (Section 6.8), the proponent develops a BEM (Sections 6.6 and 6.7) and SEM (Section 6.19) in order to calculate the emissions predicted to occur in the absence of the project. The selected baseline type is confirmed to represent the most plausible baseline scenario by considering alternative scenarios in section 7.

Figure 2: Determination of the Baseline Scenario



Section 6 provides detailed guidance for how to determine the baseline scenario and the emissions predicted to occur in the absence of the project.

Since there may be multiple groups of agents acting differently in the baseline scenario, more than one project accounting area may be required within a given project area. A project accounting area is the area for which a unique set of baseline emissions models are parameterized and applied to determine baseline emissions.

If the agents are sequential, they contribute to a cascade of degradation. In the cascade of degradation, the first agent is the primary agent and the subsequent agents are the secondary agents. Often the primary agent creates new roads or infrastructure, providing new access points to secondary agents that ultimately convert degraded forest to non-forest. Each agent may be associated with different drivers. It is important to identify the agents and drivers of conversion in order to design project activities that will successfully mitigate conversion and in order to characterize the baseline scenario.

The baseline scenario for each baseline type is characterized by baseline emissions models that predicts what would have happened in each project accounting area had the project not been initiated. The baseline emissions models incorporate all the necessary accounting for emissions from degradation, deforestation, conversion and loss of SOC. The baseline scenario for each selected carbon pool is described in section 6.5.

The baseline emissions models are a function of time and some external, quantifiable drivers of conversion such as population density, length of road in the region or median household income. These external, quantifiable drivers of conversion are called covariates due to their correlation with observed conversion in the region. The fundamental basis for these models are three parameters (α, β, and θ) estimated by observing conversion in a reference area over a historical reference period. The reference area may surround the project area, may be near to the project area or be in the same geographic region as the project area.

The baseline scenario may include legally-sanctioned commercial logging if the project proponent can demonstrate that as a result of legally-sanctioned commercial logging, the project area would have been ultimately deforested in the baseline scenario resulting from a cascade of degradation. This may be the case if during the course of commercial logging, the primary agent creates new roads or infrastructure which provides new access points to secondary agents that ultimately degrade the forest to non-forest.

The baseline scenario may incorporate project accounting areas with baseline types that involve:

- Planned or unplanned avoided conversion and degradation in addition to deforestation.
- Spatially explicit accounting for conversion.

The baseline emissions models for each project accounting area are parameterized differently depending on the associated baseline type. The project proponent should first identify the baseline type for each project accounting area in section 6.3 and then select the necessary parameters as indicated in Figure 3 in section 6.7. If more than one project accounting area is identified, then apply these sections independently to each project accounting area.

Finally, a proxy area is used to characterize the end carbon stocks in the baseline scenario for each identified baseline type (see section 6.4).

If a jurisdictional baseline has been established and is applicable to the project activity, it may be used per VCS requirements.

PD Requirements: Determining the Baseline Scenario
The project description must include the following with respect to the baseline scenario: **PDR.17** Show that the identified baseline type is the most plausible baseline scenario identified in section 7.

6.1 Identifying the Agents and Drivers

This section is to be applied to identify the agents and drivers of conversion and subsequently define project accounting areas.

The baseline scenario must include at least one agent of conversion, but may include more. These agents may act sequentially to cause conversion in the baseline scenario. The PRA can be used to identify these agents (see Appendix E). The project proponent must provide the information in the below PD requirements regardless of whether a PRA is used.

Where the agents (or class of agents) and drivers of conversion are not cleary identifiable, statistics about the agents and drivers obtained from published or unpublished sources may be used to demonstrate their prevalence. If, during validation, the agents (or class of agents) and drivers of conversion are found to be not clearly identifiable and published or unpublished sources are not available to show their prevalence, a participatory rural appraisal (PRA) must be conducted per the guidance in Appendix E. The PRA is a tool that suffices to identify the agents (or class of agents) and drivers of conversion in the event that the agents and drivers are not clearly identifiable.

PD Requirements: Agents and Drivers of Conversion
The project description must include the following: **PDR.18** A list of the agents and drivers of conversion, including quantitative descriptions of agent mobilities. **PDR.19** A narrative describing the agents and drivers of conversion.

PDR.20 Descriptions of agents and drivers including any useful statistics and their sources.

PDR.21 A list of external drivers (covariates) of conversion used in the model, if any, that may be identified as part of a PRA, expert knowledge or literature (eg, median household income, road density, rainfall).

6.1.1 Primary Agents and Drivers

Distinguishing between the primary and secondary agents and drivers is important for Type F-P1.a and F-P1.b, in which legally-sanctioned commercial logging or agriculture precedes deforestation. For grassland baseline types G-P2, G-U1 and G-U2, it is assumed that there is no grassland degradation before conversion. Therefore, only a single agent or class of agents and drivers can result in the conversion of native grassland. In type F-P1.a and F-P1.b baselines, the agent carrying out the legally-sanctioned conversion is the primary agent. The primary agent provides the access and infrastructure to the secondary agents of conversion. As a result, the emissions from biomass in the early years of the baseline scenario are not logistic over time, but rather linear as a result of a regulated harvest schedule.

Other baseline types may also have primary and secondary agents acting in a cascade of degradation. However, the emissions from biomass resulting from primary and secondary agents are assumed to be logistic over time as demonstrated by observing historical conversion in the reference area.

6.1.2 Secondary Agents and Drivers

Baseline emissions resulting from the secondary class of agents are assumed to be logistic over time as demonstrated by observing conversion in the reference area. For the secondary agents in baseline type F-P1.a (APD), if a specific agent is identified in the baseline scenario, the reference area must be determined based on the activities of the most-likely agent who would have acquired control of and cleared the project area. If not, the reference area will be based on the most-likely class of agents to have acted in the project area. The reference area must be appropriate for the agents and drivers of deforestation that the project proponent identifies, and be in conformance with the criteria in Appendix D.

Under the F-P1.b scenario, the frontier configuration is assumed for the baseline, a consequence of the road network created by the primary agents of deforestation. The reference area must be appropriate for the agents and drivers of deforestation that the project proponent identifies, and be in conformance with the criteria in Appendix D.

6.2 Delineating Project Accounting Areas

This section is to be applied to delineate each project accounting area based on constraints to conversion. Project accounting areas must be defined based on the constraints associated with the identified agents and drivers of conversion. Agents may be constrained by areas that are too remote, steep, infertile or rocky to be accessed and converted.

Project accounting areas must not overlap and per current VCS requirements, forested project accounting areas must be forested and grassland project accounting areas must meet the definition of native grasslands as of the project start date and for at least 10 years prior to the project start date. Each project accounting area must be subject to conversion in the baseline scenario. For example, if the agent of conversion is constrained by steep slopes, the project accounting area would not contain these inaccessible slopes. Each project accounting area must be measured to determine its area in hectares.

The project accounting area may be optionally delineated based on the results of a participatory rural appraisal or expert knowledge (see Appendix E).

The geographic or physical boundaries of the project accounting areas must be clearly delineated by considering, at minimum, the following:

- Topography
- Roads
- Major rivers and perennial streams
- Land use/vegetation type classification
- Total area

For AUC baseline types (G-U1 and G-U2), the project proponent must take into account the patch size at which land conversion typically occurs (eg, areas unsuitable for crops may still be plowed if they are a small part of a larger suitable parcel). The minimum patch size must be 250m x 250m.

The set of all delineated project accounting areas in the project area is denoted $\mathcal{A}$. The sum of these areas must be less than or equal to the project area.

PD Requirements: Project Accounting Areas
The project description must include the following:
PDR.22 A digital (GIS-based) map of the project accounting areas, including aerial or satellite imagery showing that they are comprised of forest or native grassland as of the project start date and 10 years prior to the project start date.
PDR.23 Justify the project accounting areas using the identified agents and drivers of conversion, constraints to conversion, and attributes listed above in section 6.2.
For Avoided Unplanned Conversion (AUC) baseline types G-U1 and G-U2 (see section 6.3), the project description must include the following:
PDR.24 Selection of patch size at which land conversion typically occurs.
PDR.25 Justification of selection of patch size for delineation of project accounting area.

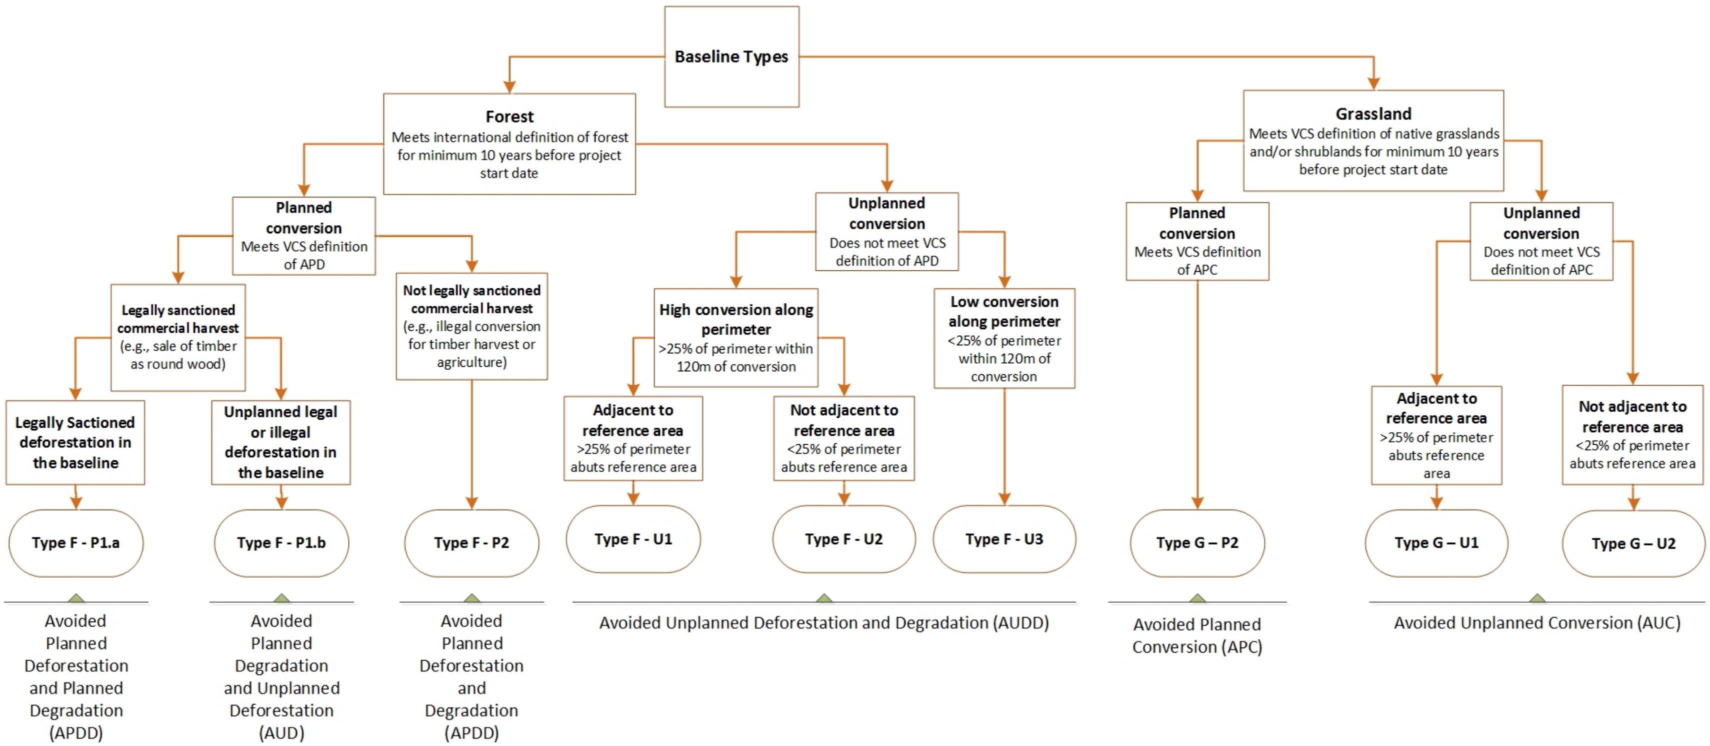
Monitoring Requirements: Project Accounting Areas
The monitoring report must include the following:
MR.6 A digital (GIS-based) map of the project accounting areas with at least the above minimum requirements for delineation of the geographic boundaries.

6.3 Identifying Baseline Types

This section is to be applied separately to each project accounting area to identify its baseline type.

The baseline emissions models account for emissions differently depending on the baseline type. A decision tree is presented in Figure 3. To determine the baseline type for a project accounting area, first determine whether the area qualifies as forest or native grassland. The baseline scenario for each baseline type is given in section 6.5, which must match most plausible baseline scenario identified in section 7.

Figure 3: Decision Tree to Determine Baseline Type



6.3.1 Forest Baseline Types

Where deforestation is initiated by the primary agent through legally-sanctioned commercial harvest (eg, sale of timber as round wood) and the area is ultimately converted to non-forest by the secondary agent through planned deforestation (eg, conversion to agriculture), the baseline type is F-P1.a.

Where deforestation is initiated by the primary agent through legally-sanctioned commcercial harvest and the area is ultimately converted to non-forest by the secondary agent through unplanned deforestation (eg, subsistance agriculture), the baseline type is F-P1.b.

Where deforestation occurs in a planned fashion but does not take place as a result of legally-sanctioned activities (eg, clearing for a plantation), it is planned non-commercial conversion and the baseline type is F-P2 (eg, the land is illegally logged or cleared for agriculture).

The baseline for the legally-sanctioned commercial harvest component of baseline types F-P1.a and F-P1.b is established using management plans from the primary agent. The secondary agents of conversion of F-P1.a and F-P1.b being carried out by the secondary agents of conversion are assumed to follow a frontier pattern of deforestation stemming from the roads. The project proponent must demonstrate that infrastructure that leads to deforestation would have existed in the baseline. To do this, projects may produce permits, construction plans, contracts or tenders, budgets, or other evidence of the intent to construct roads. Alternatively, the proponent must demonstrate that it is in fact common practice for comparable commercial logging outfits to build roads and other access infrastructure in order to legally degrade under a logging concession and that the primary agent has sufficient access to the project area to build infrastructure in the forest project accounting area. This can include the demonstration of a major road(s) leading to the project area, granting large machinery access to the project area and/ or definitive plans to build such infrastructure in the near future. The combination of demonstrating the construction of logging infrastructure in the reference area and roads having either been already built or plans for such roads showing clear access up to (but not necessarily within) the forest project accounting area will satisfy the requirement to show that such infrastructure would have been built in the baseline. For baseline type F-P1.b, a spatial algorithm of the baseline emissions models is required to conservatively determine baseline emissions over time (see sections 8.1.1.5.1 and 8.1.2.4.1).

If the baseline scenario does not meet the definition of APD, then determine the length of perimeter along the boundaries of the project area that is within 120 meters of deforestation that occurred within 10 years prior to the project start date. If this length is less than 25% of the entire perimeter of the project area, then the baseline type is F-U3. If 25% or more of the project area perimeter is 120 meters or less from deforestation, and if 25% or more of the project area perimeter also abuts the reference area, then the baseline type is F-U1. If 25% or more of the project area perimeter is 120 meters or less from deforestation but does not abut the reference area then the baseline type is F-U2.

Per the VCS *AFOLU Requirements*, the configuration of Type F-U1 and F-U2 must be mosaic while Type F-U3 may be mosaic or frontier. Type F-U3 requires a spatial algorithm of the baseline emissions models to conservatively determine baseline emissions over time (see section 8.1.1.5.1).

If the baseline type is F-U1, also see the requirements in section 8.4.1.2.

The selected baseline type must not change after validation and remains in effect for the entire project lifetime.

PD Requirements: Identifying the Baseline Type - Forest
The project description must include the following: **PDR.26** If Types F-P1.a, F-P1.b or F-P2 are selected, justification for meeting the definition of APD in the current VCS-approved AFOLU Requirements. **PDR.27** If Type F-P1.a or F-P1.b is selected, evidence of legally-sanctioned commercial harvest in the baseline scenario. **PDR.28** If Type F-P1.a is selected, evidence of legally-sanctioned deforestation in the baseline scenario. **PDR.29** If Type F-P1.b is selected, evidence of frontier configuration: Projects must demonstrate that the agent of degradation had access to the project area AND that comparable agents create roads for extraction of timber AND/OR Projects may produce permits, construction plans, contracts or tenders, budgets, or other evidence of the intent to construct roads. **PDR.30** If Type F-U1 is selected, a spatial analysis of the project area showing that at least 25% of the perimeter is within 120 meters of deforestation that occurred within 10 years prior to the project start date and showing that the reference area is adjacent to at least 25% of the project area. **PDR.31** If Type F-U2 is selected, a spatial analysis of the project area showing that at least 25% of the perimeter is within 120 meters of deforestation that occurred within 10 years prior to the project start date. **PDR.32** If Types F-U1, F-U2 or F-U3 is selected, a spatial analysis of the project area showing that it is within 120 meters of deforestation that occurred within 10 years prior to the project start date.

6.3.2 Grassland Baseline Types

For each grassland project accounting area, determine whether the baseline scenario meets the current definition of avoided planned conversion in the VCS *AFOLU Requirements*. The project proponent must provide evidence that the project area was intended to be converted in the absence of the project, and must meet the definition of anthropogenic land-use conversion. Native grassland and shrubland conversion shall be defined as, and limited to, the conversion of native grassland or shrubland from its natural state to one of anthropogenic use. This includes the land-use categories of agriculture, development (including housing) or other anthropogenic land-use discernable from remotely sensed imagery. Conversion to grazing lands and/or pasture shall not be included in the grassland/shrubland converted category, for the following reasons:

- In some cases, cattle or other grazing actually results in increased carbon stocks, and therefore may not represent a net carbon reduction.
- It is conservative to exclude pasture/grazing lands from the converted category.

Pasture/grazing lands are highly difficult to identify using nominal remote sensing techniques, and would thus prove impossible to recognize using the BEM model.
The conversion of native grassland / shrubland should be discernable using the same techniques as used for REDD type baseline models. Pixel pattern, texture and context should be employed to delineate anthropogenically converted native grassland / shrubland from its natural state, just as deforested areas are delineated from natural forest within the BEM. In cases where the agent of conversion is not the landowner, the project proponent may determine the baseline scenario using historical and current conversion activities of the most likely agent who would have acquired the project area in the absence of the project. If the baseline scenario meets the definition of APC, then the baseline type is planned conversion (G-P2).

If the baseline scenario does not meet the definition of APC, but still meets the definition of native grassland / shrubland conversion, determine the portion of the project area perimeter that abuts the reference area. If 25% or more of the project area perimeter abuts the reference area, then the baseline type is G-U1. Conversely, if less than 25% of the project area perimeter abuts the reference area, then the baseline type is G-U2.

If the baseline type is G-U1, also see the requirements in section 8.4.1.2.

PD Requirements: Identifying the Baseline Type - Grassland
The project description must include the following: **PDR.33** If Type G-P2 is selected, justification for meeting the definition of APC in the current VCS-approved AFOLU Requirements. Justification must include evidence of intent to convert the project area and that the converted land-use category would meet the definition of native grassland / shrubland conversion.

PDR.34	If Type G-U1 is selected, a spatial analysis of the project area showing that the reference area is adjacent to at least 25% of the project area.

6.4 Delineating Proxy Areas

This section is to be applied separately for each identified project accounting area, however proxy areas for each project accounting area may partially or entirely overlap. Therefore, an individual proxy area must be identified for each project accounting area, but two or more proxy areas may share identical boundaries.

The proxy area is used to estimate residual carbon stocks of the end land use in the baseline scenario associated with a particular project accounting area. It must be located in the same general region as the project area, but not necessarily adjacent to the project area. The proxy area must also be physically accessible to the project proponent, as ongoing ground-based measurement will be necessary. For each project accounting area, the proxy area must be similar to the corresponding project accounting area with respect to vegetation, landscape configuration and climatic conditions.

The proxy area must represent areas already converted to the end land use (eg, non-forest or converted native grassland) in the baseline scenario as of the project start date. There is no minimum or maximum size for the proxy area, however it must have a similar landscape configuration to the project accounting area. The proxy area must not include the project area but may overlap with the reference area. The proxy area must not be altered after the first monitoring period unless there is a baseline reevaluation (see section 6.20).

The proxy area must be delineated per the requirements of Appendix D.

PD Requirements: Delineation of the Proxy Areas
The project description must include the following information with respect to the proxy area:
PDR.35 A map of the delineated boundaries.
PDR.36 Maps or other evidence that the proxy area's site characteristics and landscape configuration is similar to its respective project accounting area, including: • Vegetation; • Climatic conditions (eg, mean temperature, rainfall, etc.); • Topographic constraints to conversion (slope, aspect, elevation); • Land use and/or land cover; • Soil map (if available) or other soil information;

- Applicable infrastructure (eg, water ways, roads, railroad, airports, provision of electricity, and other access points); and
- Ownership/tenure boundaries that influence conversion (eg, government holdings, private holdings and reserves).

PDR.37 A narrative describing the rationale for selection of proxy area boundaries, including the proxy area's similarity to the corresponding project accounting area with respect to vegetation, soil and climatic conditions.

PDR.38 Results of a spatial analysis to demonstrate the proxy area is converted, on average, as of the project start date.

6.5 Baseline Scenarios for Selected Carbon Pools

The following sections describe how the baseline emissions models are applied to each pool and any additional assumptions used in determining baseline emissions. The BGB pool is described in section 6.5.4, and the DW pool is described in section 6.5.2. Accounting for emissions from decay relative to source of emissions is outlined in Table 5 below.

Table 4: Decay Emissions by Carbon Pool

Carbon Pool	Soil	Below-Ground	Dead Wood	Wood Products
AGMT			Decay in DW (from slash)	Decay in WP (from log export by wood product type)
AGOT			Decay not Considered (not applicable)	
AGNT				
BGMT		Decay from BGB		
BGOT				
BGNT				
SOC	Decay in SOC (as a result of land-use conversion)			
SD		Decay not Considered (not applicable)		
LD				

The categories shown across the top of the table (columns) are decay pools per AFOLU requirements. The left side of the table (rows) shows carbon pools defined by this methodology. Table 5 shows the intersection of these two categories. Where there are blank spaces, the carbon pools are not applicable to the decay pools. For example, the AGMT (Above-Ground Merchantable Tree) carbon pool does not apply to the Below-Ground decay pool, thus the cell where they intersect is left blank.

The residual carbon stocks associated with the end land use in the baseline scenario are characterized by the proxy area for all baseline types (see section 6.4).

6.5.1 Baseline Scenario for Livestock

Livestock grazing may occur in the baseline scenario, but any emissions from this activity are conservatively assumed to be zero and are not credited. Livestock grazing or conversion to pasture must not be the primary driver of conversion, as decribed in section 6.3.2. Any emissions from livestock grazing in the project area, however, must be quantified as described in section 8.2.4.

PD Requirements: Describing the Baseline Scenarios for Selected Carbon Pools
The project description must include the following: **PDR.39** A qualitative description of the baseline scenario for each selected carbon pool.

6.5.2 Baseline Scenario for AGMT

In baseline types F-P1.a and F-P1.b, above-ground commercial portions of commercially viable trees are assumed to be removed (see section 8.1.6.1), and then converted to long-lived wood products (see section 8.1.6), accounted for as in Appendix C. The non-merchantable portion of merchantable trees (ie, the slash) is decayed linearly over ten years (see section 8.1.3). Primary agents are presumed to initiate the removal of merchantable trees; this initial degradation by primary agents is followed by secondary agents of conversion who remove remaining merchantable trees. It is conservative to account for the emissions from logging slash as a decay source, even if in reality these materials would have been burned or used for fuel.

Similarly in baseline types F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2, above-ground commercial portions of commercially viable trees are assumed to be removed (see sections 8.1.6.2, 8.1.6.3 and 8.1.6.4), and then converted to long-lived wood products by the agents of conversion (see section 8.1.6). The portions of merchantable trees that do not have commercial value are likewise decayed linearly over ten years (see section 8.1.3). The same process that occurs in F-P2, F-U1, F-U2, G-U1 and G-U2 is assumed to occur in baseline type F-U3, but merchantable trees are conservatively assumed to be removed first in the stratum with the lowest carbon stocks and last in the stratum with the highest carbon stocks (see section 8.1.1.5).

The baseline scenario for above-ground merchantable trees is directly related to the BEM (see section 8.1.1), which predicts the emissions from conversion and degradation over time, the decay of wood products over time (see section 8.1.6), and decay of slash (see section 8.1.3). In all cases, it is possible that above-ground merchantable tree biomass will exist after the agents of conversion have acted upon the forest or native grassland. This residual biomass must be determined using permanent plot measurements in the proxy area (see section 6.4), as prescribed in Appendix B. The proportion of above-ground merchantable trees that is converted to long-lived wood products is addressed under the scenario for wood products (see section 6.5.8).

6.5.3 Baseline Scenario for AGOT and AGNT

In baseline types F-P1.a, F-P1.b, F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2, above-ground portions of trees that are not commercially viable (ie, other trees that are not merchantable) and above-ground non-tree biomass are assumed to be immediately burned during clearing of the land or converted to fuel wood and burned (see section 8.1.1). The same process is assumed to occur in baseline type F-U3 where AGOT and AGNT are conservatively assumed to be converted to an emission first in the stratum with the lowest carbon stocks and last in the stratum with the highest carbon stocks (see section 8.1.1.5).

The baseline scenario for above-ground other trees and non-trees is characterized by the BEM. In all cases, it is possible that AGOT and AGNT biomass will exist after the agents of conversion have acted upon the forest. This residual biomass must be determined using permanent plot measurements in the proxy area (see section 6.4), as prescribed in Appendix B.

6.5.4 Baseline Scenario for BGMT, BGOT, and BGNT

The only below-ground portions of trees and other below-ground biomass affected in during commercial activity in F-P1.a and F-P1.b are conservatively assumed to be that of merchantable trees killed by logging. This below-ground biomass is decayed over ten years (see section 8.1.4). After the completion of commercial activity, below-ground biomass is assumed to be removed or to decay over time in the soil as land is deforested and converted to its end land use.

In baseline types F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2, below-ground biomass is assumed to be partially removed or to begin decay at the time of conversion (see section 8.1.4). Below-ground biomass in Type F-U3 is conservatively assumed to be partially removed first in the stratum with the lowest carbon stocks and last in the stratum with the highest carbon stocks (see section 6.4).

The baseline scenario for below-ground biomass is directly related to the baseline emissions model. It is assumed that below-ground biomass is not converted to long-lived wood products.

6.5.5 Baseline Scenario for SD

Prior to deforestation, standing dead wood is assumed to be insignificantly impacted by commercial agents in baseline types F-P1.a and F-P1.b. Following completion of commercial activity, the mass of standing dead wood not observed in the proxy area (see section 6.4), as compared to the project, is assumed to be removed, burned or converted to fuel wood by secondary agents.

Likewise in baseline types F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2, the difference between standing dead wood stocks in the project and the proxy area is assumed to be immediately removed, burned or converted to fuel wood. The same process is assumed to occur in baseline type F-U3, though standing dead wood is conservatively assumed to be removed first in the stratum with the lowest carbon stocks and last in the stratum with the highest carbon stocks (see section 8.1.1.5).

The baseline scenario for standing dead wood is directly related to the BEM, which predicts emissions from degradation and deforestation over time. In all cases, it is possible that standing dead wood will exist after the agents of conversion have acted upon the forest. This residual biomass must be determined using permanent plot measurements in the proxy area (see section 6.4), as prescribed in Appendix B. It is assumed that standing dead wood is not converted to long-lived wood products.

6.5.6 Baseline Scenario for LD

Lying dead wood is assumed to be impacted only slightly by commercial agents in baseline types F-P1.a and F-P1.b. Following completion of commercial activity, the difference in lying dead wood stocks between the project and proxy area is assumed to be removed (see section 6.4), burned or converted to fuel wood by secondary agents.

In baseline types F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2, the difference in lying dead wood stocks between the project and proxy area is assumed to be removed, burned or converted to fuel wood beginning immediately. In baseline type U3, lying dead wood is conservatively assumed to be removed first in the stratum with the lowest carbon stocks and last in the stratum with the highest carbon stocks.

The baseline scenario for lying dead wood is directly related to the baseline emissions model, which predicts emissions from degradation, deforestation and conversion over time. In all cases, it is possible that lying dead wood will exist after the agents of conversion have acted upon the forest. This residual biomass must be determined using permanent plot measurements in the proxy area (see section 6.4), as prescribed in Appendix B. It is assumed that lying dead wood is not converted to long-lived wood products.

6.5.7 Baseline Scenario for SOC

Soil is assumed to lose its organic carbon over time as a result of land conversion to agriculture (E. Davidson & Ackerman, 1993). This loss is assumed to follow not only conversion to agriculture, but any non-forest end state with lower soil carbon stocks than the project area. The total loss is established by measurements in the proxy area (see section 6.4), while the rate is determined using one of three options given in section 6.15.

Commercial agents in baseline types F-P1.a and F-P1.b account for only slight soil carbon loss because they degrade the area but do not deforest it. As secondary agents subsequently act on and ultimately deforest the area soil carbon is assumed to eventually reach equilibrium as determined by measurements within the proxy area.

In baseline types F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2 it is assumed that soil carbon will deplete to the SOC measured in the proxy area after a long period of time (see sections 6.4 and 8.1.2.1).

The baseline scenario for soil carbon is characterized by the SEM (see sections 8.1.2.1, 8.1.2.2 and 8.1.2.3), which predicts the SOC emissions from conversion over time (see section A.2 for a description of the model). Residual soil carbon must be determined using permanent plot measurements in the proxy area (see section 6.4), as prescribed in Appendix B.

6.5.8 Baseline Scenario for WP

Biomass remaining in wood products is assumed to be restricted to AGMT biomass (see sections 8.1.6.2, 8.1.6.3 and 8.1.6.4). The proportion of biomass remaining in wood products follows the procedure in section 8.1.6 and Appendix C.

6.6 The Baseline Emissions Models

This section must be applied separately for each identified project accounting area.

The baseline emissions models characterize the baseline scenario and include the BEM and the SEM for a particular project accounting area. The BEM predicts cumulative emissions from biomass as a result of degradation, deforestation and conversion while the SEM predicts cumulative emissions from SOC as a result of conversion.

The BEM for baseline types F-P1.a and F-P1.b is given by [F.2] and includes a linear component for emissions from planned commercial harvest and a logistic component for emissions from degradation. The BEMs for the other baseline types are given by [F.3], [F.4] and [F.5]. Theoretical background on the logistic nature of degradation, deforestation and conversion are presented in Appendix A. The logistic nature of ecosystem conversion is justified using established resource economic theory.

The SEM is given by [F.6], [F.7] and [F.8]; it is also based on a logistic model of ecosystem conversion. It assumes that SOC begins to decay in the project accounting area when it is cleared from forest or native grassland.

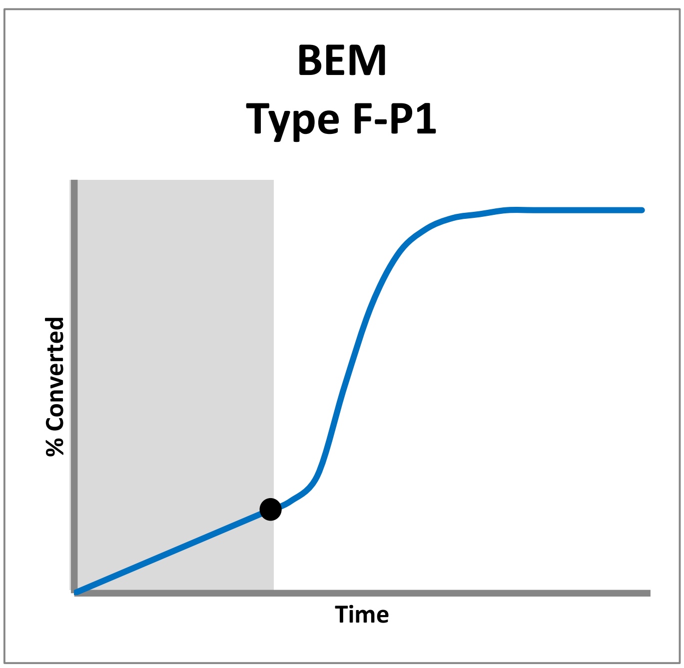
The baseline emissions models must be parameterized in terms of days relative to the project start date (see section 6.7.1 for discussion of data resolution). The models predict baseline emissions as tCO2e. These unified models dramatically simplify baseline accounting relative to other approaches, as all that is required is to determine the baseline type and select parameters based on Table 6 in section 6.7.

6.7 Parameterizing the Baseline Emissions Models

This section must be applied separately for each identified project accounting area.

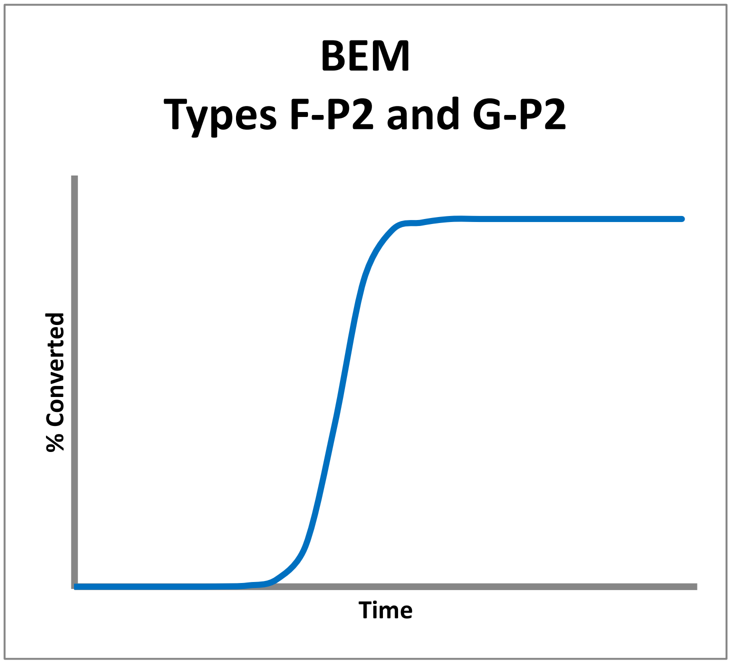
Use Table 6 to identify parameters to the baseline emissions models. Project proponents should first determine the baseline type per section 6.3. All parameters are set at the time of project validation or baseline reevaluation. Note that parameters with superscript $[m]$ are determined for each monitoring period and are specified in section 9.

Figure 4A: Example of BEM for Baseline Types F-P1.a and F-P1.b



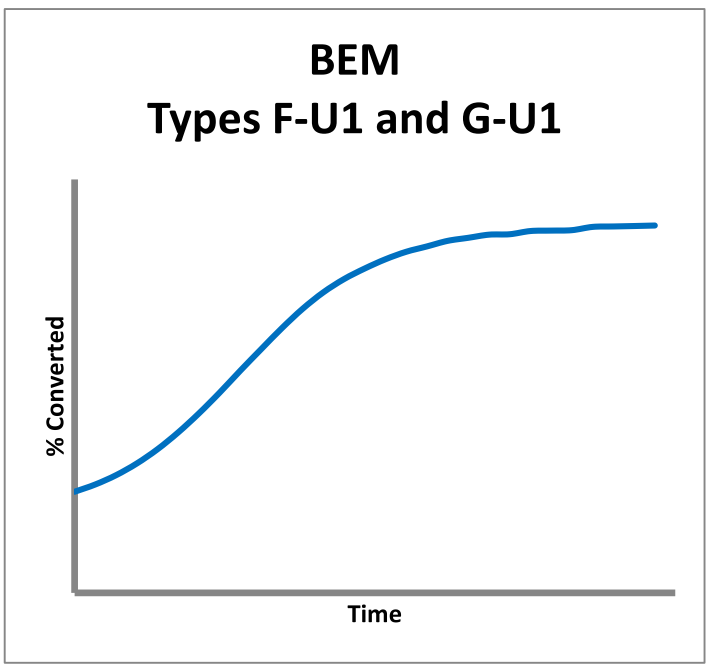
Conversion occurs at a linear rate from the time of arrival of the primary agents (t_{PA}) until the time of arrival of the secondary agents (t_{SA}), after which conversion follows a logistic curve. Actual curves for each project may vary.

Figure 4B: Example of Biomass Eissions Model for Baseline types F-P2 and G-P2.



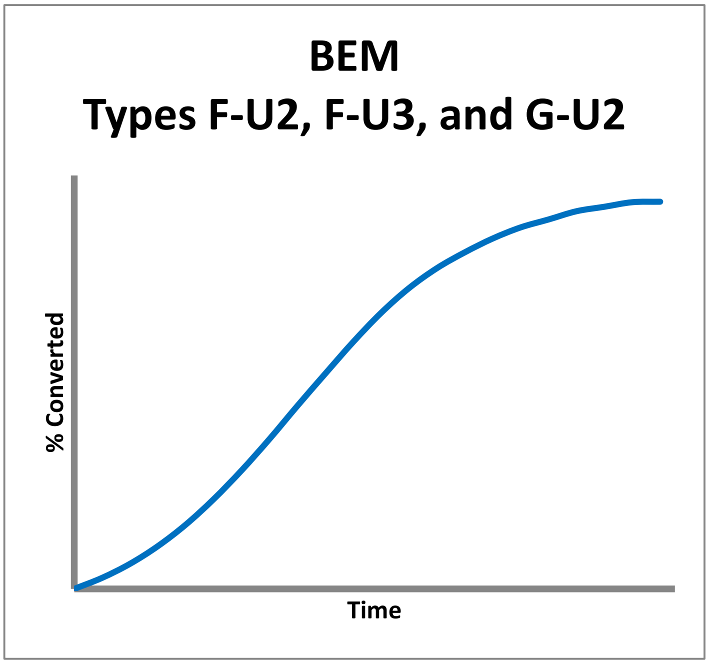
Conversion follows a steep logistic curve, reflecting the rapid conversion rates of baseline types F-P2 and G-P2. Actual curves for each project may vary.

Figure 4C: Example of BEM for Baseline Types F-U1 and G-U1



Conversion follows a logistic curve. Note that the BEM for F-U1 and G-U1 are rescaled in [F.5] so estimated baseline emissions start at zero as of the project start date. Actual curves for each project may vary.

Figure 4D: Example of BEM for Baseline Types F-U2, F-U3, and G-U2



Conversion follows a logistic curve. Actual curves for each project may vary.

Table 5: Selection of Conversion Parameters by Baseline Type

Parameter	Explanation	Section	F-P1*	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
α	Average effects of time and other covariates on degradation, deforestation and conversion (conversion parameters)	6.8	✓	✓	✓	✓	✓	✓	✓	✓
β	Effect of time on degradation, deforestation and conversion (conversion parameters)	6.8	✓	✓	✓	✓	✓	✓	✓	✓
θ	Effect of covariates on degradation, deforestation and conversion (conversion parameters)	6.8	✓	✓	✓	✓	✓	✓	✓	✓
t_{PAI}	Time of project activity instance start date relative to project start date for a project activity instance in a grouped project (days)	6.9	✓	✓	✓	✓	✓	✓	✓	✓
t_{SA}	Arrival time of secondary agents after start of commercial logging (days)	6.10	✓							
t_{PA}	Time prior to the project start date when the primary agent began commercial logging in the project accounting area (days relative to the project start date, negative)	6.11	✓							
x_0	Covariates as of the project start date.	6.12	✓	✓	✓	✓	✓	✓	✓	✓
x_{PAI}	Covariates as of the project activity instance start date for a project activity instance in a grouped project (days)	6.13	✓	✓	✓	✓	✓	✓	✓	✓
m	Commercial degradation per year (tCO2e/yr)	6.14	✓							
γ	Time shift from beginning of historic reference period to project start date (days relative to project start date)	6.15	✓ (if incl. soil)	✓				✓ (if incl. soil)		
q	Time shift between start of degradation and conversion (days)	6.16		✓	✓	✓	✓		✓	✓

r_U	Converted area or threatened perimeter in the project area at the project start date (hectares)	6.17				✓	✓			✓

+ indicates that value must be conservatively set to zero unless justified; * indicates both F-P1.a and F-P1.b)

6.7.1 Resolution of Parameter Values

In order to aid modeling, whenever possible, time is parameterized in terms of days in this methodology. Monitoring and measurement need not have that precision. For example, if the precision of the data available for m is on a monthly basis, the conversion should simply be made from months to days. It is always conservative to use a larger number for time (eg, to round up when converting units of time).

6.8 Determining Historical Conversion (α, β and θ)

This section is to be applied separately for each identified project accounting area.

A reference area and historic reference period are used to find α, β and θ, the parameters that are used to depict the historic pattern of ecosystem conversion to be applied to the project accounting area in the baseline scenario. The reference area is used to determine the landscape pattern of conversion while the reference period is used to determine the change in the cumulative proportion of conversion over time.

The parameter β is the effect of time on the cumulative proportion while θ, a vector, is the effect of certain covariates on the cumulative proportion. The parameter α is related to the combined effects of the other parameters at the start of the historic reference period.

This methodology does not specify a fixed length for the historic reference period. Instead, the reference period is defined by the availability of historic images of the reference area and the occurrence of important past events related.

Specific requirements for the reference area and historic reference period are given in sections 6.8.1 and 6.8.2.

6.8.1 Delineating Reference Areas

The reference area is defined differently for baseline types F-P1.a, F-P1.b, F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2. While the reference area is defined differently for the baseline types mentioned, the reference area selection criteria outlined below must be applied to all baseline types. A reference area must be delineated for each project accounting area. Reference areas may overlap.

6.8.1.1 Reference Area Selection Requirements

The reference area must address the following criteria in order to ensure that the agents and drivers of conversion are similar to those of the project accounting area, as well as to prove that those agents performed similarly in the reference area to the way they would have performed in the project accounting area under the baseline scenario.

1. The location and size of the reference area relative to the project accounting area:

    a. A pair of maps showing the boundaries and size of the reference area and the project accounting area, including an indication of their locations relative to each other.

    b. Written justification for the selection of the location of the reference area.

2. A description of the drivers of conversion, including the following, relative to the project area:

    a. Written description of the socio-economic conditions in the reference area and project accounting area including the following data where available:

        i. Census data depicting relevant demographics and socioeconomic conditions

        ii. PRA data

        iii. Economic studies

        iv. Maps depicting demographic data and socio-economic conditions

    b. Written description of the cultural conditions, such as historical events, cultural shifts, migration patterns, tribal traits and characteristics, and current cultural patterns including the following data where available:

        i. PRA data

        ii. Publications relevant to the cultural conditions in the area

        iii. Maps depicting cultural data

3. The location(s) of the agents of conversion relative to the project accounting area and surrounding region including the following:

    a. A paired comparison of maps of the reference area and project accounting area, including locations of settlements or other population centers. For subsequent use in determining the mobilities of the agents of conversion.

4. The mobilities of the agents of conversion relative to the project accounting area, including the following:

    a. Written description of the mobility of all primary and secondary agents in the project accounting area and reference area. Acceptable data sources should be used to demonstrate mobility, including geographic and/or anthropogenic factors that may influence their movement or access.

5. Landscape configuration of the reference area and the project accounting area, including all of the following factors:

    a. A paired comparison of maps of the reference area and project accounting area, which must include the following criteria:

        i. Topographic constraints to conversion (slope, aspect, elevation);

ii. Land use and/or land cover;

iii. Soil map (if available) or other soil information;

iv. Applicable infrastructure (eg, water ways, roads, railroad, airports, provision of electricity, and other access points);

v. Distance to important markets;and

vi. Ownership/tenure boundaries that influence conversion (eg, government holdings, private holdings and reserves).

b. Written justification of similarities between the project and reference area using acceptable data sources.

For each reference area selection criteria set out above, acceptable data sources may include any of following verifiable forms of evidence:

- Maps with underlying data from official or commonly accepted sources (eg, UN/FAO, National or Jurisdictional government, WRI, IPCC, etc.);
- A participatory rural appraisal (PRA) or other such locally applicable survey;
- Published and/or refereed literature sources; or
- Expert knowledge originating from local or generally accepted sources.
- Documented observations from the reference area not included in other surveys.

PD Requirements: Delineation of the Reference Area for Planned and Unplanned Types
The project description must include the following information with respect to each reference area: **PDR.40** A map of the delineated boundaries, demonstrating that the reference area was held by the identified baseline agent or agents and does not include the project area. **PDR.41** Results of a spatial analysis to demonstrate the reference area had as much forest or native grassland as the project accounting area at some point in time during the historic reference period. **PDR.42** Evidence that the management practices of the baseline agent in the reference area are similar to those that would have been applied to the project accounting area or areas in the baseline. **PDR.43** A description of the rationale for selection of reference area boundaries relative to the respective project accounting area.

PDR.44	The documentation required in the reference area selection requirements that the selected reference area meets the Reference Area Selection Requirements.

6.8.1.2 Baseline Types F-P1.a, F-P1.b, F-P2 and G-P2

The reference area is defined by what would have happened in the project accounting area in a planned deforestation scenario (for forest) or planned conversion scenario (for native grassland).

Where the specific primary agent of conversion can be identified for baseline types F-P2 and G-P2, the reference area is defined by an area and for a period of time controlled by that same specific primary agent of conversion. Where the specific primary agent of conversion cannot be identified, the reference area is defined by an area and for a period of time controlled by the class of agents that contains the primary agent. For example, if there is logging in or around the project area and the company doing this logging is identifiable, this company would be considered the specific primary agent of conversion. However, if the identity of this logging company is unknown, then the primary agent of conversion would be considered a part of a class of agents carrying out logging operations. All agents in a class share the same drivers of conversion. The reference area may be landholdings of the agent or areas directly affected by the agent. The reference period may begin when the agent acquired access to the reference area or when the land management objectives for the reference area changed.

As opposed to baseline types F-P2 andf G-P2 (for which there exists only a single agent of conversion), where baseline types F-P1.a or F-P1.b are selected, the reference area must be appropriate for the specific primary agent (or class of primary agent where the specific primary agent cannot be identified) *and* the specific secondary agent (or class of secondary agents where the specific secondary agent cannot be identified) of deforestation. The project proponent must identify the reference area as landholdings of the specific agents of conversion or of an agent in the class of agents.

The reference area must have as much forest as the forest project accounting area at some point in time during the historic reference period if the baseline cover type is forest. Or, the reference area must have as much native grassland as the grassland project accounting area at some point in time during the historic reference period if the baseline cover type is native grassland. If a reference area based on a single agent cannot be located to meet this requirement, landholdings from multiple agents in the class of agents may be combined to meet this requirement.

The forest or native grassland management practices used by the agent in reference area must be similar to that of the likely forest or native grassland management practices applied to the project accounting area in the baseline scenario. The reference area must not include the project area and must not be altered during the historic reference period.

PD Requirements: Defining the Reference Area for Planned Baseline Types
The project description must include the following with respect to the reference area: **PDR.45** Evidence that secondary agents have been considered in the delineation of the reference area for baseline types F-P1.a, F-P1.b.

6.8.1.3 Baseline Types F-U1, F-U2, F-U3, G-U1 and G-U2

The reference area must be in the same general region as the project area, but not necessarily adjacent to the project area. At some point in time during the historic reference period, the reference area must contain as much forested area (for F-U1, F-U2 and F-U3) or native grassland (for G-U1 and G-U2) as the project accounting area. The reference area must not include the project area and must not be altered during the historic reference period. The boundaries of the reference area must include one or more of the following:

- Environmental, natural or political boundaries.
- Major transportation infrastructure such as highways or railroads.
- Land ownership/tenure boundaries.
- Latitudinal or longitudinal degree boundaries.

The reference area must be delineated per the Reference Area Selection Requirements (section 6.8.1.1).

6.8.2 Defining the Historic Reference Period

The reference period is defined differently for baseline types F-P1.a, F-P1.b, F-P2, F-U1, F-U2, F-U3, G-P2, G-U1 and G-U2. A reference period must be delineated for each project accounting area. Reference periods must not overlap where reference areas overlap.

6.8.2.1 Baseline Types F-P1.a, F-P1.b, F-P2 and G-P2

If the specific agent of conversion can be identified, the reference period must be established when the agent acquired control of the reference area or when the land management practices employed in the reference area changed. Where landholdings from more than one agent in a class of agents are used to define the reference area, the reference period must be established by the agent that first acquired control of the landholding or when the land management practices employed in the landholding changed. Control can be obtained by the establishment of title while land management can change as a result of a change in laws, access to markets for wood products or access to new technologies, for example.

PD Requirements: Defining the Reference Period for Planned Types	
The project description must include the following with respect to the reference period:	
PDR.46	Established reference period boundaries.
PDR.47	The date when the agent acquired control of the reference area or when the land management practices employed in the reference area changed.

6.8.2.2 Baseline Types F-U1, F-U2, F-U3, G-U1 and G-U2

If the specific agent of conversion cannot be identified, the reference period must be established by important historic events as identified by the information obtained from expert knowledge or the participatory rural appraisal and corresponding analysis of agents and drivers of conversion. These events include the following:

- The arrival time of specific foreign agents of conversion, if any;
- The times when the drivers of conversion became apparent, if any; and
- The times of significant economic growth or decline.

Historic imagery of the reference area must be acquired for times before and after these events and this imagery must be used to parameterize the baseline emissions models per section 6.8.3. If no important events are identified, then the reference period should be established by the times of available historic images of the reference area.

PD Requirements: Defining the Reference Period for Unplanned Types	
The project description must include the following with respect to the reference period:	
PDR.48	Established reference period boundaries.
PDR.49	A list of available historic imagery for the reference area.
PDR.50	A timeline of important events as they relate to the agents and drivers of conversion.
PDR.51	Narrative rationale for the selection of the reference period.

6.8.3 Analyzing Ecosystem Conversion in the Reference Area

The baseline scenario is characterized by observing ecosystem conversion in the reference area assuming the same would occur in the project accounting area in the absence of the project activity. The parameters α, β and $\boldsymbol{\theta}$ are estimated from observations of land cover change in the reference area over the reference period based on a logistic function (see Appendix A). Once estimated, these parameters depict the shape of the logistic function and the cumulative emissions that would have occurred at any point in time after the project start date.

To analyze ecosystem conversion and estimate α, β and $\boldsymbol{\theta}$, historical imagery must be acquired and interpreted for land cover (see section 6.8.4). Interpretation is accomplished using a set of points distributed across the reference area (see sections 6.8.5 through 6.8.7). Weights are computed from interpretation points to account for cloud contamination, coverage and time differences in image acquisition dates (see section 6.8.6). Measures must be taken to minimize uncertainty and uncertainty must be estimated (see sections 6.8.9 and 6.8.10).

Sections 6.8.4 through 6.8.8 illustrate this approach using a fictitious example, assuming a reference area of 10km by 10km in dimension (100km^2) and a project start date of January 1 2011.

To facilitate this approach to analyzing ecosystem conversion, Wildlife Works maintains a free ArcMap GIS extension to generate and automate point interpretation and weighting.

6.8.4 Selecting Historical Imagery

Ecosystem conversion is sampled from available historical imagery of the reference area over the reference period. The project proponent must have “double coverage” for at least 90% of the reference area over the entire reference period (see Appendix A).

Fulfillment of this requirement can be demonstrated by aligning a dot grid of points over the reference area using a GIS. Then, for each co-registered image in the system, those grid points that fall over the cloud-free, visible portion of each image are copied to a new file. This is done for all images and produces the same number of shapefiles as number of images. All derived shapefiles are then merged to form a single file. One of the attributes for each point in the merged file should contain a count of corresponding time periods on which it falls. For example, if one particular grid point was observed to fall onto the cloud-free portions of six images, then the attribute count of that point in the merged shapefile would be six. In the merged file, those points with a count less than two should be discarded (hence the remaining points in the merged file representing "double-coverage"). The number of remaining points should comprise at least 90% of the total number of points within the reference area.

The minimum spatial resolution of the imagery must be 30 m. Where possible, multi-spectral imagery should be enhanced using a Tasseled-Cap transformation, Principal Components Analysis (PCA) or other similar transformation to facilitate the differentiation of forest vegetation from other land covers. To ensure that the selected imagery is of adequate spatial resolution to allow for the identification and discernment between natural, unconverted status and converted status, the project proponent must provide evidence, by providing one of the following to the VVB:

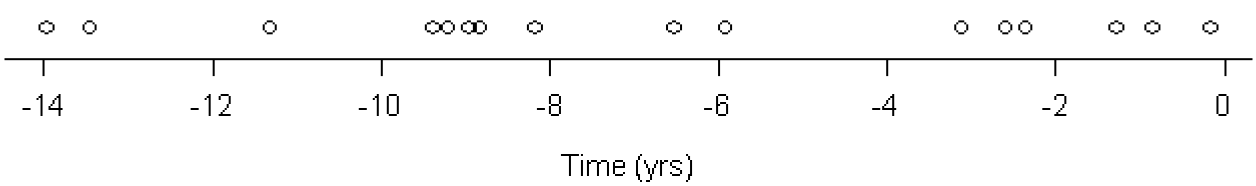
1. A set of geo-referenced photos taken on the ground in areas that represent both unconverted and converted land cover. The auditor should check that these photos

satisfy the burden of proof that adequate shape, texture and context is discernable in order to identify land cover state change between unconverted and converted status.

2. High-resolution imagery coinciding with both unconverted and converted areas within the reference area(s). This imagery should be of significantly higher spatial resolution in comparison to the imagery used for the collection of data for the BEM, and should only be used to determine the adequacy of the spatial resolution of the data to be interpreted. Accuracy and resolution of the validation imagery should be at the discretion of the auditor.

The dates of historic imagery should be plotted on a line plot and this plot should be interpreted for stationarity in the time series of imagery (see Figure 4). This is necessary to ensure the estimated time components of the image weights per equation [A.3] are unbiased. The time series is stationary if the image dates are distributed, on average, across the entire historic reference period.

Figure 4: Line Plot to Demonstrate Approximate Stationarity of Historical Imagery.



A line plot of the time series of historic images to visually confirm stationarity. The time series is stationary if the images are well distributed throughout the reference period.

All imagery must be spatially registered to the same coordinate system with accuracy less than 10% Root Mean-Squared Error (RMSE) as measured by the error relative to the pixel diagonal of the image being evaluated or relative to the absolute difference between the greatest error and the smallest error, on average across all images (Congalton, 1991). The accuracy of spatial registration is assessed empirically; each image is relative to other collocated images or a ground control point. Oblique imagery should be avoided to maintain accurate spatial registration.

PD Requirements: Historic Imagery to Parameterize α, β and θ
The project description must include the following: **PDR.52** A map of the reference area showing the area of "double-coverage". **PDR.53** Quantification of "double coverage"(greater than 90%).

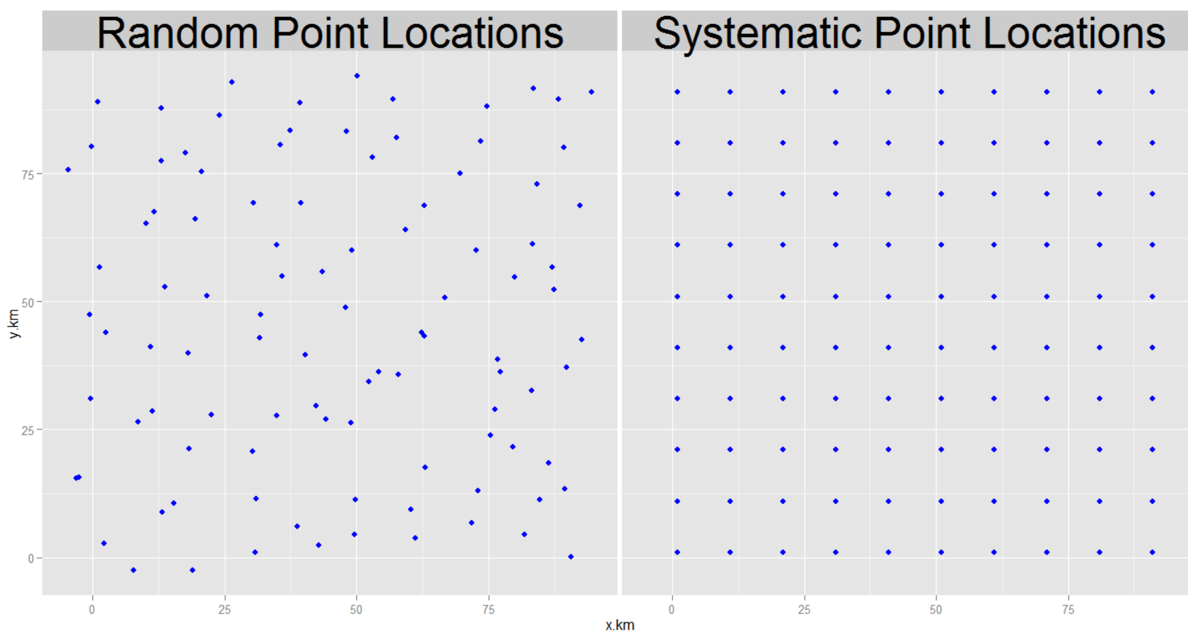
PDR.54	A line plot of the historic image dates to confirm stationarity.
PDR.55	Evidence that all image pixels are not more than 30m x 30m.
PDR.56	Empirical evidence that imagery is registered to within 10% RMSE, on average.

6.8.5 Determining Sample Size

Sample size determination is optional, but a minimum sample size may be estimated within +/- 15% of the estimated proportion of conversion in the reference area during the historic reference period.

To optionally determine sample size, a pilot sample of interpretation points may be distributed across the reference area either randomly or systematically on a grid to estimate the ultimate sample size used to estimate α, β and $\boldsymbol{\theta}$ (for an example, see Figure 5). The pilot sample should be large enough to obtain a rough estimate of the population variance. Depending on the size of the reference area and the prevalence of conversion during the reference period, a good minimum sample size is approximately 300 points in the reference area. If a grid is used, then it must feature a random origin.

Figure 5: Systematic Versus Random Sampling



Types of sample points distributed across the example reference area: random (left) and systematic (right).

Forest or native grassland state (forest/non-forest or native grassland/anthropogenic conversion) is observed at each interpretation point that falls on the cloud-free portion of each image. Visually interpret all images at each point and record forest or native grassland state (0 for forest/native grassland or 1 for non-forest/ anthropogenic conversion) and the image date in a table, one table for each point, for all points in the pilot sample and all images.

When interpreting a point, use its context to determine the presence of forest/native grassland. For example, if the point falls onto a pixel and it is unclear whether the pixel is forested, but it is clear that all surrounding pixels are agriculture, its context implies that forest is absent at the point.

For each image, record the number of points that fall on the cloud-free portion in a list.

Next, for each point, sort its table by image date from oldest to most-recent (for example see Figure 6). Discard those points for which the first conversion entry in the table is 1 (forest or native grassland absent); conversion cannot be observed without initially observing forest or native grassland. Each row in each table for each non-discarded point is now an observation as defined by equation [F.11]. For each row, calculate an observation weight using equation [A.6] for each state observation where $\#(observations\ at\ x_i, y_i)$ is the number of rows in the table and $\#(observations\ at\ t_i)$ is the number of points recorded in the list for the image with its image date.

Figure 6: Table of State Observations for a Sample Point in the Reference Area

Image	Date	State Observation	Weight
1	9/6/1992	0	0.34045
2	3/10/1994	0	0.2236
3	3/13/1995	0	0.54361
4	6/1/1998	0	0.64526
5	9/22/1998	1	0.4363
6	7/15/2001	1	0.62354
7	1/30/2003	1	0.11469
8	3/9/2003	1	0.1233
9	1/29/2005	1	0.63760
10	4/11/2007	1	0.3548

Table for a non-discarded x_i, y_i sample points sorted by image date.

Next, for each remaining table – one for each non-discarded point – aggregate its rows into a single master table. For each row in the master table, normalize its weight by dividing each weight by the sum of all weights, so that all the weights add to one. The master table may still include locations in the reference area that do not experience conversion during the reference period.

The master table, constructed from the pilot sample, contains rows that correspond to observations of forest state, observation times and weights. If the exact date of the image is known, the exact date should be included in the master table (if not known exactly, see guidance in section 6.7.1). A Horvitz-Thompson estimator of the standard deviation of conversion state σ_{EM} in the reference area is given in equation [F.13] where o_i corresponds to an observed state, w_i corresponds to a normalized weight for the i^{th} row and $\mathcal{I}$ is the set of all rows in the master table.

The minimum sample size m_{DF} in the space of the reference area required for parameterizing α, β and $\boldsymbol{\theta}$ to within +/- 15% on average is estimated by [F.12]. This is the number of sample points to be placed in the reference area to parameterize α, β and $\boldsymbol{\theta}$. This number differs from n_{DF} which represents the total number of state observations across both time and space.

6.8.6 Sampling Conversion

The BEM is designed around the concept that natural and converted land-use categories are difficult, and in some cases impossible, to distinguish using traditional wall-to-wall, pixel-based remote sensing techniques. This is because such techniques use pixel-by-pixel analysis of spectral reflectance properties alone, and often fail to delineate the land-use categories required to accurately calculate ecosystem conversion rates (eg, native grassland from anthropogenically converted grassland, etc.). That said, the BEM requires manual, “heads-up” image interpretation of the sample set described below, which is overlaid on the remotely sensed imagery collected as described in Section 6.8.4. This allows for the identification of land-use categories using shape, texture and context attributes, which typically can only be completed by human analysts engaged in manual image interpretation. It should be noted that the BEM does not support automated, pixel-by-pixel classification techniques, and project proponents should not attempt to replace or sidestep manual image interpretation with an automated process such as a maximum likelihood or nearest neighbor classifier, as this tends to introduce significant errors into the model.

Sampling conversion to parameterize α, β and $\boldsymbol{\theta}$ is similar to the procedure for estimating sample size using a pilot sample in section 6.8.5, except that the sample size must be at least $\hat{m}_{DF}$ to achieve +/- 15% average precision in estimated parameters. The observed state vector $\boldsymbol{o}$, time vector $\boldsymbol{t}$ and the weight vector $\boldsymbol{w}$ used to fit the model comprise columns of the master table.

PD Requirements: Sampling Conversion to Parameterize α, β and θ
The project description must include the following: **PDR.57** The sample size. **PDR.58** A map of the reference area showing the sample point locations.

6.8.7 Discarded Sample Points

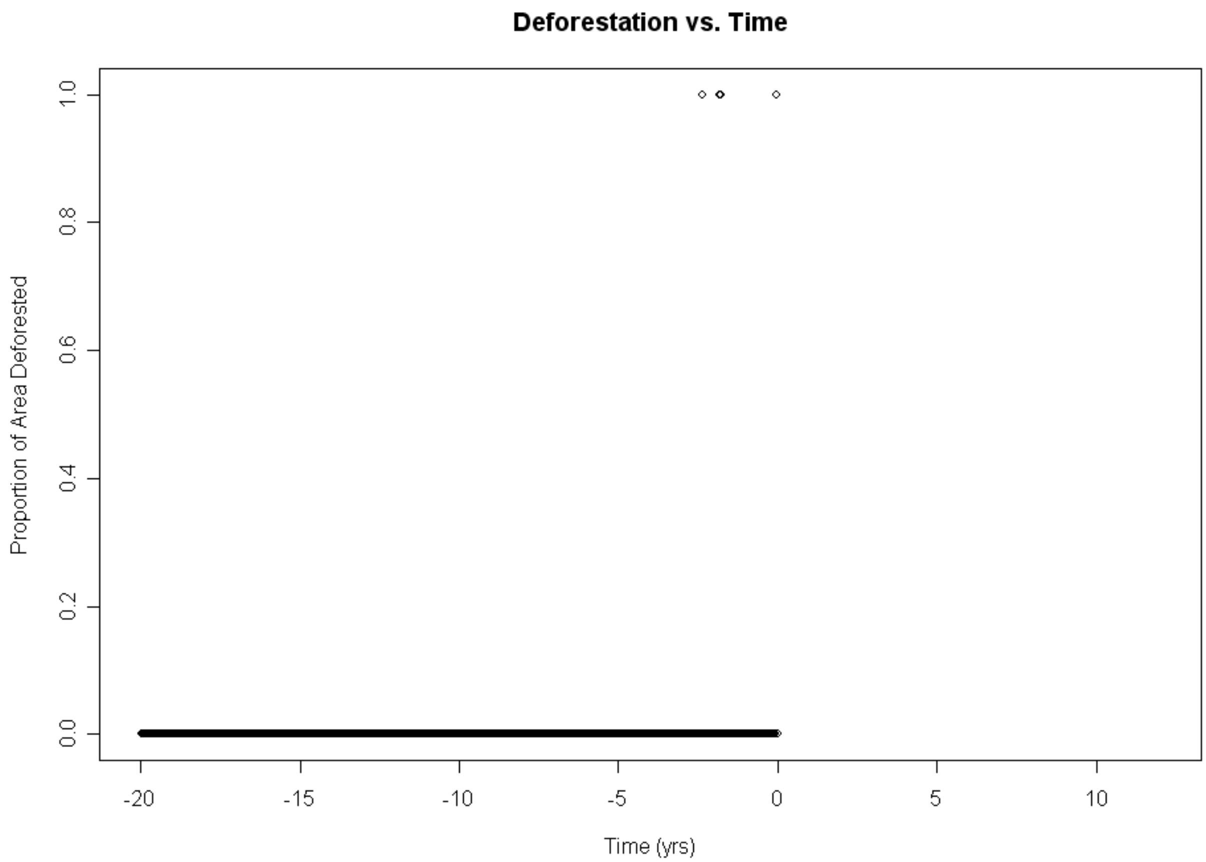
When sampling ecosystem conversion in the reference area, some sample points must be discarded because in their initial observations they were already in a state of conversion or agriculture. Conversion cannot be observed without initially observing forest or native grassland. As such, these points must not be considered when estimating the minimum sample size.

In the master table, an attribute should be retained for all non-discarded sample points so that these sample points can be mapped back to locations in the reference area. The Wildlife Works export to text file tool automatically discards sample points whose initial observations were converted, as they are of no use to the BEM model.

6.8.8 Parameterizing $\boldsymbol{\alpha}$, $\boldsymbol{\beta}$ and $\boldsymbol{\theta}$

The logistic function defined by equation [A.4] is fit using the sample data depicting patterns of conversion in the reference area as well as conversion data for the historic reference period. The sample conversion data include the state observation vector $\boldsymbol{o}$ and the time vector $\boldsymbol{t}$ (see Appendix A). A plot of these vectors shows that land cover states are zeros and ones (for an example, see Figure 6). The time vector is expressed as the numbers of days relative to the project start date. If the historic reference period occurs before the project start date, the values of the time vector will be negative. Upon baseline reevaluation, some values will be positive because land cover state is observed after the project start date up to the time of baseline reevaluation.

Figure 7: Plot of Example State Observations Over Time



A graph of the state vector over time for the example reference area showing ones and zeros.

Covariate data are collected for interpretation point in the reference area. As such, covariate data may need to be interpolated from their sources (eg, census data that may only be collected once every 10 years). These data are used to estimate the linear predictor of the logistic function where $\boldsymbol{\theta}$ is the parameter vector (see Appendix A).

In order to avoid the possibility of perverse incentive in model fitting, covariate data must originate from the following sources:

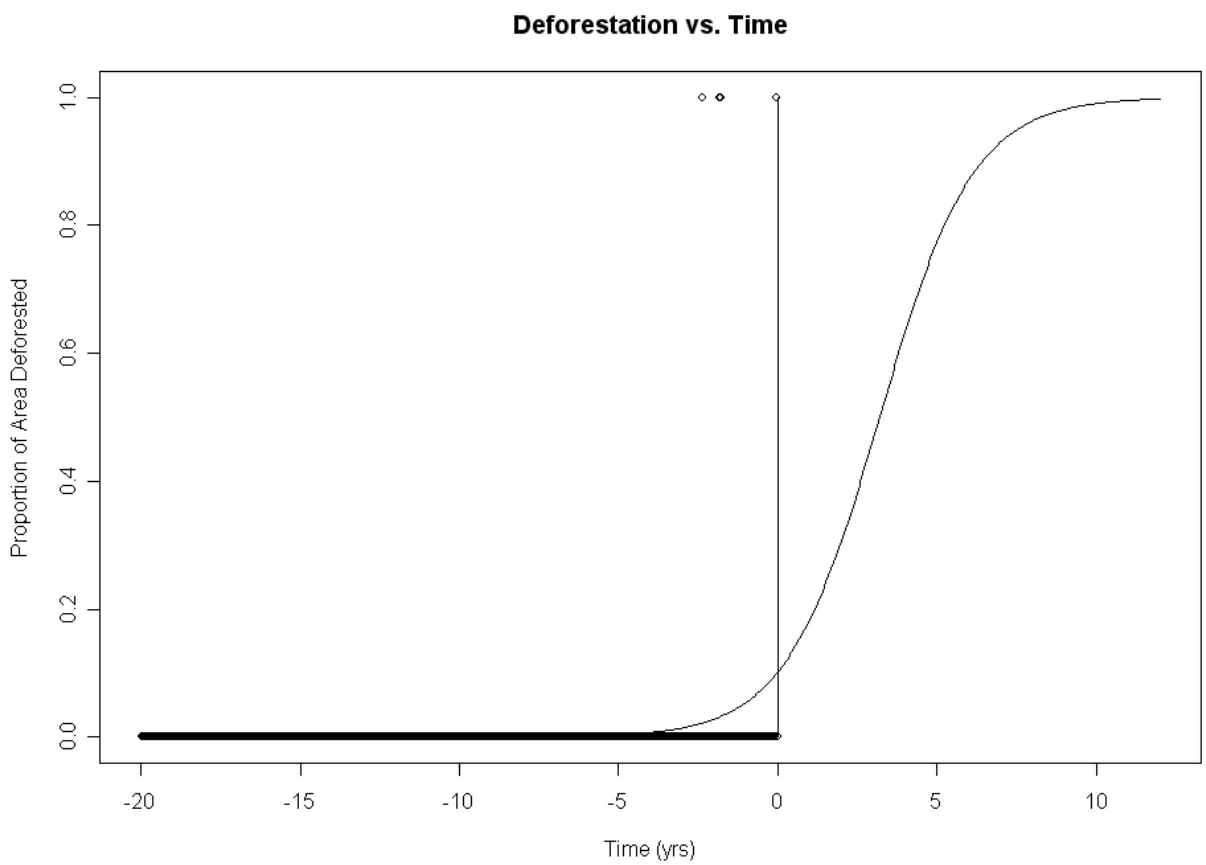
- Government publications.
- Publications by an independent third party.
- Peer reviewed literature.

These sources must be publicly available per current VCS requirements.

The parameters are found using IRLS with an initial weight vector $\boldsymbol{w}$ that corrects for spatial and temporal artifacts from sampling historic imagery (see Venables & Ripley, 2002 for information on model fitting with IRLS).

Given all possible covariate parameters $\boldsymbol{\theta}$, select the best subset of covariate parameters $\widehat{\boldsymbol{\theta}}$ using AIC as a measure of fit. For information on model selection see Davidson (2003) and Freedman (2009). The fit model must be plotted with conversion state over time and the project start date (for an example see Figure 8).

Figure 8: Graph of an Example Logistic Function Determined by α, β and θ.



A graph of the estimated logistic function over time for the example reference area relative to the project state at time zero for a forested baseline type.

PD Requirements: Parameterizing α, β and θ	
The project description must include the following:	
PDR.59	The covariates that were considered and their data sources.
PDR.60	The parameters in θ that were evaluated during model selection.
PDR.61	The parameters in $\hat{\theta}$ of the selected model.

PDR.62	The rationale used for selecting $\hat{\theta}$ including comparisons of AIC.

6.8.9 Minimizing Uncertainty

Observation error must be mitigated as much as possible by developing a protocol for the interpretation of land cover state from remotely-sensed imagery. Training should ideally be provided to the interpreter(s).

Observation data must be checked for inconsistencies. For example, observations of forest state over time at any one point in space probably do not transition from forest to non-forest, and then back to forest during the reference period (for an example, see Figure 9). A list of "impossible" or "unlikely" forest or native grassland state transitions must be developed, and each point that matches the criteria should be reexamined.

Figure 9: Table of State Observations to Identify Possible Errors.

Image	Date	State Observation
1	9/6/1992	0
2	3/10/1994	0
3	3/13/1995	0
4	6/1/1998	0
5	9/22/1998	1
6	7/15/2001	1
7	1/30/2003	0
8	3/9/2003	1
9	1/29/2005	1
10	4/11/2007	1

Table for an x_i, y_i sample point featuring a potential interpretive error at image date 1/2003.

A random subset of sampled points must be interpreted by a different person than the first point interpreter, and these observations must be checked against the observations made by the interpreter or interpretive team members to identify any systematic misinterpretation. If it is not possible to determine the correct state for a point, it is conservative to mark the transition to a converted state to a later date in the historic reference period when that transition is apparent. If desirable, the conversion date of a point or set of points may be determined by asking persons with first-hand knowledge of that conversion date. All systematic errors must be corrected.

PD Requirements: Minimizing Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$
The project description must include the following: **PDR.63** A protocol for interpreting land cover state from imagery, which must include guidance for interpreting the following: • Discerning conversion features using shape, texture and context in the reference area landscape • Addressing seasonal variation of vegetation (phenology) within imagery • Identifying and addressing the characteristics of specific landscape configurations (ie, mosaic forest, grassland, etc.) **PDR.64** The results of an independent check of the interpretation. **PDR.65** Evidence that systematic errors, if any, from the independent check of the interpretation were corrected.

6.8.10 Estimating Uncertainty

Uncertainty in estimated parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\boldsymbol{\theta}}$ is estimated using [F.13]. This is the standard error of weighted point observations where the i^{th} observation of forest state is o_i, multiplied by the current estimated baseline emissions in the project accounting area across all selected carbon pools (see section 8.1).

PD Requirements: Estimating Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$
The project description must include the following: **PDR.66** The estimated uncertainty $\hat{\sigma}_{EM}$ from [F.13] and statistical summaries from model fitting software, if available. **PDR.67** Reference to uncertainty calculations.

6.9 Determining t_{PAI}

This section is to be applied separately for each identified project accounting area when the project is a grouped project.

The parameter t_{PAI} is the number of days after the project start until the project activity instance start date for the project activity instance associated with a particular project accounting area.

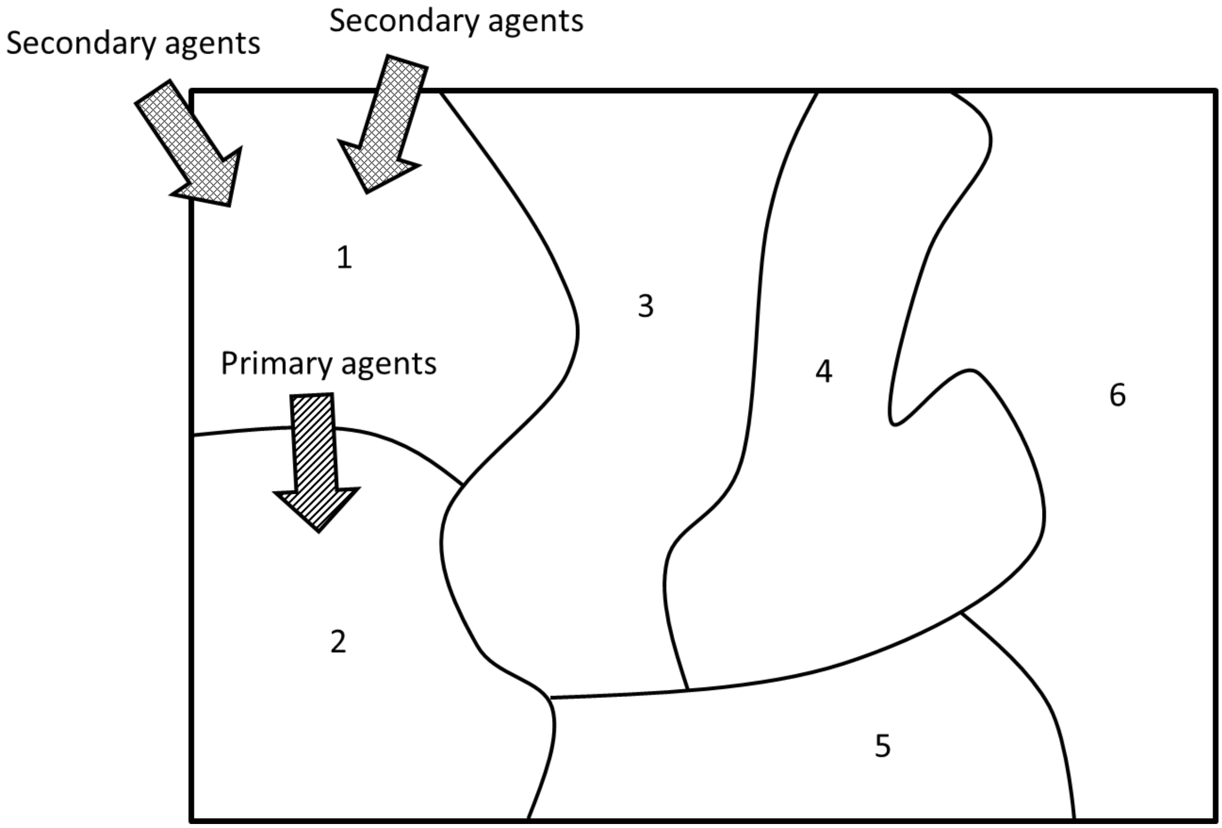
Monitoring Requirements: Determining t_{PAI}
The monitoring report must include the following if the project is a grouped project: **MR.7** For each project activity instance in the group, its project activity instance start date. **MR.8** For each project accounting area, the value of $\hat{t}_{PAI}$.

6.10 Determining t_{SA}

This section is to be applied separately for each identified forest project accounting area having a baseline type F-P1.a or F-P1.b.

The parameter t_{SA} is the number of days after the primary agent begins commercial logging until when the secondary agent of deforestation is likely to begin degrading the forest project accounting area under the baseline scenario. This parameter can be determined from the results of the PRA or expert knowledge. In many cases of legally-sanctioned commercial logging, it is the length of the logging period to harvest the first regulated harvest unit. Often, due to unsustainable harvest plans, corruption, or indifference, the logging infrastructure may be exploited by secondary agents in the cascade of degradation. Often, after the commercially viable timber has been removed from the primary agent's first harvest unit, the primary agent will abandon that area and secondary agents will enter to further degrade and ultimately deforest the area.

Figure 10: Cutting Cycle Under a Type F-P1.a Project Scenario.



When unsustainable harvest occurs, after the primary agents abandon a timber harvest area to move to another area (1 to 2 in the figure above), secondary agents will move in and continue to degrade and deforest that area. The length of time between the entry of primary agents to a harvest area and the arrival of secondary agents is t_{SA}.

In the case when the parameter is the length of the first cutting cycle and the primary agent's harvest plans for the forest project accounting area cannot be obtained, the first observed instance of deforestation apparently caused by secondary agents can be used as a conservative value for the parameter (parameterized in terms of days after the start of the historic reference period). When evaluating possible values for this parameter, a larger number is always more conservative than a smaller number. This parameter must be greater than or equal to zero.

PD Requirements: Parameterizing t_{SA}
The project description must include the following: **PDR.68** The parameter $\hat{t}_{SA}$ as the number of days after the primary agent begins commercial logging until when the secondary agent of deforestation is likely to begin degrading the forest project accounting area.

PDR.69	A description of how $\hat{t}_{SA}$ was obtained.
PDR.70	Harvest plans for the forest project accounting area under the baseline scenario, results from the PRA or analysis of the reference area to determine the parameter.

6.11 Determining t_{PA}

This section is to be applied separately for each identified forest project accounting area having a baseline type F-P1.a or F-P1.b.

The parameter t_{PA} is the number of days relative to the project start date when the primary agent began or would have begun legally-sanctioned commercial logging in the forest project accounting area. This can only be established by harvest plans prepared for the forest project accounting area or by public record. In most cases, the primary agent would have started commercial logging in the forest project accounting area at the project start date and in these cases, the parameter should be set to zero. (For baseline type F-P2 and G-P2, the parameter is always zero.) In other cases when the primary agent has already started logging as of the project start date, the parameter will be negative (days relative to the project start date at time zero). In other cases when the primary agent would have started logging after the project start date, the parameter will be positive.

PD Requirements: Parameterizing t_{PA}	
The project description must include the following:	
PDR.71	The parameter $\hat{t}_{PA}$ as the number of days relative to the project start date when the primary agent began or would have begun legally-sanctioned commercial logging in the forest project accounting area.
PDR.72	A description of how $\hat{t}_{PA}$ was obtained.
PDR.73	Harvest plans for the forest project accounting area under the baseline scenario or public records to support the determination of the parameter.

6.12 Determining x_0

This section is to be applied separately for each identified project accounting area.

The parameter $\boldsymbol{x}_0$ is a vector of covariate data as of the project start date. See section 6.8.8 and Appendix A for more information on covariates.

If covariate values are used to predict a rate of conversion higher than the rate observed in the reference area during the historic reference period, the project proponent must provide clear evidence to substantiate the use of the covariate data.

PD Requirements: Determining x_0
If covariates to conversion are used, the project description must include the following: **PDR.74** A table of covariate values as of the project start date and a description of how the values were determined including any interpolation or extrapolation methods. If covariates are used to predict a rate of conversion higher than the rate of observed in the reference area during the historic reference period, the project description must include the following: **PDR.75** Justification for why the rate of conversion predicted by covariates exceeds the rate indicated from historical conversion patterns.

6.13 Determining x_{PAI}

This section is to be applied separately for each identified project accounting area when the uped project.

The parameter x_{PAI} is a vector of covariate data as of the project activity instance start date for the project activity instance associated with a particular project accounting area. See section 6.8.8 and Appendix A for more information on covariates.

Monitoring Requirements: Determining x_{PAI}
The monitoring report must include the following if the project is a grouped project: **MR.9** A table of covariate values as of the project activity instance start dates and a description of how the values were determined including any interpolation or extrapolation methods.

6.14 Determining m

This section is to be applied separately for each identified forest project accounting area having a baseline type F-P1.a or F-P1.b.

The parameter m is the average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging. It is not the volume of harvested wood. If AGMT and

BGMT are selected carbon pools then it must include carbon in both the above-ground and below-ground portions of merchantable trees cut each year. If only AGMT is selected then it need only include the above-ground portion.

The project proponent must estimate m using timber harvest plans, if available, which apply to the forest project accounting area and were developed by the specific agent of deforestation under the baseline scenario. In the absence of timber harvest plans, m may be conservatively determined from the measurement of carbon stocks in merchantable trees in the forest project accounting area using equation [F.1] where $C_{AGMT}^{[m=0]}$ and $C_{BGMT}^{[m=0]}$ are determined prior to the first monitoring event or at the first monitoring event, and t_m is the number of days in the project lifetime or the length of time the primary agent would have harvested the entire merchantable trees in the baseline scenario. If BGMT is not a selected pool, then $C_{BGMT}^{[m=0]}$ can be set to zero. If t_m is the project lifetime, this method can only be used if the project end date is after the date on which the primary agent would have concluded legally-sanctioned commercial logging in the forest project accounting area under the baseline scenario. Regardless of which method is used to estimate m, timber harvests in the baseline scenario must comply with the legal maximum allowable cut as published by the relevant national authority of the country where the project is located.

This parameter must be greater than zero.

This methodology deliberately omits prescribing accounting for re-growth and residual damage in order to conservatively simplify accounting. In commercial logging, the emissions from residual damage will exceed carbon sequestration from re-growth.

PD Requirements: Parameterizing m	
The project description must include the following:	
PDR.76	The parameter $\hat{m}$ as the average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging.
PDR.77	Documentation of how m was determined. This may include an analysis of carbon stocks in merchantable trees in the forest project accounting area, timber harvest plans for the project accounting area or reference to a publication containing the maximum allowable cut applicable to the project area. The parameter must be greater than zero.

6.15 Determining γ

This section is to be applied separately for each identified project accounting area having a planned baseline type (F-P1.a, F-P1.b, F-P2 or G-P2). The parameter γ is the number of days between the beginning of the historical reference period and the project start date.

PD Requirements: Determining γ
The project description must include the following: **PDR.78** The project shift parameter γ as the number of days between the beginning of the historical reference period and the project start date.

6.16 Determining q

This section is to be applied separately for each identified project accounting area.

The parameter q is the number of days between the onset of degradation and the beginning of conversion. This parameter can be determined by expert knowledge, results from the PRA or reports from peer-reviewed literature. It is always conservative to set this parameter equal to zero and any other value must be justified. When evaluating possible values for this parameter, it is always conservative to select a lower number. This parameter must be greater than or equal to zero.

PD Requirements: Parameterizing q
The project description must include the following: **PDR.79** The parameter q as the number of days between the onset of degradation and the beginning of conversion. **PDR.80** If the default of zero is not selected for q, then a justification for the determination of q.

6.17 Determining r_U

This section is to be applied separately for each identified project accounting area having a baseline type of Type F-U2, F-U3, or G-U2.

The parameter r_U is set to position the baseline emissions models relative to the onset rate of conversion immediately adjacent to the project area at the project start date. There are two permissible methods by which this parameter can be determined:

1. In the first method, the ratio of converted perimeter to the total threatened perimeter along the boundaries of the project area must be measured as of the project start date. Converted perimeter is defined as the total perimeter that has been converted prior to the project start date within 120 meters inside or outside the project area boundary, which can be measured from any point in time up until the project start date. Threatened

perimeter is defined as that which is vulnerable as of the project start date to conversion by being accessible to the local agents of conversion and has not yet been converted. Threatened perimeter does not include converted perimeter. Examples of non-threatened perimeter include perimeter that abuts a national park, is surrounded by steep slopes that prohibit access to the project area boundary (as defined by project proponent), or is adjacent to water. For forest baseline types, non-threatened perimeter also may include naturally-occurring non-forest within 120 m of the project area boundary.

$$r_U = \frac{converted\ perimeter}{threatened\ perimeter}$$

For example, consider the situation in which the project area has a total perimeter of 500 km. If 200 km of this perimeter is adjacent to a national park, and 30 km is naturally-occurring non-forest within 120 m on either side of the perimeter, then the total threatened perimeter is 270 km. If 150 km of this perimeter becomes converted, then r_U will be (150/270, or 0.556).

2. Alternatively, r_U can be quantified using the ratio of converted area within the project area to the sum of all project accounting areas less the area that is converted. Conversion is defined as area that has been converted prior to the project start date from forest to non-forest or from native grassland to anthropogenic conversion.

$$r_U = \frac{converted\ area}{sum\ of\ all\ project\ accounting\ areas - converted\ area}$$

Both of these methods rely on the identification of conversion relative to the project area boundary or in the project area. Images or data used to determine conversion must not be older than ten years prior to the project start date. Both of these methods require images or data from two points in time be analyzed. Measurement units for the denominator and the numerator must be the same. Depending on the state of conversion at the project start date, the ratio may be greater than one.

PD Requirements: Parameterizing r_U
The project description must include the following: **PDR.81** The parameter $\hat{r}_U$ as the ratio of converted perimeter to total threatened perimeter, or the ratio of converted area to total project accounting area(s), as of the project start date. **PDR.82** Description of how $\hat{r}_U$ was obtained. **PDR.83** Results of GIS analysis to determine or measure $\hat{r}_U$ in the project area including the dates of images used to identify conversion.

6.18 The Decay Emissions Model

This section is to be applied separately for each identified project accounting area.

The Decay Emissions Model accounts for decay from biomass and dead wood from all pools considered. It uses the same parameters from section 6.7 as the BEM. No additional parameters are required. The Decay Emissions Model is given by [F.10], and predicts linear decay over a ten-year period. The Decay Emissions Model for dead wood and below-ground biomass are based on the VCS default decay models for these pools.

6.19 The Soil Emissions Model

This section must be applied separately for each identified project accounting area if SOC is an included carbon pool.

The SEM is given by [F.6], [F.7] and [F.8]; it predicts the exponential decay of SOC over time. The Decay Emissions Model for carbon in soil, given by [F.9], contains λ_{SOC}, a parameter that characterizes the decay of SOC over time. The parameter λ_{SOC} should be determined using a default value or empirical estimation per section 6.19.1.

6.19.1 Determining λ_{SOC}

If SOC is included as a carbon pool the parameter λ_{SOC} must be determined with the use of one of the three methods as outlined in sections 6.19.2, 6.19.3 and 6.19.4.

6.19.2 Default Values for λ_{SOC}

The default value for λ_{SOC} is 0.2 and is derived from E. Davidson & Ackerman (1993). Projects located in tropical climates may apply this default value. This is a default that may become out of date and is subject to periodic re-assessment. All other projects must empirically estimate λ_{SOC} or use appropriate decay rates from peer-reviewed literature.

6.19.3 Empirically Estimating λ_{SOC}

In order for the project proponent to estimate λ_{SOC} from empirically measured data, the project proponent must perform a “space for time” substitution, as it is impractical to repeatedly sample the same recently-converted forest or native grassland patch over the project crediting period (required to generate enough measurements to derive a soil decay curve). The space for time substitution allows the project proponent to make many measurements at the same point in time, over a range of agricultural fields, distributed spatially within the reference area, that were converted at *known times*.

Given expert knowledge of the reference area, including knowledge of farming practices and culture, the project proponent may apply empirically measured soil carbon results to mathematically derive a value for λ_{SOC}. This should involve a statistically sound method such as temporal regression or trend analysis, and must be accepted by the validator at project validation.

If the project proponent opts to measure λ_{SOC} empirically, measurements must be taken within the same reference area that meets the requirements listed in section 6.8.1. This serves to ensure that parameterization of the Decay Emissions Model is representative of common farming practices in the region.

PD Requirements: Empirically Estimating λ_{SOC}	
If $\boldsymbol{\lambda_{soc}}$ is estimated using data, the project description must include the following:	
PDR.84	Description of how samples from the reference area were selected including stratification, if any.
PDR.85	A map of sample locations in the reference area.
PDR.86	A table showing the conversion time for each area (farm or otherwise) from which samples were taken.
PDR.87	Description of and statistics for the method applied to estimate $\hat{\lambda}_{SOC}$.
PDR.88	Graph of projected decay model over project lifetime.

6.19.4 Literature Estimates for $\boldsymbol{\lambda_{SOC}}$

Literature estimates may be taken from peer-reviewed scientific or government publications rather than using the default value or empirically estimating λ_{soc}. Publications must come from the same ecotype and soil type as the project, include the same soil profile considered, have an adequate sample size and published measures of precision (per Appendix B) , and be generally representative of the project area. The field experiments performed by the authors of the peer-reviewed literature must be based on data from replicated field experiments whose management treatments with a duration of at least five years.

PD Requirements: Literature Estimates for λ_{SOC}	
If an alternate $\boldsymbol{\lambda_{soc}}$ is used, the project description must include the following:	
PDR.89	Inclusion of decay model on which parameter is based.

PDR.90	Explicit description of referenced literature, including project location, sampling methodology, included species, sample size, duration of field experiments, and decay parameter upon which decay is based.
PDR.91	Graph of projected decay model over project lifetime.
PDR.92	If decay model is based on any other element besides carbon, defense of ability to predict carbon decay must be provided.

6.20 Baseline Reevaluation

The baseline scenario must be reevaluated per current VCS requirements. Prior to baseline reevaluation, the project proponent may choose to conduct a new PRA and subsequent analyses to re-appraise the baseline scenario (see section 6.1). The project proponent must reassess certain elements of the baseline scenario per sections 6.20.1 and 6.20.2.

PD Requirements: Baseline Reevaluation	
Upon a baseline revision, the project description must include the following as of the current monitoring period:	
PDR.93	All required documentation as specified in section 6 for the project prior to the baseline reevaluation.
PDR.94	All required documentation as specified in section 6 for the project after the baseline reevaluation including the reevaluation period.
PDR.95	A narrative of the reevaluation including any obstacles and how they were overcome.

6.20.1 Reevaluation of the Reference Area and Period

This section is to be applied separately for each identified project accounting area.

The reference area may be resized to be larger or smaller than prior to baseline reevaluation to reflect the following changes:

- Refine the boundaries of the reference area and delineate new boundaries to exclude any new REDD projects or additions to the project area, based on the results of the new PRA or expert knowledge.
- Extend the reference period – the new period should reflect the time since the start of the original reference period up to the time of the most recent baseline reevaluation.

The new reference area must meet all requirements specified in section 6.8.1. If the new reference area does not meet these requirements, then the project is not eligible for additional crediting for monitoring periods subsequent to the baseline reevaluation until a new reference area can be defined that meets the requirements specified in section 6.8.1.

Projects that share the same reference area are eligible for crediting for all monitoring periods.

PD Requirements: Reevaluation of the Reference Area and Period
Upon a baseline revision, the project description must include the following as of the current monitoring period: **PDR.96** A map of the new reference area.

6.20.2 Re-parameterization of α, β and θ

This section is to be applied separately for each identified project accounting area.

The baseline emissions models must be re-parameterized by adding new observations of land cover state per section 6.7 and the values for α, β and θ must be re-estimated per section 6.8. The data from observations of prior reference areas should remain unchanged even though the boundaries of the prior reference areas may be different than those of the current reference area. The re-parameterized values must be used for all monitoring periods subsequent to baseline reevaluation.

PD Requirements: Re-parameterization of α, β and θ
Upon a baseline revision, the project description must include the following as of the current monitoring period: **PDR.97** Summary of new data observed in the new reference area. **PDR.98** The re-parameterized values $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

This methodology uses a project method for determining additionality.

Project proponents must demonstrate additionality using the latest version of the VCS *Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities*.

The common practice test must demonstrate that project activities will address at least one driver of conversion in such a way that the driver would not have been addressed had the project not been undertaken.

PD Requirements: Demonstration of Project Additionality	
The project description must include the following:	
PDR.99	A list of alternative land use scenarios to the project.
PDR.100	Justification for the selected baseline scenario. This justification can include expert knowledge, results from the participatory rural appraisal and ex-ante estimates of avoided emissions (see sections 6.1 and 8.4.7).
PDR.101	An investment or barriers analysis proving that the project is not the most economical option.
PDR.102	A common practice analysis including a list of project activities and the drivers of conversion that they address.
PDR.103	Evident compliance with the minimum requirements of the aforementioned VCS tool. This evidence may be the same as the evidence provided to meet reporting requirements listed in section 4.

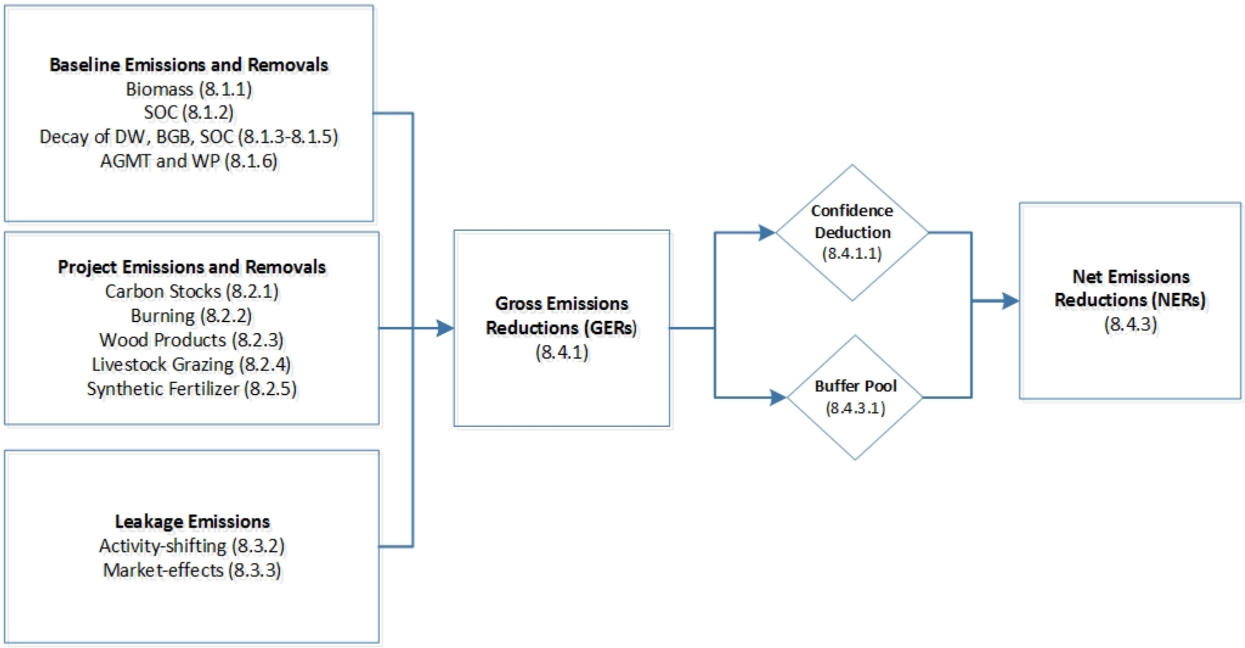
8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND/OR REMOVALS

Cumulative emissions reductions and/or removals are quantified as those since the project crediting period start date up to the end of the current monitoring period. Current gross emissions reductions and/or removals (GERs) are quantified as the difference between cumulative emissions up to the end of the current monitoring period and cumulative emissions up to the end of the previous monitoring period, minus any project emissions that have occurred during the current monitoring period, emissions from leakage and carbon not decayed in certain decay pools (see section 8.4.1 and Figure 11).

Net emissions reductions and/or removals (NERs) are GERs minus a confidence deduction (if any) and buffer pool allocation (see section 8.4.3). NERs are determined for each project accounting area and if the project area contains multiple project accounting areas, summed across project accounting areas (see sections 8.4.3 and 8.4.5).

For each project accounting area, apply sections 8.1, 8.2, 8.3.2, and 8.4.1. If the baseline scenario includes legally-sanctioned or illegal logging, use section 8.3.3 to determine market leakage, if any. Use section 8.4.1 to determine GERs for each project accounting area. If the baseline type for a project accounting area is F-U1 or G-U1 see the special requirements in section 8.4.1.2.

Figure 11: Flow Diagram for the Quantification of GHG Emissions Reductions and/or Removals



8.1 Baseline Emissions

This section is to be applied separately for each identified project accounting area. The baseline emissions $E_{B\,\Delta}^{[m]}$ for the current monitoring period are given by [F.15]. This is a function of the cumulative baseline emissions at the beginning and end of the current monitoring period as given by [F.16]. After this quantity is verified, it becomes fixed when determining emissions at subsequent monitoring events. It is possible that $E_{B\,\Delta}^{[m]}$ could be less than zero due to conditions in the proxy area and parameter effects in the baseline emissions models over time. However, for most projects, this value will be positive indicating baseline emissions would have occurred in the absence of the project.

If any of the following pools are not selected, their corresponding values in [F.15] are zero: SOC, BGB, DW or WP.

Monitoring Requirements: Baseline Emissions
The monitoring report must include the following: **MR.10** Calculations of current baseline emissions $E_{\mathrm{B}\,\Delta}^{[m]}$ as of the current monitoring period.

MR.11	Calculations of baseline emissions $E_{B\,\Delta}^{[m-1]}$ from prior monitoring periods.
MR.12	Calculations of cumulative baseline emissions for each selected pool ($E_{B\,BM}^{[m]}$ and $E_{B\,SOC}^{[m]}$) and undecayed carbon ($C_{B\,BGB}^{[m]}$, $C_{B\,DW}^{[m]}$, $C_{B\,SOC}^{[m]}$ and $C_{B\,WP}^{[m]}$), as of the current monitoring period.

8.1.1 Calculating Baseline Emissions from Biomass

Baseline emissions from biomass are determined based on the baseline type and selected carbon pools. For each selected carbon pool in biomass (BM), the appropriate BEM is applied to calculate baseline emissions per the following sections. Baseline emissions from biomass for the current monitoring period are based on the average carbon stock in selected carbon pools from AGMT, AGOT, AGNT, BGMT, BGOT and BGNT given by [F.17] for the project accounting area and [F.18] for the proxy area. This set of selected carbon pools in biomass $\mathcal{B}$ is a subset of all selected carbon pools $\mathcal{C}$ (see section 5.4).

The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[\boldsymbol{m}]$ are calculated by equations [F.19], [F.20], [F.21], and [F.22] discussed in sections 8.1.1.1, 8.1.1.2, 8.1.1.3 and 8.1.1.4. Once verified, these quantities do not change when calculating baseline emissions for subsequent monitoring periods.

Monitoring Requirements: Baseline Emissions from Biomass	
The monitoring report must include the following:	
MR.13	Calculations of cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ for the current monitoring period.
MR.14	Calculations of cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ for all prior monitoring periods.

8.1.1.1 Calculating Cumulative Baseline Emissions from Biomass for Type F-P1.a

The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[m]$ are calculated by [F.19]. The variables $c_{P\,BM}^{[m=0]}$ is the average carbon stocks in biomass as measured in the project accounting area prior to the first monitoring event for F-P1.a. $c_{B\,BM}^{[m]}$ is the average carbon stocks in biomass as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.1.2 Calculating Cumulative Baseline Emissions from Biomass for Types F-P2 and G-P2

The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[m]$ are calculated by [F.20]. The variable $c_{P\,BM}^{[m=0]}$ is the average carbon stocks in biomass as measured in the project account area prior to the first monitoring event, $c_{B\,BM}^{[m]}$ is the average carbon stocks in biomass as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.1.3 Calculating Cumulative Baseline Emissions from Biomass for Types F-U1 and G-U1

The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[m]$ are calculated by [F.22]. The variable $c_{P\,BM}^{[m=0]}$ is the average carbon stocks in biomass as measured in the project account area prior to the first monitoring event, $c_{B\,BM}^{[m]}$ is the average carbon stocks in biomass as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.1.4 Calculating Cumulative Baseline Emissions from Biomass for Types F-U2 and G-U2

The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[m]$ are calculated by [F.21]. The variable $c_{P\,BM}^{[m=0]}$ is the average carbon stocks in biomass as measured in the project account area prior to the first monitoring event, $c_{B\,BM}^{[m]}$ is the average carbon stocks in biomass as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.1.5 Calculating Cumulative Baseline Emissions from Biomass for Type F-U3 and F-P1.b

When the baseline type is Type F-U3 or F-P1.b, a spatial model called the spatial algorithm is used to conservatively estimate baseline emissions from biomass by carbon pool per AFOLU requirements (see section 8.1.1.5.1). The cumulative baseline emissions from biomass $E_{B\,BM}^{[m]}$ as of monitoring period $[m]$ are calculated by [F.24] using the spatial algorithm (see section 8.1.1.5.1). Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods.

8.1.1.5.1 The Spatial Algorithm for Biomass

Of all possible spatial models, the spatial algorithm is the most conservative possible for depleting carbon stocks in the baseline scenario.

To implement the spatial algorithm, first order the estimates of average carbon stocks across all selected carbon pools in biomass from lowest to highest, $1,2 \dots n$ by stratum for all strata in the project accounting area. Use [F.23] to estimate the average carbon in biomass for each stratum s.

This ordering should be conducted at the first monitoring period and then the order should be fixed for subsequent monitoring periods. Every monitoring period, apply the spatial algorithm given by [F.24] to determine cumulative emissions for each selected carbon pool in biomass. The spatial algorithm uses the weighted average carbon stocks across all strata currently being depleted in the baseline. Weighted average carbon stocks are calculated as in [B.35]. The spatial algorithm is denoted as $BEM_{SP}\left(wc_{P\ i\ BM}^{[m=0]}, c_{B\ BM}^{[m]}, t^{[m]}, x^{[m]}\right)$. The average carbon in biomass in the proxy area $c_{B\ BM}^{[m]}$ is given by [F.18].

Monitoring Requirements: Applying the Spatial Algorithm
The monitoring report must include the following: **MR.15** The order of strata from lowest carbon stocks to highest carbon stocks based on the average across all pools. **MR.16** Calculations for each step which are carried through from monitoring period to monitoring period. **MR.17** Calculations of cumulative baseline emissions from biomass $E_{B\ BM}^{[m]}$ for prior monitoring periods.

8.1.2 Calculating Baseline Emissions from SOC

Baseline emissions from SOC are determined based on the baseline type if the SOC pool is selected. The appropriate SEM is applied to calculate baseline emissions per the following sections. Baseline emissions from SOC for the current monitoring period are based on the average carbon stock in SOC in the project accounting area and in the proxy area.

The current baseline emissions from SOC $E_{\mathrm{B}\ \Delta SOC}^{[m]}$ are estimated as [F.26] from all types other than F-P1.b and F-U3, which is the difference in cumulative baseline emissions for the current monitoring period $E_{B\ SOC}^{[m]}$ and the cumulative baseline emissions for the prior monitoring $E_{B\ SOC}^{[m-1]}$ (fixed at prior monitoring event). Current baseline emissions from SOC $E_{\mathrm{B}\ \Delta\ SOC}^{[m]}$ are used to calculate carbon not decayed in soil (see section 8.1.5).

For baseline types F-P1.b and F-U3, current baseline emissions from SOC $E_{\mathrm{B}\ \Delta SOC}^{[m]}$ are calculated as in [F.29], using the spatial algorithm in 8.1.2.4.1.

Monitoring Requirements: Baseline Emissions from SOC for Types F-P1.a, F-P1.b, F-P2, and G-P2
The monitoring report must include the following: **MR.18** An estimate of current baseline emissions from SOC $E_{\mathrm{B}\,\Delta\,SOC}^{[m]}$ as of the current monitoring period. **MR.19** An estimate of cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ for the current monitoring period. **MR.20** Calculations of cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ for all prior monitoring periods.

8.1.2.1 Calculating Baseline Emissions from SOC for Types F-P1.a, F-P2, and G-P2

Baseline emissions from SOC for Types F-P1.a, F-P2, and G-P2 are calculated using the SEM. The cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ as of monitoring period $[m]$ are estimated by [F.25]. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods.

8.1.2.2 Calculating Baseline Emissions from SOC for Type F-U1 and G-U1

baseline emissions from SOC for Types F-U1 and G-U1 are estimated using the SEM. The cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ as of monitoring period $[m]$ are estimated by [F.27]. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods.

8.1.2.3 Calculating Baseline Emissions from SOC for Types F-U2 and G-U2

Baseline emissions from SOC for Types F-U2 and G-U2 are estimated using the SEM. The cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ as of monitoring period $[m]$ are estimated by [F.28]. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods.

8.1.2.4 Calculating Baseline Emissions from SOC for Types F-U3 and F-P1.b

Baseline emissions from SOC for Types F-U3, and F-P1.b are estimated using the SEM. The cumulative baseline emissions from SOC $E_{B\,SOC}^{[m]}$ as of monitoring period $[m]$ are estimated by [F.29]. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods.

8.1.2.4.1 The Spatial Algorithm for SOC

Of all possible spatial models, the spatial algorithm is the most conservative possible for depleting carbon stocks in the baseline scenario.

To implement the spatial algorithm, first order the estimates of average carbon stocks in SOC from lowest to highest, $1,2 \ldots n$ by stratum for all strata in the project accounting area.

This ordering should be conducted at the first monitoring period and then the order should be fixed for subsequent monitoring periods. Every monitoring period, apply the spatial algorithm given by [F.29] to determine cumulative emissions for SOC. The spatial algorithm uses the weighted average carbon stocks across all strata currently being depleted in the baseline. Weighted average carbon stocks are calculated as in [B.35]. The spatial algorithm is denoted as $SEM_{sp}\left(c_{P\ i\ SOC}^{[m=0]}, c_{B\ SOC}^{[m]}, t^{[m]}, x^{[m]}\right)$.

8.1.3 Calculating Carbon Not Decayed in DW

Calculate carbon in non-decayed DW using [F.36] where $\mathcal{M}$ is the set of all monitoring periods including the current and past monitoring periods. The cumulative emissions from DW $E_{B\ DW}^{[m]}$ are calculated by [F.34] where cumulative emissions from AGMT $E_{B\ AGMT}^{[m]}$ are calculated in sections 8.1.6.1, 8.1.6.2 and 8.1.6.3 and the slash portion of total above-ground carbon stock $p_{SL}^{[m]}$ is estimated in B.2.7 as part of monitoring (see section 9). Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods. For the first monitoring period, the cumulative emissions from the prior monitoring period, DW $E_{B\ DW}^{[i-1]}$ are zero

Monitoring Requirements: Carbon Not Decayed in DW
The monitoring report must include the following:
MR.21 An estimate of carbon stored in non-decayed DW $C_{B\ DW}^{[m]}$ for the current monitoring period.
MR.22 An estimate of cumulative baseline emissions from DW $E_{B\ DW}^{[m]}$ for the current monitoring period.
MR.23 An estimate of cumulative baseline emissions from AGMT $E_{B\ AGMT}^{[m]}$ for the current monitoring period.
MR.24 Calculations of cumulative baseline emissions from DW $E_{B\ DW}^{[m]}$ for all prior monitoring periods.

MR.25	Calculations of cumulative baseline emissions from AGMT $E_{B\ AGMT}^{[m]}$ for all prior monitoring periods.

8.1.4 Calculating Carbon Not Decayed in BGB

Calculate carbon in non-decayed BGB using [F.32] where $\mathcal{M}$ is the set of all monitoring periods including the current and past monitoring periods. The cumulative emissions from BGB $E_{B\ BGB}^{[m]}$ are calculated by [F.30] where cumulative emissions from biomass $E_{B\ BM}^{[m]}$ are calculated in section 8.1.1 or 8.1.1.5. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods. For the first monitoring period, the cumulative emissions from the prior monitoring period, BGB $E_{B\ BGB}^{[i-1]}$ are zero.

Monitoring Requirements: Carbon Not Decayed in BGB	
The monitoring report must include the following:	
MR.26	An estimate of carbon stored in non-decayed BGB $C_{\mathrm{B}\ BGB}^{[m]}$ for the current monitoring period.
MR.27	An estimate of cumulative baseline emissions from BGB $E_{B\ BGB}^{[m]}$ for the current monitoring period.
MR.28	Calculations of cumulative baseline emissions from BGB $E_{B\ BGB}^{[m]}$ for all prior monitoring periods.

8.1.5 Calculating Carbon Not Decayed in SOC

Calculate carbon in non-decayed SOC using [F.33], where $\boldsymbol{\lambda_{SOC}}$ is determined in section 6.19.1 and $\boldsymbol{\mathcal{M}}$ is the set of all monitoring periods including the current and past monitoring periods. The cumulative emissions from SOC $\boldsymbol{E_{B\ SOC}^{[m]}}$ are calculated in section 8.1.2.1, 8.1.2.2 or 8.1.2.3. Once verified, this quantity does not change when calculating baseline emissions for subsequent monitoring periods. For the first monitoring period, the cumulative emissions from the prior monitoring period, SOC $E_{B\ SOC}^{[i-1]}$ are zero.

Monitoring Requirements: Carbon Not Decayed in SOC	
The monitoring report must include the following:	
MR.29	An estimate of carbon stored in non-decayed SOC $C_{\mathrm{B}\ SOC}^{[m]}$ for the current monitoring period.

8.1.6 Determining Carbon Stored in WP

If logging is included in the baseline scenario, carbon stored in long-lived wood products must be accounted for using Appendix C. To use Appendix C, certain measurements of carbon stocks in the project accounting area are required from monitoring (see section 9), determined using Appendix B.

Use the following sections to estimate cumulative emissions from AGMT, $E_{B\ AGMT}^{[m]}$ in [C.1] by baseline type.

Monitoring Requirements: Carbon Stored in Wood Products
The monitoring report must include the following: **MR.30** Carbon stored in long-lived wood products $C_{B\ WP}^{[m]}$ after 100 years. **MR.31** Calculations to determine $C_{B\ WP}^{[m]}$.

8.1.6.1 Calculating Cumulative Emissions from AGMT for Types F-P1.a and F-P1.b

Calculate cumulative emissions from AGMT $E_{B\ AGMT}^{[m]}$ using [F.37]. If the BGMT pool is not selected then set $c_{P\ BGMT}^{[m=0]}$, $c_{B\ BGMT}^{[m=0]}$ and r_{RS} to zero. This quantity is used in sections 8.1.3 and 8.1.6, but not directly in the calculation of cumulative baseline emissions.

The variable $c_{P\ AGMT}^{[m=0]}$ is the average carbon stocks in above-ground merchantable trees as measured in the project accounting area prior to the first monitoring event, $c_{B\ AGMT}^{[m]}$ is the average carbon stocks in above-ground merchantable trees as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.6.2 Calculating Cumulative Emissions from AGMT for Types F-P2 and G-P2

For Type F-P2, calculate cumulative emissions from AGMT $E_{B\ AGMT}^{[m]}$ using [F.38]. If the BGMT pool is not selected then set $c_{P\ BGMT}^{[m=0]}$, $c_{B\ BGMT}^{[m=0]}$ and r_{RS} to zero. This quantity is used in sections 8.1.3 and 8.1.6, but not directly in the calculation of cumulative baseline emissions.

The variable $c_{P\ AGMT}^{[m=0]}$ is the average carbon stocks in above-ground merchantable trees as measured in the project accounting area prior to the first monitoring event, $c_{B\ AGMT}^{[m]}$ is the average carbon stocks in above-ground merchantable trees as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.6.3 Calculating Cumulative Emissions from AGMT for Types F-U1 and G-U1

For Types F-U1, and G-U1 calculate cumulative emissions from AGMT $E_{B\ AGMT}^{[m]}$ using [F.39]. If the BGMT pool is not selected then set $c_{P\ BGMT}^{[m=0]}$, $c_{B\ BGMT}^{[m=0]}$ and r_{RS} to zero. This quantity is used in sections 8.1.3 and 8.1.6, but not directly in the calculation of cumulative baseline emissions.

The variable $c_{P\ AGMT}^{[m=0]}$ is the average carbon stocks in above-ground merchantable trees as measured in the project accounting area prior to the first monitoring event, $c_{B\ AGMT}^{[m]}$ is the average carbon stocks in above-ground merchantable trees as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.1.6.4 Calculating Cumulative Emissions from AGMT for Types F-U2, F-U3, and G-U2

For Types F-U2 and F-U3, calculate cumulative emissions from AGMT $E_{B\ AGMT}^{[m]}$ using [F.40]. If the BGMT pool is not selected then set $c_{P\ BGMT}^{[m=0]}$, $c_{B\ BGMT}^{[m=0]}$ and r_{RS} to zero. This quantity is used in sections 8.1.3 and 8.1.6, but not directly in the calculation of cumulative baseline emissions.

The variable $c_{P\ AGMT}^{[m=0]}$ is the average carbon stocks in above-ground merchantable trees as measured in the project accounting area prior to the first monitoring event, $c_{B\ AGMT}^{[m]}$ is the average carbon stocks in above-ground merchantable trees as measured in the proxy area, $t^{[m]}$ is the time of the monitoring event and $x^{[m]}$ is the monitored covariates as of the time of the monitoring event. These variables are monitored per section 9.

8.2 Project Emissions

Project emissions for any monitoring period $[m]$ are calculated from the events of biomass consumption through fire, burning, logging or other disturbance. Current project emissions for the current monitoring period $E_{P\ \Delta}^{[m]}$ are estimated as [F.41]. Emissions from forest fire, grass fire, natural disturbances and logging are inherently captured by the monitoring of carbon stocks in the project area. Total project emissions for the current monitoring period can be negative if some major disturbance event occurs. The project proponent must have sufficient ongoing observation of the project lands such that disturbance that is likely to be greater than *de minimis* will be detected. These observations may consist of staff on the ground, aerial observation, remote sensing, or some other method that captures conversion in a timely manner.

This section is to be applied to each project accounting area.

8.2.1 Calculating Emissions from Changes in Project Stocks

Emissions from forest fires, grass fires, natural disturbance, logging and other events within the project accounting areas are inherently captured by the monitoring of forest carbon stocks. Nevertheless, maps of significant events are necessary to aid verification of carbon stock estimates. Current emissions from changes in project carbon stocks are calculated in [F.41] as the last term on the left-hand side, the difference between carbon stocks from the prior monitoring period and the current monitoring period. In order to estimate these carbon stocks, the project accounting areas may need to be re-stratified per Appendix B as part of monitoring (see section 9).

Monitoring Requirements: Emissions Events in Project Area
The monitoring report must include the following:
MR.32 A map of the boundaries of any significant disturbance in the project accounting areas during the monitoring period.
MR.33 Evidence that plots were installed into these disturbed areas and were measured per section 9.

8.2.2 Calculating Emissions from Burning

Current emissions from the burning of woody or herbaceous biomass as a result of project activities in the project area must be recorded as the weight (in tonnes) of woody or herbaceous biomass consumed during each burning event. If the production of sustainable charcoal occurs within the project accounting areas, then it must be accounted for under emissions from burning. Emissions from the controlled burning of woody or herbaceous biomass are equivalent to the sum of all burning events $\mathcal{E}^{[m]}$ during the monitoring period as defined by [F.42].

Monitoring Requirements: Emissions from Burning from Project Activities
The monitoring report must include the following:
MR.34 A table of events when woody or herbaceous biomass was burned during the monitoring period, showing the weight of woody or herbaceous biomass in tonnes and the date consumed.

8.2.3 Determining Carbon Stored in WP

If logging is a project activity, the project proponent can choose to measure the mass of logs exported from the project accounting areas and then apply an equation to account for milling inefficiencies, wastage and decay at the mill using procedures in Appendix C.

Wood lost due to wastage and milling inefficiencies over time is calculated and decayed per Appendix C.

Monitoring Requirements: Carbon Stored in Wood Products from Project Activities	
The monitoring report must include the following:	
MR.35	Carbon stored in long-lived wood products $C_{P\,\Delta\,WP}^{[m]}$ after 100 years.
MR.36	Scale reports or records of carbon in log production by wood products type $C_{P\,ty}^{[m]}$.
MR.37	Calculations to determine $C_{P\,\Delta\,WP}^{[m]}$.

8.2.4 Calculating GHG Emissions from Livestock Grazing

If grazing of livestock occurs within the project area during the current monitoring period, the project proponent must calculate greenhouse emissions as a result of grazing. Current greenhouse gas emissions from livestock $E_{P\,\Delta\,LS}^{[m]}$ is given by equation [F.43] , based on IPCC Good Practice Guidelines and IPCC Guidelines for National Greenhouse Gas Inventories. This procedure involves the identification of livestock species, their IPCC default emissions factors (see Table 14), and the number of head per species. The number of head per species of livestock grazing within the project area is monitored per the requirements in section 9.3.2.

In some projects, emissions from grazing may be deemed *de minimis* as per VCS requirements.

Monitoring Requirements: Livestock Grazed in the Project Area	
The monitoring report must include the following:	
MR.38	A report or record of the number of livestock per species of livestock $n_{LS\,i}$ being grazed within the project area $\mathrm{n}_{\mathrm{LS\,i}}$.
MR.39	Emissions released due to livestock grazing $\mathrm{E}_{\mathrm{P\,\Delta\,LS}}^{[\mathrm{m}]}$.
MR.40	Calculations to determine $\mathrm{E}_{\mathrm{P\,\Delta\,LS}}^{[\mathrm{m}]}$.

Table 14: IPCC Default Emission Factors for Livestock in Developed and Developing Countries

IPCC Default Emission Factors (kg CH4 head^{-1} yr^{-1})		
Livestock	**Developed countries**	**Developing countries**
Buffalo	55	55
Sheep	8	5
Goats	5	5

Camels	46	46
Horses	18	18
Mules and Donkeys	10	10
Deer	20	20
Alpacas	8	8
Swine	1.5	1

8.2.5 Calcuating N_2O Emissions from the Use of Synthetic Fertilizers

If project activities includes the use of synthecitc nitrogen fertilzers to improve agricultural yields, then N_2O emissions must be quantified. Use the CDM tool *Estimation of direct and indirect (eg, leaching and runoff) nitrous oxide emission from nitrogen fertilization* to calculate emissions released due to use of synthetic fertilizer $\mathrm{E}_{\mathrm{P}\,\Delta\,\mathrm{SF}}^{[\mathrm{m}]}$.

Monitoring Requirements: Synthetic Fertilizer in the Project Area
The monitoring report must include the following: **MR.41** A report or record of the quantity of synthetic fertilizer applied in the project area. **MR.42** Emissions released due to use of synthetic fertilizer $\mathrm{E}_{\mathrm{P}\,\Delta\,\mathrm{SF}}^{[\mathrm{m}]}$. **MR.43** Calculations to determine $\mathrm{E}_{\mathrm{P}\,\Delta\,\mathrm{SF}}^{[\mathrm{m}]}$.

8.3 Leakage

This section is to be applied separately for each identified project accounting area. Activity-shifting leakage results from the activities of the agent of conversion due to the project activities and applies to all projects. Market leakage applies to projects that cause a reduction in the supply of commodities (either legally sanctioned, illegal or both) in the baseline scenario. The applicability of these types of leakage depends upon the baseline type.

Emissions from activity-shifting leakage are calculated using the Leakage Emissions Model and an activity-shifting leakage area, while emissions from market leakage are estimated using a market leakage area and default values specified in the AFOLU Requirements. To calculate market leakage, the project proponent must use either the production approach (section 8.3.3.4) or discount approach (section 8.3.3.3) as deemed appropriate through the flowchart in figure 13.

Total emissions from leakage for the current monitoring period $E_{L\,\Delta}^{[m]}$ are calculated by [F.44]. The cumulative emissions from leakage for the current monitoring period are given by [F.45], the sum of cumulative emissions from activity-shifting leakage in forest strata $E_{L\ ASF}^{[m]}$, the activity-shifting leakage in grassland strata $E_{L\ ASG}^{[m]}$ and market leakage $E_{L\ ME}^{[m]}$ for the current monitoring period. Once estimated for the current monitoring period, these cumulative emissions from leakage $E_{L}^{[m]}$ are fixed for subsequent monitoring periods.

If market leakage is not considered, then cumulative emissions from market leakage $E_{L\ ME}^{[m]}$ should be set to zero (see section 8.3.3). If the emissions from activity-shifting leakage in forest strata $E_{L\ ASF}^{[m]}$, in grassland strata $E_{L\ ASG}^{[m]}$ or market leakage $E_{L\ ME}^{[m]}$ are negative (indicating "negative leakage"), then their value must be set to zero. If the total emissions from leakage for the current monitoring period are negative (indicating "negative leakage") then the value of $E_{L\ \Delta}^{[m]}$ should be set to zero.

8.3.1 Leakage Mitigation Strategies

Projects must include activities designed to reduce ecosystem conversion resulting from at least one of the drivers identified in section 6.1. The types of activities most appropriate vary based on the specific drivers identified, as well as local socio-economic conditions. Project activities must not result in a significant increase in project GHG emissions. Emissions from project activities must be shown to be *de minimis* using either peer reviewed literature or the use of the CDM A/R methodological *Tool for testing significance of GHG emissions in A/R CDM project activities*. Examples of these activities may include, but are not limited to:

- Developing economic opportunities for local communities that encourage protection, such as employment as protected-area guards or ecotourism guides.
- Developing alternative incomes not derived from conversion.
- Introducing improved agricultural practices that result in a decreased demand for newly cleared land.
- Developing sustainable means of producing fuel wood.
- Developing sustainably-produced timber to replace supply eliminated by conservation of project lands.
- Secure land tenure to enable ongoing sustainable management of lands or investment in productive capacity of lands.

Project activities must be monitored to demonstrate their effect on leakage mitigation. Possible monitoring approaches vary by project and may include:

- The number of people that directly benefit from the activity.
- The number of units distributed as a result of an activity (such as number of trees, foodstuffs, vaccines or dollars).
- The time devoted to implementing an activity.

- Community surveys about the effectiveness of an activity.

PD Requirements: Leakage Mitigation Strategies	
The project description must include the following:	
PDR.104	A list of project activities designed to mitigate leakage.

Monitoring Requirements: Leakage Mitigation Strategies	
The monitoring report must include the following:	
MR.44	A description of project activities that have been implemented since the project start date and the estimated effects of these activities on leakage mitigation.

8.3.1.1 Commodity Production for Leakage Mitigation

Mitigation activities can avoid leakage by increasing production elsewhere, to replace production forgone by the project (see section 8.3.3.4). Also, mitigation activities can reduce demand for the forgone goods and services. An example of replacing forgone supply would be a project that helps farmers increase crop productivity, increasing the total amount of crops produced without increasing the area farmed. An example of reducing demand would be converting local people from inefficient three-stone hearths for cooking to efficient wood stoves, allowing the same amount of food to be cooked with substantially less consumption of fuel wood. For each type of commodity that is being reduced or replaced, amounts must be monitored and verified. Amounts are production increased or consumption decreased, not effort or activity. For example, where fuel consumption decreased as a result of a program that gets families to switch from open-hearth cooking fires to efficient stoves, the project proponent would have to monitor usage of stoves and fuel, and calculate the reduction in the amount of wood fuel consumed. It would not be sufficient to merely report the number of stoves distributed.

There are two alternative approaches to quantifying mitigation. One approach is to implement specific activities and monitor those activities. For example, a project could provide technical assistance to farmers or access to high yielding seeds and measure increases in crop yields on farms that are assisted.

Alternatively, total production in the country can be monitored. If, across the entire country, total production of a category of goods remains constant or increases, then there was 100% replacement of the predicted amount of forgone production of that category of goods.

Monitoring Requirements: Commodity Production for Leakage Mitigation
The monitoring report must include the following: **MR.45** A list of mitigation activities reduce demand for forgone goods and services. **MR.46** Quantities for the reduction or replacement of goods and services if they are used in section 8.3.3.4. **MR.47** Methods for measuring the reduction or replacement of goods and services.

8.3.2 Estimating Emissions from Activity-Shifting Leakage

Activity-shifting leakage is estimated by directly observing conversion (and, in the case of forest baseline types, degradation) in the activity-shifting leakage area (see section 8.3.2.1). The project proponent must establish leakage plots per the requirements in this section and in Appendix B. The activity-shifting leakage area is identified by the project proponent as an area to which activity-shifting leakage is most likely to be displaced, and must be monitored throughout the project lifetime for leakage that may be caused to the project activity.

In the instance where there is no accessible forest or native grassland for the agents of conversion other than the project, then activity-shifting leakage from the project cannot occur. In this instance, there need not be an activity shifting leakage area. This can be demonstrated using the PRA and/or expert knowledge, coupled to analysis of forested, native grassland or native shrubland areas accessible to the agents of conversion, those nearest to the project. In all other cases, there must be one activity shifting leakage area for each project accounting area.

Cumulative emissions from activity-shifting leakage for the current monitoring period $E_{L\ AS}^{[m]}$ are estimated by [F.46] and [F.47] using the Leakage Emissions Model. Once verified, this quantity becomes fixed for subsequent monitoring periods. For the first monitoring period, cumulative emissions from activity-shifting leakage $E_{L\ ASF}^{[m]}$ and $E_{L\ ASG}^{[m]}$ are zero. Carbon stocks in the project accounting area and the proxy area, $c_P^{[m]}$ and $c_B^{[m]}$ are the sum of all selected carbon pools for the current monitoring period (tCO2e/ha).

Monitoring Requirements: Estimating Emissions from Activity-Shifting Leakage
The monitoring report must include the following: **MR.48** Calculated cumulative emissions from activity-shifting leakage for the current monitoring period $E_{L\ ASF}^{[m]}$, $E_{L\ ASG}^{[m]}$ and supporting calculations.

MR.49	Calculated cumulative emissions from activity-shifting leakage for the prior monitoring periods $E_{L\ AS}^{[m]}$ and $E_{L\ ASG}^{[m]}$. If an activity-shifting leakage area is not installed, then include results from the participatory rural appraisal and/or expert knowledge, with an analysis of the nearest suitable forest cover for activity shifting leakage.

8.3.2.1 Delineating the Activity-Shifting Leakage Area

The activity-shifting leakage area must be in the same general region as the project area, but not necessarily adjacent to the project area. As of the project start date, the activity-shifting leakage area must be entirely unconverted (ie, in a forest or native grassland state), and no larger than the project accounting area, or no larger than the geographic area in the case of grouped projects. The activity-shifting leakage area must not include the project area but can overlap with the reference area. In many cases, the reference area will contain the activity-shifting leakage area. The activity-shifting leakage area may not be altered after the first monitoring period unless a baseline reevaluation is triggered per section 6.20.

The activity-shifting leakage area must be delineated per the requirements of Appendix D.

If, upon application of Appendix D, the resultant activity-shifting leakage area is smaller than the project accounting area or cannot be defined (has zero size), the project proponent must provide clear justification for the size of the area. This may be the case if the project proponent is protecting the last remaining forest, native grassland or native shrubland in the region as a project activity. In this case, there may be few or no areas to which the agents can shift their activity.

For foreign agents whose activities may not be restricted to the general region of the project area, the project proponent must show that the foreign agents are unlikely to shift their activities outside the activity-shifting leakage area.

The boundaries of the activity-shifting leakage area may be revised without requiring a baseline reevaluation if one of the following criteria is met:

1. Conservation activity is established in the activity-shifting leakage area such that the agents of conversion no longer have access to the activity-shifting leakage area or a portion thereof.
2. In the case of a grouped project where a new project activity instance(s) is added such that a new activity-shifting leakage area must be created for its associated project accounting area.

The monitoring report must reflect all changes to the activity-shifting leakage area. In the case of forests refer to section 8.3.2.3 and for native grasslands refer to section 8.3.2.4 for requirements for each.

PD Requirements: Delineation of the Activity-Shifting Leakage Area
The project description must include the following information with respect to the activity-shifting leakage area: **PDR.105** A map of the delineated boundaries. **PDR.106** Maps of the landscape configuration, including: Topography (elevation, slope, aspect); Recent land use and land cover (either a thematic map created by the project proponent or publicly available map); Access points; Soil class maps (if available); Locations of important markets; Locations of important resources like waterways or roads; and Land ownership/tenure boundaries. **PDR.107** A narrative describing the rationale for selection of activity-shifting leakage area boundaries. If the activity-shifting leakage area is smaller than the project accounting area or cannot be defined, justification for the size of the area. If foreign agents have been identified as an agent of conversion, justification that they are unlikely to shift their activities outside the activity-shifting leakage area. **PDR.108** Results of a spatial analysis to demonstrate the activity-shifting leakage area is entirely in a non-converted state (eg, forested or native grassland) as of the project start date. **PDR.109** Results of a spatial analysis to demonstrate the activity-shifting leakage area is no larger than the project accounting area.

Monitoring Requirements: Change to the Activity-Shifting Leakage Area
The monitoring report must include the following if there is a change to the activity-shifting leakage area: **MR.50** A description and justification of the change to the activity-shifting leakage area. **MR.51** A map of the delineated boundaries. **MR.52** Maps of the landscape configuration, including:

Topography (elevation, slope, aspect);

Recent land use and land cover (either a thematic map created by the project proponent or publicly available map);

Access points;

Soil class maps (if available);

Locations of important markets;

Locations of important resources like waterways or roads; and

Land ownership/tenure boundaries.

MR.53 A narrative describing the rationale for selection of activity-shifting leakage area boundaries. If the activity-shifting leakage area is smaller than the project accounting area or cannot be defined, justification for the size of the area.

MR.54 Results of a spatial analysis to demonstrate the activity-shifting leakage area is entirely in a non-converted state (eg, forested or native grassland) as of the project start date.

MR.55 Results of a spatial analysis to demonstrate the activity-shifting leakage area is no larger than the project accounting area.

8.3.2.2 The Leakage Emissions Model

The Leakage Emissions Model given by [F.48] and [F.49] estimates cumulative emissions from activity-shifting leakage and is based on the parameterization of α, β and θ and others from section 6.7. Equation [F.48] is for forested project accounting areas while [F.49] is for grassland project accounting areas.

Upon baseline reevaluation, the leakage model is updated to reflect the re-parameterization of α, β and θ (see section 6.20) and other parameters remain unchanged per section 6.20.

8.3.2.3 Estimating $p_{L\,DEG}^{[m]}$ for Forest

The parameter $p_{L\,DEG}^{[m]}$ is estimated at least every five years using Appendix B and monitoring requirements (see Appendix B.2.8 and section 9). This parameter must be applied at each monitoring event, including for the first monitoring period despite zero leakage. Although Appendix B does not prescribe sample sizes to estimate this parameter, it is in the project proponent's best interest to choose a large enough sample size in order to minimize sampling variation that may result in sudden leakage events. Conversion of a single plot in the fifth monitoring period, for example, would have a significant effect on this parameter if the project proponent only monitored 15 leakage plots.

Monitoring Requirements: Estimating $p_{L\ DEG}$
The monitoring report must include the following: **MR.56** The estimated value $\hat{p}_{L\ DEG}^{[m]}$ for the current monitoring period and supporting calculations. **MR.57** The calculated value $\hat{p}_{L\ DEG}^{[m=0]}$ calculated for the first monitoring period.

8.3.2.4 Estimating $p_{L\ CON\ G}^{[m]}$ for Grasslands

The parameter $p_{L\ CON\ G}^{[m]}$ is estimated at least every five years using Appendix B and monitoring requirements (see Appendix B.2.11 and section 9). This parameter must be applied each monitoring event including for the first monitoring period despite zero leakage. Although Appendix B does not prescribe sample sizes to estimate this parameter, it is in the project proponent's best interest to choose a large enough sample size in order to minimize sampling variation that may result in sudden leakage events. Conversion of a single plot in the fifth monitoring period, for example, would have a significant effect on this parameter if the project proponent only monitored 15 leakage plots.

Monitoring Requirements: Estimating $p_{L\ CON\ G}$
The monitoring report must include the following: **MR.58** The estimated value $\hat{p}_{L\ CON\ G}^{[m]}$ for the current monitoring period and supporting calculations. **MR.59** The calculated value $\hat{p}_{L\ CON\ G}^{[m=0]}$ calculated for the first monitoring period.

8.3.3 Determining Emissions from Market Leakage

Market leakage occurs when production of commodities – most likely timber or agricultural products – shifts elsewhere to make up for the lost supply resulting from project activities. Market leakage is that which is not directly caused by the agents of conversion, but is the consequence of supply and demand effects in the national commodity market. For example, a reduction in supply of wood products may result in increased logging elsewhere within national boundaries. The project proponent must account for this shift in production per current AFOLU Requirements and the flowchart provided in Figure 12. Apply sections 8.3.3.2, 8.3.3.3 and 8.3.3.4 of this methodology according to the flowchart.

When the agents and drivers of conversion only use land converted in the baseline for subsistence, no market leakage will occur as a result of the project, and potential leakage, if any, is restricted to the activity-shifting type (see section 8.3.2). If emissions from market leakage do not need to be accounted for, the cumulative emissions from market leakage $E_{L\,ME}^{[m]}$ for every monitoring period will be zero.

Commodities produced for export outside the country of origin do not need to be considered, per AFOLU Requirements. If there is no change in market commodities due to the project, market leakage does not occur and need not be accounted for.

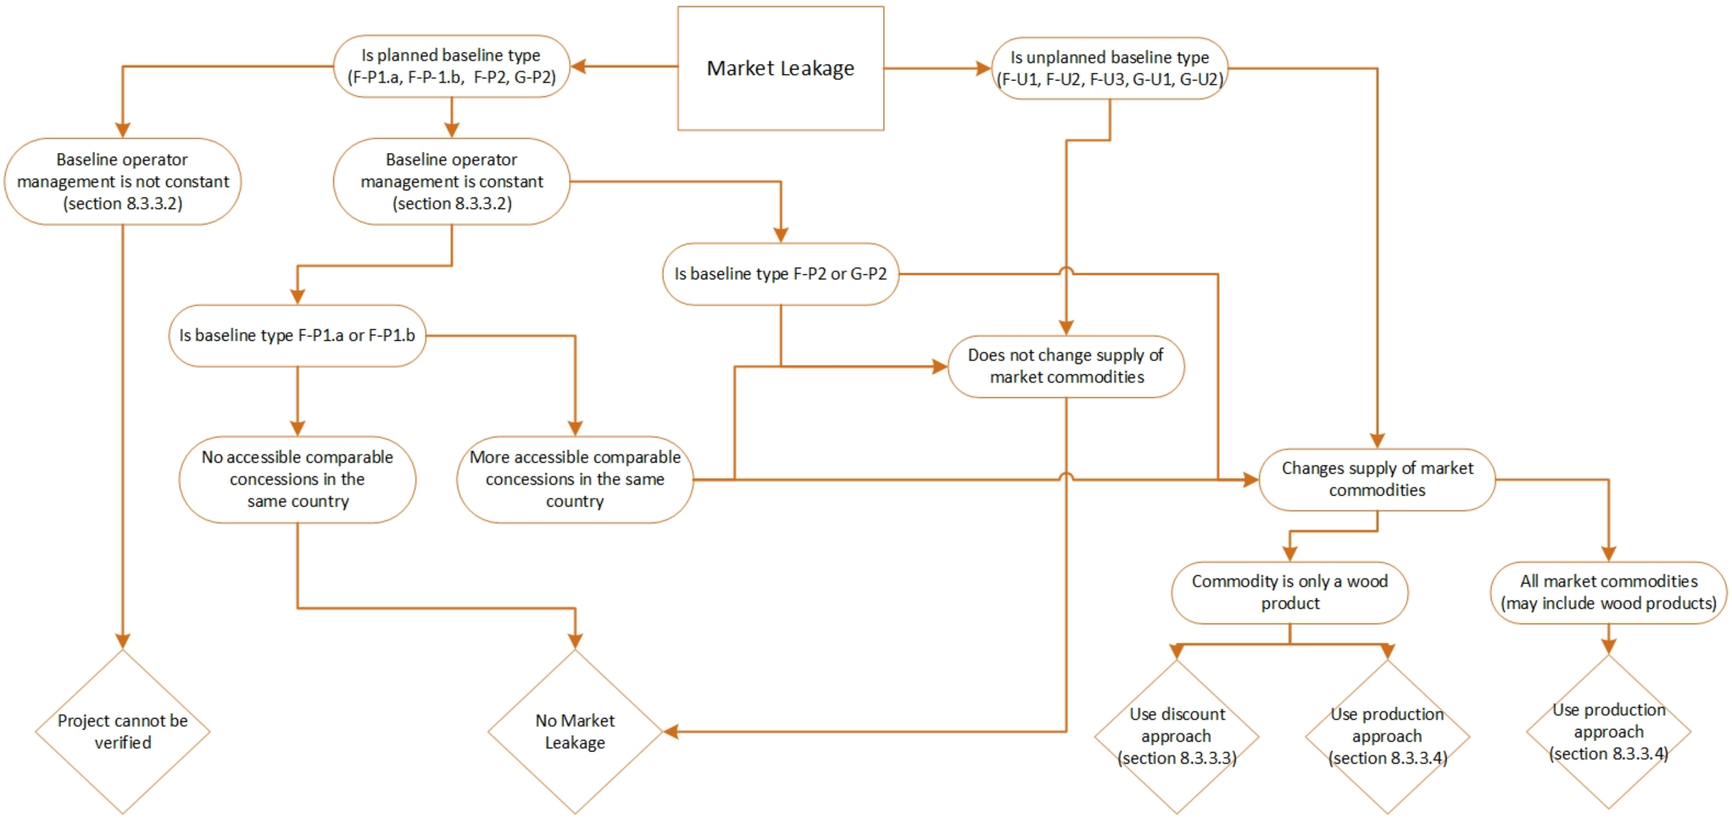
In baseline types F-P1.a and F-P1.b, market leakage is partially an effect of the reduction in timber harvested from the project area. In the case that all available comparable concessions (those with equivalent or substitutable products) within the same national boundaries have been allocated, and all legally sanctioned operators are cutting to the maximum allowable limit, then the supply of legal timber from the national market is fixed. In this case, there is no more timber legally available for harvest, and so a change in the harvest volume to meet demand cannot occur. If there are barriers to an alteration of the rate of illegal logging which follows legal logging (ie, primary and secondary agents) or illegal logging cannot increase in the same country, then leakage from illegal logging may be *de minimis* or not occur.

If, on the other hand, comparable concessions are available or other legal or illegal operators can increase their harvest volumes, then leakage can occur as a result of the project. In this eventuality, project proponents must apply the discount approach to determine market leakage from wood products (section 8.3.3.3) and the production approach (section 8.3.3.4) for other commodities.

The proponent must demonstrate that no leakage has occurred inside the project proponent's ownership per section 8.3.3.1.

Monitoring Requirements: Determining Emissions from Market Leakage
The monitoring report must include the following: **MR.60** The selected approach to determining emissions from market leakage. **MR.61** Estimated cumulative emissions from market leakage for the current monitoring period $E_{L\,ME}^{[m]}$ and supporting calculations. **MR.62** Calculated cumulative emissions from market leakage for the prior monitoring periods $E_{L\,ME}^{[m]}$.

Figure 12: Decision Tree to Determine Mrket Leakage Approach.



8.3.3.1 Ensuring No Leakage Within Project Proponent's Ownership

The project proponent must demonstrate that no leakage occurs outside the project area but within the project proponent's operations, including areas where the project proponent owns, manages, or has legally sanctioned rights to use land within the country where the project is located. The project proponent must identify other locations under its control and show that management plans and land-use designations have not changed as a result of the project.

In cases where the project proponent is an entity with a conservation mission, this requirement may be satisfied with documented evidence that it is against the organization's policy to change the land use of other owned and managed lands, along with evidence that such a policy has been followed historically.

Monitoring Requirements: Ensuring No Leakage Within Project Proponent's Ownership
The monitoring report must include the following: **MR.63** Provide location-by-location evidence that management plans and land-use designations of all areas under the project proponent's control within the country have not changed as a result of the project. For entities with a conservation mission, provide evidence of the organization's policy not to change the land use of other owned and managed lands, and evidence of compliance with such a policy.

8.3.3.2 Ensuring Constancy of Baseline Operator Management

For baseline types F-P1.a F-P-1.b, F-P2 and G-P2, if the specific agent of conversion is known, the management plan and/or land-use designations for the baseline agent's other lands must be demonstrated to have been unchanged due to project implementation.

Monitoring Requirements: Ensuring Constancy of Baseline Operator Management
The monitoring report must include the following: **MR.64** Provide evidence in the form of GIS imagery, PRA evidence, or the baseline operator's management plan that management plans or land-use designations have not changed in the baseline operator's other lands.

8.3.3.3 Discount Approach for Wood Products

If the projects that affect the supply of wood products, lead to increased GHG emissions in other locations in the same country, then market leakage has occurred. The discount approach to determining emissions is one of three methods to determine a discount factor $p_{L\,ME}$:

1. Use the most conservative discount factor of 0.7 from Table 7,
2. Quantify the ratio of merchantable biomass to biomass in a market leakage area and use Table 7, or
3. Identify and justify a discount factor using peer-review publication, government publication or scientific literature.

If necessary, establish the market leakage area per section 8.3.3.3.1. In the market leakage area, estimate $c_{L\ AGMT}$ and $c_{L\ BM}$, where $c_{L\ BM}$ is given by [F.50] and $\mathcal{B}$ is the set of all selected carbon pools in biomass (from AGMT, AGOT, AGNT, BGMT, BGOT and BGNT). These estimates must be established at the time of validation using Appendix B or literature. Cumulative emissions from market leakage are quantified by [F.51].

Table 6: Market Discount Factors by Proportion of Merchantable Biomass (ie, market leakage area to project area)

$p_{L\ ME}$	Condition
0.1*	Project activity leads to a shift in harvests across time periods but minimal change in total timber harvest over time
0.2	$\frac{c_{L\ AGMT}}{c_{L\ BM}} > \frac{c_{P\ AGMT}^{[m=1]}}{c_{P\ BM}^{[m=1]}}$
0.4	$\frac{c_{L\ AGMT}}{c_{L\ BM}} > \frac{c_{P\ AGMT}^{[m=1]}}{c_{P\ BM}^{[m=1]}} + 0.15$
0.4	$\frac{c_{L\ AGMT}}{c_{L\ BM}} < \frac{c_{P\ AGMT}^{[m=1]}}{c_{P\ BM}^{[m=1]}} - 0.15$
0.7	$\frac{c_{L\ AGMT}}{c_{L\ BM}} < \frac{c_{P\ AGMT}^{[m=1]}}{c_{P\ BM}^{[m=1]}}$

* If the lowest factor in the table is selected, it must be justified by the project proponent.

PD Requirements: Determining the Market Discount Factor	
The project description must include the following:	
PDR.110	The selected discount factor $p_{L\ ME}$.
PDR.111	Calculations of $c_{L\ AGMT}$ in the market leakage area, including references to literature if cited.

If the lowest discount factor (0.1) is selected from Table 7 or is not determined using a market leakage area (such as from literature), the project description must include the following:

PDR.112 Justification for the selection of the discount factor.

8.3.3.3.1 Delineating the Market Leakage Area

The market leakage area must be in the same country as the project area, but not necessarily adjacent to the project area. As of the project start date, the market leakage area must be entirely un-converted (ie, still forest or native grassland) and be as large as or larger than the project accounting area. The market leakage area must not include the project area or the reference area. The market leakage area must not be altered after the time of validation.

PD Requirements: Delineation of the Market Leakage Area
The project description must include the following information with respect to the market leakage area if such an area is defined:
PDR.113 A map of the delineated boundaries.
PDR.114 Maps of the landscape configuration, including: • Topography (elevation, slope, aspect); • Recent land use and land cover (either a thematic map created by the project proponent or publicly available map); • Access points; • Soil class maps (if available); • Locations of important markets; • Locations of important resources like waterways or roads; and • Land ownership/tenure boundaries.
PDR.115 A narrative describing the rationale for selection of market leakage area boundaries.
PDR.116 Results of a spatial analysis to demonstrate the market leakage area is entirely forested as of the project start date.
PDR.117 Results of a spatial analysis to demonstrate the market leakage area is as large or larger than the project accounting area.

8.3.3.4 Production Approach for Other Commodities

If changes have occurred in the supply of market commodities or wood products, then market leakage has occurred. If the commodities are only wood products, then the discount approach (section 8.3.3.3) or the production approach may be used to calculate leakage. However, if the commodities include any commodities other than wood products, the production approach must be used to calculate market leakage. To calculate market leakage using the production approach, apply the VCS *Global Commodity Leakage Module: Production Approach* and the relevant criteria and procedures from the associated JNR Leakage Tool. Such module and tool must be applied in a manner appropriate to project-level application. Where VCS issues a relevant project-level leakage tool and production approach leakage module, project proopnents must apply the latest version of such module and the relevant criteria and procedures from the associated tool.

For use of the VCS production approach, the total area of avoided conversion of forest to non-forest and avoided conversion of native grassland to non-grassland must be calculated, which as stated above, is referred to in the above-mentioned VCS leakage tool generally as “area of avoided deforestation.” To calculate the “area of avoided deforestation” $A_{B\,\Delta\,PAA}^{[m]}$ referenced in the tool, use [F.52]. The cumulative emissions from market leakage for the prior monitoring periods $E_{L\,ME}^{[m]}$ must be the sum of all calculated market leakage per the tool, across all current and prior monitoring periods. It is important to note that the methodology accounts for market leakage on a cumulative basis while the tool on a monitoring period basis (hence the Δ in the subscript of $A_{B\,\Delta\,PAA}^{[m]}$).

If no carbon pools in biomass are selected (see section 5.4) then let $c_{P\,BM}^{[m]} - c_{B\,BM}^{[m]} = 1$ in [F.52] and the calculation of $E_{B\,BM}^{[m]}$.

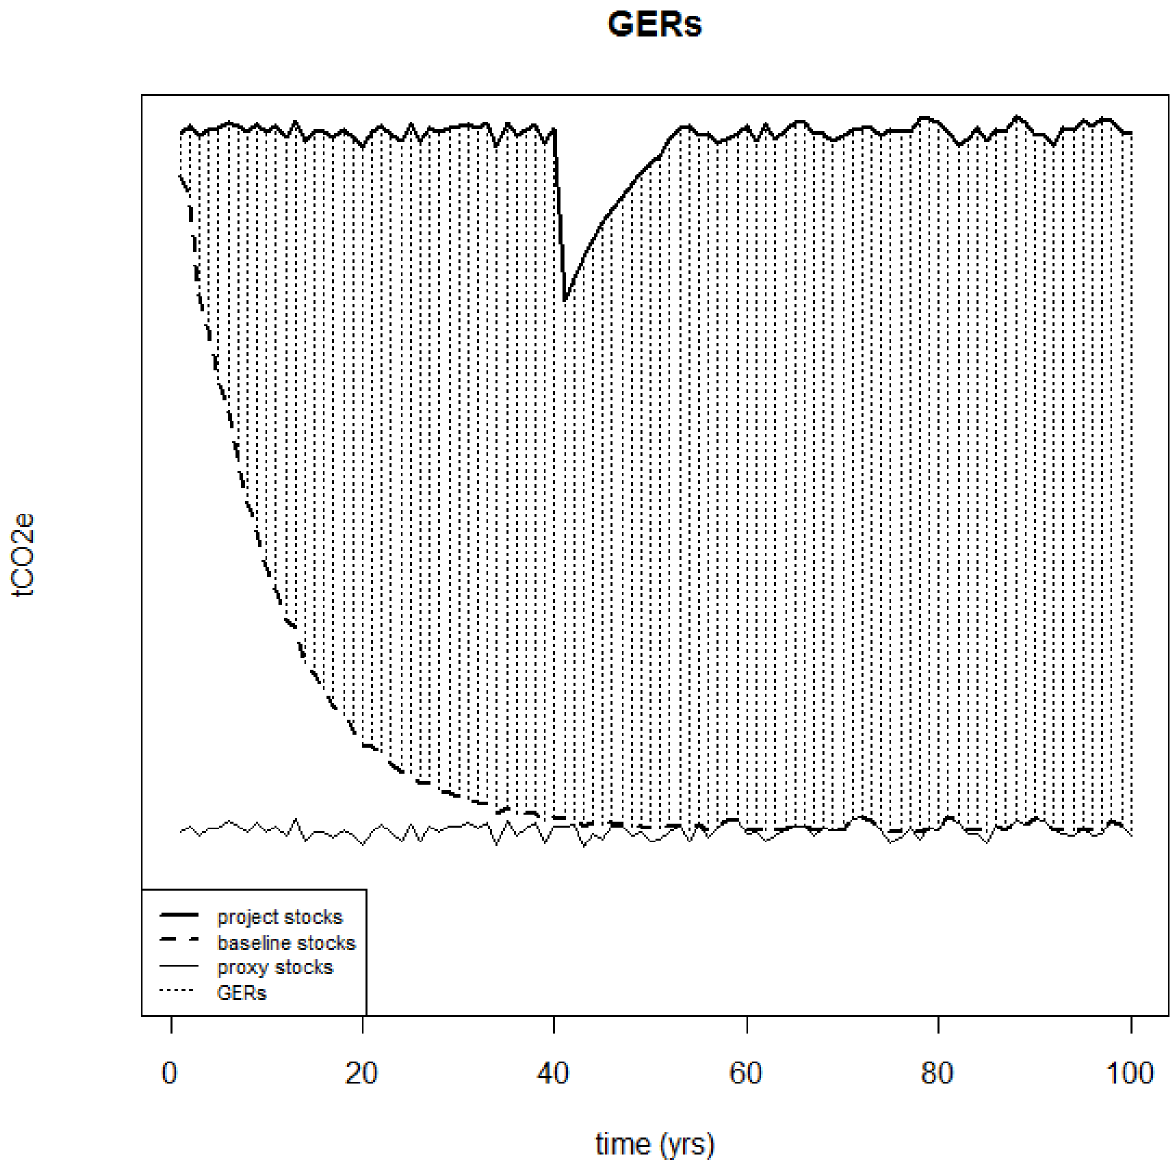
8.4 Summary of GHG Emission Reductions and/or Removals

To quantify NERs, first quantify GERs including the confidence deduction (if any) and subtract the buffer account allocation. For validation and planning purposes, *ex-ante* estimates may be generated (see sections 8.4.1 and 8.4.3). *Ex-ante* estimates are not eligible for crediting (see section 8.4.7). These quantities should be calculated for each project accounting area. If multiple project accounting areas exist in the project area, then NERs should be summed across project accounting areas per section 8.4.5.

8.4.1 Quantifying Gross Emissions Reductions

The GERs for a monitoring period $[m]$ and project accounting area are quantified as [F.53]. Quantified GERs should be rounded down to the nearest whole number.

Figure 13: Hypothetical Graph of Gross Emissions Reductions Over Time.



This figure represents hypothetical GERs over time, where the difference between the project and the baseline stocks are the GERs, and monitored proxy stocks determine the lowest possible stocks in the baseline. The temporary drop in GERs in year 40 of this graph represents a major emissions event such as fire or hurricane that resulted in an efflux of GHG gases from the project. This hypothetical graph does not show discounts for leakage or uncertainty.

Monitoring Requirements: Quantification of GERs
The monitoring report must include the following: **MR.65** Quantified GERs for the current monitoring period including references to calculations. **MR.66** Quantified GERs for the prior monitoring period. **MR.67** A graph of GERs by monitoring period for all monitoring periods to date.

8.4.1.1 Determining Deductions for Uncertainty

The confidence deduction $E_U^{[m]}$ is determined by [F.57], which is a linear combination of weighted standard errors of estimates from baseline emissions models and carbon stock measurements. The confidence deduction is not based on propagation of error. If the confidence deduction $E_U^{[m]}$ is negative, then it should be set to zero.

Monitoring Requirements: Confidence Deduction
The monitoring report must include the following: **MR.68** The confidence deduction $E_U^{[m]}$ and estimated standard errors used to determine the confidence deduction. **MR.69** Reference to calculations used to determine the confidence deduction.

8.4.1.2 Using a Linear Model for Gross Emissions Reductions

A linear model for GERs may be used for project accounting areas with baseline type F-U1 or G-U1 if the GERs predicted by the linear model are conservatively less than GERs quantified by [F.53] for each project accounting area.

A linear model for GERs may be optionally used for other project accounting areas as long as the GERs generated by the linear model are conservatively less than GERs quantified by [F.53] for each project accounting area.

When using a linear model, the quantified GERs must be rounded down to the nearest whole number. The linear model may change from monitoring period to monitoring period as long as the GERs predicted by the linear model are conservatively less than [F.53], and emissions at time zero are zero (ie, the model intercept is zero).

Monitoring Requirements: Quantification of NERs Using a Linear Model
The monitoring report must include the following if a linear model is selected: **MR.70** The linear model used to generate GERs for the current monitoring period. **MR.71** A graph of GERs from the linear model by monitoring period for all monitoring periods to date that used a linear model.

8.4.2 Determining Reversals

In the event that the quantified GERs for any monitoring period are negative as a result of carbon stock losses, the project proponent must follow the VCS procedures for loss events. If subsequent to baseline reevaluation per section 6.20, the new baseline emissions models fall below the old model this does not constitute a reversal. Rather, if credits were generated from avoided conversion prior to baseline reevaluation at a level greater than predicted by the new baseline model after baseline reevaluation, then the project proponent may not generate any new credits from avoided conversion until the new baseline emissions models reaches the previous level of predicted conversion that generated these credits.

At the end of the project crediting period, the project proponent must estimate the final level of cumulative baseline emissions using the most current baseline emissions model and use this estimate to quantify the total number of cumulative credits per equation [F.53]. If this estimate is greater than the number of credits issued during the project crediting period, then this difference must be addressed through the AFOLU Pooled Buffer Account.

Monitoring Requirements: Reversal Event
The monitoring report must include the following if there is a reversal: **MR.72** A description of the reversal including which pools contributed to the reversal and reasons for its occurrence.

8.4.2.1 Determining Reversals as a Result of Baseline Reevaluation

If immediately upon baseline reevaluation GERs for the current monitoring period $E_{\Delta\,\mathrm{GER}}^{[m]}$ (as determined by [F.53]) are negative, this event does not constitute a reversal if the project proponent can demonstrate that this event was caused by new data observed in the reference area. However if this event is not a reversal, the project is not eligible for crediting until the sum of GERs to-date $E_{GER}^{[m]}$ as determined by [F.54] are once again positive.

If after baseline reevaluation GERs for subsequent monitoring periods after the monitoring period immediately following the baseline reevaluation are negative, those GERs $E_{\Delta\, GER}^{[m]}$ constitute reversals.

Monitoring Requirements: Reversal Event as a Result of Baseline Reevaluation
The monitoring report must include the following if there is a reversal as a result of baseline reevaluation:
MR.73 A description of the reversal including a summary of new data obtained in the reference area.

8.4.3 Quantifying Net Emissions Reductions for a PAA

The total NERs generated during a monitoring period $[m]$ are determined by [F.55], which are GERs minus buffer account allocation.

Monitoring Requirements: Quantification of NERs for a PAA
The monitoring report must include the following:
MR.74 Quantified NERs for the current monitoring period including references to calculations.
MR.75 Quantified NERs for the prior monitoring period.
MR.76 A graph of NERs by monitoring period for all monitoring periods to date.

8.4.4 Determining Buffer Account Allocation

Determining the allocation of GERs to the buffer account should conform to current VCS requirements. Those GERs allocated to the buffer account are denoted by $E_{BA}^{[m]}$.

Monitoring Requirements: Buffer Account
The monitoring report must include the following:
MR.77 Reference to the VCS requirements used to determine the buffer account allocation.
MR.78 Reference to calculations used to determine the buffer account allocation.

8.4.5 Quantifying Net Emissions Reductions across PAAs

In the case where there are multiple project accounting areas in a single project area, the NERs for each project accounting area will be quantified individually, and then summed to determine the total NERs for the current monitoring period for the project.

Monitoring Requirements: Quantification of NERs across PAAs
The monitoring report must include the following: **MR.79** Quantified NERs for the current monitoring period including references to calculations. **MR.80** Quantified NERs for the prior monitoring period. **MR.81** A graph of NERs by monitoring period for all monitoring periods to date.

8.4.6 Determining Vintages in a Monitoring Period

When the current monitoring period spans more than one calendar year, NERs must be allocated by year proportional to the number of calendars days in each year relative to the total number of days in the current monitoring period.

Monitoring Requirements: Vintages
The monitoring report must include the following: **MR.82** Quantified NERs by vintage year for the current monitoring period including references to calculations.

8.4.7 *Ex-Ante* Estimation of NERs

Under the VCS, *ex-ante* estimates of the net carbon benefits of the project are only required to determine whether decreases in carbon pools or increases in GHG emissions are insignificant and need not be measured and monitored. Additionally, *ex-ante* estimates of project benefits may be useful to project proponents for planning purposes. Use the project crediting period to estimate *ex-ante* project benefits.

The most significant factor in estimating project carbon benefits is likely to be an estimate of avoided baseline emissions, which is derived from an estimate of carbon stocks and the baseline models. Estimates of *ex-ante* avoided baseline emissions can be made by assuming that the total carbon stock in the project area is equal to the initial carbon stock for each future monitoring period. This conservatively ignores growth of the existing forest or native grassland, assuming that each carbon pool is at a steady state prior to project initiation. The projected avoided baseline emissions are estimated by applying the baseline emissions models as described in sections 6 where monitoring period $[m]$ always indicates the initial carbon stock or IPCC defaults.

If project activities include woody biomass burning, controlled grassland burning, or the sustainable production of charcoal or logging, estimates of emissions due to these activities should be included in the *ex-ante* estimate of project benefits using the procedures in sections 8.4.1 and 8.4.3. The project proponent may assume that the demand for charcoal remains constant at a rate determined prior to project implementation. Because *ex-ante* data for leakage monitoring are unlikely to be available, *ex-ante* estimates of leakage should be estimated using expert knowledge and, if available, experience with past projects. For the purpose of assessing the significance of decreases in carbon pools or increases of emissions due to project activities, it is conservative to underestimate avoided baseline emissions and overestimate leakage and project emissions in *ex-ante* estimates of carbon benefits.

Using the assumptions outlined above, estimate the *ex-ante* NERs $E_{\Delta\,NER}^{[m]}$ for each monitoring period $[m]$ as [F.55] where $E_{\Delta\,GER}^{[m]}$ is GERs for the current monitoring period, $E_{U}^{[m]}$ is the confidence deduction and $E_{BA}^{[m]}$ is the buffer account allocation.

Reporting of *ex-ante* estimates is only required if the project proponent demonstrates that a carbon pool is expected to increase in the baseline or a project emissions source is excluded from accounting under the *de minimis* rule.

PD Requirements: *Ex-Ante* Estimation of NERs
In the case when *ex-ante* estimates are used to prove the significance of emissions sources or estimate the quantity of NERs over the project crediting period, the project description must include the following: **PDR.118** The projected avoided baseline emissions, project emissions and leakage for each monitoring period and vintage year over the lifetime of the project. **PDR.119** A narrative description of sources used to estimate the leakage rate and demonstration that the estimated rate is conservative. **PDR.120** If included in project activities, a description of procedures used to estimate the rate of biomass burning, charcoal production or logging and demonstration that these estimates are conservative.

8.4.8 Evaluating Project Performance

Project performance must be evaluated each monitoring event and deviations from ex-ante NERs must be described. Deviations in credit generation from *ex-ante* estimates may result from changes in the quality of data (literature estimates versus carbon stock estimates), occurrence of disturbance events or baseline re-evaluation.

Monitoring Requirements: Evaluating Project Performance
The monitoring report must include the following: **MR.83** Comparison of NERs presented for verification relative to NERs from *ex-ante* estimates. **MR.84** Description of the cause and effect of deviations from *ex-ante* estimates.

9 MONITORING

The procedures appropriate for estimating the carbon stock in each pool to be monitored are detailed in Appendix B. They provide a means of estimating the total carbon stock in selected pools within the project accounting area and the uncertainty of that estimate at a given point in time. These procedures are used both for establishing the initial carbon stock within the project accounting area and the carbon stock at each monitoring event $[m]$. Project proponents may deviate from the procedures detailed in Appendix B per current VCS requirement, including a description of the deviation and justification for the deviation.

In addition to monitoring carbon stocks, project proponents must monitor species and heads of livestock within the project area to determine greenhouse gas emissions from grazing activities. The procedures for the measurement of livestock heads are detailed in Appendix B. Project proponents may deviate from the procedures detailed in Appendix B per current VCS requirement, including a description of the deviation and justification for the deviation.

9.1 Data and Parameters Available at Validation

See,below for a complete list of all variables, data and parameters and a description of the frequency of monitoring for each, these variables are also shown in Appendix G. These are the only variables that must be reported in the PD.

Data / Parameter	α
Data unit	Unitless
Description	Combined effects of β and θ at the start of the historic reference period
Equations	[F.3], [F.5], [F.6], [F.8]
Source of data	Reference area and historic reference period
Value applied	

Justification of choice of data or description of measurement methods and procedures applied	Time and place in which the logistic model is fit.
Purpose of Data	
Comments	

Data / Parameter	β
Data unit	Unitless
Description	Effect of time on the cumulative proportion of conversion over time
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]
Source of data	Reference area and historic reference period
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Time and place in which the logistic model is fit.
Purpose of Data	
Comments	

Data / Parameter	γ
Data unit	Days
Description	Time shift from beginning of historic reference period to project start date
Equations	[F.3], [F.6]
Source of data	Historic reference period
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Time in which the logistic model is fit.
Purpose of Data	
Comments	

Data / Parameter	θ
Data unit	Unitless

Description	Effect of certain covariates on the cumulative proportion of conversion over time
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]
Source of data	Reference area and historic reference period
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Time and place in which the logistic model is fit.
Purpose of Data	
Comments	

Data / Parameter	λ_{SOC}
Data unit	Proportion (unitless)
Description	Exponential soil carbon decay parameter
Equations	[F.9], [F.33]
Source of data	Default values, literature estimates or empirical estimation based on reference area sampling
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	A conservative default or values derived from direct measurement by the project proponent or from the literature are acceptable.
Purpose of Data	
Comments	

Data / Parameter	$\hat{\sigma}_{EM}$
Data unit	Standard deviation (unitless)
Description	The estimated standard deviation of the state observations used to fit the logistic function
Equations	[F.12], [F.14], [B.31]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of	

measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$\mathcal{B}$
Data unit	Set
Description	The set of all selected carbon pools in biomass. Is a subset of $\mathcal{C}$
Equations	[F.17], [F.18], [F.23], [F.50]
Source of data	PDD
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$\mathcal{C}$
Data unit	Set
Description	The set of all selected carbon pools
Equations	
Source of data	Monitoring records
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$\mathcal{I}$
Data unit	Set

Description	The set of all observations of conversion. When superscripted with a monitoring period, the conversion observations are taken for leakage analysis
Equations	[F.13]
Source of data	Remote sensing image interpretation or field observations in the leakage area
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$\mathcal{M}$
Data unit	Set
Description	The set of all monitoring periods
Equations	[F.32], [F.33], [F.36], [F.54], [F.56]
Source of data	Monitoring records
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$\mathcal{T}$
Data unit	Set
Description	The set of all species/categories of livestock
Equations	[F.43]
Source of data	Monitoring records
Value applied	
Justification of choice of data or description of	

measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	A_{PAA}
Data unit	ha
Description	Area of project accounting area
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8], [F.41], [F.52], [F.57]
Source of data	GIS analysis prior to sampling
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	A_{PX}
Data unit	ha
Description	Area of proxy area
Equations	[F.57]
Source of data	GIS analysis prior to sampling
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$c_{L\ p}$
Data unit	t CO_2e / ha
Description	Carbon stocks in project leakage area
Equations	[F.50]

Source of data	Leakage area sampling
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Direct measurement
Purpose of Data	
Comments	

Data / Parameter	$f_{LS\ i}$
Data unit	kg CH_4 head^{-1} yr^{-1}
Description	Emission factor for the defined livestock population, i
Equations	[F.43]
Source of data	IPCC default values
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Obtained directly from IPCC default values.
Purpose of Data	
Comments	

Data / Parameter	m
Data unit	t CO_2e / yr
Description	Average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging
Equations	[F.2]
Source of data	Timber harvest plans or measurement of carbon stocks in merchantable trees in the *project accounting area*
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the two data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	n_d
Data unit	
Description	Number of spatial points in the reference area
Equations	[F.14]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	o_i
Data unit	Binary
Description	State observation for the i^{th} sample point in the reference area
Equations	[F.13]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	$p_{L\,ME}$
Data unit	Unitless
Description	Portion of leakage related to market
Equations	[F.51]
Source of data	8.3.3
Value applied	

Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	q
Data unit	Days
Description	Lag between start of degradation and conversion
Equations	[F.3], [F.4], [F.5]
Source of data	Expert knowledge, results from the PRA or reports from peer-reviewed literature
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Commonly accepted methods in the social sciences, choice determined and justified by project proponent
Purpose of Data	
Comments	

Data / Parameter	$r_{CF\ b}$
Data unit	Unitless
Description	Carbon fraction of biomass for burned wood or herbaceous material *b*
Equations	[F.42]
Source of data	Literature estimates or direct measurement
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	r_{RS}

Data unit	Unitless
Description	Expansion factor for above-ground biomass to below-ground biomass (root/shoot ratio)
Equations	[F.30]
Source of data	Reviewed literature, allometry, or IPCC default values
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	r_U
Data unit	Unitless
Description	Onset proportion of conversion immediately adjacent to project area
Equations	[F.4]
Source of data	GIS analysis and image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Positions the baseline emissions models relative to the instantaneous rate of conversion
Purpose of Data	
Comments	

Data / Parameter	t
Data unit	Days
Description	Time since project start date
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8], [F.10]
Source of data	Monitoring records
Value applied	
Justification of choice of data or description of	

measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	t_i
Data unit	Days
Description	The point in time of the observation made at point *i*
Equations	[F.11], [A.6]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	t_{PA}
Data unit	Days
Description	Time prior to the project start date when the primary agent began commercial logging in the project accounting area
Equations	[F.1], [F.2], [F.3], [F.6]
Source of data	Harvest plans prepared for the project accounting area, or by public record
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the two data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	t_m
Data unit	Days

Description	Length of project or logging in baseline scenario
Equations	[F.1]
Source of data	PD
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	t_{PL}
Data unit	Days
Description	Length of project crediting period
Equations	[F.5]
Source of data	PD
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	t_{PAI}
Data unit	Days
Description	Number of days after the project start date for the start of a project activity instance in a grouped project
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]
Source of data	PD
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the two data sources if both are available

Purpose of Data	
Comments	

Data / Parameter	t_{SA}
Data unit	Days
Description	Arrival time of secondary agents after start of commercial logging
Equations	[F.2]
Source of data	Participatory rural appraisal, or expert knowledge
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the two data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	w_i
Data unit	Unitless
Description	Weight applied to the i^{th} sample point in the reference area
Equations	[A.6], [F.13]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	x
Data unit	Unitless
Description	Covariate values
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]
Source of data	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery

Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	x_i
Data unit	Geographic coordinates
Description	Latitude of the i^{th} sample point
Equations	[F.11], [A.6]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

Data / Parameter	x_o
Data unit	Unitless
Description	Covariate values as of the project start date
Equations	[F.4], [F.5], [F.6], [F.7], [F.8]
Source of data	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	x_{SA}

Data unit	Unitless
Description	Covariate values as of the arrival of the secondary agents
Equations	[F.2]
Source of data	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	Should use the most accurate of the data sources if both are available
Purpose of Data	
Comments	

Data / Parameter	y_i
Data unit	Geographic coordinates
Description	Longitude of the i^{th} sample point
Equations	[F.11], [A.6]
Source of data	Remote sensing image interpretation
Value applied	
Justification of choice of data or description of measurement methods and procedures applied	
Purpose of Data	
Comments	

PD Requirements: Data and Parameters Available at Validation
The project description must include the following: **PDR.121** The value for each variable in Appendix G.

9.2 Data and Parameters Monitored

See below for a complete list of all variables monitored, data and parameters and a description of the frequency of monitoring for each, these variables are also shown in Appendix H. These variables must be reported in the monitoring report along with metrics for leakage mitigation per section 8.3.1.

Generally, Appendix B should be used to monitor the project accounting area, activity-shifting leakage area and proxy area. However, the project proponent can request a deviation from these methods provided in Appendix B. All deviations must be identified in the monitoring plan.

Data / Parameter:	$\mathcal{W}^{[m]}$
Data unit:	Set
Description:	The set of all burned wood or herbaceous material
Equations	[F.42]
Source of data:	Monitoring records
Description of measurement methods and procedures to be applied:	N/A
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$A_{B\,\Delta\,PAA}^{[m]}$
Data unit:	ha
Description:	Area of avoided conversion
Equations	[F.52]
Source of data:	Generated from equation
Description of measurement methods and procedures to be applied:	8.3.3.4
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$A_{P\ 1}^{[m=0]}$
Data unit:	ha
Description:	Area of project accounting area stratum 1 prior to first verification event
Equations	[F.24]
Source of data:	GIS analysis prior to sampling
Description of measurement methods and procedures to be applied:	GIS analysis of best available data B.1.1
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Cross-check of GIS analysis
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$A_{P\ 2}^{[m=0]}$
Data unit:	ha
Description:	Area of project accounting area stratum 2 prior to first verification event
Equations	[F.24]
Source of data:	GIS analysis prior to sampling
Description of measurement methods and procedures to be applied:	GIS analysis of best available data B.1.1
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Cross-check of GIS analysis

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$A_{P\ n}^{[m=0]}$
Data unit:	ha
Description:	Area of project accounting area stratum n prior to first verification event
Equations	[F.24]
Source of data:	GIS analysis prior to sampling
Description of measurement methods and procedures to be applied:	GIS analysis of best available data B.1.1
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Cross-check of GIS analysis
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$B_{b}^{[m]}$
Data unit:	Tonnes
Description:	Biomass in burned wood or herbaceous material b
Equations	[F.42]
Source of data:	Measurements of biomass
Description of measurement methods and procedures to be applied:	Scale
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_B^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline carbon stocks at the end of the current monitoring period
Equations	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.57]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	B.2,6.4
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{B\ BGB}^{[m]}$
Data unit:	tCO_2e
Description:	Carbon not decayed in BGB at the end of the current monitoring period
Equations	[F.16]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	8.1.4
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{B\ DW}^{[m]}$
Data unit:	tCO_2e
Description:	Carbon not decayed in DW at the end of the current monitoring period
Equations	[F.16]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	8.1.3
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{B\ SOC}^{[m]}$
Data unit:	tCO_2e
Description:	Carbon not decayed in SOC at the end of the current monitoring period
Equations	[F.16]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	8.1.5
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{B\ WP}^{[m]}$
Data unit:	tCO_2e
Description:	Carbon not decayed in WP at the end of the current monitoring period
Equations	[F.16]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	Appendix C
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{B\ AGMT}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline carbon stocks in above-ground merchantable trees at the end of the current monitoring period
Equations	[F.37], [F.38], [F.39], [F.40]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.1
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{B\ BGMT}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline carbon stocks in below-ground merchantable trees at the end of the current monitoring period
Equations	[F.37], [F.38], [F.39], [F.40]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.1
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{P\ AGMT}^{[m=0]}$
Data unit:	tCO_2e
Description:	Project carbon stocks in above-ground merchantable trees at project start
Equations	[F.1]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.1
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$C_{P\ BGMT}^{[m=0]}$
Data unit:	tCO_2e
Description:	Project carbon stocks in below-ground merchantable trees at project start
Equations	[F.1]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.3
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{B\ b}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline scenario average carbon stock in selected carbon pools
Equations	[F.18] [F.24]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	Appendix B.1.5
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{B\ BM}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline carbon stocks in biomass at the end of the current monitoring period
Equations	[F.19], [F.20], [F.21], [F.24], [F.52]
Source of data:	Appendix B.2
Description of measurement methods and procedures to be applied:	Every time measured (≤ 5 yrs)
Frequency of monitoring/recording:	Review of monitoring records
QA/QC procedures to be applied:	
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{B\ SOC}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Baseline soil carbon stocks at the end of the current monitoring period
Equations	[F.25], [F.27], [F.28]
Source of data:	Proxy area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.6
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_P^{[m]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks at the end of the current monitoring period
Equations	[F.41], [F.57]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_P^{[m-1]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks at the beginning of the current monitoring period
Equations	[F.41]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	Prior monitoring period
QA/QC procedures to be applied:	Already reviewed

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_P^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks prior to first verification event
Equations	[F.7]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ 1\ BM}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks in biomass in stratum 1 prior to first verification event
Equations	[F.24]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ 2\ BM}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks in biomass in stratum 2 prior to first verification event
Equations	[F.24]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ 3\ BM}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks in biomass in stratum 3 prior to first verification event
Equations	[F.24]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ n\ BM}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks in biomass in stratum n prior to first verification event
Equations	[F.24]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ AGMT}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project carbon stocks in above-ground merchantable trees prior to first verification event
Equations	[F.37], [F.38], [F.39], [F.40]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.1
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ BM}^{[m=0]}$
Data unit:	tCO_2e
Description:	Project carbon stocks in biomass prior to first verification event
Equations	[F.19], [F.20], [F.21], [F.52]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ b}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Average carbon in biomass in the project accounting area
Equations	[F.17]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	

Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ s\ b}^{[m]}$
Data unit:	tCO_2e / ha
Description:	Average carbon in biomass for each project accounting area stratum s
Equations	[F.23]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2
Frequency of monitoring/recording:	Every time measured (≤ 5 yrs)
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$c_{P\ SOC}^{[m=0]}$
Data unit:	tCO_2e / ha
Description:	Project soil carbon stocks prior to first verification event
Equations	[F.25], [F.27], [F.28]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix B.2.6
Frequency of monitoring/recording:	First monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	

Calculation method:	
Comments:	

Data / Parameter:	$C_{P\,\Delta\,WP}^{[m]}$
Data unit:	tCO_2e
Description:	Project carbon stocks in wood products at the end of the current monitoring period
Equations	[F.41]
Source of data:	Project accounting area sampling
Description of measurement methods and procedures to be applied:	Appendix C
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{\Delta\,GER}^{[m]}$
Data unit:	tCO_2e
Description:	GERs for the current monitoring period
Equations	[F.55], [F.57]
Source of data:	Area measurements
Description of measurement methods and procedures to be applied:	8.4.1
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of GER calculations

Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{\Delta\ GER}^{[i]}$
Data unit:	tCO_2e
Description:	GERs for monitoring period i
Equations	[F.54]
Source of data:	Area measurements
Description of measurement methods and procedures to be applied:	8.4.1
Frequency of monitoring/recording:	Prior monitoring period
QA/QC procedures to be applied:	Review of GER calculations
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{\Delta\ NER}^{[i]}$
Data unit:	tCO_2e
Description:	NERs for monitoring period i
Equations	[F.56]
Source of data:	Area measurements
Description of measurement methods and procedures to be applied:	8.4.3
Frequency of monitoring/recording:	Prior monitoring period
QA/QC procedures to be applied:	Review of NER calculations
Purpose of data:	

Calculation method:	
Comments:	

Data / Parameter:	$E_B^{[m]}$
Data unit:	tCO_2e
Description:	Cumulative baseline emissions at the end of the current monitoring period
Equations	[F.15]
Source of data:	Proxy area measurements
Description of measurement methods and procedures to be applied:	8.1
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_B^{[m-1]}$
Data unit:	tCO_2e
Description:	Cumulative baseline emissions at the beginning of the current monitoring period
Equations	[F.15]
Source of data:	Proxy area measurements
Description of measurement methods and procedures to be applied:	8.1
Frequency of monitoring/recording:	Prior monitoring period

QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\,\Delta}^{[m]}$
Data unit:	tCO_2e
Description:	Change in baseline emissions
Equations	[F.9], [F.10], [F.14], [F.53], [F.57]
Source of data:	Proxy area measurements
Description of measurement methods and procedures to be applied:	8.1
Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\,\Delta\,BGB}^{[i]}$
Data unit:	tCO_2e
Description:	Change in baseline emissions from below-ground biomass during monitoring period i
Equations	[F.32]
Source of data:	Monitoring the proxy area
Description of measurement methods and procedures to be applied:	Appendix B.2.3
Frequency of monitoring/recording:	Prior monitoring period

QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\,\Delta\,DW}^{[i]}$
Data unit:	tCO_2e
Description:	Baseline emissions from dead wood in monitoring period i
Equations	[F.36]
Source of data:	Measurements in the proxy area
Description of measurement methods and procedures to be applied:	Appendix B.2.4 and B.2.5
Frequency of monitoring/recording:	Prior monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\,\Delta\,SOC}^{[m]}$
Data unit:	tCO_2e
Description:	Baseline change in emissions from soil carbon
Equations	[F.15],[F.33]
Source of data:	Measurements in the proxy area
Description of measurement methods and procedures to be applied:	8.1.2.1, 8.1.2.2, 8.1.2.3, Appendix B.2.6
Frequency of monitoring/recording:	Every monitoring period

QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\ \Delta\ SOC}^{[i]}$
Data unit:	tCO_2e
Description:	Baseline emissions from soil carbon in monitoring period i
Equations	[F.33]
Source of data:	Measurements in the proxy area
Description of measurement methods and procedures to be applied:	8.1.2.1, 8.1.2.2, 8.1.2.3, Appendix B.2.6
Frequency of monitoring/recording:	Prior monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\ AGMT}^{[m]}$
Data unit:	tCO_2e
Description:	Cumulative baseline emissions from above-ground commercial trees at the end of the current monitoring period
Equations	[F.34], [F.51]
Source of data:	Measurements in the proxy area
Description of measurement methods and procedures to be applied:	8.1.6.1, 8.1.6.2, 8.1.6.3

Frequency of monitoring/recording:	Every monitoring period
QA/QC procedures to be applied:	Review of monitoring records
Purpose of data:	
Calculation method:	
Comments:	

Data / Parameter:	$E_{B\ BGB}^{[m]}$
Data unit:	tCO_2e
Description:	Cumulative baseline emissions from below-ground biomass at the end of the current monitoring period
Equations	[F.31]
Source of data:	Measurements in the proxy area

Monitoring Requirements: Data and Parameters Monitored
The monitoring report must include the following: **MR.85** List of parameters from Appendix H, their values and the time last measured. **MR.86** Quality assurance and quality control measures employed for each. **MR.87** Description of the accuracy of each.

9.3 Description of the Monitoring Plan

The requirements for sampling depend on the baseline type identified for the project and the selected carbon pools. Pools may be conservatively excluded if the sum of all emissions from optional pools not selected is less than 5% of the total project benefit for the project lifetime. The conservative exclusion of *de minimis* pools can be demonstrated using *ex-ante* estimates (see section 8.4.7). Conservative exclusions must always meet current VCS requirements. All plots must be measured for the first verification. All leakage plots, proxy area plots and project accounting area plots must be remeasured at least every five years, or after a significant event that changes stocks in the proxy or project accounting areas. Note that plots may not be re-measured every monitoring period if the length of the monitoring period is less than five years and there are no significant events that change carbon stocks. All heads of livestock being grazed within the project area must be measured for the first verification (unless deemed to be *de minimis*) and remeasured at least every five years.

All deviations from Appendix B must be described in the monitoring report. At every monitoring (verification) event, new deviations to the monitoring plan must be described in the monitoring report.

PD Requirements: Description of the Monitoring Plan
In the case when *ex-ante* estimates are used to prove the significance of emissions sources or estimate the quantity of NERs over the project crediting period, the project description must include the following: **PDR.122** Summary of sampling procedures for the project accounting areas, with a copy of a sampling protocol used to carry out measurements. **PDR.123** Summary of sampling procedures for the proxy areas, with a copy of a sampling protocol used to carry out measurements. **PDR.124** Summary of sampling procedures for the activity-shifting leakage areas, with a copy of a sampling protocol used to carry out measurements.

Monitoring Requirements: Description of the Monitoring Plan
The monitoring report must include the following: **MR.88** Documentation of training for field crews. **MR.89** If included in project activities, a description of procedures used to estimate the rate of biomass burning and charcoal production and demonstration that these estimates are conservative. **MR.90** Documentation of data quality assessment such as a check cruise and plots of the data such as diameter distributions by strata or plot. **MR.91** Maps of a stratification (if any) and references to plot allocation. **MR.92** List of plot GPS coordinates. **MR.93** Description of plot sizes and layout (such as the use of nests and their sizes) for each carbon pool. **MR.94** If applicable, a detailed description of the process used to develop allometric equations, to include:

Sample size

Distribution (eg, diameter) of the sample

Model fitting procedure

Model selection

MR.95 The estimated carbon stock, standard error of the total for each stock, and the sample size for each stratum in the area selected.

MR.96 Log export monitoring records and standard operating procedure in the project area, if there is commercial harvest in the project scenario.

MR.97 Deviations from the measurement methods set out in Appendix B or the monitoring plan, per current VCS requirement.

MR.98 The frequency of monitoring for each plot for all plots – all plots should be measured for the first verification. All leakage plots should be measured every verification, and all proxy and project accounting area plots at least every five years, or after a significant event that changes stocks.

9.3.1 Monitoring Carbon Stocks

This methodology employs fixed area plots coupled with allometric equations for estimating carbon stocks in trees. Carbon stocks in dead wood are estimated using fixed area plots for the standing dead wood pool and line intersect sampling for the lying dead wood pool. Allometric equations or destructive sampling may be used for estimating non-tree carbon stocks. Soil carbon is estimated using soil samples collected from soil cores or pits. Carbon in log production to wood products is estimated by estimating merchantable volume on fixed area measurement plots. These sampling procedures are designed to detect both increases in carbon stocks, such as those that occur as a result of forest growth, and decreases in carbon stocks, such as changes that may take place as a result of degradation or natural disturbance events.

Carbon stocks must be estimated for the first monitoring period by sampling all plots in all strata in the project, activity-shifting leakage and proxy areas. After the first monitoring period, all plots and all strata in the project and the activity-shifting leakage areas must be re-measured at least every five years, a process which may be accomplished on an intermittently rotating basis. If the baseline scenario includes commercial wood products and the project proponent elects to use the market leakage area, the proponent must measure AGMT in the market leakage area.

Project proponents must install a stratified random sample of permanent plots in the project area and leakage areas and, if required based on the selected pools and guidance above, the proxy area. It is recommended that all quantities selected for measurement be measured on the same plots (as described in Appendix B), but different sampling schemes for each pool may be employed if the project proponent determines that this improves the efficiency of sampling. In particular, soil carbon stocks may require a sampling framework distinct from that applied for other pools.

9.3.2 Monitoring Livestock

If livestock grazing is occurring within the project area boundary, the number of each species of livestock being grazed must be determined. It is recommended that the project proponent conduct a headcount of all livestock species within the project area to determine exact population numbers, but different sampling schemes for livestock estimation may be employed if the project proponent finds that this improves the efficiency of sampling. For a detailed description of procedures for monitoring livestock populations within the project area, refer to Appendix B. It is always conservative to overcount the number of livestock being grazed in the project area.

9.3.3 Allometric Equations

When available, allometric equations from existing IPCC, government, or peer reviewed literature may be used. Equations should be derived from trees of a wide range of diameters and, if included, heights and should not be used beyond the size range for which they were developed. When equations are selected from literature, justification must be provided for their applicability to the project area considering climatic, edaphic, geographical and taxonomic similarities between the project location and the location in which the equation was derived. When possible, species-specific equations should be used. If generalized equations developed for wide scale application are used, they must be validated using the procedures below.

Allometric equations may change or be supplemented each monitoring period as allometry improves. Every monitoring period all selected equations must be justified per the following sections.

Monitoring Requirements: Sources of Allometry	
The monitoring report must include the following:	
MR.99	A list of all selected allometric equations used to estimate biomass for trees and non-trees.
MR.100	For each selected allometric equation, a list of species to which it is being applied and the proportion of the total carbon stocks predicted by the equation.
MR.101	For each selected allometric equation, indication of when it was first employed to estimate carbon stocks in the project area (monitoring period number and year of monitoring event).
MR.102	For each selected allometric equation, indication of whether was validated per sections 9.3.3.1 or 9.3.3.2.

MR.103	Documentation of the source of each selected allometric equation and justification for their applicability to the project area considering climatic, edaphic, geographical and taxonomic similarities between the project location and the location in which the equation was derived.

9.3.3.1 Validating Previously Developed Allometric Equations

When equations are taken or modified from existing literature that is not similar to the project area as described above or are selected from a biome-wide database, such as those provided in Tables 4.A.1 to 4.A.3 of the GPG-LULUCF (IPCC, 2006), they must be verified by measurements of trees within the project area or in stands similar to the project stands in the same forest type as project stands and near the project area. It is always best and most accurate to use equations developed from trees in the project area or from existing literature that is based on research in areas similar to the project area. The project proponent should commit to improve and update allometric equations over time to reduce uncertainty.

Equations may be validated by showing good correspondence of predictions from the equation to field measurements of biomass based on: (a) destructive harvesting of trees in or near the project area, (b) direct physical measurements of at least the bole, and major branch segments combined with valid expansion factors for branches and foliage or, (c) a combination of direct measurement of boles and use of conservative expansion factors or a sampling approach for branches that precludes double-counting branch and bole measurement.

An equation must be validated using a representative sample within the size range observed in the inventory. The sample size must be at least 30 unless the number of trees to which it is being applied is less than 100, in which case it must be equal to 30% of the number of trees to which it is being applied.

An equation is valid if:

1. The predicted biomass is within +/- 15% of that measured, using the measurement methods described above, determined by the ratio of the sum of all measurements to the sum of all predictions (ratio of sums).
2. OR the cumulative biomass for all measured trees in the validation sample are greater than that predicted by the equation.
3. OR an adjustment factor is applied to the equation that results in the predicted biomass being within +/-15% of the measured biomass using the methods described above.

In the case where the representative sample does not include a tree that is as large or larger than the largest tree in the inventory (a right-censored sample), the project proponent must demonstrate that the equation selected does not over-predict biomass for very large trees by demonstrating two additional criteria.

1. That the biomass measurement of the largest tree in the representative sample is greater than its predicted biomass by the equation.
2. That the equation behaves similarly beyond the range of measurements taken for the representative sample. To demonstrate this, do the following:
    a. Find the first order derivative of the equation.
    b. Determine the value of the derivative given the measurements of the largest tree in the representative sample.
    c. Determine the value of the derivative given the measurements of the largest tree in inventory to which the equation is applied.
    d. Compare the values from (b) and (c). The value from (c) must be no more than 10% greater than the value from (b).

Monitoring Requirements: Validating Previously Developed Allometry	
The monitoring report must include the following:	
MR.104	A list of allometric equations validated by destructive sampling.
MR.105	For each, the number of trees (or non-trees) destructively sampled and the location where the measurement were made relative to the project area.
MR.106	A field protocol used to measure destructively sampled trees (or non-trees).
MR.107	Justification that the field protocol for the destructive measurement method conservatively estimates biomass.
MR.108	For each allometric equation in the list, a figure showing all the descriptive measurements of biomass compared to predicted values from its selected allometric equation.

9.3.3.2 Validating Newly Developed Allometric Equations

If allometric equations are developed for the project area, the guidance provided by Parresol (1999) should be used to fit appropriate statistical models. New models must be validated using leave-one-out cross validation as follows:

Assume a model of the form $y = f(\boldsymbol{x})$, where y is measured biomass and $\boldsymbol{x}$ is a vector of regressors.

1. Temporarily remove observation $(y_{i,}\boldsymbol{x}_i)$ from the dataset used to fit the model.

1. Refit the model, f_{-i} , with the remaining data points and use it to estimate $\hat{y}_i$, the predicted biomass at the point that was removed from the dataset prior to model fitting as given by equation [B.24].
2. Estimate the cross-validated error for this data point, $\hat{e}_i$, expressed as a proportion of the true biomass using equation [B.25].
3. Repeat 1-3 for each observation.
4. Calculate the mean cross-validated error $\bar{E}$ as equation [B.26], where $\mathcal{X}$ is the set of all observations used in model fitting.

The developed equation is considered valid if $\bar{E} < 15\%$.

Monitoring Requirements: Validating Newly Developed Allometry
The monitoring report must include the following: **MR.109** A list of allometric equations cross validated. **MR.110** For each, the number of trees (or non-trees) destructively sampled to build the equation and the location where the measurements were made relative to the project area. **MR.111** A field protocol used to measure trees (or non-trees) when developing the equation. **MR.112** Justification that the field protocol for the measurement method to build the equation conservatively estimates biomass. **MR.113** For each allometric equation in the list, the value of $\bar{E}$.

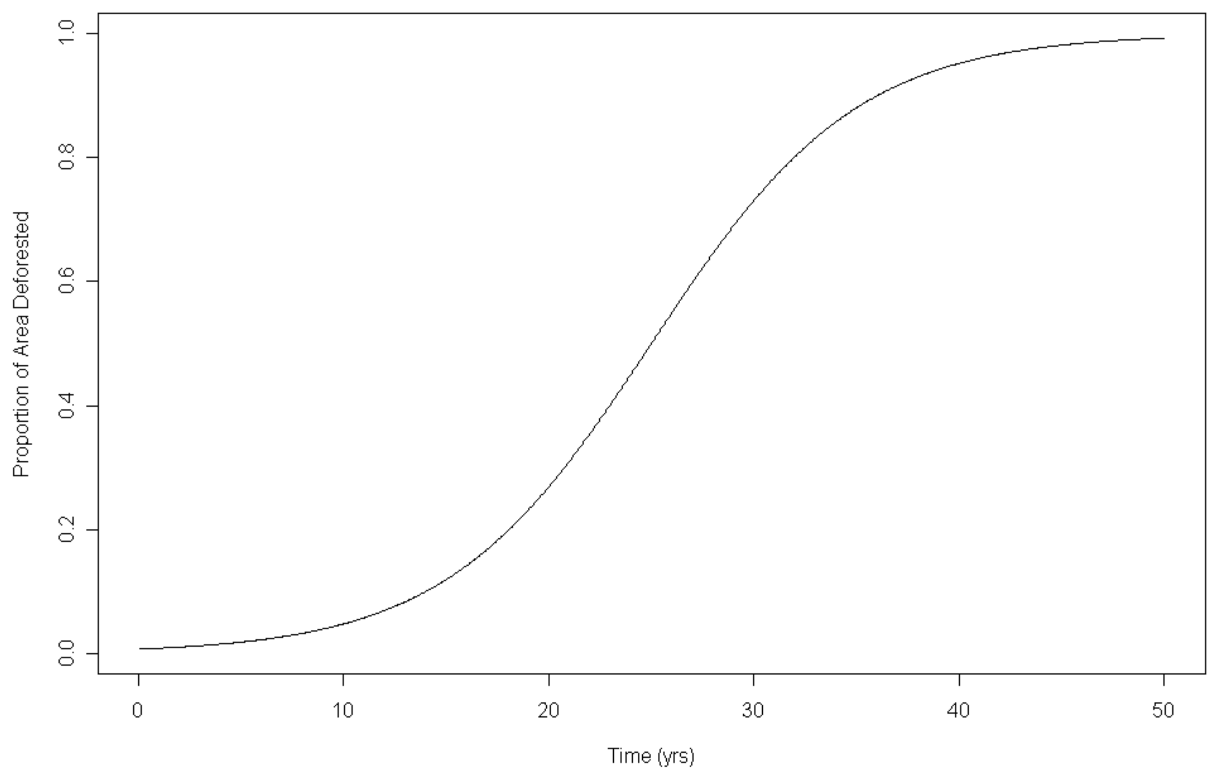
APPENDIX A: THEORETICAL BACKGROUND

A.1 Logistic Function for α, β and θ

This background section contains general information about the model and the selected approach to fitting the model rather than specific methods used to build the baseline emissions models, and is not required to run the model itself.

Natural resource conversion over time is inherently bounded by the size of the area that is subject to conversion and has been shown to exhibit logistic behavior over time (Arellano-Neri & Frohn, 2001; Kaimowitz, Mendez, Puntodewo, & Vanclay, 2002; Linkie, Smith, & Leader-Williams, 2004; Ludeke, Maggio, & Reid, 1990; Mahapatra & Kant, 2005). Figure 14 illustrates this behavior: the rate of ecosystem conversion is low at beginning, steadily increases and tapers off at the end of the time period.

Figure 14: Generalized Graph of Logistic Conversion Over Time
The logistic model of conversion, showing the transition from forest to non-forest of a given area



This behavior can be interpreted using economic theory (eg, see Reis and Guzman 1992). At the beginning of conversion in an area, agents are scarce and resources are plentiful; this leads to increasing resource exploitation. Conversely, toward the end, agents are plentiful and resources are scarce, decreasing exploitation.

Based on these concepts and their support in the literature as described above, this methodology assumes that ecosystem conversion is logistic when bounded by the reference area or project accounting area(s). Specifically, it assumes that conversion over time exhibits the implicit form defined by equation [A.4].

The parameter vector $\boldsymbol{\theta}$ included in equation [A.4] represents the aforementioned numeric covariates to conversion which are identified using expert knowledge or the participatory rural appraisal. The function η is called the linear predictor given time and conversion covariate parameters $\boldsymbol{\theta}$. Fitting equation [A.4] is equivalent to estimating the linear predictor as $\hat{\eta}$ where the linear predictor is defined by equation [A.5].

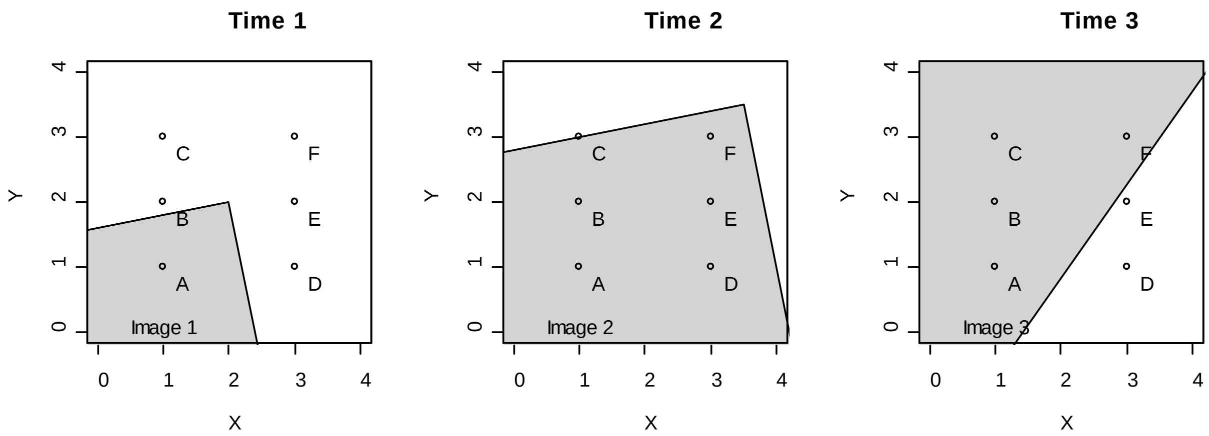
A.1.1 Probabilities and Weights for Conversion State

Fitting [A.4] requires some historic information about the land cover state in the space of the reference area over time. Observations of land cover state in the reference area can be made over the reference period as a first step to fitting equation [A.4]. These observations can be made using a sample of unique points in time and space where the state observation for the i^{th} sample point is defined by [F.11], which is a function of time t_i, latitude x_i and longitude y_i. State observations in space can be made at random or on a lattice (systematic grid). Since states are observed in historic images, however, observations in time can only be made at the times for which imagery is available.

Spatial availability of historic imagery over the reference area might not be uniform. Additionally, the entire space of the reference area might not be equally observed over time. To correct for any resulting bias, we estimate the probability of observing any one particular sample point using equation [A.1]. The probability of observing an image in time is not independent of space. For example, consider a scenario in which a government entity obtained aerial imagery along a highway for a road expansion project in the reference area five years prior to the project start date. Then, a second set of imagery was obtained after the road expansion was complete. Equation [A.3] accounts for the fact that the probability of observing an image in the reference area at any given time is dependent on that image’s proximity to the construction project.

The conditional probability of observing a sample point in space given time is [A.2] and the probability of observing any sample point in time is simply the intensity of the process [A.3]. Hence the correction factor is proportional to the inverse of the probability of observing any one particular sample point which is [A.6], and is called the observation weight.

Figure 15: Examples for Calculating Observation Weights
An example of three images at different times used to calculate the observation weights of sample points.



For example, to calculate the observation weight of a point (x, y, t) as defined by equation [A.6], one must know the number of times the point was observed in the reference area and the number images that the point falls onto during the reference period where the point falls onto in the cloud-free portion of each image. If there are six points in the reference area and three images in the historic reference period, as shown in Figure 15, then the weight of point A at time 3 in the figure is calculated as

$$\frac{1}{3 \times 4} = \frac{1}{12}$$

while the weight of point D at time 2 is calculated as

$$\frac{1}{1 \times 5} = \frac{1}{5}.$$

Point D at time 2 is given more weight than point A at time 3 because it is observed less often.

The model defined by equation [A.4] is fit using iteratively reweighted least squares (IRLS) with initial weights $\boldsymbol{w}$, the observation weights, and given the observed covariates and states $\boldsymbol{o}$ in vector format. See Venables & Ripley (2002) for information on how to fit a logistic model with IRLS using the free statistical program R.

Akaike Information Criterion (AIC) is used to select the best nested model in $\boldsymbol{\theta}$. See Davidson (2003) or Freedman (2009) for information about linear predictors and logistic models.

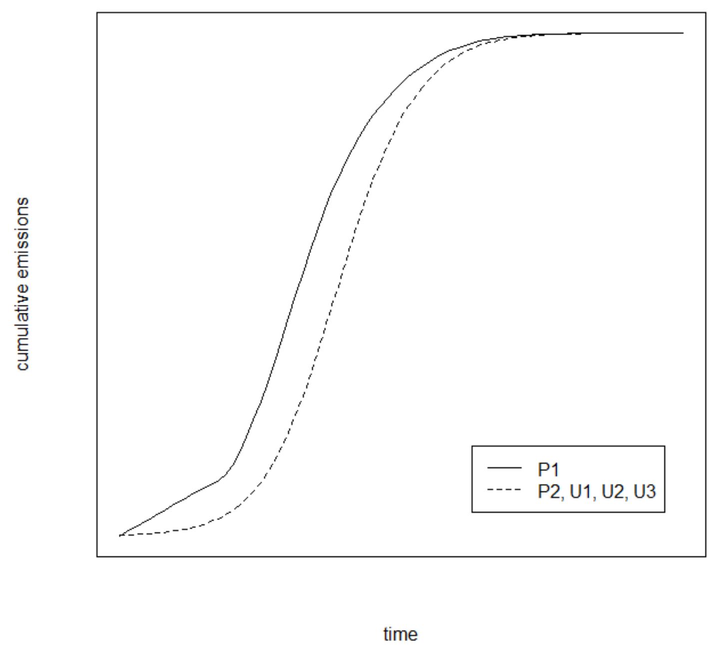
The residuals of the model defined by equation [A.4] are assumed to be stationary over the reference period. That is, the mean and variance of the residuals are time invariant.

After model selection and fitting, the cumulative conversion as a proportion of an area can be predicted for future times using equation [A.4].

A.1.2 Linear Behavior of Emissions from Legally-Sanctioned Commercial Logging

In a planned commercial scenario, a baseline operator would degrade the forest at a given linear rate mandated by the cutting limits placed by the national government or the concession. When harvest is not sustainable (eg, more volume is extracted than incremental growth in a given time and space) than the forest is degraded. If the baseline operator protects the area harvested from deforestation during forest operations but not afterwards, deforestation is preceded by linear degradation.

Figure 16: Graph of Cumulative Emissions from Conversion for the Different Baseline Types
The figure shows a generalized graph of cumulative emissions over time. An equal volume per unit time is degraded under a planned commercial scenario until secondary agents arrive and begin deforestation, following a logistic model after t_{sa} for type F-P1.a and F-P1.b, while for other baseline types emissions follow the logistic model from t_0.



The combined emissions from the linear degradation and the subsequent logarithmic deforestation are explained by the baseline emissions model, equation [F.19], and illustrated by the above generalized graph of linear degradation followed by deforestation.

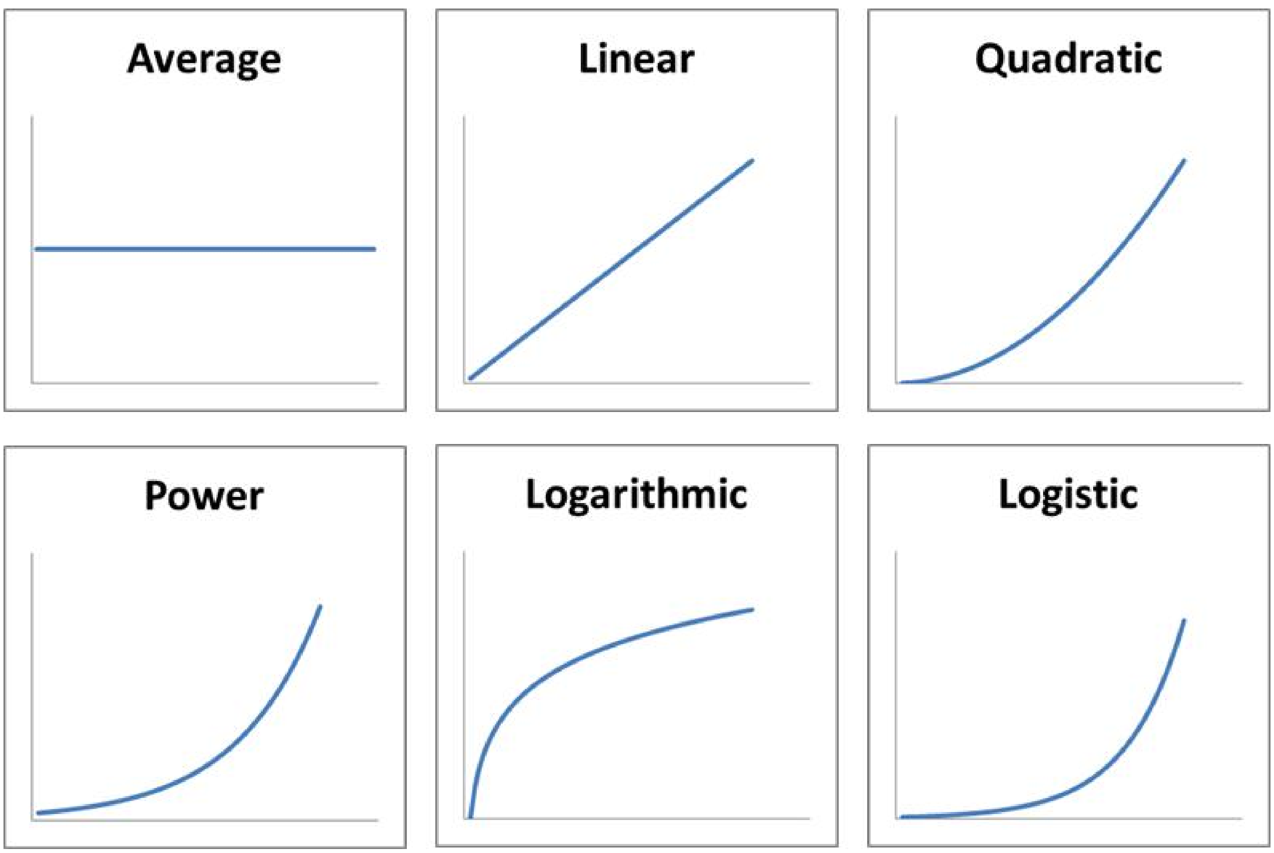
A.1.3 Relationship of the Logistic Function to Other Function Types

The logistic function specified by [A.4] is related to a variety of rate functions employed in other REDD+ programs and methodologies. The rate function of [A.4] corresponds to its first-order derivative with respect to its linear predictor:

$$\frac{\exp[\eta(t,\boldsymbol{\theta})]}{(1+\exp[\eta(t,\boldsymbol{\theta})])^2}.$$

The different types of functions are displayed graphically in Figure 17. Traditionally, other REDD+ national and sub-national programs and methodologies have employed linear functions to estimate future conversion rate trends. The logistic function specified by [A.4] represents the economic theory of resource consumption (ie, ecosystem conversion) within a discrete area over time, as presented in section [A.1]. None of the other rate functions generally used in REDD+ programs provide the same depiction of this resource economic theory. If the economic theory presented in section A.1 is accepted as the most realistic depiction of resource consumption, it can then be stated that the logisitic function may be a more reasonable approximation of the conversion process than other function types.

Figure 17: Graphs of General Functional Forms



A.2 Soil Exponential Decay Model

This background section contains general information about the exponential decay model for soil which underpins the SEM and the selected approach to fitting the exponential decay model, rather than specific instructions on how to build the model.

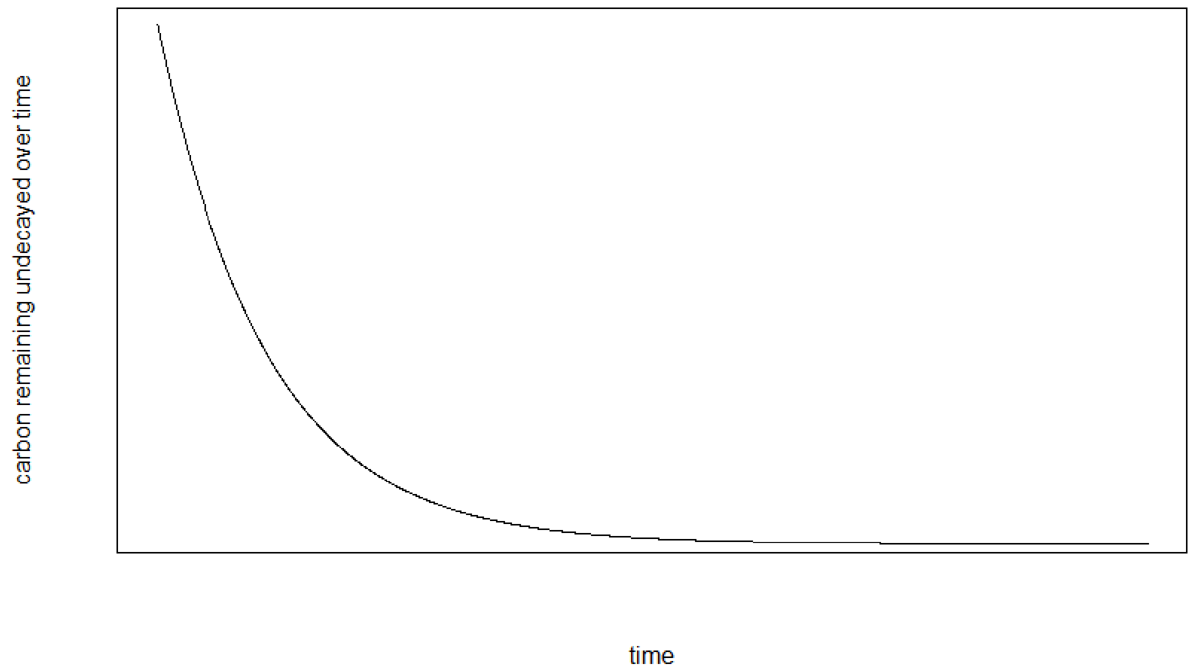
Literature suggests that the amount of carbon loss in soil following conversion from forest to non-forest or from native grassland to anthropogenic conversion follows an exponential decay (loss) curve due to decomposition processes. The majority of loss occurs within the uppermost soil horizons (eg, top 20-30 cm) for soil and within the first few years for all decaying pools (Olson 1963, Davidson and Ackerman 1993). An exponential decay function integrates cumulative loss, where λ represents the exponential soil C decay parameter and describes decay of the carbon that will eventually be lost. Following ecosystem conversion, only a portion of the carbon stock is lost; ie, organic carbon stocks decline towards a new equilibrium level over time, reaching some maximum carbon loss proportion that ultimately depends on both the depth of the soil column and cultivation practices over time for soil. These factors vary on a project-by-project basis. Hence a project developer's selected value for λ be evaluated on a project-by-project basis (see section 6.19).

Per section 6.19, project proponents must select an exponential decay parameter, λ, by either

1. Using a value from peer-reviewed scientific literature that is as appropriate for the project (see section 6.19.4),
2. Estimate the parameter, $\hat{\lambda}$, using empirically measured data per section 6.19.3, or
3. Utilize the conservative default value for the selected pool. The default value provided in this methodology is only appropriate for the tropics (see section 6.19.2).

If the project proponent choses option 2, measurement sampling of soil carbon from the proxy area (see section 6.4) is used to estimate λ_{SOC} using a process known as a "space for time substitution", a well documented method in the ecological literature. This process assumes that soil C stocks in the proxy area (that has been previously converted) are representative of the soil C levels that would be obtained over time in the project area if it were to be converted to some end land use. If the sample data are obtained from soil columns with equal depth and the data are collected from agricultural soils of known age, then the sample mean should be used to estimate λ_{SOC}, per Davidson & Ackerman, 1993. It should be noted that this methodology does not explicitly prescribe duration of time required to accurately derive a value for λ_{SOC}. The authors were purposely inexplicit in this regard, as it is in the proponent's best interest to collect data that represents a period of time after the soil carbon stock has reached a new equilibrium state (no longer declining). If $\lambda_{SOC}$is derived from converted areas that are "too recent", clearly the estimate of proportional soil loss, λ_{SOC} will be biased toward less decay than may ultimately occur. It is therefore recommended to sample in farms between 5 and 20 years in age to capture complete soil carbon decay in tropical ecosystems.

Figure 18: Exponential Decay Model
This figure depicts the exponential nature of decay in the soil carbon pool.



A.3 Model for Spatial Component

The spatial model applies to baseline type U3. This model does not attempt to determine where ecosystem conversion is most likely to have occurred in the project, but rather conservatively assumes that the stratum with the lowest carbon stocks is harvested first. Strata are then assumed to be deforested sequentially moving from lowest to the highest stocked strata.

This approach is thus the most conservative accounting possible for the potential patterns of conversion. It avoids the complexities and sources of error inherent in attempts to predict the spatial patterns of conversion that could lead to an over-issuance of NERs.

A.4 Equations for Theoretical Background

$P(t_i, x_i, y_i) = P(x_i, y_i \mid t_i)P(t_i)$	[A.1]
Variables	$P(t_i, x_i, y_i)$= probability of observation in a point in space and time t_i= the time of the i^{th} sample point x_i= the latitude of the i^{th} sample point y_i= the longitude of the i^{th} sample point
Section References	A.1.1
Comments	Probability of observing any one sample point in space and time.

$P(t_i, x_i, y_i) = \frac{\#(observations\ at\ x_i, y_i) \times \#(observations\ at\ t_i)}{\#(historic\ images) \times \#(total\ observations)}$	[A.2]
Variables	$P(t_i, x_i, y_i)$= probability of observation in a point in space and time t_i= the time of the i^{th} sample point x_i= the latitude of the i^{th} sample point y_i= the longitude of the i^{th} sample point
Section References	A.1.1
Comments	The conditional probability of observing a sample point in space given time.

$P(t_i) = \frac{1}{\#(historic\ images)}$	[A.3]

Section References	A.1.1, 6.8.4
Comments	The probability of observing any sample point in time with a given number of historical images

$$F_{DF}(t,\eta) = \frac{1}{1+\exp[-\eta(t,\theta)]}$$ [A.4]	
Variables	F_{DF} = proportion of cumulative conversion η = linear predictor given time and conversion covariates; t = time θ = parameter vector of covariates
Section References	A.1, 6.8.8
Comments	Logistic model of cumulative conversion bounded by a reference or project area. (Arellano-Neri & Frohn, 2001; Kaimowitz et al., 2002; Linkie et al., 2004; Ludeke et al., 1990; Mahapatra & Kant, 2005)

$$\eta = \alpha + \beta t + \theta x^T + \delta_{PR}$$ [A.5]	
Variables	α = combined effects of β and θ at the start of the historic reference period β = effect of time on the cumulative proportion of conversion over time t = time since project start date θ = parameter vector of covariates x^T = covariate value δ_{PR} = project lag parameter
Section References	A.1
Comments	linear predictor given time and conversion covariates

$$w_i \propto \frac{1}{\#(observations\ at\ x_i, y_i) \times \#(observations\ at\ t_i)}$$ [A.6]	
Variables	w_i = observation weight of point i $\#(observations\ at\ x_i, y_i)$ = number of observations throughout time at point x_i, y_i $\#(observations\ at\ t_i)$ = number of observations across space at time t_i
Section References	A.1.1

Comments	Observation weight

APPENDIX B: CARBON STOCK AND LIVESTOCK MEASUREMENT

B.1 General Sampling Guidelines for Carbon Stocks

Sample plots are used to estimate carbon stocks in selected pools at a particular point in time. Changes in measured carbon stocks are used in conjunction with the cumulative emissions model to quantify the net GHG emissions or removals as a result of project activities. Changes on measured plots should reflect both changes due to natural processes such as growth and mortality and changes due to human activity, such as management, harvest, or degradation. In order to avoid bias, plots should be marked inconspicuously, so that if degradation or management activities do occur in the area, they apply uniformly to both areas within an established monitoring plot and areas outside of those plots.

Project proponents may carry out their inventory using either a random or a systematic (grid-based) sample within each stratum. Systematic sampling helps ensure uniform coverage of the area sampled and can be cost efficient, but risks bias if the sampling units coincide with periodicity in the population. To minimize this risk:

- Project proponents must identify any periodic variation potentially present in the project area due to topography, management history, or other factors and document how the sampling design avoids bias that may result from these periodicities.
- If line-plot cruises or other linearly based methods are used, effort should be made to make cruise lines run perpendicular to slopes, rather than along contours, whenever possible.
- Systematic samples should employ a randomized start point.

The optimum plot size in a carbon inventory is a function of the variability in carbon stocks inherent in the population and measurement costs, including the cost of traveling between plots within the area to be measured. In general, as plot size increases, the variance in carbon stocks across plots within a population decreases. Aside from stratification, inventory precision can be improved by increasing either the size or number of plots measured. Plot size should be chosen by the project proponent based on experience with similar forest types, reviews of technical literature, and, optionally, a pilot sample. If a pilot sample is used, plots can optionally be installed using the largest plot radius under consideration and measurements of distance from plot center to each tree recorded. This allows for the synthetic construction of plots of smaller size. The required sample size to obtain the targeted precision level for each plot radius under consideration can then be computed using the appropriate equations described below. If a pilot sample is not feasible or desired, the between-plot variance of a new plot size can be estimated from the between plot variance of a known plot size using equation [B.1]. It should be noted that many project proponents perform "feasibility studies" in a potential project area; this presents an optimal opportunity to establish and measure a pilot sample and explore alternative sampling methodologies (which may require a deviation from the methods provided in this appendix).

Project proponents may use different-sized plots for different carbon pools. For example, project proponents may choose to use a nested plot design in which small trees are measured on a plot of smaller radius than the radius of the plot for large trees.

B.1.1 Stratification for Improving Sampling Efficiency

Stratification is recommended (but not strictly required) as a tool for minimizing sampling error. If two or more strata can be identified within the project area with similar carbon stocks and relatively small variance in relation to the variance of the total project area, stratification should reduce uncertainty in carbon stock estimation. The equations presented here assume stratification is used. However, if the project area is not stratified, the equations listed in this section are still applicable. In this case, all sums across strata include only a single element. The standard error equations given in this methodology assume that stratum sizes are known exactly. To ensure this assumption is valid, strata should be delineated prior to and independent of sampling. Stratification may be revised at any monitoring period prior to subsequent forest re-measurement.

B.1.2 Stratification for Delineating Harvestable Areas

A GIS analysis should be used to delineate harvestable areas considering slope, access constraints, local regulations (eg, required stream buffers or restrictions on harvest unit size), forest type, available harvest and skidding techniques, management plans, etc. Estimates of carbon stocks in merchantable tree and wood products ratios should be calculated only from data collected in strata classified as harvestable according to this analysis. Document all assumptions used to delineate harvestable areas. In the project area the sum delineated harvestable areas will probably be equal to the size of one or more project accounting areas.

B.1.3 Estimating Required Sample Size and Plot Allocation

This methodology makes no specific requirements with regard to the sample size used in a carbon stock inventory. Rather, guidelines for estimating required sample size as a function of desired precision are provided. The methodology discounts credit generation based on the magnitude of sampling error that results from an inventory. If an inventory does not achieve a desired degree of precision *ex-post*, project proponents may choose to install additional plots in order to decrease uncertainty and reduce confidence deductions, regardless of the sample sizes suggested by the equations provided in this section.

Each stratum must contain at least two sample plots. In planning inventory activities, the project proponent may use the following guidelines for estimating sample size and allocating plots to strata. This step is not required, but may be useful in planning an inventory of carbon stocks that minimizes expenditures required to achieve a specified precision level. The three methods below can be used to estimate the number of plots and allocation of those plots to strata that will maximize sampling efficiency based on the amount of information available prior to sampling. A pilot sample or literature review may be conducted to initially estimate the mean and standard deviation of carbon stocks in each stratum before making use of these guidelines. For more information on how to determine the size of a pilot sample see (Avery & Burkhart, 2002)

B.1.3.1 Proportional Allocation

If the only information available is the area of each stratum as delineated on a GIS, proportional allocation can be used. Determine the total estimated sample size $\hat{n}_{TOTAL}$ using equation [B.2], then determine the number of plots $\hat{n}_k$ in each stratum k using equation [B.3].

B.1.3.2 Neyman Allocation

If the area of each stratum as well as an estimate of the population variance of each stratum is available, Neyman allocation can be expected to improve sampling efficiency over proportional allocation, and is thus preferred. First determine the proportion of plots, w_k, that will fall in each stratum using equation [B.4]. Estimate the total sample size $\hat{n}_{TOTAL}$ using equation [B.5] where $\hat{\sigma}_k^2$ can be estimated from a pilot sample using equation [B.8]. Finally, estimate the number of plots $\hat{n}_k$ in each stratum k using equation [B.7].

B.1.3.3 Optimal Allocation

If for the area, an estimate of variance and an estimate of the relative cost of sampling is available for each stratum, optimal allocation can be used. First determine the proportion of plots, w_k, that will fall in each stratum using equation [B.6]. Estimate the total sample size $\hat{n}_{TOTAL}$ using equation [B.5] where $\hat{\sigma}_k^2$ can be estimated from a pilot sample using equation [B.8]. Finally, estimate the number of plots $\hat{n}_k$ in each stratum k using equation [B.7]. The cost estimate need not be in any particular unit, only a relative cost is required (eg, if the sampling cost of one stratum is twice that of another due to remote access, the values 1 and 2 may be used for the relative costs).

B.1.4 Estimating Means, Totals and Standard Errors for Stratified Samples

The estimated total quantity of interest within a sampled area is given by equation [B.9], where $\boldsymbol{y}_{j,k}$ is the plot-level quantity of interest from plot $\mathbf{j}$ in stratum $\boldsymbol{k}$, given in units per unit area. For example, if the quantity of interest is total carbon stock in trees, $\boldsymbol{y}_{j,k}$ would represent the result of applying an allometric equation to each measured tree in plot $\mathbf{j}$, converting to carbon units, summing the results, and dividing by the area of plot $\boldsymbol{j}$ as described in the procedures given below for estimating carbon stocks in above-ground trees. In the case of monitoring degradation in the activity-shifting leakage area, $\boldsymbol{y}_{j,k}$ is the observed degradation on a leakage plot (see section B.2.8).

The standard error of the total is estimated first by calculating the between-plot variance $\hat{\sigma}_k^2$ within each stratum using equation [B.8], then estimating the standard error using equation [B.10]. This estimate includes the finite population correction factor $\frac{N_{P,k}-\#(\mathcal{P}_k)}{N_{P,k}}$. Note that $N_{P,k}$, the total number of possible plots in stratum k, is given by dividing the area of the stratum by the plot size. The finite population correction factor can be conservatively excluded from the standard error formula and should not be used in estimating soil carbon stocks. Also note that separate variance estimators are used for line intersect samples of lying dead wood and are provided in that section below.

In the case that a project area is not stratified, the provided equations are still applicable, but summations across strata include only a single element.

B.1.5 Summing Pools and Uncertainties

Total carbon stocks within an area can be estimated by simply summing the totals estimated using the methods given below as shown in equation [B.33]. The standard error of such a sum can be estimated from the individual standard errors using equation [B.34].

B.2 Stock Estimation Techniques Applicable to Specific Carbon Pools

B.2.1 Estimating the Average Carbon in AGMT and AGOT

Variables: $c_{AGMT}^{[m]}$ and $c_{AGOT}^{[m]}$

Carbon stocks in live trees are estimated using allometric equations. Allometric equations commonly require recording the diameter at breast height and species or species group for each tree within the measurement plots. Some equations require additional measurements, such as height or wood density. When wood density measurements are required, the guidance provided by Williamson & Wiemann (2010) should be followed in data collection. Allometric equations should be chosen or developed based on the guidance in section 9.3.3. It is very important to use or develop high quality allometric equations that are applicable to the region and species being inventoried.

To ensure a consistent inventory across monitoring periods, the project proponent should clearly document tree measurement procedures, including procedures for locating and monumenting plots; recording and archiving data; calibrating equipment; including or excluding trees that fall on the edge of a plot; and rules for measuring trees that lean, have irregular stems, buttresses, or stilt roots.

Note that merchantable and non-merchantable trees are sampled using identical methods and utilize the same plots, but stock estimates for each pool must be computed separately for use in the baseline emissions model. Prior to sampling, the project proponent must conduct a GIS analysis as described in section B.1.2 to determine which strata of the project area are harvestable. Further, project proponents must document clear rules for classifying individual trees as merchantable or non-merchantable. These rules should consider, at a minimum, species, size class, and defect. Merchantability status of each measured tree should be assigned in the field, and recorded on field data sheets. Training should be provided to field crews to ensure that the application of these rules is consistent.

Project proponents may elect to use different plot sizes (ie, a nested design) for measurement of trees based on their size to improve inventory efficiency.

To estimate the average carbon stock in merchantable or non-merchantable above-ground trees:

1. Estimate the carbon stock of each measured tree using an appropriate allometric equation as given in equation [B.11] (see section 9.3.3 to determine appropriate allometric equations). Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied.
2. Sum the biomass of all trees within each plot and divide by plot area as given in equation [B.14], where $x_{i,j,k}$ is the carbon stock in tonnes CO2e of tree i on plot j in stratum k as estimated in step 3. This provides an estimate of the plot level total biomass per unit area.
3. Use equation [B.9] as discussed in section B.1.4 to estimate the average carbon stock in above-ground trees, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (2).
4. Use equations [B.8] and [B.10] to estimate the standard error of the total carbon stock in above-ground trees, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (2).

B.2.1.1 Palm Biomass

The allometric equation based methods described for trees can be applied to estimating above-ground biomass of palms as well. Table 4.A.2 of the IPCC Good Practice Guidance for Land Use, Land Use Change and Forestry provides a source of allometric equations relevant to palms. Additionally, more locally relevant equations may be available in the technical literature. Allometric equations for palms typically are based upon height, rather than diameter. Height can be measured using an electronic hypsometer, height pole, or clinometer and tape. Procedures for conducting these measurements must be clearly documented and be consistent with the expected inputs of the selected equations. Total palm biomass and its associated standard error can be calculated using the steps above as described for above-ground tree biomass.

B.2.2 Estimating the Average Carbon in AGNT

Variables: $c_{AGNT}^{[m]}$

Non-tree biomass includes grasses, sedges, herbaceous plants, woody shrubs and any trees smaller than the minimum diameter specified for using the methods described for tree biomass. Non-tree biomass can be estimated using either destructive sampling in a clipped plot, allometric equations, or a combination of the two approaches. Clip plots are appropriate for annual plants and small shrubs. Allometric equations are appropriate for perennials and large shrubs. If both methods are used simultaneously, clear rules must be established to ensure no double counting of non-tree biomass occurs.

B.2.2.1 Destructive Sampling Method

In this method, above-ground biomass is estimated by harvesting the biomass in a plot of known area, drying and weighing the harvested sample, and calculating the mass per unit area. Alternatively, wet mass may be measured on each plot and empirically adjusted to compensate for moisture content. These plots constitute separate measurement units from the plots used for tree biomass estimation, though they may exist inside the tree plot. The area of the clipped plot will typically be much smaller than the area of tree biomass plots and may be selected by the project proponent. Large plots allow for more precision in the estimation of carbon stocks, but require more effort to sample. If permanent plots are used, the location of the clip plot within the larger tree plot should not be the same during each measurement period to avoid bias that may result from clipping the same area during each measurement period, as repeated clipping may impact the productivity of the site. If the plot happens to fall in a location with little to no non-tree biomass (for example, because a large tree occupies most of the plot area), the plot should not be moved. In the field, a sampling frame can be placed over the ground to accurately determine the area to be clipped. All vegetation originating within this frame should be clipped to a consistent height above the ground, preferably as near to ground level as is feasible. Each sample should then be dried and weighed.

1. Clip all above-ground biomass within each clip plot and determine its dry mass. This can be done by either (a) collecting biomass and later drying and weighing it in a lab, or (b) collecting a representative and well mixed subsample of biomass to estimate average moisture content. This subsample is then dried and weighed in the lab and equation [B.16] can be used to estimate the dry biomass.
2. Estimate the plot level carbon stock in tonnes CO2e on each plot using equation [B.15].
3. Use equation [B.9] as discussed in section B.1.4 to estimate the average carbon stock in above-ground non-tree biomass, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (2).
4. Use equations [B.8] and [B.10] to estimate the standard error of the total carbon stock in above-ground non-tree biomass, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (2).

B.2.2.2 Allometric Equation Method

Allometric equations can be applied to estimate the above-ground biomass of non-trees. These equations might be size-class or species-specific, and may be based on, eg, stem diameter, percent cover, or number of stems. The general procedure for estimating carbon stocks in above-ground trees is applicable to non-trees when applying allometric equations.

1. Estimate the carbon stock represented by each measurement using an appropriate allometric equation as given in equation [B.12] (see section 9.3.3 to determine appropriate allometric equations). Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied.

2. Sum the biomass of all trees within each plot and divide by plot area as given in equation [B.14], where $x_{i,j,k}$ is the carbon stock in tonnes CO2e of tree i on plot j in stratum k as estimated in step 3. This provides an estimate of the plot level total biomass per unit area.

3. Use equation [B.9] as discussed in section B.1.4 to estimate the average carbon stock in above-ground non-tree biomass, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (4).

4. Use equations [B.8] and [B.10] to estimate the standard error of the total carbon stock in above-ground trees, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (4).

B.2.3 Estimating the Average Carbon in BGMT, BGOT and BGNT

Variables: $c_{BGMT}^{[m]}$, $c_{BGOT}^{[m]}$, and $c_{BGNT}^{[m]}$

Below-ground biomass is estimated by applying a root to shoot ratio (such as those given in Table 4.4 of the IPCC Guidelines for NI Greenhouse Gas Inventories) or equation (such as those documented by Cairns et al 1997) to the above-ground biomass estimate for the above-ground large tree, above-ground small tree, and above-ground non-tree carbon pools. Ratios or equations are to be selected by the project proponent. They must be suited to the region and vegetation type to which they are to be applied and must be justified by the project proponent through a review of peer-reviewed scientific literature or through supporting field evidence.

1. Estimate the above-ground carbon stock of the relevant pool (trees or non-tree biomass) using the guidance of that section.

2. Estimate the below-ground biomass by multiplying the selected root: shoot ratio by the above-ground biomass estimate (when a ratio is selected), or by applying the selected equation to the above-ground estimate for each tree or non-tree carbon stock estimate.

3. Sum the below-ground biomass of all measurement units within each plot and divide by plot area as given in equation [B.14] where $x_{i,j,k}$ is the below-ground carbon stock in tonnes CO2e of tree i on plot j in stratum k as estimated in step 3. This provides an estimate of the plot level below-ground biomass per unit area.

4. Use equation [B.9] as discussed in section B.1.4 to estimate the average carbon stock in below-ground biomass, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (3).

5. Use equations [B.8] and [B.10] to estimate the standard error of the total carbon stock in below-ground biomass, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (3).

B.2.4 Estimating the Average Carbon in SD

Variables: $c_{SD}^{[m]}$

Carbon in standing dead wood is estimated on fixed area plots by first categorizing standing dead trees into two decomposition classes:

- Trees with branches and twigs that resemble live trees (except for leaves) (Class I)
- Trees that show loss of twigs, branches or bole mass (Class II)

B.2.4.1 Decay Class I

The carbon stock in trees of decay Class I (intact trees) is estimated using the allometric equation approach as described for live trees:

1. Estimate the carbon stock represented by each tree using an appropriate allometric equation as given in equation [B.13] (see section 9.3.3 to determine appropriate allometric equations). Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied.

B.2.4.2 Decay Class II

The carbon stock of standing trees in decay Class II is conservatively estimated as the biomass in only the remaining bole. Diameter at breast height and height and density should be measured on each tree in decomposition class 2. The diameter at the top of the stem can be measured using a relascope or similar instrument, or it can be conservatively assumed to be zero. Wood density should be estimated using a sample taken from each tree. See Williamson & Wiemann (2010) for proper techniques for estimating specific gravity and converting between specific gravity and density estimates. The volume of the bole of each dead tree is then estimated as the frustum of a cone. To estimate the carbon stock for each decay Class II dead tree:

1. Estimate the volume of the bole using equation [B.17].
2. Estimate the carbon stock for each dead tree using equation [B.18] where $v_{i,j,k}$ is the volume of the i^{th} tree in decay class II in plot j, stratum k as calculated in step (1).

B.2.4.3 Total Standing Dead Wood

To estimate the total carbon stock in the standing dead pool:

1. Sum the carbon stocks of dead trees within each plot (both decay Class I and decay Class II) and divide by plot area as given in equation [B.14] where $x_{i,j,k}$ is the carbon stock in tonnes CO2e of tree i on plot j in stratum k as estimated for the relevant decay class as described above. Use trees in both decay classes for this summation. This provides an estimate of the plot level total biomass per unit area.
2. Use equation [B.9] as discussed in section 6.5.5 to estimate the average carbon stock in standing dead wood, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (1).

3. Use equations [B.8] and [B.10] to estimate the standard error of the total carbon stock in above-ground standing dead wood, where $y_{j,k}$ is the plot level estimate of CO2e/ha produced in step (1).

B.2.5 Estimating the Average Carbon in LD

Variables: $c_{LD}^{[m]}$

Lying dead wood is sampled using the line intersect method. At each plot, establish two transects of at least 50m length through the plot center. The first transect should be oriented at a random angle, while the second transect should be oriented perpendicularly to the first transect. Record the diameter and density class of each piece of lying dead wood that intersects the vertical plane established by each transect. The diameter should be measured at the point of intersection. If a piece of lying dead wood is forked and intersects the transect at more than one point, each point of intersection should be recorded separately. The minimum measurement diameter may be established on a project-specific basis, but should be documented and held constant across all measurement periods. Each piece of measured wood should be classified as sound, intermediate or rotten using the machete test as recommended by the IPCC Good Practice Guidance for Land-Use, Land Use Change and Forestry (4.3.3.5.3) (IPCC, 2006). The mean oven dry density of dead wood, $\bar{\rho}_d$, in each decay class d, must be estimated as the mean of a sample taken down logs within the project area. See Williamson & Wiemann (2010) for proper techniques for estimating specific gravity and converting between specific gravity and density estimates. The sample should be large enough to achieve a standard error of the mean within +/- 15% at a 95% confidence level.

1. Estimate the total carbon stock $y_{j,k}$, per unit area for stratum k transect j as equation [B.19] where $x_{i,j,k,d}$ is the diameter of the i^{th} piece of lying dead wood equation in density class d, transect j, stratum k.
2. From $y_{j,k}$, estimate y_k, the total carbon stock in lying dead wood in stratum k as equation [B.20].
3. From $y_{j,k}$, estimate the variance of carbon in lying dead wood in stratum k,$\hat{\sigma}_k^2$, as equation [B.21].
4. Estimate the average stock in lying dead wood as equation [B.22].
5. Estimate the standard error of the total carbon stock in lying dead wood U_{LD} as equation [B.23].

The estimation of carbon in lying dead wood may be conservatively omitted at the discretion of the project proponent.

B.2.6 Estimating the Average Soil Organic Carbon

Variables: $c_{SOC}^{[m]}$

When the soil carbon pool is selected, soil carbon must be measured using a purposive sample in the proxy areas and a random sample in the project accounting areas. In designing this sample, project proponents should take care to ensure that the sampling scheme incorporates all types of land use and states that occur within the proxy area under the baseline scenario (ie, fallow fields, active fields, etc.). To derive a representative sample and reduce uncertainty, it is recommended that the proxy area be stratified (eg, soil taxonomic class, landscape position, land use) and the ensuing sampling scheme be designed according to these strata. A stratified random approach is suggested in order to achieve maximum explanation of agricultural variance in the reference area. The stratification scheme and sample size applied for estimation of soil carbon may be different from that used for estimation of carbon in biomass pools. It is further suggested that samples are taken from similar strata in the project area and reference area, so as to achieve an accurate comparison of different land use types present in the project ecosystem. Further guidance on sample allocation (eg, Neyman allocation) can be found section B.1.2 above.

Estimation of soil carbon stocks requires collection of soil samples from the field that are later analyzed in a laboratory. In general, three variables are required to estimate soil carbon content: bulk density, the organic carbon content, and soil depth. Multiple aliquots of soil, from different depths, may be measured separately, but when calculating the number of plots for the purpose of calculation statistical confidence intervals each location only counts as one sample. Soil carbon stocks are typically not estimated over the entire depth of the soil column, but are rather estimated in the upper horizons of the soil where the majority of soil carbon is present. Sample depth may be selected by the project proponent, but a consistent total depth for soil sampling should be established, and this depth should be no less than the depth to which soil is disturbed during farming, typically a minimum of 30cm.

Samples may be extracted using a soil core or by digging a soil pit. Because of the high degree of spatial variability in soil carbon stocks, it is recommended that several samples be taken from different randomly selected locations within each sampling site (ie, farm reference region or stand in project area) and mixed prior to measurement in the laboratory. Alternatively, several samples for different soil horizons may be analyzed separately and analysis results combined after-the-fact. If soil pits are used, multiple horizons should be extracted (at least 3 are recommended) to ensure that the soil is being measured to a sufficient spatial resolution along its depth. Bulk density and carbon concentration should be measured for each individual soil horizon, as it is important to apply these individual measurements to achieve mass-equivalent measurement. A consistent total depth for soil sampling should be established, and this depth should be no less than the depth to which soil is disturbed during farming, typically a minimum of 30cm. In soils with coarse fragments (> 2mm), both density and carbon concentration should be based on the fine fraction of the soil. To accomplish this, the soil sample must be sieved through a 2mm sieve, with the volume of coarse fragments determined separately (by water immersion or by weighing the fragments and dividing by the density of rock fragments, often given as 2.65 g/65). See correction factor in equation [B.27]. Also, the density of fine soil can be calculated by dividing the mass of fine soil by the total volume of the sample, without separate calculation of the volume or mass of coarse fragments. Whatever method used, it should be completely documented and consistently applied.

If bulk density for the within-project measurements differs significantly from the reference area measurements (such as due to compaction that results from harvesting operations), measurements should be evaluated on a mass-equivalent basis. See Ellert, Janzen & Entz, (2002) and Ellert & Bettany (1995) for appropriate methods.

The guidance provided in section 4.3.3.5.4 of the GPG-LULUCF (IPCC, 2006) should be adhered to when choosing laboratory methods for analyzing soil carbon content. Bulk density and carbon concentration should be evaluated by a laboratory that follows internationally recognized standards (eg, FAO standards) to minimize errors and bias.

To collect field samples suitable for laboratory estimates of organic carbon:

1. Remove all vegetation and litter from the surface of the selected sample location. Including even small amounts of surface organic material can significantly bias estimates of soil carbon stocks.
2. Insert a soil carbon probe to the selected depth (typically 30cm), using a rubber mallet if necessary due to soil compaction.
3. Extract soil from the corer or probe into a bag and clearly label with the sampling location and an indicator that the sample is for soil carbon determination (rather than bulk density)
4. It is recommended that this process be repeated several times at each sampling location (eg, each plot may contain four separate SOC samples) and results aggregated to reduce the impact of small scale spatial variability in soil carbon content.
5. Send the sample to a laboratory for organic carbon analysis.

To collect field samples suitable for laboratory analysis of bulk density:

1. Dig a soil pit at each sampling location to at least the selected soil sampling depth (typically 30 cm).
2. Insert a soil ring with known volume into the side of the pit to collect a known volume of soil. Care should be taken to ensure no soil falls from the ring, but do not pack soil into the ring.
3. Take additional samples throughout the depth of the pit to represent the change in bulk density with depth. For example, in a 30 cm pit one sample may be taken at the midpoint of the upper half of the sampling pit and a second sample and the midpoint of the lower half of the pit. Each sample increment should be taken from a different, undisturbed vertical column of soil from the side of the pit.
4. Combine the soil samples taken in a bag clearly labeled as a bulk density sample and record the representative volume of soil (volume of the ring multiplied by the number of rings taken.

5. Send the sample to a laboratory for bulk density analysis.

To estimate the total stock in soil carbon:

1. Calculate the corrected bulk density for each plot using equation [B.27].
2. Estimate the soil carbon stock per unit area, $SOC_{j,k}$, for plot j, stratum k using equation [B.28].
3. Estimate the average stock in soil carbon as equation [B.9].
4. Estimate the variance within each stratum as equation [B.8].
5. Estimate the standard error of the total carbon stock in soil carbon as equation [B.10], excluding the finite population correction factor $\left(\frac{N_{P,k}-\#(\mathcal{P}_k)}{N_{P,k}}\right)$.

B.2.7 Estimating the Proportion of Carbon in Slash and Wood Product Classes

Variables: $p_{SL}^{[m]}$, $p_{sawnwood}^{[m]}$, $p_{panels}^{[m]}$, $p_{roundwood}^{[m]}$, $p_{paper}^{[m]}$

Merchantable volume is used to compute carbon stocks in log production. These estimated stocks can then be compared to the total carbon in merchantable trees as described in section C.1 to estimate wood products ratios that are used in accounting for carbon stocks in long lived wood products. Measurements required for these calculations can be taken on the same plots used for carbon stock estimation. When sampling is used to estimate wood product ratios for input into harvested wood products calculations, project proponents must stratify the area to determine which areas are harvestable according to the guidance provided in section B.1.2. Data used for calculations in this section should be taken only from strata classified as harvestable.

For each merchantable tree measured in the field, record its likely product class among the following:

1. Sawnwood (dimension lumber, etc.)
2. Woodbase panels (plywood, decorative panels, etc.)
3. Other industrial roundwood (poles, pilings, fence posts, etc.)
4. Paper and paperboard

Determination of likely product classes should be based on local knowledge of markets and should consider, at a minimum, species, size class, and defects. Determine of likely product classes should be based on local knowledge of markets and should consider, at a minimum, species, size class, and defects. Merchantability should also consider the cost of extraction and where the cost of logging and transportation is greater than the market value of the wood, the trees should be classified as non-merchantable. Project proponents must document rules for assigning trees to product classes based on relevant local knowledge and training should be provided to field crews to ensure consistent application of these rules. Documented rules for merchantability should be applied consistently for a given monitoring period.

For each merchantable tree species, a volume equation must be selected. If locally derived volume equations or tables are available they should be used, with field sampling designed to collect the specific data required by the selected equation or table. Project proponents should document the source and justify the applicability of all volume equations utilized. If locally derived equations are not available, volume can be estimated using the equations provided in this methodology.

1. On each merchantable tree per measurement plot record the DBH, merchantable height, top diameter (or a fixed diameter that defines merchantable height), species, and likely product class. This can be done while making measurements for total above-ground carbon as described in section B.1.
2. Calculate the total above-ground carbon stock of each measured tree using an allometric equation as described in step (1) of section B.2.1.
3. Calculate the merchantable volume of each measured tree using equation [B.17] or a locally relevant equation or volume table.
4. Calculate the carbon stock in the merchantable part of the bole using equation [B.18] where $v_{i,j,k}$ is the volume of the i^{th} tree in plot j, stratum k as calculated in step (3).
5. Confirm that the carbon stock in the merchantable part of the bole is less than the carbon stock in the total above-ground biomass of the tree. If it is not, investigate the volume and allometric equations selected and check for calculation errors.
6. Calculate the carbon stock in slash by subtracting the bole carbon stock calculated in step (4) from the total carbon stock calculated in step 2 as given in equation [B.29].
7. For each plot, estimate the total carbon stock in slash and in the merchantable boles of each category and divide by plot area as given in equation [B.14] where $x_{i,j,k}$ is the carbon stock in either slash(step 6) or the merchantable part of the bole (step 4) as appropriate. This results in 5 quantities per plot ($c_{SL,j,k}$, $c_{sawnwood,j,k}$, $c_{panels,j,k}$, $c_{roundwood,j,k}$, and $c_{paper,j,k}$).
8. For each of the 5 quantities estimated in step 7 use equation [B.9] as discussed in section B.1.4 to estimate the total carbon in the relevant category where $y_{j,k}$ is the plot level estimate in tCO2e/ha produced in step (7).
9. Calculate the wood products ratio for each category by dividing the estimate of total carbon in the relevant category as calculated in step (8) by the sum of the five totals as given in equation [B.30]. The five resulting ratios should sum to 1.0.

B.2.8 Estimating Proportion of Degradation in Forests

Degradation in the activity-shifting leakage area must be assessed by a visual sample on plots within the activity-shifting leakage area. This sample is used at the end of the first monitoring period in order to estimate the lag period for the leakage model and at every subsequent monitoring period in order to estimate actual emissions due to leakage. Because the leakage area is unlikely to be under the control of the project proponent, the sampling methods described are designed to be fast and require no modification to the site. Project proponents must be able to access the leakage area, however, to perform the required sampling.

Within the activity-shifting leakage area, randomly select a sample of point locations with uniform probability with a minimum sample size $\hat{m}_L$ determined by equation [B.31]. These point locations become the corners of the fixed-area plots used to estimate degradation, deforestation and conversion in the leakage area permanently throughout the project lifetime. Select plot dimensions so that each plot area is large enough that degradation will be observed if degradation is occurring on the adjacent landscape. It is recommended that plots be at least one hectare (eg, a 100m x 100m square plot). The dimensions of all plots should be the same. Visit these plots to observe the proportion of degradation. The proportion of degradation can be estimated using either (a) estimates of crown cover taken with a spherical densitometer (for forested baseline types); (b) visual estimates of degradation.

Neither the plot boundaries nor locations should be visibly marked on the ground, as they most likely exist in areas outside the project's control and visible marking may lead to preferential treatment of these plots. Rather, they should be monumented using a GPS and optionally a buried monument.

These sample plots must be observed at least every five years to estimate leakage. Use equation [B.9] to estimate $p_{L\ DEG}$ where $y_{j,k}$ are plot-level measurements of degradation obtained using either method described below.

Regardless of the method applied, uncertainty in measurement should be reduced as much as possible by developing a field protocol for sampling forest degradation. Training should be provided to collection teams.

B.2.9 Spherical Densiometer Method

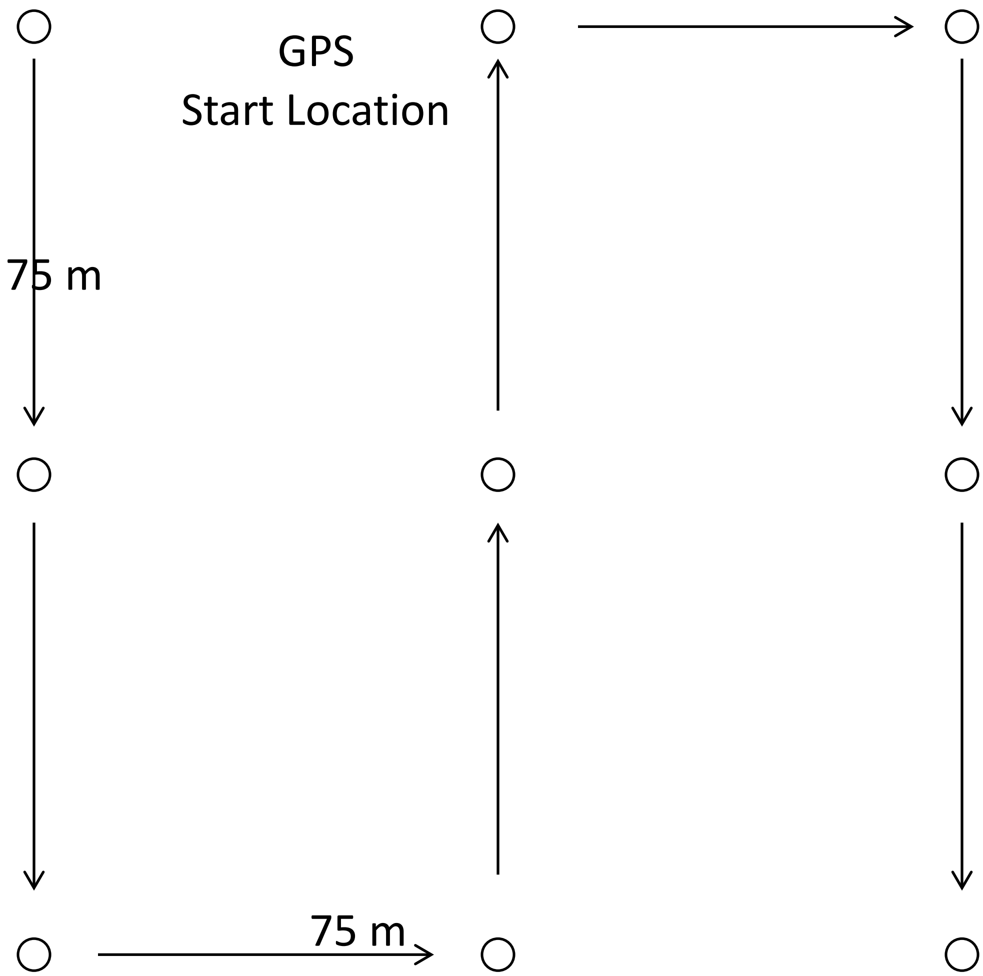
A spherical densitometer consists of a small hemispherical mirror engraved with a grid and is used to estimate crown closure by counting portions of the grid through which canopy gaps are visible. This method can be used for forested baseline types (F-P1.a, F-P1.b, F-P2, F-U1, F-U2 and F-U3). The spherical densiometer method of estimating percent degradation is more repeatable and less subjective than visual assessment, and thus should be preferred when feasible. At times, however, estimating degradation using this method will not be possible. For example, in drought-deciduous forests the dry season is most suitable for fieldwork, but at this time the canopy is in a leaf-off condition.

To use this method, crown cover must be estimated in both the leakage area and in non-degraded forest within the project area.

1. Navigate to the randomly determined plot location with a GPS.

2. Using a compass, walk a predetermined path through the degradation plot, stopping periodically to take crown cover estimates. A potential crown cover sampling scheme is illustrated in Figure 19.
3. Calculate the proportion of degradation in each leakage plot by dividing the average canopy cover in the leakage area plot by the average canopy cover measured in undegraded strata of the project area estimated using the same procedure.

Figure 19: Plot Sampling Scheme for Spherical Densiometer



In this sampling scheme, the random GPS start location is located at the northwest corner of the plot. By pacing and using a compass, the observer walks the perimeter and center of the 2.25 hectare plot and observes crown cover at 9 points in the plot, as illustrated. Crown cover should be observed according to the instructions provided with the spherical densiometer and converted to a percent. This typically involves mentally subdividing each grid cell on the densiometer into four smaller points and counting the number of points in which canopy openings are visible. The most common densiometers have 24 large squares which are then subdivided into a total of 96 points. The percent cover for these densiometers can be given by equation [B.32]. It is good practice to take four densiometer readings at each observation point, one facing in each cardinal direction, and average the results. The percent crown cover from all readings made within a plot should be averaged (ie, nine points with four readings at each point), with that average constituting a single observation for the entire plot.

B.2.10 Visual Estimates of Degradation

If the densiometer method is not practical, visual estimates of degradation can be made in the leakage area. Walk throughout each plot in the leakage area and observe the percentage of above-ground biomass that is absent as evidenced by presence of stumps for each plot area. Record a factor for each plot using the following ordinal scale in Table 10. Note that for native grassland baseline types (G-P2, G-U1 and G-U2), the ordinal scale may be confined to either 0 or 1 (not converted and converted, respectively). Also note that for native grassland baseline types, visual estimates of degradation may be obtained using remote-sensing data (such as Geo-Eye or Ikonos imagery).

Table 7: Factors for Visually Estimating Degradation.

Factor	Proportion of degradation
0.0	0%
0.2	0-19%
0.4	20-39%
0.6	40-59%
0.8	60-79% (severe degradation)
1.0	80-100% (including complete conversion)

Protocols for estimating the percentage of absent biomass must be developed by the project proponent and their conservativeness justified at validation and verification.

B.2.11 Estimating Activity-Shifting Leakage in Grasslands

Monitoring methods for activity-shifting leakage must use a land-use land-cover classification of the appropriate leakage area(s) to determine the land use conversion from native grasslands in these areas. This land-cover classification may be a supervised, pixel-based classification or use a point interpretation approach as in section 6.8. It should be noted that the activity-shifting leakage model is separate and unrelated to the BEM, and we suggest this choice of remote sensing classification types only for the activity-shifting leakage model. As stated in section 6.8.6, the BEM does not support automated, pixel-by-pixel classification techniques, and project proponents should not attempt to replace or sidestep manual image interpretation for the BEM with an automated process such as a maximum likelihood or nearest neighbor classifier. That said, whichever approach is selected for the activitiy shifting leakage model, it must meet the minimum tolerances for precision and accuracy required when constructing the project baseline.

If in the baseline native grasslands exist in a degraded state longer than a given monitoring period (eg, due to overgrazing), the project proponents must install permanent monitoring plots in the unconverted portion of the activity-shifting leakage area(s). All selected pools for native grasslands must be measured in these plots.

B.3 Guidelines for Determining Livestock Populations Within Project Area

A complete list of all livestock species and populations present within the project area boundary should be compiled. To determine the number of heads of livestock being grazed within the project area boundary, it is recommended that the project proponents conduct an inventory of the number of livestock within each species category. This may involve directly counting each animal that is grazed within the project area, if possible. The number of livestock heads that are grazed within the project area should accurately reflect changes in population size due to deaths or population growth. It is always conservative to overcount the number of headsof livestock grazed within the project area.

If the proposed method of inventory is impractical for determining the number of livestock grazed within the project area, the project proponent may choose to employ an alternative sampling scheme that they have determined to improve sampling efficiency. Any deviations from a direct count of individual livestock must be justified within the monitoring report per current VCS requirement. All samples must give an estimate of the number of heads of livestock by species with an overall precision of +/- 15% at the 90% confidence level.

B.4 Guidelines for Developing Allometric Equations

Allometric equations for shrubs can be developed by harvesting a representative sample from the project area, drying and weighing the sample, and relating the sampled biomass to variables easily measured in the field. The independent variables that are suitable for predicting shrub biomass may vary across environments and vegetation types and may include but are not limited to number of stems, stem diameter, height, size class, crown diameter, and percent cover. In some situations, developing a continuous equation that represents shrub mass as a function of one or more of the above variables is not practical. In this case, a simple average of the biomass of the sample collected per stem or per plant can be used instead. Where appropriate to project vegetation types, separate averages for different size classes and species of shrubs should be used.

When developing allometric equations for trees, measurements of tree volume, density or biomass must be made across a range of tree sizes. Models must be used to predict biomass based on covariate metrics such as diameter, height and specific gravity.

All allometric equations must be validated per section 9.3.3.2.

B.5 Minimizing Uncertainty and Collecting Consistent Data

To ensure that carbon stocks are estimated in a way that is accurate, verifiable, transparent, and consistent across measurement periods, the project proponent must establish and document clear standard operating procedures and procedures for ensuring data quality. At a minimum, these procedures must include:

- Comprehensive documentation of all field measurements carried out in the project area. This document must be detailed enough to allow replication of sampling in the event of staff turnover between monitoring periods.
- Training procedures for all persons involved in field measurement or data analysis. The scope and date of all training must be documented.
- A protocol for assessing the accuracy of plot measurements using a check cruise and a plan for correcting the inventory if errors are discovered.
- Protocols for assessing data for outliers, transcription errors, and consistency across measurement periods.
- Data sheets must be safely archived for the life of the project. Data stored in electronic formats must be backed up.

B.6 Equations for Carbon Stock Measurement

$$\hat{\sigma}_2^2 = \hat{\sigma}_1^2 \sqrt{\frac{a_1}{a_2}}$$ [B.1]	
Variables	$\hat{\sigma}_2^2$= variance of plot of size 2 (unknown plot) $\hat{\sigma}_1^2$ = variance of plot size 1 (known plot) a_1 = area of plot of size 1 a_2 = area of plot of size 2
Section References	B.1
Comments	This equation is used to estimate the effect of changing plot area on between-plot variance. a_1 is assumed to be a plot area associated with an estimated variance $\hat{\sigma}_1^2$, while a_2 is the plot area for which variance is to be estimated. Freese (1962)

$$\hat{n}_{TOTAL} = \frac{1}{\left(\frac{0.15 \times \bar{x}}{1.96 \times \hat{\sigma}_{\bar{x}}}\right)^2 + \frac{a_{plot}}{\sum_{k \in \mathcal{S}} A_k}}$$ [B.2]

Variables	$\hat{n}_{TOTAL}$ = estimated total number of plots required $\bar{x}$ = estimated mean of a quantity to be sampled in the area $\hat{\sigma}_{\bar{x}}$ = estimated standard deviation of a quantity to be sampled in the area a_{plot} = area of a plot $\mathcal{S}$ = set of all strata in the area. A_k = area of stratum k $\mathcal{S}$ = set of all strata in the area.
Section References	B.1.3.1
Comments	This equation is used to estimate sample size when stratum-specific estimates of standard deviation are unavailable. 0.15 represents an allowable error of 15% of the mean, while 1.96 represents the Z statistic from a normal distribution associated with the 95% confidence level. Avery & Burkhart (2002)

$$\hat{n}_k = \hat{n}_{TOTAL} \frac{A_k}{\sum_{k \in \mathcal{S}} A_k} \quad [B.3]$$

Variables	$\hat{n}_k$ = estimated total number of plots required in stratum k $\hat{n}_{TOTAL}$ = estimated total number of plots required A_k = area of stratum k $\mathcal{S}$ = set of all strata in the area.
Section References	B.1.3.2
Comments	This equation is used to estimate the required number of plots in stratum k under proportional allocation. Avery & Burkhart (2002)

$$w_k = \frac{A_k \hat{\sigma}_k}{\sum_{j \in \mathcal{S}} A_j \hat{\sigma}_j} \quad [B.4]$$

Variables	w_k = the proportion of plots allocated to stratum k A_j or A_k = area of stratum j or k $\hat{\sigma}_j$ or $\hat{\sigma}_k$= estimated standard deviation of a quantity to be sampled in stratum j or k $\mathcal{S}$ = set of all strata in the area.
Section References	B.1.3.2

Comments	This equation is used to estimate the proportion of plots in each stratum under Neyman allocation. Avery & Burkhart (2002); Shiver & Borders (1996)

$$\hat{n}_{total} = \frac{\sum_{k \in \mathcal{S}} \frac{A_k^2 \hat{\sigma}_k^2}{w_k}}{\left(\frac{0.15 \times \sum_{k \in \mathcal{S}} A_k \times \bar{x}}{1.96 \times a_{plot}}\right)^2 + \sum_{k \in \mathcal{S}} A_k \, \hat{\sigma}_k{}^2}$$ [B.5]	
Variables	$\hat{n}_{TOTAL}$ = estimated total number of plots required (count) A_k = area of stratum k w_k = the proportion of plots allocated to stratum k $\bar{x}$ = estimated mean of a quantity to be sampled in the project area $\hat{\sigma}_k$= estimated standard deviation of a quantity to be sampled in stratum k $\mathcal{S}$ = set of all strata in the area
Section References	B.1.3.2, B.1.3.3
Comments	This equation is used to estimate the total sample size of a stratified sample. Avery & Burkhart (2002); Shiver & Borders (1996)

$$w_k = \frac{A_k \hat{\sigma}_k / \sqrt{c_k}}{\sum_{j \in \mathcal{S}} A_j \, \hat{\sigma}_j / \sqrt{c_j}}$$ [B.6]	
Variables	w_k = the proportion of plots allocated to stratum k A_j or A_k = area of stratum j or k $\hat{\sigma}_j$ or $\hat{\sigma}_k$= estimated standard deviation of a quantity to be sampled in stratum j or k $\mathcal{S}$ = set of all strata in the area. c_j or c_k= estimated cost of sampling carbon stocks in stratum j or k
Section References	B.1.3.3
Comments	This equation is used to estimate the proportion of plots in each stratum under optimal allocation. Shiver & Borders (1996)

$$\hat{n}_k = \hat{n}_{TOTAL} w_k$$ [B.7]

Variables	$\hat{n}_{TOTAL}$ = estimated total number of plots required $\hat{n}_k$ = estimated total number of plots required in stratum k w_k = the proportion of plots allocated to stratum k
Section References	B.1.3.3
Comments	This equation is used to estimate the number of plots in each stratum. Shiver & Borders (1996)

$$\hat{\sigma}_k^2 = \frac{\sum_{j\in\mathcal{P}_k}(y_{j,k})^2 - \left(\sum_{j\in\mathcal{P}_k} y_{j,k}\right)^2/\#(\mathcal{P}_k)}{\#(\mathcal{P}_k)-1}$$ [B.8]	
Variables	$\hat{\sigma}_k^2$ = estimated variance in stratum k $y_{j,k}$= a quantity estimated for or measured on plot j in stratum k $\mathcal{P}_k$ = set of all plots in stratum k
Section References	B.1.4
Comments	The equation is used to estimate the within-stratum variance of the variable y for stratum k.

$$z = \frac{1}{\sum_{k\in\mathcal{S}} A_k}\sum_{k\in\mathcal{S}}\frac{A_k}{n_k}\sum_{j\in\mathcal{P}_k} y_{j,k}$$ [B.9]	
Variables	z = the estimated average in the sampled area, for carbon this is c and for degredation this is $p_{L\ DEG}$ A_k = the area of stratum k n_k = number of plots in stratum k $y_{j,k}$= a quantity estimated for or measured on plot j in stratum k $\mathcal{P}_k$ = set of all plots in stratum k $\mathcal{S}$ = set of all strata
Section References	B.1.4, B.2.1, B.2.2.2, B.2.3, B.2.4.3, B.2.6, B.2.7
Comments	This is a generic equation used to estimate totals from plot level estimates.

$$\text{U} = \sqrt{\sum_{k\in\mathcal{S}}\left[\frac{A_k^2\hat{\sigma}_k^2}{\#(\mathcal{P}_k)}\left(\frac{N_{P,k}-\#(\mathcal{P}_k)}{N_{P,k}}\right)\right]}$$ [B.10]

Variables	U = estimated standard error of the total for the selected carbon pool $\hat{\sigma}_k^2$ = estimated variance in stratum k A_k = area of stratum k $N_{P,k}$ = total number of possible plots in stratum k $\mathcal{P}_k$ = set of all plots in stratum k $\mathcal{S}$ = set of all strata in the area
Section References	B.2.1, B.2.2.1, B.2.2.2, B.2.3, B.2.4.3, B.2.6,
Comments	This equation is used to estimate the standard error of the total from a stratified sample from a finite population. Shiver & Borders (1996)

$$x_{i,j,k} = \frac{44}{12} \times \frac{1}{1{,}000} \times f_{SPC}(\bullet) \times p_{CF\ SPC} \quad [B.11]$$

Variables	$x_{i,j,k}$ = carbon stock in CO_2e represented by tree i on plot j in stratum k $f_{SPC}(\bullet)$ = allometric equation for species SPC $p_{CF\ SPC}$= carbon fraction for species SPC
Section References	B.2.1
Comments	This equation is for the determination of the above-ground carbon stock for each measured tree in the AGOT and AGMT carbon pools using an allomtetric equation. This equation is used to estimate the carbon stock for the i^{th} tree in plot j, stratum k. Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied. Carbon fraction for species SPC are unitless. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1{,}000}$ represents a conversion from kg to tonnes.

$$x_{i,j,k} = \frac{44}{12} \times \frac{1}{1{,}000} \times f_{SPC}(\bullet) \times p_{CF\ SPC} \quad [B.12]$$

Variables	$x_{i,j,k}$ = carbon stock in CO_2e represented by tree i on plot j in stratum k $f_{SPC}(\bullet)$ = allometric equation for species SPC $p_{CF\ SPC}$= carbon fraction for species SPC
Section References	B.2.2.2
Comments	This equation is for the determination of the above-ground carbon stock for the non-tree (AGNT) carbon pool using an allomtetric equation. This equation is used to estimate the carbon stock for the i^{th} non-tree in plot j, stratum k. Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied. Carbon fraction for species SPC are unitless. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1,000}$ represents a conversion from kg to tonnes.

$$x_{i,j,k} = \frac{44}{12} \times \frac{1}{1,000} \times f_{SPC}(\bullet) \times p_{CF\ SPC} \quad [B.13]$$

Variables	$x_{i,j,k}$ = carbon stock in CO_2e represented by tree i on plot j in stratum k $f_{SPC}(\bullet)$ = allometric equation for species SPC $p_{CF\ SPC}$= carbon fraction for species SPC
Section References	B.2.4.1
Comments	This equation is for the determination of the above ground carbon stock for each measured standing dead tree with decay class I using an allomtetric equation. This equation is used to estimate the carbon stock for the i^{th} standing dead wood in plot j, stratum k. Note that this equation assumes the selected allometric equation computes biomass in kilograms, and may need to be modified if equations with other units are applied. Carbon fraction for species SPC are unitless. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1,000}$ represents a conversion from kg to tonnes.

$$y_{j,k} = \frac{1}{a_{j,k}} \sum_{i \in \mathcal{X}_{j,k}} x_{i,j,k}$$ [B.14]	
Variables	$y_{j,k}$= a quantity estimated for or measured on plot j in stratum k $a_{j,k}$ = area of plot j in stratum k $x_{i,j,k}$ = a quantity estimated for or measured for individual i on plot j in stratum k $\mathcal{X}_{j,k}$ = set of all measurements of a type in plot j in stratum k
Section References	B.2.1, B.2.2.2, B.2.3, B.2.4.3, B.2.7
Comments	This is a generic equation used to estimate plot level totals expressed per unit area from measurements made on individuals.

$$y_{j,k} = \frac{44}{12} \times \frac{1}{1{,}000} \times \frac{p_{CF\ SPC} \times m_{dry,j,k}}{a_{j,k}}$$ [B.15]	
Variables	$y_{j,k}$ = carbon stock in non-tree biomass that results from a destructive sample $p_{CF\ SPC}$ = carbon fraction for species SPC $a_{j,k}$ = area of plot j in stratum k $m_{dry,j,k}$ = dry mass of non-tree sample harvested from clip plots in plot j, stratum k
Section References	B.2.2.1
Comments	This equation is used to estimate the carbon stock in non-tree biomass that results from a destructive sample. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1{,}000}$ represents a conversion from kg to tonnes.

$$m_{dry,j,k} = m_{wet,j,k} \frac{m_{dry,subsample}}{m_{wet,subsample}} \quad [B.16]$$

Variables	$m_{dry,j,k}$ = dry mass of non-tree sample harvested from clip plots in plot j, stratum k $m_{wet,j,k}$ = wet mass of non-tree sample harvested from clip plots in plot j, stratum k $m_{dry,subsample}$ = dry mass of subsample of non-tree biomass collected to estimate dry:wet ratio $m_{wet,subsample}$= wet mass of subsample of non-tree biomass collected to estimate dry:wet ratio
Section References	B.2.2.1
Comments	This equation is used to estimate dry biomass as a function of the ratio of dry to wet biomass in a subsample of harvested vegetation.

$$v_{i,j,k} = \frac{\pi h_{i,j,k}(r^2_{BASE,i,j,k} + r^2_{TOP,i,j,k} + r_{BASE,i,j,k} \times r_{TOP,i,j,k})}{3}$$	[B.17]
Variables	$v_{i,j,k}$ = volume of the i^{th} tree in plot j, stratum k $h_{i,j,k}$ = height of the i^{th} tree in plot j in stratum k $r_{BASE,i,j,k}$ = base radius of the i^{th} tree in plot j in stratum k $r_{TOP,i,j,k}$ = top radius of the i^{th} tree in plot j in stratum k
Section References	B.2.4.2, B.2.7
Comments	This equation is the volume of a truncated cone and is used to estimate the bole volume of standing dead trees in decay class II and merchantable volume of trees for wood products carbon estimates. Units for radius and height must be given in meters.

$$x_{i,j,k} = \frac{44}{12} \times p_{CF\ SPC} \times \rho_{SPC} \times v_{i,j,k}$$	[B.18]
Variables	$x_{i,j,k}$ = carbon stock for the i^{th} tree in decay class II in plot j, stratum k $p_{CF\ SPC}$ = carbon fraction for species SPC ρ_{SPC} = wood density of species SPC $v_{i,j,k}$ = volume of the i^{th} tree in decay class II in plot j, stratum k
Section References	B.2.4.2, B.2.7

Comments	This equation is used to estimate the carbon stock for the i^{th} tree in decay class II in plot j, stratum k. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units.

$$y_{j,k} = \frac{44}{12} \times \frac{1}{10{,}000} \times \frac{1}{1{,}000} \times \sum_{d \in \mathcal{D}} \frac{p_{CF\ DW} \times \bar{\rho}_d \times \pi^2 \sum_{i \in \mathcal{X}_{j,k}} x_{i,j,k,d}^2}{8 l_j}$$ [B.19]	
Variables	$y_{j,k}$ = total carbon stock in lying dead wood for stratum k transect j $p_{CF\ DW}$ = carbon fraction of dry matter for dead wood $\bar{\rho}_d$= average density of dead wood in decay class d $x_{i,j,k,d}$ = diameter of i^{th} piece of lying dead wood on transect j in stratum k, decay class d l_j = length of transect j $\mathcal{D}$ = the set of all decay classes $\mathcal{X}_{j,k}$ = set of all measurements of lying dead wood in plot j in stratum k
Section References	B.2.5
Comments	This equation is used to estimate the carbon stock in lying dead wood per unit area for stratum k transect j The variables $x_{i,j,k,d}$ and l_j must be measured in meters. $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1{,}000}$ represents a conversion from kg to tonnes. $\frac{1}{10{,}000}$ represents a conversion from m^2 to hectares.

$$y_k = \frac{\sum_{j \in \mathcal{L}_k} l_j y_{j,k}}{\sum_{j \in \mathcal{L}_k} l_j}$$ [B.20]	
Variables	y_k = average carbon stock per unit area in lying dead wood in stratum k l_j = length of transect j used for measuring lying dead wood. $y_{j,k}$ = total carbon stock in lying dead wood for stratum k transect j $\mathcal{L}_k$ = set of all transects used for measurement of lying dead wood in stratum k

Section References	B.2.5
Comments	This equation is used to estimate the total carbon stock in lying dead wood in stratum k. This equation is a weighted average where the weights are proportional to transect length. In the common case where all transects are the same length, it simplifies to the average: $y_k = \frac{1}{\#(\mathcal{L}_k)} \sum_{j \in \mathcal{L}_k} y_{j,k}$ (Shiver & Borders, 1996)

$$\hat{\sigma}_k^2 = \frac{\sum_{j \in \mathcal{L}_k} \left(y_{j,k}\right)^2 - \left(\sum_{j \in \mathcal{L}_k} y_{j,k}\right)^2 / \#(\mathcal{L}_k)}{\#(\mathcal{L}_k) - 1} \quad \text{[B.21]}$$

Variables	$\hat{\sigma}_k^2$ = variance of carbon stock in lying dead wood for stratum k transect j $y_{j,k}$ = total carbon stock in lying dead wood for stratum k transect j $\mathcal{L}_k$ = set of all transects used for measurement of lying dead wood in stratum k
Section References	B.2.5
Comments	This equation is used to estimate the variance of carbon in lying dead wood in stratum k

$$c_{LD} = \frac{1}{\sum_{k \in \mathcal{S}} A_k} \sum_{k \in \mathcal{S}} A_k y_k \quad \text{[B.22]}$$

Variables	c_{LD} = estimated average carbon stock in lying dead wood at monitoring period A_k = area of stratum k y_k = average carbon stock per unit area in lying dead wood in stratum k $\mathcal{S}$ = set of all strata in the area
Section References	B.2.5
Comments	This equation is used to estimate the average carbon stock in lying dead wood.

$$U_{LD} = \sqrt{\sum_{k \epsilon \mathcal{S}} \left[\frac{A_k^2 \hat{\sigma}_k^2}{\#(\mathcal{L}_k)}\right]} \quad \text{[B.23]}$$

Variables	U_{LD} = estimated standard error of the total for carbon stock in lying dead wood A_k = the area of stratum k $\hat{\sigma}_k^2$ = estimated variance of lying dead wood samples in stratum k $\mathcal{S}$ = set of all strata in the area $\mathcal{L}_k$ = set of all transects used for measurement of lying dead wood in stratum k
Section References	B.2.5
Comments	This equation is used to estimate the standard error of the total from a line intersect sample used to estimate carbon in lying dead wood. Shiver & Borders (1996)

$$\hat{y}_i = f_{-i}(x_i) \quad [B.24]$$

Variables	$\hat{y}_i$ = predicted value for observation i f_{-i}= model fit using all points in dataset except observation i x_i = independent variable associated with observation i
Section References	9.3.3.2
Comments	This is the predicted value at observation i that results from fitting a model using all points but observation i during cross validation.

$$\hat{e}_i = \frac{\hat{y}_i - y_i}{y_i} \times 100\% \quad [B.25]$$

Variables	$\hat{e}_i$ = cross-validated residual for observation i $\hat{y}_i$ = predicted value for observation i y_i = observed dependent variable for observation i
Section References	9.3.3.2
Comments	This is the cross validated residual for point *i*, expressed as a percentage.

$$\bar{E} = \frac{\sum_{i \in \mathcal{X}} \hat{e}_i}{\#(\mathcal{X})} \quad [B.26]$$

Variables	$\bar{E}$ = mean cross-validated error $\hat{e}_i$ = cross-validated residual for observation i $\mathcal{X}$ = the set of all observations
Section References	9.3.3.2
Comments	This equation estimates mean cross-validated error, a measure of bias in the dataset $\mathcal{X}$.

$$\rho_{soil,j,k} = \frac{m_{soil,j,k} - m_{rf,j,k}}{v_{soil,j,k} - v_{rf,j,k}} \quad [B.27]$$

Variables	$\rho_{soil,j,k}$ = bulk density of fine portion of soil sample in plot j in stratum k $m_{soil,j,k}$ = dry mass of soil sample take from plot j in stratum k. $m_{rf,j,k}$ = dry mass of rock fraction of soil sample in plot j in stratum k $v_{soil,j,k}$ = total volume of soil sample in plot j in stratum k $v_{rf,j,k}$ = volume of coarse fragments (> 2mm) in soil sample taken in plot j in stratum k
Section References	B.2.6,
Comments	This equation estimates the bulk density of soil, corrected to exclude the rock fraction (fragments >2 mm).

$$SOC_{j,k} = \frac{44}{12} \times 10 \times p_{CF\ soil,j,k} \times \rho_{soil,j,k} \times d_{j,k} \times (1 - \frac{v_{rf,j,k}}{v_{soil,j,k}}) \quad [B.28]$$

Variables	$SOC_{j,k}$ = soil carbon stock in plot j stratum k $\rho_{soil,j,k}$ = bulk density of fine portion of soil sample in plot j in stratum k $p_{CF\ soil,j,k}$ = carbon fraction of soil sample in plot j in stratum k $d_{j,k}$ = depth of soil sample in plot j in stratum k $v_{soil,j,k}$ = total volume of soil sample in plot j in stratum k $v_{rf,j,k}$ = volume rock fragments (> 2mm) in soil sample taken in plot j in stratum k
Section References	B.2.6

Comments	This equation is used to estimate the carbon stock in soil in stratum k plot j $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. The conversion factor 10 represents a conversion from kg to tonnes and from m^{-2} to ha^{-1}.

$$C_{slash,i,j,k} = C_{total,\mathrm{i},j,k} - C_{bole,i,jk}$$ [B.29]	
Variables	$C_{slash,i,j,k}$ = Carbon stock in slash for the i^{th} tree on plot j in stratum k $C_{total,i,j,k}$ = Total above-ground carbon stock for the i^{th} tree on plot j in stratum k $C_{bole,i,j,k}$ = Carbon stock in the merchantable part of the bole for the i^{th} tree on plot j in stratum k
Section References	B.2.7
Comments	This equation is an intermediate step in estimating the slash and wood products ratios.

$$p_i = \frac{C_i}{\sum_{i \in \mathcal{W}} C_i}$$ [B.30]	
Variables	p_i = Wood products ratio for class i C_i = Total carbon in wood products class i $\mathcal{W}$ = The set of all wood products classes (slash, sawnwood, woodbase panels, other industrial roundwood, and paper/paperboard)
Section References	B.2.7
Comments	This equation calculates their percentage of total carbon in log production expected to be allocated to each of the four wood products classes.

$$\hat{m}_L \geq \left(\frac{\hat{\sigma}_{DF} 1.64}{0.15}\right)^2$$ [B.31]	
Variables	$\hat{m}_L$ = the estimated minimum sample size in the leakage area. $\hat{\sigma}_{DF}$ = the estimated standard deviation of the state observations used to fit the logistic function
Section References	B.2.8, 6.8.10

Comments	The estimated sample size in the leakage area. Based on a normal approximation and rewritten from an approximate confidence interval at 90% with threshold of +/- 15% of the estimated mean. $\hat{m}_{FD}$ has an upper bound of 98, the maximum sample size. For a small estimated conversion rate, a larger sample than estimated is recommended. Lohr (2009)

$P = 100 - (1.04 * n)$ [B.32]	
Variables	P = percent cover estimate n = number of observed openings in densiometer reading
Section References	B.2.9
Comments	This formula applies to spherical densitometers with 24 grid cells, assuming four potential count points per grid cell.

For estimates of the project accounting area $$c_P = \sum_{j \in \mathcal{C}} c_j$$ [B.33] For estimates of the project accounting area $c_B = \sum_{j \in \mathcal{C}} c_j$	
Variables	c_P = average carbon stock in the project accounting area c_B = average carbon stock in the proxy area $\mathcal{C}$ = the set of selected carbon pools
Section References	B.1.5
Comments	This equation is used to estimate the average carbon stock in all selected carbon pools.

For estimates of the project accounting area $$U_P = \sqrt{\sum_{j \in \mathcal{C}} U_j^2}$$ For estimates of the proxy area $$U_B = \sqrt{\sum_{j \in \mathcal{C}} U_j^2}$$	[B.34]
Variables	U_P = estimated standard error of total carbon stocks in the project accounting area U_B = estimated standard error of total carbon stocks in the project accounting area $\mathcal{C}$ = the set of selected carbon pools U_j = estimated standard error of carbon pool j
Section References	B.1.5
Comments	This equation is used to combine the standard errors of the totals for selected carbon pools.

$$\frac{wc_{Sn} = c_1 A_1 + c_2 A_2 + \ldots c_i A_i}{A_i + A_2 + \ldots\ A_i}$$	[B.35]
Variables	wc_{Sn} = weighted average carbon stocks for selected strata, tCO2e/ha c_i = average carbon stocks in stratum i, tCO_2e/ha A_i = area of stratum i, ha
Section References	B.1.4
Comments	This equation calculates the average carbon stocks in terms of $tCO_2e\ ha^{-1}$ across a given set of strata weighted by pool size.

APPENDIX C: WOOD PRODUCTS

It is conservative to omit long-lived wood products as a result of project activities but required to consider them in the baseline scenario. If the project proponent chooses to estimate carbon stored in long-lived wood products as a result of the project activity, see section C.1 of this appendix.

Carbon in wood products remaining after 100 years is estimated using [C.1], which was derived from Winjum et al. (1998).

Wood products are classified as sawnwood, woodbase panels, other industrial roundwood, or paper & paperboard, each product type being considered separately. The fraction of wood lost to waste during the milling process (w), given in Table 11, is constant across product types but dependent upon country type. Table 12 provides fractions of wood products lasting at least 5 years (l_{ty}) by product type, and annual oxidation fractions (f_{ty}) for each of the three major forest regions by product type.

In order to estimate emissions-equivalent remaining sequestered in each wood product type (ty) after 100 years, the above-ground merchantable tree emissions are multiplied by the fraction remaining after milling ($1 - w$), the fraction of wood products that last 5 years or more (l_{ty}), and the fraction remaining after applying the oxidation fraction (f_{ty}) over the subsequent 95 years. All product types are summed to obtain the total emissions equivalent sequestered in wood products after 100 years.

Table 8: Milling Wood Waste Fraction ($\boldsymbol{w}$).

Country Type	$\boldsymbol{w}$
Developing	0.24
Developed	0.19

Proportion of wood lost during the milling process, from Winjum et al. (1998).

Table 9: Long-lived Wood Fractions ($\boldsymbol{l_{ty}}$) and Oxidation Fractions ($\boldsymbol{f_{ty}}$).

Product Type	$\boldsymbol{l_{ty}}$	$\boldsymbol{f_{ty}}$, Boreal	$\boldsymbol{f_{ty}}$, Temperate	$\boldsymbol{f_{ty}}$, Tropical
Sawnwood	0.8	0.005	0.01	0.02
Woodbase panels	0.9	0.010	0.02	0.04
Other industrial roundwood	0.7	0.020	0.04	0.08
Paper and paperboard	0.6	0.005	0.01	0.10

Proportion of timber remaining intact as wood products after 5 years, and annual rate of loss of wood products by forest region, both from Winjum et al. (1998).

If the project proponent wishes, the values for l_{ty} and f_{ty} in Table 13 may be applied to all product types in either the baseline or project scenario to ensure a conservative estimate. The use of these values assumes that all harvested wood goes into wood products in the baseline scenario, and none of it does in the project scenario.

Table 10: Conservative Values for Long-lived Wood Fractions ($\boldsymbol{l_{ty}}$) and Oxidation Fractions ($\boldsymbol{f_{ty}}$).

Scenario	$\boldsymbol{l_{ty}}$	$\boldsymbol{f_{ty}}$
Baseline	1	0
Project	0	1

Applicable to all wood product types.

C.1 Estimating Carbon Stored in WP Using Log Production

If as a result of project activities carbon is stored in wood products, use the methods provided in this appendix and equation [C.2] which is based on the measure log production.

C.2 Equations for Wood Products

$$C_{B\,WP}^{[m]} = (1-w)\left(E_{B\,AGMT}^{[m]}\right)\sum_{ty\in\mathcal{T}} p_{ty}^{[m]} l_{ty}\left(1-f_{ty}\right)^{95}$$ [C.1]	
Variable	$C_{B\,WP}^{[m]}$ = tCO2e sequestered in long-lived wood products after 100 years w = milling wood waste fraction ty = wood product type $E_{B\,AGMT}^{[m]}$= tCO2e sequestered in above-ground merchantable trees $\mathrm{p}_{ty}^{[M]}$ = portion of harvested carbon in product type ty (estimated using Appendix B) l_{ty} = fraction of wood products in product type ty remaining after 5 years f_{ty} = annual oxidation fraction of wood products in product type ty
Section References	8.1.6
Comments	Determining carbon stored in wood products in the baseline.

$$C_{P\,\Delta\,WP}^{[m]} = (1-w)\sum_{ty\in\mathcal{T}} C_{P\,ty}^{[m]} l_{ty}\left(1-f_{ty}\right)^{95}$$	[C.2]
Variable	$C_{P\,\Delta\,WP}^{[m]}$ = tCO2e sequestered in long-lived wood products after 100 years w = milling wood waste fraction ty = wood product type $C_{ty}^{[m]}$=Carbon measured in log production for each wood product class l_{ty} = fraction of wood products in product type ty remaining after 5 years f_{ty} = annual oxidation fraction of wood products in product type ty
Section References	8.2.3
Comments	Determining carbon stored in wood products in the project.

APPENDIX D: AREA SELECTION CRITERION

The boundaries and size of the area must address the following criteria in order to ensure that the agents and drivers of conversion in the area are similar to those of the project area:

1. The locations of the agents of conversion relative to the project area.
2. The mobilities of the agents of conversion relative to the project area.
3. The drivers of conversion including the following relative to the project area:
    a. Socio-economic conditions; and
    b. Cultural conditions.
4. Landscape configuration including the following relative to the project accounting area:
    a. Topographic constraints to conversion (slope, aspect, elevation);
    b. Land use and/or land cover constraints to ecosystem conversion;
    c. Access points that may constrain ecosystem conversion;
    d. Areas of limited soil productivity;
    e. Distance to important markets;
    f. Proximity to important resources (water, electricity, transportation); and
    g. Ownership/tenure boundaries that constrain conversion (government holdings, private holdings and reserves).

The interpretation of the above criteria is subjective and the project proponent should choose boundaries for the area that result in a conservative baseline scenario when evaluating the above criteria. Maps showing the following analyses may be helpful to the project proponent and VVB for identifying the boundaries and size of the area:

- Mapping the locations of agents of conversion.
- Buffering the locations of agents based on the distance of their mobility.
- Provincial, district-level or local maps showing the relative socioeconomic conditions of local communities.
- Mapping the locations of important cultural places.
- Digital elevation models.
- Maps of topographic surveys.
- Maps of land use and land cover.
- Mapping the locations of access points that may constrain conversion.
- Maps of soil productivity.
- Buffering the locations of important markets according to agent mobility.

- Maps of important resources (water, electricity, transportation).
- Maps of ownership boundaries (government holdings, private holdings and reserves).

The area may be similar to the project area by virtue that they are located in the same region and are probably subject to the same agents and drivers of conversion. However, for substantiation that the same agents or class of agents and drivers of conversion are present, the project proponent should clearly demonstrate similarity between the project area and area using the following criteria:

1. The area and project area must be located with the same proximity to the agents of conversion (for instance if the agents reside in a town, the project area and area must be similar in distance from a town in which agents of conversion reside. These may be the same agents, or they may be different, but similar agents.)
2. Agents of conversion must have access (legal or otherwise) to the area. The same agents need not have access to all areas, but the agents with access to each area must be similar in regards to the drivers of conversion identified in section E.2.
3. The area has similar conditions to the project area:
    a. Socio-economic conditions; and
    b. Cultural conditions.
4. The area has similar landscape configuration to the project accounting area (for instance, the same topography and land cover).
5. In the case of the reference area, it must have at least the same area of forest or native grassland cover as the project accounting area at some point in time during the historic reference period. This can be demonstrated by a thematic classification of land cover in the reference area at some point in the reference period and the project accounting area, analysis of a dot grid or by some other credible method.

APPENDIX E: THE PARTICIPATORY RURAL APPRAISAL

The participatory rural appraisal is a voluntary survey of the populace surrounding the project area and may be used to identify the agents and drivers of conversion, delineate the reference area and identify strategies to mitigate ecosystem conversion in the project area.

The participatory rural appraisal utilizes a questionnaire to identify the agents and drivers of conversion. The survey should sample as many community members, community leaders, customary leaders and public officials as possible given time and expense constraints. The sample size selected by the project proponent affects the creditability of the agents and drivers identified using the appraisal and a very low sample size may negatively affect the validation opinion. The questionnaire should be anonymous and may contain both closed and open-ended questions. The questionnaire can be issued in written form or administered orally to individuals or groups of people, as is deemed appropriate by local culture and custom. Incentives should be considered to increase the number of responses, taking care not to bias results with said incentives. The questions are designed by the project proponents on an individual project basis and should address the following issues:

1. Possible agents of conversion, including:
    a. Foreign groups;
    b. Local groups;
    c. Regional groups;
    d. Customary and traditional groups;
    e. Community groups;
    f. Authorities and governments;
    g. Illegal activities; and
    h. Other possible agents.
2. Possible drivers of conversion, including:
    a. Historic problems with community sustainability;
    b. Livelihoods;
    c. Economies;
    d. Rural wages;
    e. General scarcity issues;
    f. Prices of agricultural products;
    g. Costs of agricultural inputs;
    h. Human-wildlife interaction;
    i. Illegal or black markets;

   j. Historical and current forest uses;
   k. Population density;
   l. Socio-economic conditions; and
   m. Property-ownership systems;
   n. Other possible drivers.

3. Possible time components of degradation and conversion, including;
   a. Arrival of foreigners;
   b. Time between the beginning of degradation and ultimate conversion (see section 6.16);
   c. The length of time between the creation of access points into forest until secondary agents enter the forest resulting in degradation and ultimately conversion (see sections 6.10 and 6.11)
   d. Changes in transportation infrastructure;
   e. Events of significant importance such as droughts or floods;
   f. Regional climatic trends;
   g. Events of significant population growth;
   h. Events of significant economic growth or decline;
   i. Expected community needs;
   j. War or other conflicts;
   k. Changes in policies; and
   l. Other possible time components.

4. Possible constraints to degradation and conversion, including:
   a. Access issues;
   b. Soil productivity;
   c. Topography;
   d. Proximity to markets;
   e. Proximity to other resources (water, electricity, transportation);
   f. Protected areas;
   g. Ownership types (government, private, reserve) ; and
   h. Other possible constraints.

5. Relative importance of drivers and agents of conversion in respondents' estimation (a relative numerical rank).

6. Possible solutions to community un-sustainability.

E.1 Analyzing the Agents of Conversion

Analyze responses from the survey with respect to the agents of conversion by first enumerating the responses to agent-based questions. Then, group these responses by the agents identified in the responses. Next, rank groups by the number of responses that fall within any particular group. One response may fall into more than one group. Consider responders' ranking of relative importance when ranking groups. Sort the list of groups by decreasing rank and for each agent of conversion in the list, and describe its mobility. Also provide a description of the agent relative to possible drivers of conversion and any useful statistics about the agent obtained from published or unpublished sources.

The sorted list of agents forms the basis for developing project activities that mitigate conversion in order of importance. Elements of the list may identify possible covariates which could be included as numeric drivers of conversion in the baseline emissions models. These covariates must be quantifiable, such as population density data from periodic census or head of cattle in a local community.

E.2 Analyzing the Drivers of Conversion

Analyze responses from the survey with respect to the drivers of conversion by first enumerating the responses to driver-based questions. Then, group these responses by the drivers identified in the responses. Rank these groups by the numbers of responses that fall within in any particular group. One response may fall into more than one group. Consider responders' ranking of relative importance when ranking groups. Sort the list of groups by decreasing rank. Also provide any useful statistics about the driver obtained from published or unpublished sources.

The sorted list of drivers forms the basis for developing project activities that mitigate conversion in order of importance. Elements of the list may identify possible covariates which could be included as numeric drivers of conversion in the baseline emissions models.

APPENDIX F: EQUATIONS IN THE METHODOLOGY

$$\widehat{m} = \frac{365\left(C_{P\,AGMT}^{[m=0]} + C_{P\,BGMT}^{[m=0]}\right)}{t_{PL} - t_{PA}}$$	[F.1]
Variables	$C_{P\,AGMT}^{[m=0]}$, $C_{P\,BGMT}^{[m=0]}$, t_{PL}, t_{PA},
Section References	6.14
Comments	Average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging, per hectare. $C_{P\,BGMT}^{[m=0]}$ should be set to zero if BGMT is not a selected pool.

$$BEM_{P1}(c_P, c_B, t, x) = \frac{m(t - t_{PA})}{365(1 + e^{t-t_{SA}-t_{PA}-t_{PAI}})} + \frac{A_{PAA}(c_P - c_B)e^{t-t_{SA}-t_{PA}-t_{PAI}} + \frac{HA_{P1}(c_P,c_B)t}{t_{PL}-t_{PAI}}}{(1 + e^{t-t_{SA}-t_{PA}-t_{PAI}})\left[1 + e^{\ln\left(\frac{365A_{PAA}(c_P-c_B)}{m(t_{SA}-t_{PAI})}-1\right)-\beta(t-t_{SA}-t_{PA}-t_{PAI})-\theta(x-x_{PAI}-x_{SA})^T}\right]} - HA_{P1}(c_P, c_B)$$ where $$HA_{P1}(c_P, c_B) = \frac{m}{365(1 + e^{-t_{SA}-t_{PA}-t_{PAI}})} + \frac{A_{PAA}(c_P - c_B)e^{-t_{SA}-t_{PA}-t_{PAI}}}{(1 + e^{-t_{SA}-t_{PA}-t_{PAI}})\left[1 + e^{\ln\left(\frac{365A_{PAA}(c_P-c_B)}{m(t_{SA}-t_{PAI})}-1\right)+\beta(t_{SA}+t_{PA}+t_{PAI})-\theta(x_o-x_{SA}-x_{PAI})^T}\right]}$$	[F.2]
Variables	m, $c_P^{[m]}$, $c_B^{[m]}$, x_o, t, β, θ, x, t_{PA}, t_{SA}, x_{SA}, A_{PAA}, t_{PL}, t_{PAI}
Section References	6.6
Comments	BEM for Types F-P1.a and F-P1.b. For F-P1.b, the spatial algorithm should be used for C_p

$$BEM_{P2}(c_P, c_B, t, x) = \frac{(c_P - c_B)A_{PAA} + \frac{HA_{P2}(c_P, c_B)t}{t_{PL} - t_{PAI}}}{1 + e^{-\alpha - \beta(t + \gamma + 0.5q - t_{PAI}) - \theta(x - x_{PAI})^T}} - HA_{P2}(c_P, c_B) \quad \text{[F.3]}$$

where

$$HA_{P2}(c_P, c_B) = \frac{(c_P - c_B)A_{PAA}}{1 + e^{-\alpha - \beta(\gamma + 0.5q - t_{PAI}) - \theta(x_0 - x_{PAI})^T}}$$

Variables	m, $c_P^{[m]}$, $c_B^{[m]}$, t_{PA}, t, α, β, γ, q, θ, x, A_{PAA}, t_{PL}, t_{PAI}
Section References	8.1.1, 6.6
Comments	BEM for Type F-P2 and G-P2

$$BEM_{U2,3}(c_P, c_B, t, x) = \frac{A_{PAA}(c_P - c_B) + \frac{HA_{U2,3}(c_P, c_B)t}{t_{PL}}}{1 + e^{\ln\left(\frac{1}{r_U}\right) - \beta(t + 0.5q) - \theta(x)^T}} - HA_{U2,3}(c_P, c_B) \quad \text{[F.4]}$$

where

$$HA_{U2,3}(c_P, c_B) = \frac{A_{PAA}(c_P - c_B)}{1 + e^{\ln\left(\frac{1}{r_U}\right) - \beta(0.5q) - \theta(x_0)^T}}$$

Variables	$c_P^{[m]}$, $c_B^{[m]}$, x_o, t, β, θ, q, x, A_{PAA}, t_{PL}, r_U, $t_{PAI}t_{PAI}$
Section References	8.1.1, 6.6
Comments	BEM for Types F-U2, G-U2 and F-U3

$$BEM_{U1}(c_P, c_B, t, x) = \frac{A_{PAA}(c_P - c_B)}{1 + e^{-\beta(t + 0.5q - t_{PAI}) - \theta(x - x_{PAI})^T - \alpha}} \quad \text{[F.5]}$$

Variables	$c_P^{[m]}$, $c_B^{[m]}$, x_o, t, α, β, θ, q, x, A_{PAA}, t_{PL}, $t_{PAI}t_{PAI}$
Section References	8.1.1, 6.6

Comments	BEM for Type F-U1 and G-U1

$$SEM_P(c_P, c_B, t, x) = \frac{A_{PAA}(c_P - c_B)}{1 + e^{-\alpha-\beta(t+\gamma-t_{PA}-t_{PAI})-\theta(x-x_{PAI})^T}}\left[1 + \frac{t}{t_{PL} + t_{PL}e^{-\alpha-\beta(\gamma-t_{PA}-t_{PAI})-\theta(x_0-x_{PAI})^T}}\right] - \frac{A_{PAA}(c_P - c_B)}{1 + e^{-\alpha-\beta(\gamma-t_{PA}-t_{PAI})-\theta(x_0-x_{PAI})^T}} \quad [F.6]$$

Variables	$c_B^{[m]}, c_P^{[m]}, t_{PA}, \alpha, \beta, \theta, \gamma, t, x, x_o, A_{PAA}, t_{PAI}$
Section References	8.1.1, 6.6
Comments	SEM for Types F-P1.a, F-P1.b, F-P2 and G-P2 (for F-P2 and G-P2, t_{PA} = 0). For F-P1.b, C_p should be calculated using the spatial algorithm

$$SEM_{U2,3}(c_P, c_B, t, x) = \frac{A_{PAA}(c_P - c_B)}{1 + e^{\ln\left(\frac{1}{r_U}\right)-\beta(t-t_{PAI})-\theta(x-x_{PAI})^T}}\left[1 + \frac{t}{t_{PL} + t_{PL}e^{\ln\left(\frac{1}{r_U}\right)-\theta(x_0-x_{PAI})^T+\beta t_{PAI}}}\right] - \frac{A_{PAA}(c_P - c_B)}{1 + e^{\ln\left(\frac{1}{r_U}\right)-\theta(x_0-x_{PAI})^T+\beta t_{PAI}}} \quad [F.7]$$

Variables	$c_{B\,SOC}^{[m]}\ c_B^{[m]}, c_P^{[m]}, x_o, \beta, \theta, t, x, A_{PAA}, r_U, t_{PAI}$
Section References	8.1.1, 6.6
Comments	SEM for Types F-U2, G-U2 and F-U3

$$SEM_{U1}(c_P, c_B, t, x) = \frac{A_{PAA}(c_P - c_B)}{1 + e^{-\beta(t - t_{PAI}) - \theta(x - x_{PAI})^T - \alpha}}\left[1 + \frac{1}{1 + e^{-\alpha - \theta(x_0 - x_{PAI})^T - \beta t_{PAI}}}\right] - \frac{A_{PAA}(c_P - c_B)}{1 + e^{-\alpha - \theta(x_0 - x_{PAI})^T - \beta t_{PAI}}}$$ [F.8]	
Variables	$c_B^{[m]}$, $c_P^{[m]}$, x_o, β, θ, t, x, A_{PAA} α, t_{PAI}
Section References	
Comments	SEM for Type F-U1 and G-U1

$$DEM_{SOC}\left(E_{B\,\Delta}^{[m]}, t, t^{[m-1]}\right) = E_{B\,\Delta}^{[m]} - \frac{365 E_{B\,\Delta}^{[m]}}{\lambda_{SOC}(t - t^{[m-1]})}\left[\frac{\lambda_{SOC}\left(t - t^{[m-1]}\right)}{365} + e^{-\frac{-\lambda_{SOC}\left(t - t^{[m-1]}\right)}{365}} - 1\right]$$ [F.9]	
Variables	t, $t^{[m-1]}$, λ_{SOC}, $E_{B\,\Delta}^{[m]}$
Section References	6.19
Comments	DEM for SOC

$$DEM_{DW,BGB}\left(E_{B\,\Delta}^{[m]}, t, t^{[m-1]}\right) = \frac{E_{B\,\Delta}^{[m]}}{1 + e^{t - t^{[m-1]} - 3650}}\left[1 - \frac{t - t^{[m-1]}}{3650}\right]$$ [F.10]	
Variables	$E_{B\,\Delta}^{[m]}$, $t^{[m]}$, $t^{[m-1]}$, t
Section References	6.18
Comments	DEM for DW and BGB

$$o_i = \begin{cases} 1 \; if \; deforested \; at \; (t_i, x_i, y_i) \\ 0 \; if \; forested \; at \; (t_i, x_i, y_i) \end{cases}$$ [F.11]	
Variables	t_i, x_i, y_i

Section References	6.8.5
Comments	Observation of forest state at a given point in space and time.

$$\widehat{m}_{EM} \geq \frac{1}{2}\left(\frac{\hat{\sigma}_{EM}1.64}{0.01}\right)^2$$	[F.12]
Variables	$\hat{\sigma}_{EM}$
Section References	6.8.5
Comments	The minimum sample size $\widehat{m}_{EM}$ in the space of the reference area required for fitting the logistic function. Based on a normal approximation and rewritten from an approximate confidence level at 90% with threshold of +/- 1% of the estimated mean. +/- 15% of the mean cannot be used as the threshold because of problems associated with peak variance. The ½ factor assumes at least double-coverage to get the sample size in the reference area. $\widehat{m}_{EM}$ has an upper bound of 4802, the maximum sample size. (Lohr, 2009) Constant 1.64 is the Z value at the 90% confidence level. Constant of 0.01 is the level of precision.

$$\hat{\sigma}_{EM} = \sqrt{\left[\sum_{i \in \mathcal{I}} w_i o_i\right]\left[1 - \sum_{i \in \mathcal{I}} w_i o_i\right]}$$	[F.13]
Variables	o_i, w_i, $\mathcal{I}$
Section References	6.8.5
Comments	Standard deviation of observed conversion derived from an estimate of variance for a Bernoulli random variable (Lohr, 2009).

$$U_{EM}^{[M]} = \frac{E_{B\,\Delta}^{[m]}\hat{\sigma}_{EM}}{\sqrt{n_d}}$$	[F.14]
Variables	$E_{B\,\Delta}^{[m]}$, n_d, $\hat{\sigma}_{EM}$
Section References	6.8.10

Comments	An approximate estimate of uncertainty for the logistic function of conversion, assuming a normal approximation (Lohr, 2009). Uncertainty in emissions models based on sample statistics for conversion parameters.

$$E_{B\,\Delta}^{[m]} = E_{B}^{[m]} - E_{B}^{[m-1]}$$ [F.15]	
Variables	$E_{B}^{[m]}$, $E_{B}^{[m-1]}$

Section References	8.2
Comments	project emissions

$$E_{P\ \Delta\ BRN}^{[m]} = \left(\frac{44}{12}\right) 0.66 \sum_{b \in \mathcal{W}^{[m]}} r_{CF\ b}\ B_{b^{[m]}}$$ [F.42]	
Variables	$r_{CF\ b}$, $W^{[m]}$, $B_b^{[m]}$
Section References	8.2.2

Comments	Project Emissions from Burning (1-0.33=0.66) account for the proportion of mass burned assumed to be water (Simpson & Sagoe, 1991) 44/12 is the ratio of the mass of carbon dioxide to the mass of carbon used to convert to CO2e units

$$E_{P\,\Delta\,LS}^{[m]} = \sum_{i \in T} \left(\frac{f_{LS\,i} n_{LS\,i}}{10^3} \right) \times 21$$ [F.43]	
Variables	$E_{P\,\Delta\,LS}^{[m]}$, $f_{LS\,i}$, $n_{LS\,i}$, T
Section References	8.2.4
Comments	Project Emissions from Livestock Grazing 21 = conversion from tCH4 to tCO2e

$$E_{L\,\Delta}^{[m]} = E_{L}^{[m]} - E_{L}^{[m-1]}$$ [F.44]	
Variables	$E_{L}^{[m]}$, $E_{L}^{[m-1]}$
Section References	8.3
Comments	Total emissions from leakage for the current monitoring period. $E_{L\,\Delta}^{[m]}$ cannot be less than zero.

$$E_{L}^{[m]} = E_{L\,ASF}^{[m]} + E_{L\,ASG}^{[m]} + E_{L\,ME}^{[m]}$$ [F.45]	
Variables	$E_{L\,ASF}^{[m]}$, $E_{L\,ME}^{[m]}$, $E_{L\,ASG}^{[m]}$
Section References	8.3
Comments	cumulative emissions from leakage

$$E_{L\ ASF}^{[m]} = LEM\left(c_P^{[m]}, c_B^{[m]}, p_{L\ DEG}^{[m]}, t^{[m]}, x^{[m]}\right)$$	[F.46]
Variables	$t^{[m]}$, $c_B^{[m]}$, $c_P^{[m]}$, $p_{L\ DEG}^{[m]}$, $x^{[m]}$
Section References	8.3.2
Comments	Cumulative emissions from activity-shifting leakage in forested areas

$$E_{L\ ASG}^{[m]} = LEM\left(c_P^{[m]}, c_B^{[m]}, p_{L\ CON\ G}^{[m]}, t^{[m]}, x^{[m]}\right)$$	[F.47]
Variables	$t^{[m]}$, $c_B^{[m]}$, $c_P^{[m]}$, $p_{L\ DEG}^{[m]}$, $x^{[m]}$
Section References	8.3.2
Comments	Cumulative emissions from activity-shifting leakage in grassland project accounting areas

$$LEM_F(c_P, c_B, p_{L\ DEG}, t, x) = p_{L\ DEG}^{[m]} A_{AS}(c_P - c_B) - \frac{A_{AS}(c_P - c_B)}{1 + e^{\ln\left(\frac{1}{p_{L\ DEG}^{[m=0]}} - 1\right) - \beta t - \theta (x_0 - x)^T}}$$	[F.48]
Variables	β, θ, t, x, x_o, $c_B^{[m]}$, $c_P^{[m]}$, $p_{L\ DEG}^{[m]}$, $p_{L\ DEG}^{[m=0]}$
Section References	8.3.2.2
Comments	Leakage Emissions Model for activity shifting leakage in forested project accounting areas

$$LEM_G(c_P, c_B, p_{L\ DEG}, t, x) = p_{L\ CON\ G}^{[m]} A_{AS}(c_P - c_B) - \frac{A_{AS}(c_P - c_B)}{1 + e^{\ln\left(\frac{1}{p_{L\ CON\ G}^{[m=0]}} - 1\right) - \beta t - \theta (x_0 - x)^T}}$$	[F.49]
Variables	β, θ, t, x, x_o, $c_B^{[m]}$, $c_P^{[m]}$, $p_{L\ DEG}^{[m]}$, $p_{L\ DEG}^{[m=0]}$

Section References	8.3.2.2
Comments	Leakage Emissions Model for activity shifting leakage in grassland project accounting areas

$$c_{L\,BM} = \sum_{p \in \mathcal{B}} c_{L\,p}$$	[F.50]
Variables	$c_{L\,p}$, B
Section References	8.3.3.3
Comments	Used to determine the discount factor in Table 7

$$E_{L\,ME}^{[m]} = p_{L\,ME} E_{B\,AGMT}^{[m]}$$	[F.51]
Variables	$p_{L\,ME}$, $E_{B\,AGMT}^{[m]}$
Section References	8.3.3.3, 8.1.6
Comments	Cumulative emissions from market leakage of wood products under the discount approach

$$A_{B\,\Delta\,PAA}^{[m]} = \frac{E_{B\,BM}^{[m]}}{c_{P\,BM}^{[m]} - c_{B\,BM}^{[m]}} - \frac{E_{B\,BM}^{[m-1]}}{c_{P\,BM}^{[m-1]} - c_{B\,BM}^{[m-1]}}$$	[F.52]
Variables	$c_{P\,BM}^{[m]}$, $c_{B\,BM}^{[m]}$, $E_{B\,BM}^{[m]}$, $A_{B\,\Delta\,PAA}^{[m]}$, A_{PAA}
Section References	8.3.3.4, 8.3.3

Comments	"Area of avoided conversion" under the production approach. For the first monitoring period, the term $\frac{E_{B\,BM}^{[m-1]}}{c_{P\,BM}^{[m-1]}-c_{B\,BM}^{[m-1]}} = 0$. This equation conservatively over estimates baseline conversion in the project accounting area because $E_{B\,BM}^{[m]}$ may include emissions from degradation.

$$E_{\Delta\,GER}^{[m]} = E_{\mathrm{B}\,\Delta}^{[m]} - E_{\mathrm{P}\,\Delta}^{[m]} - E_{\mathrm{L}\,\Delta}^{[m]} - E_{U}^{[m]}$$	[F.53]
Variables	$\mathrm{E}_{\mathrm{B}\,\Delta}^{[\mathrm{m}]}$, $\mathrm{E}_{\mathrm{P}\,\Delta}^{[\mathrm{m}]}$, $\mathrm{E}_{\mathrm{L}\,\Delta}^{[\mathrm{m}]}$, $E_{U}^{[m]}$
Section References	8.4.1, 8.4.1.2, 8.4.2, 8.4.2.1
Comments	GERs for the current monitoring period

$$E_{GER}^{[m]} = \sum_{i \in \mathcal{M}} E_{\Delta\,GER}^{[i]}$$	[F.54]
Variables	M, $\mathrm{E}_{\Delta\,\mathrm{GER}}^{[\mathrm{m}]}$
Section References	8.4.2.1
Comments	Cumulative GERs to-date

$$E_{\Delta\,NER}^{[m]} = E_{\Delta\,GER}^{[m]} - E_{BA}^{[m]}$$	[F.55]
Variables	$\mathrm{E}_{\Delta\,\mathrm{GER}}^{[\mathrm{m}]}$, $E_{\Delta\,NER}^{[m]}$, $\mathrm{E}_{\mathrm{BA}}^{[\mathrm{m}]}$
Section References	8.4.3, 8.4.7
Comments	NERs for the current monitoring period

$$E_{NER}^{[m]} = \sum_{i \in \mathcal{M}} E_{\Delta\,NER}^{[i]}$$ [F.56]	
Variables	$\mathcal{M}$, $E_{\Delta\,NER}^{[i]}$
Section References	8.4.7
Comments	Cumulative NERs to-date

$$E_{U}^{[m]} = E_{B\,\Delta}^{[m]} \left[\frac{1.64}{E_{B\,\Delta}^{[m]} + A_{PAA} c_{P}^{[m]} + A_{PX} c_{B}^{[m]}} \sqrt{\left(U_{EM}^{[M]}\right)^2 + \left(U_{P}^{[m]}\right)^2 + \left(U_{B}^{[m]}\right)^2} - 0.15 \right]$$ [F.57]	
Variables	$c_{P}^{[m]}$, $c_{B}^{[m]}$, $E_{B\,\Delta}^{[m]}$, $U_{EM}^{[M]}$, $U_{B}^{[m]}$, $U_{P}^{[m]}$, A_{PX}, A_{PAA}, $E_{U}^{[m]}$, $E_{B\,\Delta}^{[m]}$
Section References	8.4.1.1
Comments	Confidence deduction based on uncertainty in emissions models, carbon stock estimates in the project accounting area and carbon stock estimates in the proxy area. $E_{U}^{[m]}$ must be greater than zero; otherwise $E_{U}^{[m]} = 0$. Constant 1.64 is the Z value at the 90% confidence level.

APPENDIX G: VALIDATION VARIABLES

Data / Parameter	Unit	Description	Source of Data	Used in Equations	Justification	Comment
$\boldsymbol{\alpha}$	unitless	Combined effects of β and θ at the start of the historic reference period	Reference area and historic reference period	[F.3], [F.5], [F.6], [F.8]	Time and place in which the logistic model is fit	
$\boldsymbol{\beta}$	unitless	Effect of time on the cumulative proportion of conversion over time	Reference area and historic reference period	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8],	Time and place in which the logistic model is fit	
$\boldsymbol{\gamma}$	days	Time shift from beginning of historic reference period to project start date	Historic reference period	[F.3], [F.6]	Time in which the logistic model is fit	
$\boldsymbol{\theta}$	unitless	Effect of certain covariates on the cumulative proportion of conversion over time	Reference area and historic reference period	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]	Time and place in which the logistic model is fit	
$\boldsymbol{\lambda_{SOC}}$	proportion (unitless)	Exponential soil carbon decay parameter	Default values, literature estimates or empirical estimation based on reference area sampling	[F.9], [F.33]	A conservative default or values derived from direct measurement by the project proponent or from the literature are acceptable	
$\boldsymbol{\hat{\sigma}_{EM}}$	standard deviation (unitless)	The estimated standard deviation of the state observations used to fit the logistic function	Remote sensing image interpretation	[F.12], [F.14], [B.31]	-	
$\boldsymbol{\mathcal{B}}$	set	The set of all selected carbon pools in biomass. Is a subset of $\mathcal{C}$	PDD	[F.17], [F.18], [F.23], [F.50]	-	

Data / Parameter	Unit	Description	Source of Data	Used in Equations	Justification	Comment
$\mathcal{C}$	set	The set of all selected carbon pools	Monitoring records		-	
$\mathcal{I}$	set	The set of all observations of conversion. When superscripted with a monitoring period, the conversion observations are taken for leakage analysis.	Remote sensing image interpretation or field observations in the leakage area.	[F.13]	-	
$\mathcal{M}$	set	The set of all monitoring periods	Monitoring records	[F.32], [F.33], [F.36], [F.54], [F.56]	-	
$\mathcal{T}$	set	The set of all species/categories of livestock	Monitoring records	[F.43]	-	
A_{PAA}	ha	Area of project accounting area	GIS analysis prior to sampling	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8], [F.41], [F.52], [F.57],	-	
A_{PX}	ha	Area of proxy area	GIS analysis prior to sampling	[F.57]	-	
$c_{L\,p}$	tCO2e/ha	Carbon stocks in project leakage area	Leakage area sampling	[F.50]	Direct measurement	
$f_{LS\,i}$	kg CH_4 head^{-1} yr^{-1}	Emission factor for the defined livestock population, i	IPCC default values	[F.43]	Obtained directly from IPCC default values	

Data / Parameter	Unit	Description	Source of Data	Used in Equations	Justification	Comment
$\boldsymbol{m}$	tCO2e/yr	Average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging	Timber harvest plans or measurement of carbon stocks in merchantable trees in the *project accounting area*	[F.2]	Should use the most accurate of the two data sources if both are available	
$\boldsymbol{n_d}$		Number of spatial points in the reference area	Remote sensing image interpretation	[F.14]	-	
$\boldsymbol{o_i}$	binary	State observation for the i^{th} sample point in the reference area	Remote sensing image interpretation	[F.13]	-	
$\boldsymbol{p_{L\,ME}}$	unitless	Portion of leakage related to market	8.3.3	[F.51]	-	
$\boldsymbol{q}$	days	Lag between start of degradation and conversion	Expert knowledge, results from the PRA or reports from peer-reviewed literature	[F.3], [F.4], [F.5],	Commonly accepted methods in the social sciences, choice determined and justified by project proponent	
$\boldsymbol{r_{CF\,b}}$	unitless	Carbon fraction of biomass for burned wood or herbaceous material b	Literature estimates or direct measurement	[F.42]	-	
$\boldsymbol{r_{RS}}$	unitless	Expansion factor for above-ground biomass to below-ground biomass (root/shoot ratio)	Reviewed literature, allometry, or IPCC default values	[F.30]	-	
$\boldsymbol{r_U}$	unitless	Onset proportion of conversion immediately adjacent to project area	GIS analysis and image interpretation	[F.4]	Positions the baseline emissions models relative to the instantaneous rate of conversion	

Data / Parameter	Unit	Description	Source of Data	Used in Equations	Justification	Comment
t	days	Time since project start date	Monitoring records	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8],[F.10],	-	
t_i	days	The point in time of the observation made at point i	Remote sensing image interpretation	[F.11], [A.6]	-	
t_{PA}	days	Time prior to the project start date when the primary agent began commercial logging in the *project accounting area*	Harvest plans prepared for the *project accounting area*, or by public record	[F.1], [F.2], [F.3], [F.6]	Should use the most accurate of the two data sources if both are available	
t_m	days	Length of project or logging in baseline scenario	PD	[F.1]		
t_{PL}	days	Length of project crediting period	PD	[F.5]		
t_{PAI}	days	Number of days after the project start date for the start of a project activity instance in a grouped project	PD	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8]		
t_{SA}	days	Arrival time of secondary agents after start of commercial logging	Participatory rural appraisal, or expert knowledge	[F.2]	Should use the most accurate of the two data sources if both are available	
w_i	unitless	weight applied to the i^{th} sample point in the reference area	Remote sensing image interpretation	[A.6], [F.13]		

Data / Parameter	Unit	Description	Source of Data	Used in Equations	Justification	Comment
$\boldsymbol{x}$	unitless	Covariate values	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.8],	Should use the most accurate of the data sources if both are available	
$\boldsymbol{x_i}$	geographic coordinates	Latitude of the i^{th} sample point	Remote sensing image interpretation	[F.11], [A.6]	-	
$\boldsymbol{x_o}$	unitless	Covariate values as of the project start date	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery	[F.4], [F.5], [F.6], [F.7], [F.8],	Should use the most accurate of the data sources if both are available	
$\boldsymbol{x_{SA}}$	unitless	Covariate values as of the arrival of the secondary agents	Participatory Rural Appraisal, analysis of public records, and/or expert interpretation of inventory data or remotely sensed imagery	[F.2]	Should use the most accurate of the data sources if both are available	
$\boldsymbol{y_i}$	geographic coordinates	Longitude of the i^{th} sample point	Remote sensing image interpretation	[F.11], [A.6]	-	

APPENDIX H: MONITORING VARIABLES

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC	Comment
$\mathcal{W}^{[m]}$	set	The set of all burned wood or herbaceous material	Monitoring records	N/A	[F.42]	Every monitoring period	Review of monitoring records	
$A_{B\,\Delta\,PAA}^{[m]}$	ha	Area of avoided conversion	Generated from equation	8.3.3.4	[F.52]	Every monitoring period	Review of monitoring records	
$A_{P\,1}^{[m=0]}$	ha	Area of project accounting area stratum 1 prior to first verification event	GIS analysis prior to sampling	GIS analysis of best available data B.1.1	[F.24]	First monitoring period	Cross-check of GIS analysis	
$A_{P\,2}^{[m=0]}$	ha	Area of project accounting area stratum 2 prior to first verification event	GIS analysis prior to sampling	GIS analysis of best available data B.1.1	[F.24]	First monitoring period	Cross-check of GIS analysis	
$A_{P\,n}^{[m=0]}$	ha	Area of project accounting area stratum n prior to first verification event	GIS analysis prior to sampling	GIS analysis of best available data B.1.1	[F.24]	First monitoring period	Cross-check of GIS analysis	
$B_{b}^{[m]}$	tonnes	Biomass in burned wood or herbaceous material b	Measurements of biomass	Scale	[F.42]	Every monitoring period	Review of monitoring records	
$c_{B}^{[m]}$	tCO2e/ha	Baseline carbon stocks at the end of the current monitoring period	Proxy area sampling	Appendix B.2,6.4	[F.2], [F.3], [F.4], [F.5], [F.6], [F.7], [F.57]	Every time measured (≤ 5 yrs)	Review of monitoring records	

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC	Comment
$C_{B\ BGB}^{[m]}$	tCO2e	Carbon not decayed in BGB at the end of the current monitoring period	Proxy area sampling	8.1.4	[F.16]	Every monitoring period	Review of monitoring records	
$C_{B\ DW}^{[m]}$	tCO2e	Carbon not decayed in DW at the end of the current monitoring period	Proxy area sampling	8.1.3	[F.16]	Every monitoring period	Review of monitoring records	
$C_{B\ SOC}^{[m]}$	tCO2e	Carbon not decayed in SOC at the end of the current monitoring period	Proxy area sampling	8.1.5	[F.16]	Every monitoring period	Review of monitoring records	
$C_{B\ WP}^{[m]}$	tCO2e	Carbon not decayed in WP at the end of the current monitoring period	Proxy area sampling	Appendix C	[F.16]	Every monitoring period	Review of monitoring records	
$c_{B\ AGMT}^{[m]}$	tCO2e/ha	Baseline carbon stocks in above-ground merchantable trees at the end of the current monitoring period	Proxy area sampling	Appendix B.2.1	[F.37], [F.38], [F.39], [F.40]	Every time measured (≤ 5 yrs)	Review of monitoring records	
$C_{B\ BGMT}^{[m]}$	tCO2e/ha	Baseline carbon stocks in below-ground merchantable trees at the end of the current monitoring period	Proxy area sampling	Appendix B.2.1	[F.37], [F.38], [F.39], [F.40]	Every time measured (≤ 5 yrs)	Review of monitoring records	

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC	Comment
$C_{P\ AGMT}^{[m=0]}$	tCO2e	Project carbon stocks in above-ground merchantable trees at project start	Project accounting area sampling	Appendix B.2.1	[F.1]	First monitoring period	Review of monitoring records	
$C_{P\ BGMT}^{[m=0]}$	tCO2e	Project carbon stocks in below-ground merchantable trees at project start	Project accounting area sampling	Appendix B.2.3	[F.1]	First monitoring period	Review of monitoring records	
$c_{B\ b}^{[m]}$	tCO2e/ha	Baseline scenario average carbon stock in selected carbon pools	Proxy area sampling	Appendix B.1.5	[F.18] [F.24]	Every time measured (≤ 5 yrs)	Review of monitoring records	
$c_{B\ BM}^{[m]}$	tCO2e/ha	Baseline carbon stocks in biomass at the end of the current monitoring period	Proxy area sampling	Appendix B.2	[F.19], [F.20], [F.21], [F.24], [F.52]	Every time measured (≤ 5 yrs)	Review of monitoring records	
$c_{B\ SOC}^{[m]}$	tCO2e/ha	Baseline soil carbon stocks at the end of the current monitoring period	Proxy area sampling	Appendix B.2.6	[F.25], [F.27], [F.28]	Every time measured (≤ 5 yrs)	Review of monitoring records	
$c_{P}^{[m]}$	tCO2e/ha	Project carbon stocks at the end of the current monitoring period	Project accounting area sampling	Appendix B.2	[F.41], [F.57]	Every time measured (≤ 5 yrs)	Review of monitoring records	
$c_{P}^{[m-1]}$	tCO2e/ha	Project carbon stocks at the beginning of the current monitoring period	Project accounting area sampling	Appendix B.2	[F.41]	Prior monitoring period	Already reviewed	

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC	Comment
$c_{P}^{[m=0]}$	tCO2e/ha	Project carbon stocks prior to first verification event	Project accounting area sampling	Appendix B.2	[F.7]	First monitoring period	Review of monitoring records

APPENDIX I: PROJECT DOCUMENT REQUIREMENTS BY BASELINE TYPE

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.1	Applicability Conditions	For each applicability condition, a statement of whether it applies to the project. If the applicability condition does not apply to the project, justification for this conclusion.	x	x	x	x	x	x	x	x	x
PDR.2	Applicability Conditions	Where applicability conditions apply, credible evidence in the forms of analysis, documentation or third-party reports to satisfy the condition.	x	x	x	x	x	x	x	x	x
PDR.3	Applicability Conditions	Definition of forest used by the project proponent and its source.	x	x	x	x	x	x	x	x	x
PDR.4	Spatial Project Boundaries	A digital (GIS-based) map of the project area with at least the above minimum requirements for delineation of the geographic boundaries.	x	x	x	x	x	x	x	x	x
PDR.5	Spatial Project Boundaries	Credible documentation demonstrating control of the project area, or documentation that the provisos listed in the case of less than 80% project control at the time of validation delineated in section 5.1 of the methodology are met.	x	x	x	x	x	x	x	x	x
PDR.6	Temporal Project Boundaries	The project start date.	x	x	x	x	x	x	x	x	x
PDR.7	Temporal Project Boundaries	The project crediting period start date and length.	x	x	x	x	x	x	x	x	x
PDR.8	Temporal Project Boundaries	The dates for mandatory baseline reevaluation after the project start date.	x	x	x	x	x	x	x	x	x
PDR.9	Temporal Project Boundaries	A timeline including the first anticipated monitoring period showing when project activities will be implemented.	x	x	x	x	x	x	x	x	x
PDR.10	Temporal Project Boundaries	A timeline for anticipated subsequent monitoring periods.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.11	Carbon Pools	A list of the greenhouse gases considered.	x	x	x	x	x	x	x	x	x
PDR.12	Carbon Pools	A list of the selected carbon pools and evidence for the conservative exclusion of any optional pools.	x	x	x	x	x	x	x	x	x
PDR.13	Carbon Pools	The definition and evidence to support the definition of a merchantable tree if the baseline scenario or project activities include logging.	x	x	x	x	x	x	x	x	x
PDR.14	Grouped Projects	A list and descriptions of all enrolled project activity instances in the group at the time of validation.	x	x	x	x	x	x	x	x	x
PDR.15	Grouped Projects	A map of the designated geographic area within which all project activity instances in the group will be located, indicating that all instances are in the same region.	x	x	x	x	x	x	x	x	x
PDR.16	Grouped Projects	A map of the common reference area, proxy area, activity-shifting leakage area, and market leakage area.	x	x	x	x	x	x	x	x	x
PDR.17	Determining the Baseline Scenario	Show that the identified baseline type is the most plausible baseline scenario identified in section 7	x	x	x	x	x	x	x	x	x
PDR.18	Agents and Drivers of Conversion	A list of the agents and drivers of conversion, including quantitative descriptions of agent mobilities.	x	x	x	x	x	x	x	x	x
PDR.19	Agents and Drivers of Conversion	A narrative describing the agents and drivers of conversion.	x	x	x	x	x	x	x	x	x
PDR.20	Agents and Drivers of Conversion	Descriptions of agents and drivers including any useful statistics and their sources.	x	x	x	x	x	x	x	x	x
PDR.21	Agents and Drivers of Conversion	A list of external drivers (covariates) of conversion used in the model, if any, that may be identified as part of a PRA, expert knowledge or literature (eg, median household income, road density, rainfall).	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.22	Project Accounting Areas	A digital (GIS-based) map of the project accounting areas, including aerial or satellite imagery showing that they are forested as of the project start date and 10 years prior to the project start date.	x	x	x	x	x	x	x	x	x
PDR.23	Project Accounting Areas	Justify the project accounting areas using the identified agents and drivers of conversion, constraints to conversion, and attributes listed above in section 6.2.	x	x	x	x	x	x	x	x	x
PDR.24	Project Accounting Areas	Selection of patch size at which land conversion typically occurs.								x	x
PDR.25	Project Accounting Areas	Justification of selection of patch size for delineation of project accounting area.								x	x
PDR.26	Identifying the Baseline Type - Forest	If Types F-P1.a, F-P1.b or F-P2 are selected, justification for meeting the definition of APD in the current VCS-approved AFOLU Requirements.	x	x	x						
PDR.27	Identifying the Baseline Type - Forest	If Type F-P1.a or F-P1.b is selected, evidence of legally-sanctioned commercial harvest in the baseline scenario.	x	x							
PDR.28	Identifying the Baseline Type - Forest	If Type F-P1.a is selected, evidence of legally-sanctioned deforestation in the baseline scenario	x								

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.29	Identifying the Baseline Type - Forest	If Type F-P1.b is selected, evidence of frontier configuration: a. Projects must demonstrate that the agent of degradation had access to the project area AND that comparable agents create roads for extraction of timber AND/OR b. Projects may produce permits, construction plans, contracts or tenders, budgets, or other evidence of the intent to construct roads.		x							
PDR.30	Identifying the Baseline Type - Forest	If Type F-U1 is selected, a spatial analysis of the project area showing that at least 25% of the perimeter is within 120 meters of deforestation that occurred within 10 years prior to the project start date and showing that the reference area is adjacent to at least 25% of the project area.				x					
PDR.31	Identifying the Baseline Type - Forest	If Type F-U2 is selected, a spatial analysis of the project area showing that at least 25% of the perimeter is within 120 meters of deforestation that occurred within 10 years prior to the project start date.					x				
PDR.32	Identifying the Baseline Type - Forest	If Types F-U1, F-U2 or F-U3 is selected, a spatial analysis of the project area showing that it is within 120 meters of deforestation that occurred within 10 years prior to the project start date.				x	x	x			

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.33	Identifying the Baseline Type - Grassland	If Type G-P2 is selected, justification for meeting the definition of APC in the current VCS-approved AFOLU Requirements. Justification must include evidence of intent to convert the project area and that the converted land-use category would meet the definition of native grassland / shrubland conversion.							x		
PDR.34	Identifying the Baseline Type - Grassland	If Type G-U1 is selected, a spatial analysis of the project area showing that the reference area is adjacent to at least 25% of the project area.								x	
PDR.35	Delineation of the Proxy Areas	A map of the delineated boundaries.	x	x	x	x	x	x	x		
PDR.36	Delineation of the Proxy Areas	Maps or other evidence that the proxy area’s site characteristics and landscape configuration is similar to its respective project accounting area, including: Vegetation; Climatic conditions (eg, mean temperature, rainfall, etc.); Topographic constraints to conversion (slope, aspect, elevation); Land use and/or land cover; Soil map (if available) or other soil information; Applicable infrastructure (eg, water ways, roads, railroad, airports, provision of electricity, and other access points); and Ownership/tenure boundaries that influence conversion (eg, government holdings, private holdings and reserves).	x	x	x	x	x	x	x		

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.37	Delineation of the Proxy Areas	A narrative describing the rationale for selection of proxy area boundaries, including the proxy area's similarity to the corresponding project accounting area with respect to vegetation, soil and climatic conditions.	x	x	x	x	x	x	x	x	x
PDR.38	Delineation of the Proxy Areas	Results of a spatial analysis to demonstrate the proxy area is converted, on average, as of the project start date.	x	x	x	x	x	x	x	x	x
PDR.39	Describing the Baseline Scenarios for Selected Carbon Pools	A qualitative description of the baseline scenario for each selected carbon pool.	x	x	x	x	x	x	x	x	x
PDR.40	Delineation of the Reference Area for Planned and Unplanned Types	A map of the delineated boundaries, demonstrating that the reference area was held by the identified baseline agent or agents and does not include the project area.	x	x	x	x	x	x	x	x	x
PDR.41	Delineation of the Reference Area for Planned and Unplanned Types	Results of a spatial analysis to demonstrate the reference area had as much forest or native grassland as the project accounting area at some point in time during the historic reference period.	x	x	x	x	x	x	x	x	x
PDR.42	Delineation of the Reference Area for Planned and Unplanned Types	Evidence that the management practices of the baseline agent in the reference area are similar to those that would have been applied to the project accounting area or areas in the baseline.	x	x	x	x	x	x	x	x	x
PDR.43	Delineation of the Reference Area for Planned and Unplanned Types	A description of the rationale for selection of reference area boundaries.	x	x	x	x	x	x	x	x	x
PDR.44	Delineation of the Reference Area for Planned and Unplanned Types	The documentation required in the reference area selection requirements that the selected reference area meets the Reference Area Selection Requirements.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.45	Defining the Reference Area for Planned Baseline Types	Evidence that secondary agents have been considered in the delineation of the reference area for baseline types F-P1.a and F-P1.b.	x	x							
PDR.46	Defining the Reference Period for Planned Types	Established reference period boundaries.	x	x	x				x		
PDR.47	Defining the Reference Period for Planned Types	The date when the agent acquired control of the reference area or when the land management practices employed in the reference area changed.	x	x	x				x		
PDR.48	Defining the Reference Period for Unplanned Types	Established reference period boundaries.				x	x	x		x	x
PDR.49	Defining the Reference Period for Unplanned Types	A list of available historic imagery for the reference area.				x	x	x		x	x
PDR.50	Defining the Reference Period for Unplanned Types	A timeline of important events as they relate to the agents and drivers of conversion.				x	x	x		x	x
PDR.51	Defining the Reference Period for Unplanned Types	Narrative rationale for the selection of the reference period.				x	x	x		x	x
PDR.52	Historic Imagery to Parameterize α, β and θ	A map of the reference area showing the area of "double-coverage".	x	x	x	x	x	x	x	x	x
PDR.53	Historic Imagery to Parameterize α, β and θ	Quantification of "double coverage"(greater than 90%).	x	x	x	x	x	x	x	x	x
PDR.54	Historic Imagery to Parameterize α, β and θ	A line plot of the historic image dates to confirm stationarity.	x	x	x	x	x	x	x	x	x
PDR.55	Historic Imagery to Parameterize α, β and θ	Evidence that all image pixels are not more than 30m x 30m.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.56	Historic Imagery to Parameterize α, β and θ	Empirical evidence that imagery is registered to within 10% RMSE, on average.	x	x	x	x	x	x	x	x	x
PDR.57	Sampling Conversion to Parameterize α, β and θ	The sample size.	x	x	x	x	x	x	x	x	x
PDR.58	Sampling Conversion to Parameterize α, β and θ	A map of the reference area showing the sample point locations.	x	x	x	x	x	x	x	x	x
PDR.59	Parameterizing α, β and θ	The covariates that were considered and their data sources.	x	x	x	x	x	x	x	x	x
PDR.60	Parameterizing α, β and θ	The parameters in θ that were evaluated during model selection.	x	x	x	x	x	x	x	x	x
PDR.61	Parameterizing α, β and θ	The parameters in θ of the selected model.	x	x	x	x	x	x	x	x	x
PDR.62	Parameterizing α, β and θ	The rationale used for selecting θ including comparisons of AIC.	x	x	x	x	x	x	x	x	x
PDR.63	Minimizing Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$	A protocol for interpreting land cover state from imagery, which must include guidance for interpreting the following: Discerning conversion features using shape, texture and context in the reference area landscape Addressing seasonal variation of vegetation (phenology) within imagery Identifying and addressing the characteristics of specific landscape configurations (ie, mosaic forest, grassland, etc.)	x	x	x	x	x	x	x	x	x
PDR.64	Minimizing Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$	The results of an independent check of the interpretation.	x	x	x	x	x	x	x	x	x
PDR.65	Minimizing Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$	Evidence that systematic errors, if any, from the independent check of the interpretation were corrected.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.66	Estimating Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$	The estimated uncertainty σEM from [F.13] and statistical summaries from model fitting software, if available.	x	x	x	x	x	x	x	x	x
PDR.67	Estimating Uncertainty in Parameters $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$	Reference to uncertainty calculations.	x	x	x	x	x	x	x	x	x
PDR.68	Parameterizing t_{SA}	The parameter tSA as the number of days after the primary agent begins commercial logging until when the secondary agent of deforestation is likely to begin degrading the project accounting area.	x	x							
PDR.69	Parameterizing t_{SA}	A description of how tSA was obtained.	x	x							
PDR.70	Parameterizing t_{SA}	Harvest plans for the project accounting area under the baseline scenario, results from the PRA or analysis of the reference area to determine the parameter.	x	x							
PDR.71	Parameterizing t_{SA}	The parameter tPA as the number of days relative to the project start date when the primary agent began or would have begun legally-sanctioned commercial logging in the project accounting area.	x	x							
PDR.72	Parameterizing t_{SA}	A description of how tPA was obtained.	x	x							
PDR.73	Parameterizing t_{SA}	Harvest plans for the project accounting area under the baseline scenario or public records to support the determination of the parameter.	x	x							
PDR.74	Determining x_0	A table of covariate values as of the project start date and a description of how the values were determined including any interpolation or extrapolation methods.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.75	Determining x_0	Justification for why the rate of conversion predicted by covariates exceeds the rate indicated from historical conversion patterns.	x	x	x	x	x	x	x	x	x
PDR.76	Parameterizing *m*	The parameter m as the average carbon in merchantable trees cut each year as a result of legally-sanctioned commercial logging.	x	x							
PDR.77	Parameterizing *m*	Documentation of how m was determined. This may include an analysis of carbon stocks in merchantable trees in the project accounting area, timber harvest plans for the project accounting area or reference to a publication containing the maximum allowable cut applicable to the project area. The parameter must be greater than zero.	x	x							
PDR.78	Determining γ	The project shift parameter γ as the number of days between the beginning of the historical reference period and the project start date.	x	x	x				x		
PDR.79	Parameterizing *q*	The parameter q as the number of days between the onset of degradation and the beginning of conversion.	x	x	x	x	x	x	x	x	x
PDR.80	Parameterizing *q*	If the default of zero is not selected for q, then a justification for the determination of q.	x	x	x	x	x	x	x	x	x
PDR.81	Parameterizing r_U	The parameter rU as the ratio of converted perimeter to total threatened perimeter, or the ratio of converted area to total project accounting area(s), as of the project start date.					x	x			x
PDR.82	Parameterizing r_U	Description of how rU was obtained.					x	x			x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.83	Parameterizing r_U	Results of GIS analysis to determine or measure rU in the project area including the dates of images used to identify conversion.					x	x			x
PDR.84	Empirically Estimating λ_{SOC}	Description of how samples from the reference area were selected including stratification, if any.	x	x	x	x	x	x	x	x	x
PDR.85	Empirically Estimating λ_{SOC}	A map of sample locations in the reference area.	x	x	x	x	x	x	x	x	x
PDR.86	Empirically Estimating λ_{SOC}	A table showing the conversion time for each area (farm or otherwise) from which samples were taken.	x	x	x	x	x	x	x	x	x
PDR.87	Empirically Estimating λ_{SOC}	Description of and statistics for the method applied to estimate λSOC.	x	x	x	x	x	x	x	x	x
PDR.88	Empirically Estimating λ_{SOC}	Graph of projected decay model over project lifetime.	x	x	x	x	x	x	x	x	x
PDR.89	Literature Estimates for λ_{SOC}	Inclusion of decay model on which parameter is based.	x	x	x	x	x	x	x	x	x
PDR.90	Literature Estimates for λ_{SOC}	Explicit description of referenced literature, including project location, sampling methodology, included species, sample size, duration of field experiments, and decay parameter upon which decay is based.	x	x	x	x	x	x	x	x	x
PDR.91	Literature Estimates for λ_{SOC}	Graph of projected decay model over project lifetime.	x	x	x	x	x	x	x	x	x
PDR.92	Literature Estimates for λ_{SOC}	If decay model is based on any other element besides carbon, defense of ability to predict carbon decay must be provided.	x	x	x	x	x	x	x	x	x
PDR.93	Baseline Reevaluation	All required documentation as specified in section 6 for the project prior to the baseline reevaluation.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.94	Baseline Reevaluation	All required documentation as specified in section 6 for the project after the baseline reevaluation including the reevaluation period.	x	x	x	x	x	x	x	x	x
PDR.95	Baseline Reevaluation	A narrative of the reevaluation including any obstacles and how they were overcome.	x	x	x	x	x	x	x	x	x
PDR.96	Reevaluation of the Reference Area and Period	A map of the new reference area.	x	x	x	x	x	x	x	x	x
PDR.97	Re-parameterization of α, β and θ	Summary of new data observed in the new reference area.	x	x	x	x	x	x	x	x	x
PDR.98	Re-parameterization of α, β and θ	The re-parameterized values $\hat{\alpha}$, $\hat{\beta}$ and $\hat{\theta}$.	x	x	x	x	x	x	x	x	x
PDR.99	Demonstration of Project Additionality	A list of alternative land use scenarios to the project.	x	x	x	x	x	x	x	x	x
PDR.100	Demonstration of Project Additionality	Justification for the selected baseline scenario. This justification can include expert knowledge, results from the participatory rural appraisal and ex-ante estimates of avoided emissions (see sections 6.1 and 8.4.7).	x	x	x	x	x	x	x	x	x
PDR.101	Demonstration of Project Additionality	An investment or barriers analysis proving that the project is not the most economical option.	x	x	x	x	x	x	x	x	x
PDR.102	Demonstration of Project Additionality	A common practice analysis including a list of project activities and the drivers of conversion that they address.	x	x	x	x	x	x	x	x	x
PDR.103	Demonstration of Project Additionality	Evident compliance with the minimum requirements of the aforementioned VCS tool. This evidence may be the same as the evidence provided to meet reporting requirements listed in section 4.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.104	Leakage Mitigation Strategies	A list of project activities designed to mitigate leakage.	x	x	x	x	x	x	x	x	x
PDR.105	Delineation of the Activity-Shifting Leakage Area	A map of the delineated boundaries.	x	x	x	x	x	x	x	x	x
PDR.106	Delineation of the Activity-Shifting Leakage Area	Maps of the landscape configuration, including: a. Topography (elevation, slope, aspect); b. Recent land use and land cover (either a thematic map created by the project proponent or publicly available map); c. Access points; d. Soil class maps (if available); e. Locations of important markets; f. Locations of important resources like waterways or roads; and g. Land ownership/tenure boundaries.	x	x	x	x	x	x	x	x	x
PDR.107	Delineation of the Activity-Shifting Leakage Area	A narrative describing the rationale for selection of activity-shifting leakage area boundaries. If the activity-shifting leakage area is smaller than the project accounting area or cannot be defined, justification for the size of the area. If foreign agents have been identified as an agent of conversion, justification that they are unlikely to shift their activities outside the activity-shifting leakage area.	x	x	x	x	x	x	x	x	x
PDR.108	Delineation of the Activity-Shifting Leakage Area	Results of a spatial analysis to demonstrate the activity-shifting leakage area is entirely forested as of the project start date.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.109	Delineation of the Activity-Shifting Leakage Area	Results of a spatial analysis to demonstrate the activity-shifting leakage area is no larger than the project accounting area.	x	x	x	x	x	x	x	x	x
PDR.110	Determining the Market Discount Factor	The selected discount factor pL ME.	x	x	x	x	x	x	x	x	x
PDR.111	Determining the Market Discount Factor	Calculations of cL AGMT in the market leakage area, including references to literature if cited.	x	x	x	x	x	x	x	x	x
PDR.112	Determining the Market Discount Factor	Justification for the selection of the discount factor.	x	x	x	x	x	x	x	x	x
PDR.113	Delineation of the Market Leakage Area	A map of the delineated boundaries.	x	x	x	x	x	x	x	x	x
PDR.114	Delineation of the Market Leakage Area	Maps of the landscape configuration, including: a. Topography (elevation, slope, aspect); b. Recent land use and land cover (either a thematic map created by the project proponent or publicly available map); c. Access points; d. Soil class maps (if available); e. Locations of important markets; f. Locations of important resources like waterways or roads; and g. Land ownership/tenure boundaries.	x	x	x	x	x	x	x	x	x
PDR.115	Delineation of the Market Leakage Area	A narrative describing the rationale for selection of market leakage area boundaries.	x	x	x	x	x	x	x	x	x

PDR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
PDR.116	Delineation of the Market Leakage Area	Results of a spatial analysis to demonstrate the market leakage area is entirely forested as of the project start date.	x	x	x	x	x	x	x	x	x
PDR.117	Delineation of the Market Leakage Area	Results of a spatial analysis to demonstrate the market leakage area is as large or larger than the project accounting area.	x	x	x	x	x	x	x	x	x
PDR.118	*Ex-Ante* Estimation of NERs	The projected avoided baseline emissions, project emissions and leakage for each monitoring period and vintage year over the lifetime of the project.	x	x	x	x	x	x	x	x	x
PDR.119	*Ex-Ante* Estimation of NERs	A narrative description of sources used to estimate the leakage rate and demonstration that the estimated rate is conservative.	x	x	x	x	x	x	x	x	x
PDR.120	*Ex-Ante* Estimation of NERs	If included in project activities, a description of procedures used to estimate the rate of biomass burning, charcoal production or logging and demonstration that these estimates are conservative.	x	x	x	x	x	x	x	x	x
PDR.121	Data and Parameters Available at Validation	The value for each variable in Appendix G.	x	x	x	x	x	x	x	x	x
PDR.122	Description of the Monitoring Plan	Summary of sampling procedures for the project accounting areas, with a copy of a sampling protocol used to carry out measurements.	x	x	x	x	x	x	x	x	x
PDR.123	Description of the Monitoring Plan	Summary of sampling procedures for the proxy areas, with a copy of a sampling protocol used to carry out measurements.	x	x	x	x	x	x	x	x	x
PDR.124	Description of the Monitoring Plan	Summary of sampling procedures for the activity-shifting leakage areas, with a copy of a sampling protocol used to carry out measurements.	x	x	x	x	x	x	x	x	x

APPENDIX J: MONITORING REPORT REQUIREMENTS BY BASELINE TYPE

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.1	Spatial Project Boundaries	A digital (GIS-based) map of the project area with at least the above minimum requirements for delineation of the geographic boundaries.	x	x	x	x	x	x	x	x	x
MR.2	Temporal Project Boundaries	The project start date.	x	x	x	x	x	x	x	x	x
MR.3	Temporal Project Boundaries	The project crediting period start date, end date and length.	x	x	x	x	x	x	x	x	x
MR.4	Grouped Projects	A list and descriptions of all instances in the group.	x	x	x	x	x	x	x	x	x
MR.5	Grouped Projects	A map of the locations or boundaries of all instances in the group indicating that all instances are in the same region.	x	x	x	x	x	x	x	x	x
MR.6	Project Accounting Areas	A digital (GIS-based) map of the project accounting areas with at least the above minimum requirements for delineation of the geographic boundaries.	x	x	x	x	x	x	x	x	x
MR.7	Determining t_{PAI}	For each project activity instance in the group, its project activity instance start date.	x	x	x	x	x	x	x	x	x
MR.8	Determining t_{PAI}	For each project accounting area, the value of tPAI.	x	x	x	x	x	x	x	x	x
MR.9	Determining x_{PAI}	A table of covariate values as of the project activity instance start dates and a description of how the values were determined including any interpolation or extrapolation methods.	x	x	x	x	x	x	x	x	x
MR.10	Baseline Emissions	Calculations of current baseline emissions EB Δm as of the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.11	Baseline Emissions	Calculations of baseline emissions EB Δm-1 from prior monitoring periods.	x	x	x	x	x	x	x	x	x
MR.12	Baseline Emissions	Calculations of cumulative baseline emissions for each selected pool (EB BMm and EB SOCm) and undecayed carbon (CB BGBm, CB DWm, CB SOCm and CB WPm), as of the current monitoring period.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.13	Baseline Emissions from Biomass	Calculations of cumulative baseline emissions from biomass EB BMm for the current monitoring period.	x	x	x	x	x		x	x	x
MR.14	Baseline Emissions from Biomass	Calculations of cumulative baseline emissions from biomass EB BMm for all prior monitoring periods.	x	x	x	x	x		x	x	x
MR.15	Applying the Spatial Algorithm	The order of strata from lowest carbon stocks to highest carbon stocks based on the average across all pools.		x				x			
MR.16	Applying the Spatial Algorithm	Calculations for each step which are carried through from monitoring period to monitoring period.		x				x			
MR.17	Applying the Spatial Algorithm	Calculations of cumulative baseline emissions from biomass EB BMm for prior monitoring periods.		x				x			
MR.18	Baseline Emissions from SOC for Types F-P1.a, F-P1.b, F-P2 and G-P2	An estimate of current baseline emissions from SOC EB Δ SOCm as of the current monitoring period.	x	x	x				x		
MR.19	Baseline Emissions from SOC for Types F-P1.a, F-P1.b, F-P2 and G-P2	An estimate of cumulative baseline emissions from SOC EB SOCm for the current monitoring period.	x	x	x				x		
MR.20	Baseline Emissions from SOC for Types F-P1.a, F-P1.b, F-P2 and G-P2	Calculations of cumulative baseline emissions from SOC EB SOCm for all prior monitoring periods.	x	x	x				x		
MR.21	Carbon Not Decayed in DW	An estimate of carbon stored in non-decayed DW CB DWm for the current monitoring period.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.22	Carbon Not Decayed in DW	An estimate of cumulative baseline emissions from DW EB DWm for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.23	Carbon Not Decayed in DW	An estimate of cumulative baseline emissions from AGMT EB AGMTm for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.24	Carbon Not Decayed in DW	Calculations of cumulative baseline emissions from DW EB DWm for all prior monitoring periods.	x	x	x	x	x	x	x	x	x
MR.25	Carbon Not Decayed in DW	Calculations of cumulative baseline emissions from AGMT EB AGMTm for all prior monitoring periods.	x	x	x	x	x	x	x	x	x
MR.26	Carbon Not Decayed in BGB	An estimate of carbon stored in non-decayed BGB CB BGBm for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.27	Carbon Not Decayed in BGB	An estimate of cumulative baseline emissions from BGB EB BGBm for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.28	Carbon Not Decayed in BGB	Calculations of cumulative baseline emissions from BGB EB BGBm for all prior monitoring periods.	x	x	x	x	x	x	x	x	x
MR.29	Carbon Not Decayed in SOC	An estimate of carbon stored in non-decayed SOC CB SOCm for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.30	Carbon Stored in Wood Products	Carbon stored in long-lived wood products CB WPm after 100 years.	x	x	x	x	x	x	x	x	x
MR.31	Carbon Stored in Wood Products	Calculations to determine CB WPm.	x	x	x	x	x	x	x	x	x
MR.32	Emissions Events in Project Area	A map of the boundaries of any significant disturbance in the project accounting areas during the monitoring period.	x	x	x	x	x	x	x	x	x
MR.33	Emissions Events in Project Area	Evidence that plots were installed into these disturbed areas and were measured per section 9.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.34	Emissions from Burning from Project Activities	A table of events when woody or herbaceous biomass was burned during the monitoring period, showing the weight of woody or herbaceous biomass in tonnes and the date consumed.	x	x	x	x	x	x	x	x	x
MR.35	Carbon Stored in Wood Products from Project Activities	Carbon stored in long-lived wood products CP Δ WPm after 100 years.	x	x	x	x	x	x	x	x	x
MR.36	Carbon Stored in Wood Products from Project Activities	Scale reports or records of carbon in log production by wood products type CP tym.	x	x	x	x	x	x	x	x	x
MR.37	Carbon Stored in Wood Products from Project Activities	Calculations to determine CP Δ WPm.	x	x	x	x	x	x	x	x	x
MR.38	Livestock Grazed in the Project Area	A report or record of the number of livestock per species of livestock $n_{LS\,i}$ being grazed within the project area $\mathrm{n}_{\mathrm{LS\,i}}$.	x	x	x	x	x	x	x	x	x
MR.39	Livestock Grazed in the Project Area	Emissions released due to livestock grazing $\mathrm{E}_{\mathrm{P\,\Delta\,LS}}^{[\mathrm{m}]}$.	x	x	x	x	x	x	x	x	x
MR.40	Livestock Grazed in the Project Area	Calculations to determine $\mathrm{E}_{\mathrm{P\,\Delta\,LS}}^{[\mathrm{m}]}$.	x	x	x	x	x	x	x	x	x
MR.41	Synthetic Fertilizer in the Project Area	A report or record of the quantity of synthetic fertilizer applied in the project area.	x	x	x	x	x	x	x	x	x
MR.42	Synthetic Fertilizer in the Project Area	Emissions released due to use of synthetic fertilizer $\mathrm{E}_{\mathrm{P\,\Delta\,LS}}^{[\mathrm{m}]}$.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.43	Synthetic Fertilizer in the Project Area	Calculations to determine $E^{[m]}_{P\,\Delta\,LS}$.	x	x	x	x	x	x	x	x	x
MR.44	Leakage Mitigation Strategies	A description of project activities that have been implemented since the project start date and the estimated effects of these activities on leakage mitigation.	x	x	x	x	x	x	x	x	x
MR.45	Commodity Production for Leakage Mitigation	A list of mitigation activities reduce demand for forgone goods and services.	x	x	x	x	x	x	x	x	x
MR.46	Commodity Production for Leakage Mitigation	Quantities for the reduction or replacement of goods and services if they are used in section 8.3.3.4.	x	x	x	x	x	x	x	x	x
MR.47	Commodity Production for Leakage Mitigation	Methods for measuring the reduction or replacement of goods and services.	x	x	x	x	x	x	x	x	x
MR.48	Estimating Emissions from Activity-Shifting Leakage	Calculated cumulative emissions from activity-shifting leakage for the current monitoring period $\boldsymbol{E^{[m]}_{L\,AS}}$ and supporting calculations.	x	x	x	x	x	x	x	x	x
MR.49	Estimating Emissions from Activity-Shifting Leakage	Calculated cumulative emissions from activity-shifting leakage for the prior monitoring periods $\boldsymbol{E^{[m]}_{L\,AS}}$. If an activity-shifting leakage area is not installed, then include results from the participatory rural appraisal and/or expert knowledge, with an analysis of the nearest suitable forest cover for activity shifting leakage.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.50	Change to the Activity-Shifting Leakage Area	A description and justification of the change to the activity-shifting leakage area.	x	x	x	x	x	x	x	x	x
MR.51	Change to the Activity-Shifting Leakage Area	A map of the delineated boundaries.	x	x	x	x	x	x	x	x	x
MR.52	Change to the Activity-Shifting Leakage Area	Maps of the landscape configuration, including: a. Topography (elevation, slope, aspect); b. Recent land use and land cover (either a thematic map created by the project proponent or publicly available map); c. Access points; d. Soil class maps (if available); e. Locations of important markets; f. Locations of important resources like waterways or roads; and g. Land ownership/tenure boundaries.	x	x	x	x	x	x	x	x	x
MR.53	Change to the Activity-Shifting Leakage Area	A narrative describing the rationale for selection of activity-shifting leakage area boundaries. If the activity-shifting leakage area is smaller than the project accounting area or cannot be defined, justification for the size of the area.	x	x	x	x	x	x	x	x	x
MR.54	Change to the Activity-Shifting Leakage Area	Results of a spatial analysis to demonstrate the activity-shifting leakage area is entirely forested as of the project start date.	x	x	x	x	x	x	x	x	x
MR.55	Change to the Activity-Shifting Leakage Area	Results of a spatial analysis to demonstrate the activity-shifting leakage area is no larger than the project accounting area.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.56	Estimating $p_{L\ DEG}$	The estimated value pL DEGm for the current monitoring period and supporting calculations.	x	x	x	x	x	x	x	x	x
MR.57	Estimating $p_{L\ DEG}$	The calculated value pL DEGm=0 calculated for the first monitoring period.	x	x	x	x	x	x	x	x	x
MR.58	Estimating $p_{L\ CON\ G}$	The estimated value pL CON Gm for the current monitoring period and supporting calculations.	x	x	x	x	x	x	x	x	x
MR.59	Estimating $p_{L\ CON\ G}$	The calculated value pL CON Gm=0 calculated for the first monitoring period.	x	x	x	x	x	x	x	x	x
MR.60	Determining Emissions from Market Leakage	The selected approach to determining emissions from market leakage.	x	x	x	x	x	x	x	x	x
MR.61	Determining Emissions from Market Leakage	Estimated cumulative emissions from market leakage for the current monitoring period EL MEm and supporting calculations.	x	x	x	x	x	x	x	x	x
MR.62	Confidence Deduction Determining Emissions from Market Leakage	Calculated cumulative emissions from market leakage for the prior monitoring periods EL MEm.	x	x	x	x	x	x	x	x	x
MR.63	Ensuring No Leakage Within Project Proponent's Ownership	Provide location-by-location evidence that management plans and land-use designations of all areas under the project proponent's control within the country have not changed as a result of the project. For entities with a conservation mission, provide evidence of the organization's policy not to change the land use of other owned and managed lands, and evidence of compliance with such a policy.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.64	Ensuring Constancy of Baseline Operator Management	Provide evidence in the form of GIS imagery, PRA evidence, or the baseline operator's management plan that management plans or land-use designations have not changed in the baseline operator's other lands.	x	x	x						
MR.65	Quantification of GERs	Quantified GERs for the current monitoring period including references to calculations.	x	x	x	x	x	x	x	x	x
MR.66	Quantification of GERs	Quantified GERs for the prior monitoring period.	x	x	x	x	x	x	x	x	x
MR.67	Quantification of GERs	A graph of GERs by monitoring period for all monitoring periods to date.	x	x	x	x	x	x	x	x	x
MR.68	Confidence Deduction	The confidence deduction EUm and estimated standard errors used to determine the confidence deduction.	x	x	x	x	x	x	x	x	x
MR.69	Confidence Deduction	Reference to calculations used to determine the confidence deduction.	x	x	x	x	x	x	x	x	x
MR.70	Quantification of NERs Using a Linear Model	The linear model used to generate GERs for the current monitoring period.	x	x	x	x	x	x	x	x	x
MR.71	Quantification of NERs Using a Linear Model	A graph of GERs from the linear model by monitoring period for all monitoring periods to date that used a linear model.	x	x	x	x	x	x	x	x	x
MR.72	Reversal Event	A description of the reversal including which pools contributed to the reversal and reasons for its occurrence.	x	x	x	x	x	x	x	x	x
MR.73	Reversal Event as a Result of Baseline Reevaluation	A description of the reversal including a summary of new data obtained in the reference area.	x	x	x	x	x	x	x	x	x

MR #	Category	Requirement	F-P1.a	F-P1.b	F-P2	F-U1	F-U2	F-U3	G-P2	G-U1	G-U2
MR.74	Quantification of NERs for a PAA	Quantified NERs for the current monitoring period including references to calculations.	x	x	x	x	x	x	x	x	x
MR.75	Quantification of NERs for a PAA	Quantified NERs for the prior monitoring period.	x	x	x	x	x	x	x	x	x
MR.76	Quantification of NERs for a PAA	A graph of NERs by monitoring period for all monitoring periods to date.	x	x	x	x	x	x	x	x	x
MR.77	Buffer Account	Reference to the VCS requirements used to determine the buffer account allocation.	x	x	x	x	x	x	x	x	x
MR.78	Buffer Account	Reference to calculations used to determine the buffer account allocation.	x	x	x	x	x	x	x	x	x
MR.79	Quantification of NERs across PAAs	Quantified NERs for the current monitoring period including references to calculations.	x	x	x	x	x	x	x	x	x
MR.80	Quantification of NERs across PAAs	Quantified NERs for the prior monitoring period.	x	x	x	x	x	x	x	x	x
MR.81	Quantification of NERs across PAAs	A graph of NERs by monitoring period for all monitoring periods to date.	x	x	x	x	x	x	x	x	x
MR.82	Vintages	Quantified NERs by vintage year for the current monitoring period including references to calculations.	x	x	x	x	x	x	x	x	x
MR.83	Evaluating Project Performance	Comparison of NERs presented for verification relative to NERs from ex-ante estimates.	x	x	x	x	x	x	x	x	x

DOCUMENT HISTORY

Version	Date	Comment
v1.0	11 Feb 2011	Initial version released
v1.1	10 Nov 2011	Clarifications were made to the soil carbon loss model in section 6.5. Specifically, updates (all effective on issue date) were made to: 1. Clarify the lambda value in section 6.5.2. 2. Clarify the procedures for soil sampling in section 6.5.3.
v2.0	26 Oct 2012	Revisions were made to the methodology to accommodate a variety of baseline deforestation scenarios. The methodology now quantifies GHG removals from avoiding planned deforestation and unplanned deforestation in both the mosaic and frontier configurations. End land use carbon stocks are based on a proxy area. The decay of carbon from the belowground biomass, dead wood, and harvested wood products pools have been updated to decay over time and may not be assumed to be immediately released.
v2.1	13 Dec 2012	A correction was made to the methodology to insert Equation [F.9] to Appendix F which was also referenced in section 6.18, because the equation was inadvertently omitted.
v3.0	6 Jun 2014	1. Avoided Conversion of Grasslands and Shrublands (ACoGS) was added as an eligible project type under the methodology. 2. Clarification was provided for baseline type F-P1 by dividing it into baseline types F-P1.a and F-P1.b.

About GCS

GreenCollar Consulting Solutions (GCS) is an environmental markets and project services consultancy with extensive experience in the development of agriculture, forestry and other land use (AFOLU) methodologies, policy and projects throughout Asia-Pacific. Our goal is to provide the tools and support services that will help land managers realize the full commercial potential of their environmental assets. Our diverse work experience extends from agriculture and forest management methodology development and project development, to domestic and international policy advice. Our project experience includes work on some of the world's largest carbon forestry and agricultural projects and initiatives. GCS is based in Sydney and has strong strategic partnerships with firms in Europe, North America and Asia.

1 SOURCES

This methodology uses the latest versions of the following methodologies, modules and tools:

- CDM *Tool for Calculation of the Number of Sample Plots for Measurements within A/R CDM Project Activities*
- CDM *Tool for testing significance of GHG emissions in A/R CDM project activities*
- VCS methodology *VM0003 Methodology for Improved Forest Management through Extension of Rotation Age*
- VCS methodology *VM0005 Methodology for Conversion of Low-Productive Forests to High-Productive Forests*
- VCS methodology *VM0007 REDD+ Methodology Framework (REDD-MF)*
- VCS methodology *VM0011 Methodology for Improved Forest Management: Calculating GHG Benefits from Logged to Protected Forest*
- VCS tool *VT0001 Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities*

2 SUMMARY DESCRIPTION

Additionality	Project Method
Crediting Baseline	Project Method

This Logged to Protected Forest (LtPF) methodology provides a detailed procedure to estimate the net GHG emission reductions/removals resulting from the implementation of IFM projects aimed at the protection of forests that would be logged in the absence of the project.

The core methodological components are as follows:

- Determine Eligibility: Sets the criteria for eligibility of projects under the methodology
- Set Project Boundaries and Scope: Provides guidelines for defining the geographical and temporal boundaries of the project and lists the GHG emissions sources and carbon pools to be included in the project
- Assess Baseline Scenario, Additionality and Baseline Modelling: Provides guidelines to select the most conservative baseline scenario and to determine the additionality of the project

- Quantify Baseline Emissions: Provides the detailed procedure to develop conservative estimates of net greenhouse gas emissions resulting from changes in carbon stocks as a result of planned timber harvest in the baseline scenario

- Quantify Project Emissions: Provides the detailed procedure to develop conservative estimates of net greenhouse gas emissions resulting from changes in carbon stocks in the project scenario

- Quantify Leakage: Describes the approach to account for leakage arising from the implementation of project activities

- Quantify Net Emission Reductions: Provides the approach to determine the amount of net greenhouse gas emission reductions/removals at the end of each year for both the baseline and project scenarios

- Quantify Verified Carbon Units: Provides the approach to determine, on the basis of the amount of net greenhouse gas emission reductions/removals, and deductions to account for risk and uncertainty, the amount of Verified Carbon Units (VCUs) that should be credited to the project each year over the project crediting period

- Perform Ongoing Monitoring: Provides guidelines for the implementation of a monitoring plan and identifies monitored parameters to assess carbon stock change and disturbance in the project scenario.

3 DEFINITIONS

In addition to the definitions set out in VCS document *Program Definitions*, the below definitions apply to this methodology.

Commercial Timber Harvest
Removal of merchantable trees from a forest to obtain income from the wood products

Diameter at Breast Height (DBH)
A common dendrometric measurement to determine the diameter of the bole of a tree at 1.3 meters

Forestry Infrastructure
Physical infrastructure needed to carry out forestry operations, including (but not restricted to) roads, skid trails and log landings in the project area

Forest Inventory
A system for measuring the extent, quantity and condition of a forest by sampling through:

- A set of objective sampling methods designed to quantify the spatial distribution, composition and rates of change of forest parameters within specified levels of precision for the purpose of management; and
- Listing of data from such a survey

Land Parcel
The area of land within a forest specified for annual logging and timber extraction operations as defined in a timber harvest plan

Logging Slash
A component of the deadwood pool, representing the woody debris left in the forest estate that is generated during a timber harvest event

Planned Timber Harvest
Planned removal of merchantable trees from a forest to obtain income from the wood products under legal conditions for harvest and documented under a timber harvest plan

Timber Harvest Plan
Description of the methods and operations needed to harvest timber from a forest under a given set of legal conditions for harvest that includes:

- Demarcation of non-harvest areas within the forest
- Division of the harvestable forest into annual operating areas (land parcels) presented as descriptions and maps
- Design and presentation of the transport system for the removal of harvested timber products; and a description of the harvest and transport machinery used for timber harvest

3.1 Symbols and Notations

3.1.1 Physical quantities

This section presents the symbols that are used throughout the methodology to represent physical quantities used in the accounting equations.

Flows of greenhouse gas(es)

The symbol GHG is the common identifier used throughout this methodology to represent flows of greenhouse gas(es) to/from the atmosphere.

For these flows, the absolute value represents the intensity of the flow, in tCO_2e year-1, or the total amounts exchanged with the atmosphere, in tCO_2e.

Carbon stocks

The symbol C is the common identifier used throughout this methodology to represent carbon stocks. The values presented are either carbon stocks (in tC), or carbon stocks per unit area (in tC·ha-1) as indicated in the methodology described under Section 2.

Carbon stock changes

The symbol ∆C is the common identifier used throughout this methodology to represent changes in carbon stocks. The values presented could be either total changes in carbon stocks (in tC), annual changes in carbon stocks (in tC·year-1), or annual changes in carbon stocks per unit area (in tC·ha-1·year-1), as indicated in the methodology described under Section 2.

3.1.2 Scenario qualifiers

This section presents the symbols that are used throughout the methodology as scenario qualifiers, for the physical quantities used in the accounting equations as follows:

- Physical quantities referring to the baseline scenario feature the suffix (BSL)
- Physical quantities referring to the project scenario feature the suffix (PRJ)
- Physical quantities derived from baseline and project scenario accounting feature the suffix (LtPF)

4 APPLICABILITY CONDITIONS

Projects must fall within the VCS AFOLU project category “IFM: Logged to Protected Forest” as defined in the most recent version of the VCS *AFOLU Requirements* document.

Specific conditions under which this methodology is applicable are:

- Forest management in the baseline scenario must be planned timber harvest
- Under the project scenario, forest use must be limited to activities that do not result in commercial timber harvest or forest degradation
- Planned timber harvest must be estimated using forest inventory methods that determine allowable off take as volume of timber (m^3 ha-1)
- The boundaries of the forest land must be clearly defined and documented
- The baseline scenario cannot include conversion to managed plantations

- The baseline scenario, project scenario and project case cannot include wetland or peatland

- All applicability conditions of VCS and CDM tools used in conjunction with this methodology must be met.

4.1 Eligibility

Legal Right to Harvest

The legal right to harvest must pre-exist the implementation of the project.

The legal right to harvest must be issued by a relevant government body, define a legal allocation of rights to a forest timber resource, and include a plan for forest management that includes a definition of the spatial extent of the forest, the volume of the timber resource to be extracted and a description of harvesting practices.

Rights to forest management must be demonstrated by documentary proof of legal permissibility for timber harvest, intent to harvest and a description of the timber resource. This proof must be issued by the relevant (governmental) regulatory body that has designated, sanctioned or approved the project area (or areas) for forest management.

Intent to Harvest

The project proponent must demonstrate intent to harvest through the following forms of evidence originating prior to the date of all evidence in pursuit of carbon finance/consideration of IFM.

Projects must provide either:

- Documented evidence demonstrating that:

    - The project site is representative of other forestlands harvested in the country within the past two years; and,

    - The project site is within commercially viable distance to existing transport networks and a port for timber export or a mill for timber processing; or,

- A valid and verifiable government-approved timber management plan for harvesting the project area.

5 PROJECT BOUNDARY

5.1 Geographical Boundaries

The project proponent must clearly define the spatial boundaries of the project so as to facilitate accurate measuring, monitoring, accounting and verifying of the project's emission reductions and removals.

The IFM project activity may contain more than one discrete area of land.

When describing physical project boundaries, the following information must be provided per discrete area:

- Name of the project area (including compartment number, allotment number, local name)
- Unique identifier for each discrete land parcel used in the timber harvest plan
- Map(s) of the area (preferably in digital format)
- Geographic coordinates of each polygon vertex (preferably obtained from a geodetic coordinate or from a geo-referenced digital map)
- Total land area
- Details of forest land rights holder and user rights

The geographic boundaries of an IFM project are fixed and thus do not change over the project crediting period.

The geographic boundaries for leakage from market effects are those of the country in which the project area is located.

5.2 Temporal Boundaries

The temporal boundaries are defined by the project start date and length of the project crediting period.

The minimum duration of a monitoring period is one year and the maximum duration is 10 years.

5.3 Carbon Pools

The carbon pools included or excluded from the project boundary are shown in Table 1 below.

Table 1: Carbon Pools

Carbon pools	Included?	Justification / Explanation of choice
Aboveground trees	Included	The stock change in the above ground tree biomass must be estimated
Above ground non-tree	Excluded	Exclusion is always conservative when forests remains as forest
Belowground	Excluded	Unlikely to change significantly in forests remaining as forests and is difficult to measure-omission is conservative
Deadwood (logging slash)	Included in the baseline	The dead wood (logging slash) carbon pool is expected to be larger in the baseline than in the project scenario, and therefore this pool must be included
Dead wood (naturally accumulated)	Excluded	Following IPCC guidelines[1], it is assumed that carbon stocks in the naturally occurring dead wood pool (both standing and lying) are equivalent in both the project and baseline scenario, and therefore this pool is conservatively excluded. It is not conservative to account for this pool in the baseline scenario only.
Harvested wood products	Included	Will be greater in baseline than project scenario and significant
Litter	Excluded	Insignificant and exclusion is conservative
Soil organic carbon	Excluded	Exclusion is always conservative when forests remains as forest

[1]IPCC 2006, 2006 IPCC Guidelines for National Greenhouse Gas Inventories; Volume 4 AFOLU, Prepared by the National Greenhouse Gas Inventories Programme, Eggleston H.S., Buendia L., Miwa K., Ngara T. and Tanabe K. (eds). Published: IGES, Japan.

5.4 Greenhouse Gases

The emission sources included in or excluded from the project boundary are shown in Table 2 below.

The project proponent may choose to exclude to account for GHG emissions related to the combustion of fossil fuels (please refer to Section 8.1.5), which is conservative. If the project proponent decides to include accounting for GHG emissions related to fossil fuel combustion, then the specific GHGs must be tested for significance, using the most recent version of the CDM *Tool for testing significance of GHG emissions in A/R CDM project activities.*

If the application of the tool leads to the conclusion that the emission source is insignificant[2], then this GHG must be neglected. In addition, the sum of decreases in carbon pools and increases in emissions that may be neglected must be less than 5% of the total project GHG benefits.

Table 2: Emission Sources

Gas	Sources	Included?	Justification
CO_2	Combustion of fossil fuels (in vehicles, machinery and equipment)	Included, if significant	Only included if tested as significant. Otherwise excluded, which is deemed conservative, as emissions will be greater in the baseline scenario than in the project scenario.
	Removal of herbaceous vegetation	Excluded	Based on CDM EB decision reflected in paragraph11ofthe report of the23rdsessionoftheboard: cdm.unfccc.int/Panels/ar/023/ar_023_rep.pdf
CH_4	Combustion of fossil fuels (in vehicles, machinery and equipment)	Included, if significant	Only included if tested as significant. Otherwise excluded, which is deemed conservative, as emissions will be greater in the baseline scenario than in the project scenario.
	Burning of Biomass	Included	Included as CO_2 equivalent emissions
N_2O	Combustion of fossil fuels (in vehicles, machinery and equipment)	Included, if significant	Only included if tested as significant. Otherwise excluded, which is deemed conservative, as emissions will be greater in the baseline scenario than in the project

[2]http://cdm.unfccc.int/methodologies/ARmethodologies/approved_ar.html

			scenario.
	Nitrogen based fertilizer	Excluded	Potential emissions are negligible. Following the VCS update to the *Tool for AFOLU Methodological Issues and Guidance for AFOLU Projects*, emissions through the use of fertilizer are considered insignificant and are not considered here.
	Burning of Biomass	Excluded	Potential emissions are negligible

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

6.1 Selection of baseline

The project proponent must use the most recent version of the VCS tool, *VT0001 Tool for the Demonstration and Assessment of Additionality in AFOLU Project Activities* to assess which of the baseline alternatives must be excluded from further consideration.

As per the applicability conditions of this methodology, the project must demonstrate a baseline scenario of planned timber harvest. If such a baseline cannot be demonstrated, then this methodology cannot be applied.

Planned timber harvest events in the baseline scenario can occur in any year of the project activity, not just year *0*.

6.2 Modeling the baseline scenario

Once the baseline scenario of planned timber harvest is demonstrated, the project proponent must determine how to model the baseline management scenario. A Historical Baseline Scenario (Section 6.2.1) must be used where data is available, otherwise a Common Practice Baseline Scenario (Section 6.2.2) must be used.

Irrespective of which baseline scenario is used, the same formulas (as set out in Sections 8.1.1 to 8.1.6) for the quantification of baseline emissions are applied. The major difference between the historical and common practice baseline scenarios is the source of data for the majority of parameters (see Section 9.1) which are used in Sections 8.1.1 to 8.1.6 to calculate baseline emissions.

Where the historical baseline scenario is applied, the historical data pathway must be followed with regard to data sources for the majority of parameters available at validation.

Where the common practice scenario is applied, the common practice data pathway must be followed with regard to data sources for the majority of parameters available at validation.

In principle, under the historical baseline scenario, historical records of timber harvesting from the baseline agent are used to determine the values of many of the parameters available at validation, whereas under the common practice scenario other sources (eg, data from other forestry companies in the region, regional default values, legal requirements, etc.) must be used. See Sections 8 and 9.1 for further detail.

6.2.1 Historical Baseline Scenario

A baseline scenario and timber harvest plan (see Box 1 below) derived from the historical practices of the baseline agent of timber harvest must be modelled as the baseline if the following documents exist for the project proponent

1) Historical records of forest management exist for a minimum of 5 or more years preceding the project start date.
2) Historical records indicate that the management practices have surpassed the legal requirements (provided by conforming to all local and regional forest legislation).
3) Historical records that indicate that the historical management surpasses financial barriers by providing above average financial returns.

6.2.2 Common Practice Baseline Scenario

All other cases must model baseline harvest based on common practice.

Common practice is defined as timber harvest under the legal requirements for forest management and will be determined from a timber harvest plan (see Box 1 below) developed from:

1) The project area through scenario modeling as though the legal requirements were implemented in the project area; and
2) A reference area[3] (or multiple reference areas) already under timber harvest management that complies with legal requirements for forest management and selected to be representative of local common practice for timber harvest.

---

[3] Reference areas must be in the same region as the project area and must match the project area in terms of forest types, climate and elevation (identical mix of forest types ±20%; identical annual precipitation ±20%; elevation classes (500 m classes) in the reference region shall be in the same proportion as in the project area (+/-20%))
For forest types, a de minimis rule may be applied if not suitable reference area can be found. Forest types that cover less than 1% of the project area may be excluded for the purpose of finding a suitable reference area. However, in total, no more than 5% of the project area forest cover may be excluded in this way.

Common practice cannot contradict management of the baseline agent except where common practice represents a lower harvest intensity (in m^3/ha) than management by the baseline agent.

Where there is limited capacity to generate the baseline scenario using a reference site in the region of the project area, multiple reference areas may be selected to cover a country so long as the reference area criteria regarding forest types, climate and elevation are met.

Box 1: Timber Harvest Plan

The description of harvesting in the form of a timber harvest plan forms the basis of the baseline scenario for greenhouse gas accounting.

The timber harvest plan describes the harvest of timber products and must:

1) Reference the forest volume inventory (see Section 8.1.1 – parameter $V_{j,i|BSL}$) to identify the relative number of trees per hectare potentially available for harvest by species in each stratum
2) Demarcate all non-harvest areas within the forest based on legally required exclusions for environmental features such as slope, swamp areas or conservation buffers
3) Divide the harvestable forest into annual operating areas (referred to throughout this methodology as land parcels) using common practice
4) Include a design and presentation of the forestry infrastructure to harvest, skid/haul, store and move harvested timber products from the land parcels to downstream processing or market entry points. Where the project proponent accounts for emissions from forestry infrastructure, the design and presentation must include all forest roads, skidtrails and log landings that would be established under the baseline scenario as a georeferenced layer (shapefile or equivalent), and must list necessary harvest and transport machinery.
5) The timber harvest plan must follow local best practice for timber harvest practices, including planning of roads, skidtrails and log landings-and the timber resource volume and extraction quotas defined in any legal requirements.

For the purpose of estimating the net annual changes in carbon stocks resulting from planned timber harvest in the baseline scenario, a detailed planned timber harvesting schedule will be developed from the timber harvest plan, setting out details of harvest and forestry infrastructure establishment for each land parcel in the project area in terms of the following:

1) The species to be harvested[5]

2) The year(1,2,3...) in which timber harvest and/or forestry infrastructure establishment in of each land parcel is scheduled to occur

3) The number of years each land parcel is in a post-harvest and/or post forestry infrastructure establishment state during the project crediting period

4) The maximum and minimum diameters at breast height (DBH), at stump and at top for tree harvesting

5) The planned harvesting regime (clearfelling, specie/stratum-selective logging, area- selective logging)

6) The fraction of merchantable timber volume from clearing of forest roads, skidtrails and log landings that is to be processed into wood products ($F_{V,INF,HWP}$). Based on this fraction, as well as forest inventory and forestry infrastructure data, $V_{EX,INF,j,i|BSL}$ and $V_{notEX,INF,j,i|BSL}$ (see points 2 and 3 below) will be calculated.

7) The technical specifications for the categories of wood products to be harvested

8) The total volumes or fractions to be harvested, broken down by categories of wood products defined as sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other.

The planned timber harvest schedule is determined *ex ante* to reflect the timber harvesting plan as stipulated in the legal right to harvest. The *planned timber harvesting schedule* will be developed for the project area to include all land parcels within the project boundary for the proposed IFM activity.

The output of the timber harvest plan and timber harvesting schedule must be:

1) The mean extracted volume of extracted merchantable timber per unit area by species in each stratum in each year ($V_{EX,j,i|BSL}$).

2) Where the project proponent accounts for forestry infrastructure, the mean volume of merchantable timber extracted for wood processing that is harvested during the process of forestry infrastructure establishment per unit area by species in each stratum in each year ($V_{EX,INF,j,i|BSL}$).

3) Where the project proponent accounts for forestry infrastructure, the mean volume of merchantable timber that is cleared during the process of forestry infrastructure establishment and NOT extracted for wood processing per unit area by species in each stratum in each year ($V_{notEX,INF,j,i|BSL}$).

The planned timber harvesting schedule will be submitted by the project proponent as part of the project documents.

6.3 Stratification

If the proposed project area contains different forest types or forests with different carbon density, stratification must be carried out in order to improve the accuracy and precision of carbon stock estimates.

For estimation of base year carbon stocks, strata must be defined on the basis of parameters that are key variables in any method used to estimate changes in managed forest carbon stocks. Strata will include either forest type, vegetation type and/or target timber species.

Based on the availability of data regarding the nature and composition of forest stocks in the project area, stratification will be developed on the basis of either:

a) Existing vegetation mapping or stratification, where these are documented in the legal right to harvest; or,

b) Estimates developed from sampling the project area using standard forest assessment protocols specific to the forest region where the project area is located.

Baseline stratification is developed *ex ante*.

The project proponent must submit as part of the project documents a detailed description of the stratification adopted for the project area.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

The project proponent must demonstrate the additionality of the project using the most recent version of VCS tool, *VT0001 VCS Tool for the Demonstration and Assessment of Additionality in AFOLU Project Activities*.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

Calculation of baseline emissions for all land parcels under both the historical and common practice baseline scenarios requires the application of the equations presented in Sections 8.1.1 to Section 8.1.6.

Table 3 lists the baseline emissions modeled by this methodology.

Table 3: Emission Included in Baseline Modeling

Included in modelling
All projects: 1. Emission from wood product conversion 2. Decomposition of deadwood from harvested trees 3. Emissions from wood product retirement 4. Stock change due to regrowth following timber harvest 5. Decomposition of trees incidentally killed during tree felling Where project proponent accounts for forestry infrastructure: 6. Decomposition of trees killed through skid trail creation 7. Decomposition of trees killed through road construction Optional (as omission is conservative): 8. Emissions from fossil fuels burned in baseline harvesting practices
Conservatively excluded from modeling

1. Emissions through subsequent forest re-entry

Baseline projections are calculated ex-ante and are not adjusted throughout the project crediting period.

Section 8.1.1 serves to calculate carbon stocks in commercial timber volumes. Next, baseline emissions are estimated based on the calculation of deadwood (logging slash) generated in the process of timber harvest and establishment of forestry infrastructure (Section 8.1.2), the emissions resulting from production and subsequent retirement of wood products derived from timber harvesting (including timber harvesting from the establishment of forestry infrastructure (Section 8.1.3)), the combustion of fossil fuels in forestry machinery including mechanized felling, skidding / forwarding /hauling, loading and transporting inside the project area, and processing (Section 8.1.5), minus the rates of forest regrowth post-timber harvest (Section 8.1.6).

Baseline commercial timber volumes must be derived for development of the timber harvest plan and for ex-post accounting of emissions resulting from natural forest disturbance.

The equations below calculate the total emissions across the project crediting period for each emission source. Total emissions are averaged across the project crediting period to give annual emissions and are multiplied by t*, time elapsed since the start of project activity. Ex-post, t* is updated so baseline projections are available for each proposed future verification date.

Data for input into these carbon stock change calculations for the baseline scenario must be established from the same data used to create the timber harvesting plan.

Depending on which baseline scenario is applied (ie, historical or common practice), the project proponent must follow either the ‘historical data pathway’ (for historical baseline scenario) or the ‘common practice data pathway’ (for the common practice baseline scenario) when applying the formulas in Sections 8.1.1 to 8.1.6.

As a result, the sources for the majority of parameters described in Section 9.1 must be chosen accordingly:

- Under the historic data pathway: Where applicable, parameters must be based on the historical logging practices of the baseline agent.

- Under the common practice pathway: Where applicable, parameters must be based on data that reflects common practice in the region (data from other forestry companies in the region, forest management according to the legal requirements, regional default values that, in quantitative terms, reflect average values with regard to forest management. Where data is not readily identifiable as reflecting common practice, the responsible forest department, or another equivalent institution, must confirm that the value in question is considered as being common practice in the region.

8.1.1 Calculation of carbon stocks in commercial timber volumes

This section calculates $C_{HB,j,i|BSL}$, the mean carbon stock in total harvested biomass in tC·ha-1 and $C_{EX,j,i|BSL}$, the mean carbon stock in extracted timber (merchantable timber that leaves the forest) in tC·ha-1. This includes harvested biomass from the clearing of roads, skid trails and log landings, where applicable. The following calculation of merchantable volume of timber per unit area ($V_{j,i|BSL}$) that is potentially available for harvest must be based on data from field measurements in sample plots.

It is acceptable to use pre-existing forest inventory data[4] for this purpose, provided that the pre-existing data:

a) Represents the project strata;

b) Is not more than 10 years old; and,

c) Where forest inventory data is more than 10 years old, that the volume estimate derived from the pre-existing data has been validated with limited sampling within the project area.

Validation of pre-existing forest inventory data must be carried out by field surveys. For each strata, mean volume is estimated from sample plots/points measured within the project area using standard forest inventory assessment methods. The number of sample plots will be determined from application of the most recent version of the CDM tool, *Tool for Calculation of the Number of Sample Plots for Measurements within A/R CDM Project Activities*[5].

If the validated estimate of volume is within the 90% confidence interval of the corresponding estimate or is greater than the estimate calculated from pre-existing forest inventory data, the pre-existing forest inventory data may be used. If the validation estimate is less than the corresponding estimate calculated from pre-existing forest inventory data, the estimate from pre-existing data cannot be used.

Estimation of the merchantable volume of trees must be based on locally derived allometric equations or yield tables. If locally derived equations or yield tables for each species are not available, it is acceptable to use relevant regional, national or default data.

---

[4] Standard quality control / quality assurance procedures for forest inventory including field data collection and data management shall have been applied to the forest inventory assessment. Sampling data and methods shall be available for verification. Sample sizes shall have been sufficient to ensure inventory estimates are within the 95% confidence intervals with the estimated variance within +/- 15 percent from the mean.

[5]http://cdm.unfccc.int/methodologies/ARmethodologies/approved_ar.html

Yield tables or allometric equations must be used to convert field measurements of diameter (DBH, at typically 1.3 m [4.3 ft] aboveground level or above buttress where they exist), and total height H of each tree in the sample plots to merchantable volume, $V_{l,j,i,sp}$.

It is acceptable to combine DBH and allometric equations if field instruments (eg, a relascope) that measure the volume of each tree directly have been used.

The estimate of merchantable volume for each species *j* at the sample plot level will be calculated as:

$$\boldsymbol{V_{j,i,sp} = \sum_{l=1}^{L} V_{l,j,i,sp}} \qquad \textbf{(1)}$$

Where:

Vj,i,sp	Merchantable volume for species *j* in stratum *i* in sample plot *sp*, m^3;
Vl,j,i,sp	Merchantable volume for tree *l* of species *j* in stratum *i* in sample plot *sp*; m^3[6]
l	1,2,3…*l* sequence of individual trees in sample plot;
i	1,2,3 …*M* strata;
sp	1,2,3 …*SP* sample plots; and
j	1,2,3 …*J* tree species.

Therefore, the merchantable volume per unit area of species *j* in stratum *i* will be calculated as the mean merchantable volume in all sample plots in stratum *i*:

$$V_{j,i|BSL} = \frac{1}{SP} * \sum_{sp=1}^{SP} \frac{V_{j,i,sp}}{A_{sp}} \qquad \textbf{(2)}$$

Where:

$V_{j,i\|BSL}$	Mean merchantable volume per unit area of species *j* in stratum *i* in the baseline scenario, $m^3 \cdot ha^{-1}$;
$V_{j,i,sp}$	Merchantable volume for species *j* in stratum *i* in sample plot *sp*; m^3;
Asp	Area of sample plot *sp*, ha; [7]

[6] See Data and parameters not monitored (default or possibly measured one time) list for information on data selection (p51).
[7] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

i	1, 2, 3 …*M* strata;
sp	1, 2, 3 …*SP* sample plots; and
j	1, 2, 3 …*J* tree species.

$V_{j,i|BSL}$ will be used to develop the timber harvest plan (Box 1 above). The timber harvest plan sets the allowable mean extracted volume ($V_{EX,j,i|BSL}$) from this merchantable volume based on legal limits.

Further, based on $Vj_{,i|BSL}$, the timber harvest plan will specify the mean extracted volume that is harvested for the purpose of building forestry infrastructure ($V_{EX,INF,j,i|BSL}$).

Once the timber harvest plan is complete and $V_{EX,j,i|BSL}$ *as well as (*$_{VEX,INF,j,i|BSL}$*)* is calculated, the Biomass Conversion and Expansion Factors (BCEF) method[8,9] must be used to determine the carbon stock in harvested biomass.

This method is appropriate as forest inventory data and allowable harvest must be based on volume estimates to which expansion factors can be readily applied. The selected *BCEF* must have a minimum DBH compatible with the minimum DBH defined in the timber harvest plan (Box 1 above).

Therefore, the carbon stock of timber harvested per unit area for species *j* in stratum *i* will be calculated from this mean volume of extracted timber:

$$C_{HB,j,i|BSL} = (V_{EX,j,i|BSL} + V_{EX,INF,j,i|BSL}) * BCEF_R * CF_j \quad \textbf{(3)}$$

Where:

$C_{HB,j,i\|BSL}$	Mean carbon stock of harvested biomass per unit area for species *j* in stratum *i*, $tC \cdot ha^{-1}$;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species *j* in stratum *i*, $m^3 \cdot ha^{-1}$;
$V_{EX,INF,j,i\|BSL}$	Mean volume of extracted timber for forestry infrastructure per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
$BCEF_R$	Biomass conversion and expansion factor applicable to wood removals in

[8] Somogyi, Z., E. Cienciala, R. Mäkipää, P. Muukkonen, A. Lehtonen and P.Weiss. (2006) Indirect methods of large-scale forest biomass estimation, Eur.J.ForestRes. 126 (2) pp.197–207. http://dx.doi.org/10.1007/s10342-006-0125-7.
[9] IPCC. (2006) IPCC Guidelines for National Greenhouse Gas Inventories, Prepared by the National Greenhouse Gas Inventories Programme. In: Eggleston, H. S., Buendia, L. ,Miwa, K., Ngara, T., Tanabe, K. (Eds.). IGES, Japan. http://www.ipcc-nggip.iges.or.jp/public/2006gl/index.html.

	the project area, t.d.m m^{-3};[10]
CF_j	Carbon fraction of biomass for species *j*, tCt $d.m.^{-1}$;[11]
i	1,2,3 …*M* strata; and
j	1,2,3 …*J* tree species.

Not all of the harvested biomass leaves the forest because the timber harvested has two components: 1) wood removed to market (extracted timber) and 2) wood remaining in the forest as a result of harvest (see Section 8.1.2).

Therefore, the mean carbon stock of extracted timber per unit area for species *j* in stratum *i* will be calculated from the mean volume of extracted timber multiplied by density and carbon fractions:

$$C_{EX,j,i|BSL} = (V_{EX,j,i|BSL} + V_{EX,INF,j,i|BSL}) * D_j * CF_j \quad \textbf{(4)}$$

Where:

$C_{EX,j,i\|BSL}$	Mean carbon stock of extracted timber per unit area for species *j* in stratum *i*; $tC \cdot ha^{-1}$;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species *j* in stratum *i*; in $m^3 \cdot ha^{-1}$;
$V_{EX,INF,j,i\|BSL}$	Mean volume of extracted timber for forestry infrastructure per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
D_j	Basic wood density of species *j*; t d.m. m^{-3}; [12]
CF_j	Carbon fraction of biomass for species *j*, tC t $d.m.^{-1}$;
i	1,2,3 …*M* strata; and
j	1,2,3 …*J* tree species.

8.1.2 Calculation of dead wood (logging slash) generated in the process of timber harvest

This section calculates $\Delta C_{DWSLASH,i,p|BSL}$. $\Delta C_{DWSLASH,i,p|BSL}$ includes the following:

a) The change in carbon stock in dead wood (ie, logging slash) left on the forest floor following timber harvest in stratum *i* in land parcel *p*, using $C_{EX,j,i|BSL}$ and $C_{HB,j,i|BSL}$ as calculated in Section 8.1.1.

b) The change in carbon stock in dead wood (ie, logging slash) that results from residual stand damage ($C_{RSD,\ j,i|BSL}$). Residual stand damage is the breaking or uprooting of other neighboring trees during the process of tree felling. Residual stand damage is calculated using the residual stand damage factor $F_{RSD|BSL}$.

c) The change in carbon stock in dead wood (ie, logging slash) left on the forest floor following the establishment of forestry infrastructure in stratum i in land parcel *p*. This is calculated using $C_{notHB,INF,j,i|BSL}$ based on $V_{notEX,INF,j,i|BSL}$ as defined in the timber harvest plan. This does only include the emissions from entire trees left to decay as a result of forestry infrastructure construction. Emissions from logging slash of trees harvested for consequent processing during the establishment of forestry infrastructure are included under point A above.

The simplifying assumption is made that dead wood left on the forest floor following timber harvest follows a ten year linear decay function, as permitted by the *VCS AFOLU Requirements*. This decay function is applied when the net greenhouse gas emissions/removals are calculated on an annual basis in Equations 11 and 12 below.

Therefore, the change in carbon stock in the dead wood pool in stratum *i* in land parcel *p* is calculated as the difference between the total carbon stock of the harvested biomass and the carbon stock of the extracted timber, plus the residual stand damage and biomass of trees left to decay as a result forestry infrastructure establishment:

$$\Delta C_{DWSLASH,i,p|BSL} = \left[\sum_{j=1}^{J} [(C_{HB,j,i|BSL} - C_{EX,j,i|BSL}) + C_{RSD,j,i|BSL} + C_{notHB,inf,j,i|BSL}] \right] \quad \textbf{(5)}$$

Where:

$\Delta C_{DWSLASH,i,p|BSL}$	Change in carbon stock of dead wood as logging slash resulting from timber harvest per unit area in stratum *i* in land parcel *p*, in tC ha-1;
$C_{HB,j,i|BSL}$	Mean carbon stock of harvested biomass per unit area for species *j* in stratum *i*, tC·ha^{-1};
$C_{EX,j,i|BSL}$	Mean carbon stock of extracted timber per unit area for species *j* in stratum *i*, tC·ha^{-1};

$C_{RSD,j,i\|\mathrm{BSL}}$	Mean carbon stock in timber from residual stand damage per unit area for species j in stratum i, tC·ha^{-1}
$C_{notHB,inf,j,i\|\mathrm{BSL}}$	Mean carbon stock of biomass that is not harvested during the establishment of forestry infrastructure per unit area for species j in stratum i, tC·ha^{-1}
i	1, 2, 3 …*M* strata; and
j	1, 2, 3 …*J* tree species.
P	*1, 2, 3 ...P* land parcels.

The mean carbon stock in timber from residual stand damage ($C_{RSD,j,i|BSL}$) is calculated as follows:

$$C_{RSD,j,i|\mathrm{BSL}} = C_{EX,j,i|BSL} * F_{RSD|\mathrm{BSL}} \quad \textbf{(6)}$$

Where:

$C_{RSD,j,i\|\mathrm{BSL}}$	Mean carbon stock in timber from residual stand damage per unit area for species j in stratum i, tC·ha^{-1};
$C_{EX,j,i\|BSL}$	Mean carbon stock of xtracted timber per unit area for species j in stratum i, tC·ha^{-1};
$F_{RSD\|\mathrm{BSL}}$	Factor for residual stand damage, dimensionless;
i	1, 2, 3 …M strata; and
j	1, 2, 3 …J tree species;

The mean carbon stock of biomass that is not harvested during the establishment of forestry infrastructure ($C_{notHB,INF,j,i|BSL}$) is calculated as follows:

$$C_{notHB,inf,j,i|\mathrm{BSL}} = V_{notEX,inf,j,i|BSL} * BCEF_R * CF_j \quad \textbf{(7)}$$

Where

$C_{notHB,inf,j,i\|\mathrm{BSL}}$	Mean carbon stock of biomass that is not harvested during the establishment of forestry infrastructure per unit area for species j in stratum i, tC·ha^{-1}
$V_{notEX,inf,j,i\|BSL}$	Mean volume of timber that is not extracted for wood processing during the establishment of forestry infrastructure per unit area for species j in stratum i, m^3·ha^{-1};
$BCEF_R$	Biomass conversion and expansion factor applicable to wood removals in the project area, t.d.m m^{-3};
CF_j	Carbon fraction of biomass for species j, tC t d.m.$^{-1}$
i	1, 2, 3 …M strata; and
j	1, 2, 3 …J tree species

8.1.3 Calculation of baseline carbon sequestered in wood products

This section calculates the net carbon stock change resulting from wood product conversion and retirement.

In all cases where wood is harvested for conversion to wood products, carbon stock in the wood products pool must be included in the baseline case.

Carbon stocks treated here are those stocks entering the wood products pool at the time of harvest.

All factors are derived from Winjum *et al* (1998).

The carbon stock of extracted timber across species is calculated as:

$$C_{EX,i|BSL} = \sum_{j=1}^{J} C_{EX,j,i|BSL} \quad \textbf{(8)}$$

Where:

$C_{EX,i\|BSL}$	Change in carbon stock of extracted wood products resulting from timber harvest per unit area in stratum *i* in land parcel *p*, in tC ha-1;
$C_{EX,j,i\|BSL}$	Mean carbon stock of extracted wood per hectare, tC/ha;
i	1, 2, 3 …*M* strata; and
j	1, 2, 3 …*J* tree species.

The wood product class(es), *k*, (sawnwood, wood-based panels, other industrial roundwood, paper and paper board, and other) that are the anticipated end use of the extracted timber must now be selected. It is acceptable practice to assign gross percentages of volume extracted to wood product classes on the basis of local expert knowledge of harvest activities and markets.

In accordance with the *VCS AFOLU Requirements*, the amount of carbon stored in wood products that would decay within 3 years after harvest (ie, the Wood Waste (WW) and the Short Lived Fraction (SLF)), are assumed to be emitted at the time of harvest.

Wood products that are retired between 3 and 100 years after harvest (ie, the Additional Oxidized Fraction, *OF*), must be accounted according to a 20 year linear decay function. This decay function is applied when the net greenhouse gas emissions/removals are calculated on an annual basis in Equations 11 and 12 below.

All other wood product pools are considered to permanently store carbon.

Therefore, the carbon stock of extracted timber that is immediately emitted to the atmosphere at the time of harvest is calculated as:

$$C_{WP0,i|BSL} = \sum_{k} C_{EX,i,k|BSL} * (WW_k + SLF_k) \quad \textbf{(9)}$$

Where:

$C_{WP0,i\|BSL}$	Carbon stock of extracted timber from stratum *i* that is assumed to be emitted immediately at the time of harvest, in tC·ha^{-1};
$C_{EX,i\|BSL}$	Mean carbon stock of extracted timber per unit area in stratum *i*, for wood product type *k*, tC·ha^{-1};
WW_k	Fraction of biomass carbon from wood waste that is assumed to be emitted to the atmosphere immediately at the time of harvest for wood product *k*, dimensionless; [13]
SLF_k	Fraction of biomass carbon from the shortlived wood product pool that is assumed to be emitted to the atmosphere immediately at the time of harvest for wood product *k*, dimensionless
i	1,2,3 …*M* strata; and
k	Wood products (sawnwood, wood base products, etc)

The amount of extracted carbon stock that is assumed to enter the wood products pool that is not immediately emitted at harvest is calculated as per Equation 8 below:

$$C_{WPi|BSL} = \sum_{k} C_{EX,i,k|BSL} - C_{WP0,i|BSL} \quad \textbf{(10)}$$

Where:

$C_{WP,i\|BSL}$	Carbon stock of extracted timber from stratum *i* that is assumed to enter the wood products pool that is not immediately emitted at the time of harvest, in tC·ha^{-1};
$C_{EX,i\|BSL}$	Mean carbon stock of extracted timber per unit area in stratum *i*, for wood product type *k*, tC·ha^{-1};
$C_{WP0,i\|BSL}$	Carbon stock of extracted timber from stratum *i* that is assumed to be emitted immediately at the time of harvest, in tC·ha^{-1};

[13] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p51).

i	1,2,3 …*M* strata; and
k	Wood products (sawnwood, wood base products, etc)

Therefore, the carbon stock of wood products assumed to be retired between 3-100 years following harvest is calculated as:

$$C_{WP100,i|BSL} = C_{WP,i|BSL} * OF_k \quad \textbf{(11)}$$

Where:

$C_{WP100,i,p|BSL}$	Cabron stored in wood products that are assumed to be retired between 3 - 100 years after harvest from stratum i in land parcel p, tC ha-1;
$C_{WP,i|BSL}$	Carbon stock of extracted timber from stratum *i* that is assumed to enter the wood products pool that is not immediately emitted at the time of harvest, in tC·ha^{-1};
OF_k	Fraction of biomass carbon for wood product type *k* that is assumed to be emitted to the atmosphere between 3 and 100 years of timber harvest, dimensionless;[14] and
i	1,2,3 …*M* strata.

8.1.4 Change in carbon stocks due to forest regrowth after harvest

This section calculates $\Delta C_{RG,i,p|BSL}$, the carbon sequestration resulting from forest regrowth after timber harvest and establishment of forestry infrastructure in stratum *i* in land parcel *p*; tC.

The carbon sequestration in the baseline scenario resulting from forest regrowth after timber harvest up to year *t* is equal to the forest regrowth rate of each stratum.

Therefore, carbon sequestration resulting from forest regrowth after timber harvest is calculated as:

$$C_{RG,i,p|BSL} = \sum_i RGRi \quad \textbf{(12)}$$

Where:

$C_{RG,i,p|BSL}$	Carbon sequestration resulting from forest regrowth after timber harvest and establishment of forestry infrastructure in stratum *i* in land parcel *p*, tC ha^{-1}yr^{-1};

[14] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

RGR_i	Regrowth rate of forest post timber harvest post forestry infrastructure establishment for stratum i, tC $ha^{-1}yr^{-1}$; [15]
i	1,2,3 …M strata

8.1.5 Calculation of baseline emissions from the combustion of fossil fuels in forestry and wood processing machinery

The implementation of the baseline activity (selective logging and/or clearcutting) entails the use of forestry and wood processing machinery, which leads to GHG emissions from fossil fuel combustion. Omission of any or all of the associated GHG emission sources is conservative.

The total GHG emissions from fossil fuel combustion in the baseline scenario (C_{FUEL}) is determined from the summation of all the emission sources presented in Table 2 using the following equation:

$$C_{FUEL} = \frac{E_{HARVEST} + E_{HAULING} + E_{TRANSPORT} + E_{PROCESSING}}{44/12} \quad \textbf{(13)}$$

Where:

C_{FUEL}	Total carbon emissions associated with the combustion of fossil fuel in forestry and wood processing machinery, in tC
$E_{HARVEST}$	Fossil fuel emissions due to harvesting operations such as felling and snigging, in tCO_2e;
$E_{HAULING}$	Fossil fuel emissions due to log hauling, in tCO_2e;
$E_{TRANSPORT}$	Fossil fuel emissions due to log transport from collection depot to processing plant, in tCO_2e;
$E_{PROCESSING}$	Fossil fuel emissions due to electricity consumption in sawmill, in tCO_2e;

8.1.5.1 Emissions Due to Harvesting Operations

Mechanical harvesting operations of merchantable logs contributes to GHG emissions. This operation in countries containing tropical forests commonly employs chainsaws, while in other regions harvesters are employed. Fossil fuel emissions from log harvesting are determined using the following procedure:

- Step 1: For the common practice in the host country, select the typical equipment type, amount and type of fuel consumed that is employed for harvesting. Information on

[15] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

harvesting practices can be found from reports on previous and existing harvesting practices in the host country. Potential sources should be a combination of direct measurements, manufacturer specifications, historical records of the project proponent (or other forest companies) and/or peer reviewed literature values.

- Step 2: Find the fuel consumption (kL m-3) of the selected equipment from the following data sources:
  - Reports on common practice for harvesting in the host country and/or manufacturers specifications
  - Published peer reviewed studies on harvesting operations (eg, Klvac and Skoupy (2009) in Appendix 4)
  - If a range for fuel consumption is provided, the project proponent is required to provide justification for their choice of fuel consumption in the project documents. If no justification can be derived, it is conservative to select the lower end of the range.
- Step 3: Select the emission factor associated with the fuel employed for harvesting from IPCC default emission factors for CO_2, CH_4 and N_2O emissions for Off-Road Mobile Sources and Machinery for the Forestry Sector (IPCC, 2006, Volume 2, Chapter 3, Section 3.3.1, Table 3.3.1, p. 3.36).
  - Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor is provided in Appendix 1.
  - Guidance for unit conversions of fuel emission factors is provided in Appendix 2.
- Step 4: Harvesting emissions are calculated following the equation below:

$$E_{HARVEST} = FC_{HARVEST} x EF_{FUEL} x\ V_{EX,j,i|BSL}\ x\ A \qquad \textbf{(14)}$$

Where:

$E_{HARVEST}$	Fossil fuel emissions due to harvesting operations such as felling and snigging, in tCO_2e;
$FC_{HARVEST}$	Fuel consumption of equipment employed for felling and snigging per m3 of merchantable log harvested, in kL/m3;
EF_{FUEL}	Fuel emission factor, in tCO2e/kL;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
A	Logging area, in ha;
i	1, 2, 3 … M strata; and

j 1, 2, 3 … J tree species.

8.1.5.2 Emissions Due to Log Hauling

Emissions associated with log hauling to the collection depot are calculated using the following procedure:

- Step 1: Select the typical equipment type, amount and type of fuel consumed that is employed for hauling based on common practice for harvesting in the host country. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.
- Step 2: Find the fuel consumption (kL m^{-3}) of the selected equipment from reports on common practice for harvesting in the host country and/or manufacturers specifications.

  If a range for fuel consumption is provided, the Project Proponent is required to provide justification for the choice of fuel consumption factor in the project documents. If no justification can be derived, it is conservative to select the lower end of the range.
- Step 3: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Off-Road Mobile Sources and Machinery for the Forestry Sector (IPCC, 2006, Volume 2, Chapter 3, Section 3.3.1, Table 3.3.1, p. 3.36).
  - Guidance for converting the emission factors to a CO_2 equivalent (CO_2e) emission factor is provided in Appendix 1.
  - Guidance for unit conversions of fuel emission factors is provided in Appendix 2.
- Step 4: Emissions from log hauling are then determined by applying the following equation:

$$E_{HAULING} = FC_{HAULING} x EF_{FUEL} x\, V_{EX,j,i|BSL}\, x\, A \tag{15}$$

Where:

$E_{HAULING}$	Fossil fuel emissions due to log hauling, in tCO_2e;
$FC_{HAULING}$	Fuel consumption of equipment for hauling one m3 of merchantable log, in kL/m3;
EF_{FUEL}	Emissions due to log hauling, in tCO_2e/kL;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
A	Logging area, in ha;
i	1, 2, 3 …M strata; and
j	1, 2, 3 … J tree species.

8.1.5.3 Emissions Due to Log Transport

Emissions associated with log transport from the collection depot to the processing plant are calculated using the following procedure:

- Step 1: Select the vehicle: type, load capacity (m3 truck^{-1}) and type of fuel consumed for log transport based on common practice for transport in the host country. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.
- Step 2: Determine the number of trucks required using the following equation:

$$N_{TRUCKS-TRANSPORT} = \frac{V_{EX,j,i|BSL}\ x\ A}{CAP_{TRUCK}} \quad \textbf{(16)}$$

Where:

$N_{TUCKS-TRANSPORT}$	Number of truck trips required for log transport from collection depot to processing plant;
A	Logging area, in ha;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
CAP_{TRUCK}	Truck load capacity, in m3/truck;
i	1, 2, 3 … M strata; and
j	1, 2, 3 … J tree species.

- Step 3: Find the fuel efficiency (km kL^{-1}) of the selected vehicle from the following data sources:
  - Manufacturers specifications
  - Published peer reviewed studies on harvesting operations (eg, Kinjo et al., 2005).
  - If a range for fuel efficiency is provided, the Project Proponent is required to provide justification for the choice of fuel efficiency factor in the project documents. If no justification can be derived, it is conservative to select the upper end of the range.
- Step 4: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Road Transport (IPCC, 2006, Volume 2, Chapter 3, Section 3.2.1.2, Table 3.2.1-2, p. 3.16-3.21).
  - Guidance for converting the emission factors to CO2-e emission factor is provided in Appendix 1.
  - Guidance for unit conversions of fuel emission factors is provided in Appendix 2.

- Step 5: Estimate the transport distance from the collection depot to the processing plant using the digital maps of the Project Area. If transport route(s) for the baseline scenario must be hypothesized, the Project Proponent is required to provide justification for their derivation of the transport route in the project documents. In addition, to be conservative, the transport route proposed must be the minimum possible route. The total log transport distance can be determined by the following:

$$KM_{TRANSPORT-TOTAL} = KM_{TRANSPORT} x N_{TUCKS-TRANSPORT} x\ 2 \quad \textbf{(17)}$$

Where:

$KM_{TRANSPORT-TOTAL}$	Total log transport distance in km;
$KM_{TRANSPORT}$	Log transport distance from collection depot to processing plant in km;
$N_{TRUCKS-TRANSPORT}$	Number of truck trips required for log transport from collection depot to processing plant;
2	Constant, indicating return trip;

- Step 6: Emissions due to log transport are then determined by applying the following equation:

$$E_{TRANSPORT} = \frac{KM_{TRANSPORT-TOTAL}}{EFF_{VEHICLE}} x EF_{FUEL} \quad \textbf{(18)}$$

Where:

$E_{TRANSPORT}$	Emissions due to log transport haulage from felling location to the collection depot/ sawmill, intCO2-e;
$KM_{TRANSPORT-TOTAL}$	Total log transport distance in km;
$EFF_{VEHICLE}$	Fuel efficiency for vehicle type, in km/kL;
EF_{FUEL}	Fuel emission factor, in tCO_{2}-e/kL.

8.1.5.4 Emissions Due to Timber Processing

Emissions as a result of processing, where the processing plant is situated in the project area, depend on the electricity source available at the processing site. Electricity can be supplied via the national grid, or where this is not available, supplied via on-site generators. In addition, mill residue/waste may also be used as an energy source during timber processing.

To avoid double accounting, if a processing plant utilizes mill residue/waste as an electricity source, then the emissions from electricity generated by mill residue/waste must not be considered here, as these emissions are accounted for under the dead wood pool.

If grid electricity is available, then emissions due to processing will be calculated using the following procedure:

- Step 1: Select an electricity demand factor for the timber processing facility from the following data sources:
  - National electricity demand factors in relevant literature for timber processing. Various country specific electricity demand factors have been compiled in Appendix 5.
  - If a national electricity demand factor is not available, select an electricity demand factor from a country that uses similar timber processing technology to that of the project's host country
  - If a range for the electricity demand factor is provided, the project proponent is required to provide justification for the choice of electricity demand factor in the projects documents. If no justification can be derived, it is conservative to select the lower end of the range.
- Step 2: Using the volume of merchantable logs, determine the electricity consumption required for the processing mill:

$$Q_{PROCESSING} = V_{EX,j,i|BSL} \ x \ A \ x E_{DEMAND} \quad \textbf{(19)}$$

Where:

$Q_{PROCESSING}$	Quantity of electricity consumption for processing in kWh;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
A	Logging area, in ha;
E_{DEMAND}	Electricity demand for processing per volume processed, in kWh/m^3;
i	1, 2, 3 … M strata; and
j	1, 2, 3 … J tree species.

- Step 3: Select an emission factor for electricity for the host country from IEA (2009), CO_2 emissions per kWh from electricity and heat generation, pp. 101-103.
- Step 4: Apply the following equation to determine the emissions due to processing:

$$E_{PROCESSING} = Q_{PROCESSING} \ x \ EF_{ELECTRICITY} \quad \textbf{(20)}$$

Where:

$E_{PROCESSING}$	Emissions due to electricity consumption in sawmill, in tCO_2e;

$Q_{PROCESSING}$	Quantity of electricity consumption for processing in kWh;
$EF_{ELECTRICITY}$	Electricity emission factor for the host country, in tCO_2e/kWh;

If grid electricity is not available, and an on-site generator is required to power the processing facility, then calculation of processing emissions is determined from the emissions associated with fuel consumption of the generator. Apply Steps 1 and 2 of Section above to determine the electricity consumption involved for processing. Then use the following procedure:

- Step 1: Select the typical load capacity (1/4, 1/2, full load), type of fuel consumed and operating time of the generator employed to power the processing facility. Such data can be obtained from the following data sources:
    - National reports from the relevant national forestry authority
    - Published peer reviewed literature on timber processing for cases of equivalent volumes and processing modes and of a country that uses similar timber processing technology to that of the project's host country.
- Step 2: Determine the power rating of the generator from the electricity required for processing and the operating hours required:

$$PR_{GENERATOR} = \frac{Q_{PROCESSING}}{T_{GENERATOR}} \qquad \textbf{(21)}$$

Where:

$PR_{GENERATOR}$	Power rating of generator or generator size in kW;
$Q_{PROCESSING}$	Annual quantity of electricity consumption for processing in kWh;
$T_{GENERATOR}$	Operating time of generator in h;

- Step 3: Using a fuel consumption chart for the generator selected for the baseline case, apply the power rating (kW) and an appropriate load capacity (1/4, 1/2, full) to determine the fuel consumption (kL h-1) of the generator. Fuel consumption charts can be found from manufacturers of generators (see Appendix 3).
- Step 4: Select an emissions factor for the fuel employed in the generator from IPCC (2006), Volume 2, Chapter 2 Stationary Combustion, Table 2.5, p. 2.22.
- Step 5: Apply the following equation to determine emissions due to processing:

$$E_{PROCESSING} = FC_{GENERATOR} \; x \; T_{GENERATOR} \; x \; EF_{FUEL} \qquad \textbf{(22)}$$

Where:

$E_{PROCESSING}$	Emissions due to electricity consumption in sawmill in tCO_2e;

$FC_{GENERATOR}$	Fuel consumption per hour of operation of generator, in kL/h;
$T_{GENERATOR}$	Operating time of generator in h;
EF_{FUEL}	Fuel emission factor, in tCO_2e/kL;

8.1.6 Calculation of baseline scenario greenhouse gas emissions from change in carbon stocks

This section calculates $GHG_{NET|BSL}$, the net greenhouse gas emissions in the baseline scenario, in tCO_2e.

The net carbon stock change to be converted to emissions is equal to the carbon stock change as a result of timber harvest plus the carbon stock change resulting from conversion and retirement of wood products minus carbon sequestration from forest regrowth after harvest.

In order to generate the annual carbon stock change in the baseline scenario, the total net change in carbon stocks for parcels within is multiplied by the area of forest in the particular age class (ie, years since harvest in the baseline).

The annualized calculations vary between years 1, 2-10; 11-20; and all years since the start of the project activity, depending on which decay functions apply.

Therefore, the net change in carbon stock from wood products and logging slash across all parcels within the first year of harvest in the baseline is calculated as:

$$\Delta C_{NET|BSL(1)} = \sum_{i,p} A_{1,i,p} * \sum_{i=1}^{M} \left(C_{DWSLASH,i,p\backslash BSL}/10 \right) + C_{WP0,i,p\backslash BSL} + \left(C_{WP100,i,p\backslash BSL}/20 \right) \qquad \textbf{(23)}$$

Where:

$\Delta C_{NET\|BSL(1)}$	Net change in carbon stock across all parcels in the baseline scenario in the first year since harvest in the baseline scenario, in tC;
$\Delta C_{DWSLASH,i,p\backslash BSL}$	Change in carbon stock of dead wood as logging slash resulting from timber harvest per unit area in stratum *i* in land parcel *p*, in tC ha-1;
$\Delta C_{WP0,i,p\backslash BSL}$	Change in carbon stock resulting from wood product conversion and retirement from stratum *i* in land parcel *p*, that is assumed to be emitted in the first year of harvest in the baseline tC ha-1;
$\Delta C_{WP100,i,p\backslash BSL}$	Carbon stored in wood products that is assumed to be retired between 3 - 100 years after harvest from stratum i in land parcel p, tC ha-1;

$A_{1,i,p}$	Area of stratum *i* in land parcel *p* that was harvested 1 year ago, ha; [16]
i	1, 2, 3 …*M* strata; and
p	*1, 2, 3 ...P* land parcels harvested within the project crediting period.

The net change in carbon stock from wood products and logging slash across all parcels the years 2 – 10 since harvest in the baseline are calculated as:

$$\Delta C_{NET|BSL(2-10)} = \sum_{i,p} A_{2-10,i,p} * \sum_{i=1}^{M} \left((\Delta C_{DWSLASH,i,p\backslash BSL}/10) + (\Delta C_{WP100,i,p\backslash BSL}/20) \right) \quad \textbf{(24)}$$

Where:

$\Delta C_{NET\|BSL(2\text{-}10)}$	Net change in carbon stock across all parcels in the baseline scenario in years 2 - 10 since harvest in the baseline scenario, in tC;
$\Delta C_{DWSLASH,i,p\backslash BSL}$	Change in carbon stock of dead wood as logging slash resulting from timber harvest per unit area in stratum *i* in land parcel *p*, in tC ha-1;
$\Delta C_{WP100,i,p\backslash BSL}$	Carbon stored in wood products that is assumed to be retired between 3 - 100 years after harvest from stratum i in land parcel p, tC ha-1;
$A_{2-10,i,p}$	Area of stratum *i* in land parcel *p* that was harvested between 2 and 10 year ago, ha; [17]
i	1, 2, 3 …*M* strata; and
p	*1, 2, 3 ...P* land parcels harvested within the project crediting period.

The net change in carbon stock from wood products across all parcels the years 11 – 20 since harvest in the baseline are calculated as per equation 13 below. Note that, from this point, there will be no more emissions quantified from decay of logging slash in these parcels.

$$\Delta C_{NET|BSL(11-20)} = \sum_{i,p} A_{11-20,i,p} * \sum_{i=1}^{M} \left(\Delta C_{WP100,i,p\backslash BSL}/20 \right) \quad \textbf{(25)}$$

Where:

$\Delta C_{NET\|BSL(11\text{-}20)}$	Net change in carbon stock across all parcels in the baseline scenario in years 11 - 20 since the start of the project activity, in tC;

[16] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).
[17] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

$\Delta C_{WP100,i,p\backslash BSL}$	Carbon stored in wood products that is assumed to be retired between 3 - 100 years after harvest from stratum i in land parcel p, tC ha-1;
$A_{11-20,i,p}$	Area of stratum *i* in land parcel *p* that was harvested between 11 and 20 years ago, ha; [18]
i	1, 2, 3 …*M* strata; and
p	*1, 2, 3 ...P* land parcels harvested within the project crediting period.

The net change (sequestration) in carbon stock due to forest regrowth across all parcels in all years since harvest in the baseline scenario are calculated according to Equation 14 below. Note that there will be no more emissions quantified from decay of logging slash or wood products.

$$\Delta C_{NET|BSL(1+)} = \sum_{i,p} A_{t*} * \sum_{i=1}^{M} \left(-\Delta C_{RG,i,p\backslash BSL}\right) \quad \textbf{(26)}$$

Where:

$\Delta C_{NET|BSL(1+)}$	Net change in carbon stock due to forest regrowth in all parcels that have been harvested in the baseline scenario, in tC;
$\Delta C_{RG,i,p\backslash BSL}$	Carbon sequestration resulting from forest regrowth after timber harvest in stratum *i* in land parcel *p*, tC ha-1;
A_{t*}	Cumulative area harvested until time t*, ha; [19]
*t**	1, 2,….10, time elapsed since the start of the project, in years;
i	1, 2, 3 …*M* strata; and
p	1, 2, 3 *...P* land parcels harvested within the project crediting period.

Therefore, net change in carbon stock across all parcels harvested over each year of the project crediting period in the baseline scenario since the start of the project activity is calculated as:

$$\Delta C_{NET|BSL,t*} = \sum_{p=1}^{P} \left[\Delta C_{NET,p|BSL(1)} + \Delta C_{NET,p|BSL(2-10)} + \Delta C_{NET,p|BSL(11-20)} + \Delta C_{NET,p|BSL(+1)} + C_{FUEL}\right] \quad \textbf{(27)}$$

Where:

$\Delta C_{NET|BSL,t}$	Net change in carbon stock across all parcels in the baseline scenario in the year t*

[18] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

[19] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection.

	since the start of the project activity, in tC;
$\Delta C_{NET,p\|BSL(1)}$	Net change in carbon stock in the baseline scenario for all parcels *p* that are within 1 year of harvest in the baseline scenario, in tC;
$\Delta C_{NET,p\|BSL(2-10)}$	Net change in carbon stock in the baseline scenario for all parcels *p*, that were harvested between 2 – 10 years ago in the baseline scenario, in tC;
$\Delta C_{NET,p\|BSL(11-20)}$	Net change in carbon stock in the baseline scenario in parcel *p*, that were harvested between 11 – 20 years ago in the baseline scenario, in tC;
$\Delta C_{NET,p\|BSL(+1)}$	Net change in carbon stock due to forest growth in the baseline scenario for all parcels *p* that have been harvested in the baseline scenario, in tC;
C_{FUEL}	Total carbon emissions associated with the combustion of fossil fuel in forestry and wood processing machinery, in tC
*t**	Time elapsed since the start of the project, in years
p	1, 2, 3 ...*P* land parcels harvested within the project crediting period

The net carbon stock change in the baseline scenario must be converted to net greenhouse gas emissions and is calculated as:

$$GHG_{NET|BSL,t*} = \Delta C_{NET|BSL,t*} * \frac{44}{12} \tag{28}$$

Where:

$GHG_{NET\|BS,t*L}$	Net greenhouse gas emissions in the baseline scenario in the year t* since the start of the project activity, tCO_2e;
$\Delta C_{NET\|BSL}$	Net change in carbon stock across all parcels in the baseline scenario in the year t* since the start of the project activity, tC; and
44/12	Ratio of molecular weights of carbon dioxide and carbon, $tCO_2\text{-e}\ tC^{-1}$.

8.2 Project Emissions

This section calculates $GHG_{NET|PRJ}$, the net greenhouse gas emissions in the project scenario, in tCO2e.

Greenhouse gas emissions from Improved Forest Management (IFM) activities implemented in the project scenario must be accounted subject to application of the *de minimis* rule, as prescribed by the *VCS AFOLU Requirements*. Project emissions include the change in carbon stocks of ongoing forest growth, forest disturbances, and illegal logging. As commercial timber harvest and activities that result in forest degradation are not eligible under the methodology in the project scenario, emissions sources from combustion of fossil fuels from vehicles, machinery and equipment are *de minimis* and not accounted by the methodology in the project scenario.

The type and extent of the activities implemented in the project scenario will be described by the project proponent as part of the documentation submitted with the project documents.

In accordance with the applicability conditions, the project scenario does not allow commercial timber harvest. As a result, carbon stock changes due to vegetation management and fuel removal will be negligible.

Thus, net greenhouse gas emissions in the project scenario will be equal to carbon sequestration through ongoing forest growth minus any emissions resulting from forest disturbance (both illegal logging and natural disturbances).

Ex-ante and ex-post estimations of natural disturbance for the project scenario must be estimated following Section 8.2.2.1.[20]

The potential for illegal extraction of trees from the project area must be assessed ex-ante and ex-post through a participatory rural appraisal (PRA) of the communities in and surrounding the project area following Section 8.2.2.2a.[21]

At all subsequent verifications, data collected for monitored parameters for natural disturbance and illegal logging must be included using the equations given under Sections 8.2.2 and 8.2.3 below.

It is not a requirement of this methodology for the project proponent to estimate carbon stock change from forest growth in the project scenario of undisturbed forest. However, where the project proponent chooses to determine stock change from forest growth in the project scenario, a detailed sampling plan must be provided in the project documents and follow the equations in Section 8.2.1 below.

8.2.1 Ongoing forest growth in the project scenario

This section calculates $\Delta C_{AB,t|PRJ}$ annual carbon stock change in aboveground biomass of trees in the project scenario, in tCO_2e.

8.2.1.1 Allometry

The project proponent must select or develop an appropriate allometric equation for forest type/group of species j (eg, tropical humid forest or tropical dry forest) or for each species or family j (group of species) found in the inventory (hereafter referred to as species group) that

[20] *Ex ante* estimations of areas burned and naturally disturbed shall be based on historic incidence of fire and natural disturbance in the Project region.

[21] If the belief is that zero illegal logging will occur within the project boundaries then ex-ante this parameter may be set to zero if clear infrastructure, hiring and policies are in place to prevent illegal logging.

converts tree dimensions from field timber inventories on sample plots to aboveground biomass of trees.

Equation selection or development must follow the criteria described for *fj(X,Y...)*, the aboveground biomass of trees based on allometric equation for species group *j* based on measured tree variable(s), in the parameters section below.

8.2.1.2 Measurements

Only the individual trees, species and strata which were to be harvested in the baseline scenario are to be measured. The tree dimensions and minimum diameter at breast height (DBH) specified by the selected allometric equation in Section 8.2.1.1 must apply to these trees.

Any minimum values employed in inventories are held constant for the duration of the project.

8.2.1.3 Determining Sample Plot Carbon Stocks

The carbon stock in aboveground biomass for each individual tree of species group *j* in the sample plot located in stratum *i* will be estimated using the selected or developed allometric equation applied to the tree dimensions resulting from Section 8.2.1.2.

Therefore, the sum of the carbon stock in each sample plot will be calculated as:

$$C_{AB,j,i,t,sp|PRJ} = \sum_{l=1}^{L_{j,i,sp,t}} f_j(X,Y\ldots) * CF \quad \textbf{(29)}$$

Where:

$C_{AB,j,i,t,sp\|PRJ}$	Carbon stock in aboveground biomass of trees of species *j* in plot *sp* in stratum *i* at time *t* in the project scenario, tC
CF_j	Carbon fraction of biomass for tree group *j*, tC t d.m.$^{-1}$; [22]
$f_j(X,Y\ldots)$	Aboveground biomass of trees based on allometric equation for species group *j* based on measured tree variable(s), t. d.m. tree^{-1}; [23]
i	1, 2, 3, …M strata;
j	*1, 2, 3 … J* tree species;
l	*1, 2, 3, …* $L_{j,i,t,sp}$ sequence number of individual trees of species group *j* in

[22] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).
[23] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

	stratum *i* at time *t* in sample plot *sp;*
t	*0, 1, 2, 3, …*t^* years elapsed since start of the project activity; and
sp	1, 2, 3 …*SP* sample plots.

8.2.1.4 Determining Stratum Carbon Stocks

The total carbon stock in the aboveground biomass of all trees present in sample plot *sp* in stratum *i* at time *t*, must be calculated as:

$$C_{AB,i,t,sp|PRJ} = \sum_{j=1}^{J} C_{AB,j,i,sp|PRJ} \quad \textbf{(30)}$$

Where:

$C_{AB,i,t,sp\|PRJ}$	Aboveground biomass carbon stock of all trees of stratum *i* at time *t* in sample plot *sp* in the project scenario, tC;
$C_{AB,j,i,t,sp\|PRJ}$	Carbon stock in aboveground biomass of trees of species *j* in stratum *i* at time *t* in plot *sp* in the project scenario, tC;
i	1, 2, 3, …M strata;
j	*1, 2, 3 … J* tree species; and
t	*0, 1, 2, 3, …*t^* years elapsed since start of the project activity.

8.2.1.5 Determining Mean Carbon Stocks

Therefore, the mean carbon stock in aboveground biomass for each stratum per unit area is calculated as:

$$C_{AB,i,t|PRJ} = \frac{1}{SP} * \sum_{sp=1}^{SP} \left(\frac{C_{AB,i,t,sp|PRJ}}{A_{sp}} \right) \quad \textbf{(31)}$$

Where:

$C_{AB,i,t\|PRJ}$	Mean aboveground biomass carbon stock of trees in stratum *i* at time *t*, $tC \cdot ha^{-1}$;
$C_{AB,i,t,sp\|PRJ}$	Aboveground biomass carbon stock of trees in stratum *i* at time *t* in sample plot *sp*, tC;

Asp	Area of sample plot *sp*, ha; [24]
sp	*1, 2, 3 … SP* sample plots;
i	*1, 2, 3* … *M* strata; and
t	*0, 1, 2, 3* … *t** years elapsed since the start of the project activity.

8.2.1.6 Determining Carbon Stock Changes

The annual carbon stock change in aboveground biomass of trees in year *t* is the difference in mean carbon stock in aboveground biomass between sampling events and, when expressed in tCO_2e, is calculated as:

$$\Delta C_{AB,t|PRJ} = \left(\sum_{i=1}^{M}\left(A_i * \frac{C_{AB,i,t2|PRJ} - C_{AB,i,t1|PRJ}}{T}\right)\right) * \frac{44}{12} \qquad \textbf{(32)}$$

Where:

$\Delta C_{AB,t\|PRJ}$	Annual carbon stock change in aboveground biomass of trees in year *t*,tCO_2eyr^{1};
$C_{AB,i,t\|PRJ}$	Mean aboveground biomass carbon stock of trees in stratum *i* at time *t*, $tCha^{-1}$;
A_i	Area covered by stratum *i*, ha;
sp	*1, 2, 3 … SP* sample plots;
T	Number of years between monitoring time *t*1 and *t*2 (*T* = *t*2 – *t*1); years;
i	1, 2, 3 … M strata;
t	*1, 2, 3* … *t** years elapsed since the start of the project activity; and
44/12	Ratio of molecular weights of carbon dioxide and carbon, $tCO_2e\ tC^{-1}$.

The carbon stock change in aboveground biomass of trees ($\Delta C_{AB,t|PRJ}$) is the output of this section and is necessary to calculate net greenhouse gas emissions in the project scenario.

8.2.2 Forest disturbance in the project scenario

This section calculates $\Delta C_{DIST\_FR,t|PRJ}$, carbon stock change due to fire disturbance in the project scenario; tCO_2e, $\Delta C_{DIST,t|PRJ}$, carbon stock change due to non-fire natural disturbance in the project scenario; tCO_2e.

---

[24] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

8.2.2.1 Natural disturbance

It is a requirement that any greenhouse gas emissions from natural disturbance above *de minimis* that may occur in the project area are monitored.

Estimation of emissions from natural disturbance must be calculated depending on the type of disturbance event. Disturbance due to fire is calculated following Option A, and all non-fire natural disturbance (eg, wind, disease, pest events) is calculated following Option B.

Option A: Natural Disturbance - Fire

For fire damage it is assumed that a fire burning in the project scenario would also have burned in the baseline scenario. Project emissions are therefore equal to the fire damage to biomass absent in the baseline scenario (harvested and removed) but present in the project scenario.

Where fires occur *ex post* in the project area, the area burned must be delineated.

Therefore, based on the *IPCC 2006 Inventory Guidelines*, estimation of greenhouse gas emissions from biomass burning must be calculated as:

$$\Delta C_{DIST-FR,t|PRJ} = \sum_{i=1}^{M} A_{burn,i,t} * B_{i,t|PRJ} * COMF_i * G_{g,i} * 10^{-3}.GWP_{CH4} \quad \textbf{(33)}$$

Where:

$\Delta C_{DIST\_FR,t\|PRJ}$	Net greenhouse gas emissions resulting from fire disturbance in year *t*, tCO_2e
Aburn,i,t	Area burnt for stratum *i* at time *t*, ha; [25]
$B_{i,t\|PRJ}$	Average aboveground biomass stock present in the project scenario but absent in the baseline scenario before burning stratum *i*, time *t*; t d. m. ha^{-1};
$COMF_i$	Combustion factor for stratum *i*, dimensionless; [26]
Gg,i	Emission factor for stratum *i* for methane, g kg^{-1} dry matter burnt; [27]
GWP_{CH4}	Global warming potential for CH_4 (IPCC default: 21), $tCO_2e\ tCH_4^{-1}$;
i	1, 2, 3 …*M* strata; and
t	1, 2, 3, … *t** years elapsed since the start of the IFM project activity.

[25] See *Data and parameters used in monitoring* parameter list for information on data selection (p59).
[26] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).
[27] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p 51).

The average aboveground biomass stock present in the project scenario but absent in the baseline scenario before burning for a particular stratum must be calculated as:

$$B_{i,t|PRJ} = \sum_{j=1}^{J} \{V_{EX,i,j|BSL} * BCEF_R\} \quad \textbf{(34)}$$

Where:

$B_{i,t\|PRJ}$	Average aboveground biomass stock present in the project scenario but absent in the baseline before burning for stratum *i*, time *t*, t d. m. ha^{-1};
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species *j* in stratum *i*, m^3·ha^{-1};
$BCEF_R$	Biomass conversion and expansion factor applicable to wood removals in the project area, t.d.m m^{-3}; [28]
i	1, 2, 3 …*M* strata;
j	1, 2, 3 …*J* tree species; and
t	1, 2, 3, … *t** years elapsed since the start of the IFM project activity.

Option B: Natural Disturbance - Non-Fire

For non-fire natural disturbance, it is assumed that a disturbance event in the project scenario would also have occurred in the baseline scenario. Project emissions are therefore equal to the non-fire natural disturbance to biomass absent in the baseline scenario (harvested and removed) but present in the project scenario.

It is conservatively assumed that the natural disturbance is a stand-replacing disturbance, and that the biomass change as a result of the natural disturbance ($\Delta C_{DIST,t|PRJ}$) is emitted in the year of disturbance.

Where non-fire natural disturbances occur ex post in the project area, the area disturbed must be delineated.

$$\Delta C_{DIST,t|PRJ} = \sum_{i=1}^{M} \left(A_{dist,i,t} * \sum_{j=1}^{J} \{C_{AB,j,i|BSL}\} \right) * \frac{44}{12} \quad \textbf{(35)}$$

Where:

$\Delta C_{DIST,t|PRJ}$ Net greenhouse gas emissions resulting from non-fire natural disturbance in

[28] See Data and parameters not monitored (default or possibly measured one time) parameter list for information on data selection (p51).

	year t, tCO_2e ;
$A_{dist,i,t}$	Area disturbed for stratum i at time t, ha; [29]
$C_{AB,i\|BSL}$	Carbon stock in aboveground biomass per unit area in stratum i, $tC \cdot ha^{-1}$;
44/12	Ratio of molecular weights of carbon dioxide and carbon, $tCO_2e\ tC^{-1}$;
i	1, 2, 3 …M strata;
j	1, 2, 3 …J tree species; and
t	1, 2, 3, … t^* years elapsed since the start of the IFM project activity.

8.2.2.2 Illegal logging

It is a requirement that any greenhouse gas emissions from illegal logging above *de minimis* that may occur in the project area ($\Delta C_{DIST\_IL,i,t|PRJ}$) are monitored.

At the time of methodology approval, remote sensing technology using optical sensors is not capable of direct measurements of biomass and changes thereof[30] but has some capability to identify forest strata that have undergone a change in biomass[31].

As remote methods for monitoring illegal logging are not available at the time of methodology approval, the following ground-based methods must be used.

Option A: PRA

A participatory rural appraisal (PRA) of the communities surrounding the project area must be completed to determine if there is the potential for illegal extraction of trees from the project area. If this assessment finds no potential pressure for these activities then illegal logging ($\Delta C_{DIST\_IL,i,t|PRJ}$) can be assumed to be zero and no monitoring is needed.

The PRA must be repeated every 2 years.

---

[29] See data and parameters used in monitoring parameter list for information on data selection (p62).
[30] However, technology is developing rapidly, including techniques such as RADAR, SAR, or LiDAR.
[31] For example, a multi-temporal set of remotely sensed data can be used to detect changes in the structure of the forest canopy. A variety of techniques, such as Spectral Mixture Analysis (Souza et al. 2005), SAR or LiDAR, can be used under this approach but no specific technology is prescribed here. Some of the newer technologies can estimate carbon contents of forest types, if supported by field information such as sample plots to calibrate the technology and fieldwork leading to allometric equations of key species. The project proponent should use techniques that are suitable to their specific situation and that have been published in peer-reviewed papers.

Option B: Sampling

If the results of the PRA suggest that there is a potential for illegal logging activities, then limited field sampling must be undertaken.

The area that is potentially subject to degradation ($A_{DIST\_IL,i}$) uses the distance of illegal logging penetration from all access points (access buffer), such as roads and rivers or previously cleared areas, to the project area determined from the PRA.

The area subject to illegal logging must be delineated ($A_{DIST\_IL,i}$) based on an access buffer from all access points, such as roads and rivers or previously cleared areas, to the project area, with a width equal to the distance of degradation penetration.

$A_{DIST\_IL,I}$ must be sampled by surveying several transects of known length and width across the access-buffer area (equal in area to at least 1% of $A_{DIST\_IL,i}$) to determine the presence or absence of new tree stumps. The CDM tool for significance[32] must be applied to determine significance where there is evidence that trees are being harvested.

Where application of the CDM tool demonstrates that illegal logging is insignificant then illegal logging can be assumed to be zero and no monitoring is needed.

This limited sampling must to be repeated each time the PRA indicates a potential for illegal logging.

Where limited sampling provides evidence that trees are being removed in the buffer area, then systematic sampling must be implemented based on a detailed sampling plan. The sampling plan must be designed using plots systematically placed over the buffer zone so that they sample at least 3% of the area of the buffer zone ($A_{DIST\_IL,i}$). The diameter of all tree stumps will be measured and conservatively assumed to be the same as the DBH. Where the stump is a large buttress, several individuals of the same species nearby must be located and a ratio of the diameter at DBH to the diameter of buttress at the same height above ground as the measured stumps must be determined. This ratio will be applied to the measured stumps to estimate the likely DBH of the cut tree.

The aboveground carbon stock of each harvested tree will be estimated using the allometric regression equations chosen for forest growth in the project scenario[33]. The mean aboveground carbon stock of the harvested trees ($C_{DIST\_IL,i,t|PRJ}$) is conservatively estimated to be, the total emissions and, consequently all emissions enter the atmosphere.

---

[32]http://cdm.unfccc.int/EB/031/eb31_repan16.pdf

[33] If species-specific equations are used and species cannot be identified from stumps then it shall be assumed that the harvested species is the species most commonly harvested. A PRA shall be used to determine the most commonly harvested species.

This sampling procedure must be repeated every 5 years and the results annualised by dividing the total emissions by five.

Therefore, where the PRA or the limited sampling indicate no illegal logging occurring:

$$\Delta \boldsymbol{C}_{\boldsymbol{DIST-IL,t|PRJ}} = \mathbf{0} \qquad \textbf{(36)}$$

Where the PRA and the limited sampling indicate degradation is occurring, net carbon stock changes as a result of illegal logging must be calculated as:

$$\Delta C_{DIST-IL,t|PRJ} = \sum_{i=1}^{M}\left(A_{DIST-IL,j} * \frac{C_{DIST-IL,i,t|PRJ}}{AP_i}\right) x \left(1 + \frac{V_{EX,INF,j,i|BSL}}{V_{EX,j,i|BSL}}\right) + {C_{FUEL}}\Big/{\sum_{i=1}^{I} \mathrm{C}_{\mathrm{EX,i|BSL}}}\ x \frac{44}{12}\ x\ C_{DIST-IL,t|PRJ} \qquad \textbf{(37)}$$

Where:

$\Delta C_{DIST\_IL,t\|PRJ}$	Net carbon stock changes as a result of illegal logging at time *t*, tCO_2e;
$A_{DIST\_IL,i}$	Area potentially impacted by illegal logging in stratum *I*, ha; [34]
$C_{DIST\_IL,i,t\|PRJ}$	Biomass carbon of trees cut and removed through illegal logging in stratum *i* at time *t*, tCO_2e;
$V_{EX,j,i\|BSL}$	Mean volume of extracted timber per unit area for species *j* in stratum *i*, $m^3 \cdot ha^{-1}$;
$V_{EX,INF,j,i\|BSL}$	Mean volume of extracted timber for forestry infrastructure per unit area for species j in stratum i, $m^3 \cdot ha^{-1}$;
C_{FUEL}	Total carbon emissions associated with the combustion of fossil fuel in forestry and wood processing machinery, in tC;
$C_{EX,i\|BSL}$	Change in carbon stock of extracted wood products resulting from timber harvest per unit area in stratum *i* in land parcel *p*, in tC ha-1;
AP_i	Total area of illegal logging sample plots in stratum *i*, ha;[35]
i	1, 2, 3 …*M* strata in the in the project case; and
t	1, 2, 3, … *t* years elapsed since the projected start of the project activity.

This approach not only considers the carbon stock reductions due to illegal logging, but also considers fuel emissions of illegal logging operations and potential emissions from infrastructure development for conducting illegal logging.

The emissions of infrastructure development due to illegal logging are estimated by determining an expansion factor based on regular baseline harvesting practices (ie, the relation of volume extracted due to infrastructure development compared to the merchantable volume extracted). As

[34] See *Data and parameters used in monitoring* parameter list for information on data selection (p62).
[35] See *Data and parameters used in monitoring* parameter list for information on data selection (p62).

it is unlikely that illegal logging will result in large scale infrastructure development (ie, equaling the baseline scenario), this approach is considered conservative.

Fuel emissions from illegal logging operations are determined by using the specific fuel emissions of the baseline scenario (ie, total fuel emissions are divided by the total carbon stock changes due to baseline logging operations) which are then multiplied by the illegal logging volume. As it is unlikely that illegal logging would involve the deployment of large, fuel intensive machinery (ie, equaling the baseline scenario), this is considered conservative.

The calculation of emissions from illegal logging therefore requires use of both parameters available at validation (Section 9.1) and parameters monitored (section 9.2).

8.2.3 Net greenhouse gas emissions in the project scenario

This section calculates $\Delta C_{NET,t|PRJ}$, the net greenhouse gas emissions in the project scenario in year *t*, in tCO_2e.

The net greenhouse gas emissions in the project scenario are the sum of net greenhouse gas emissions resulting from fire and non-fire forest disturbance, plus any carbon stock changes that occur as a result of illegal logging, minus the annual carbon stock change in the aboveground biomass of trees due to forest growth.

Therefore, net greenhouse gas emissions in the project scenario in year *t*, is calculated as:

$$\Delta C_{NET,t|PRJ} = \left(\Delta C_{DIST-FR,t|PRJ} + \Delta C_{DIST,t,PRJ} + \Delta C_{DIST-IL,t|PRJ}\right) - \Delta C_{AB,t|PRJ} \quad \textbf{(38)}$$

Where:

$\Delta C_{NET,t\|PRJ}$	Net greenhouse gas emissions in the project scenario in year *t*, tCO_2-e;
$\Delta C_{DIST\_FR,t\|PRJ}$	Net greenhouse gas emissions resulting from fire disturbance in year *t*, tCO_2e
$\Delta C_{DIST,t\|PRJ}$	Net greenhouse gas emissions resulting from non-fire natural disturbance in year *t*, tCO_2e ;
$\Delta C_{DIST\_IL,t\|PRJ}$	Net carbon stock changes as a result of illegal logging at time *t*, tCO_2e;
$\Delta C_{AB,t\|PRJ}$	Annual carbon stock change in aboveground biomass of trees in year *t*, tCO_2e□yr^{-1}; and
t	*1, 2, 3, … t** years elapsed since start of the project activity.

The net greenhouse gas emissions across in the project scenario since the start of the project is calculated as:

$$GHG_{NET|PRJ} = \sum_{t=1}^{t^*} \Delta C_{NET,t|PRJ} \quad \textbf{(39)}$$

Where:

$GHG_{NET\|PRJ}$	Net greenhouse gas emissions in the project scenario since the start of the project activity, tCO_2e;
$\Delta C_{NET,t\|PRJ}$	Net greenhouse gas emissions in the project scenario in year *t*, tCO_2e; and
t	*1, 2, 3, … t** years elapsed since start of the project activity.

8.3 Leakage

8.3.1 Activity shifting leakage

There may be no leakage due to activity shifting.

Where the project proponent controls multiple parcels of land within the country the project proponent must demonstrate that the management plans and/or land-use designations of other lands they control have not materially changed as a result of the planned project (designating new lands as timber concessions or increasing harvest rates in lands already managed for timber) because such changes could lead to reductions in carbon stocks or increases in GHG emissions.

This must be demonstrated through:

- Historical records showing trends in harvest volumes paired with records from the with-project time period showing no deviation from historical trends;

- Forest management plans prepared ≥24 months prior to the start of the project showing harvest plans on all owned/managed lands paired with records from the with-project time period showing no deviation from management plans.

At each verification, documentation must be provided covering the other lands controlled by the project proponent where leakage could occur, including, at a minimum, their location(s), area and type of existing land use(s), and management plans.

Where activity shifting occurs or a project proponent is unable to provide the necessary documentation at first and subsequent verification, the project must not meet the requirements for verification. Therefore, the project must be subject to the conditions described in the *VCS AFOLU Guidance Document* on projects which fail to submit periodic verification after the commencement of the project. The project proponent may optionally choose to submit a methodology deviation with their future verifications to address activity shifting leakage.

Where the project proponent has control only over resource use in the project area and has no access to other forest resource, then the only type of leakage emissions calculated is GHG emissions due to market effects that result from project activity.

8.3.2 Market leakage

Leakage due to market effects is equal to the net emissions from planned timber harvest activities in the baseline scenario multiplied by an appropriate leakage factor:

$$GHG_{LK|LtPF.t*} = LF_{ME} * GHG_{NET|BSL,t*} \quad \textbf{(40)}$$

Where:

$GHG_{LK\|LtPF,t*}$	Total market leakage as a result of IFM LtPF activities, in the year t* since the start of the project activity, tCO2e;
LF_{ME}	Leakage factor for market-effects calculations, dimentionless;
$GHG_{NET\|BS,t*L}$	Net greenhouse gas emissions in the baseline scenario in the year t* since the start of the project activity, tCO_2e.

The leakage factor (see Box 2 below) is determined by considering where in the country logging will be increased as a result of the decreased timber supply caused by the project.

If the ratio of merchantable biomass to total biomass is higher in the project area, it is likely that additional logging will be performed in these areas as a result of reduced logging in the project area in the project scenario.

The leakage factor is thus defined as a dimensionless number with values between 0 and 1 assigned *ex ante* on the basis of a comparison between the ratio of merchantable biomass to total biomass across all strata in the base year, and the ratio of merchantable biomass to total biomass of the country's forest estate where harvesting would likely be displaced to.

Box 2: Leakage Factor Calculation

The leakage factor is determined by considering where in the country logging will be increased as a result of the decreased supply of the timber caused by the project. If the areas liable to be logged have a higher ratio of merchantable biomass to total biomass higher than the project area it is likely that the proportional leakage is higher and vice versa:

Therefore,

$LF_{ME} = 0$

if it can be demonstrated that no market-effects leakage will occur within national boundaries, that is if no new concessions are being assigned AND annual extracted volumes cannot be increased within existing national concessions AND illegal logging is absent (or *de minimis*) in the host country.

The amount of leakage is determined by where in the country's forest estate harvesting would likely be displaced. If harvesting is displaced to forests where a lower proportion of forest biomass is merchantable material from harvestable species than in the project area, then in order to extract a given volume higher emissions should be expected as more trees will need to be cut to supply the same volume.

In contrast if a higher proportion of the total biomass of commercial species is merchantable in the displacement forest than in the project forests, then a smaller area would have to be harvested and lower emissions would result.

Therefore, each project must calculate within each stratum the ratio of merchantable biomass to total biomass (PMP_i). This shall then be compared to the ratio of merchantable biomass to total biomass for each forest type (PML_{FT}).

The following deduction factors (LF_{ME}) shall be used:

PML_{FT} is equal (± 15%) to PMP_i $LF_{ME} = 0.4$

PML_{FT} is > 15% less than PMP_i $LF_{ME} = 0.7$

PML_{FT} is > 15% greater than PMP_i $LF_{ME} = 0.2$

Where:

PML_{FT} mean merchantable biomass as a proportion of total aboveground tree biomass for each forest type, %;

PMP_i merchantable biomass as a proportion of total aboveground tree biomass for stratum i within the project boundaries, %; and

LF_{ME} Leakage factor for market-effects calculations; dimensionless.

Where sufficient variation exists in PMP_i relative to PML_{FT} that multiple values of LF_{ME} result, then an area weighted final value for LF_{ME} shall be calculated. The area of stratum i as a proportion of the total project area shall be multiplied by LF_{ME}. All values are then summed to arrive at the area weighted final value of LF_{ME}.

8.4 Summary of GHG Emission Reduction and/or Removals

Net GHG emission reductions are calculated as:

$$GHG_{CREDITS|LtPF,t*} = GHG_{NET|BSL,t*} - GHG_{NET\backslash PRJ,t*} - GHG_{LK|LtPF,t*} \quad \textbf{(41)}$$

Where:

$GHG_{CREDITS|LtPF,t*}$	project greenhouse gas credits associated with the implementation of improved forest management (IFM) activities in the year t* since the start of the project activity, in the project scenario, tCO_2e;
$GHG_{NET|BS,t*L}$	net greenhouse gas emissions in the baseline scenario in the year t* since the start of the project activity, tCO_2e;
$GHG_{NET|PRJ,t*}$	net greenhouse gas emissions in the project scenario in the year t* since the start of the project activity, tCO_2e; and
$GHG_{LK|LtPF,t*}$	total greenhouse gas emissions due to leakage arising outside the project boundary as a result of the implementation of improved forest management (IFM) activities in the year t* since the start of the project activity, in the project scenario, tCO_2e.

8.4.1 Project Verified Carbon Units

The number of Verified Carbon Units (VCUs) for each year t in the project crediting period is the greenhouse gas emission reductions and removals adjusted for uncertainty and risk.

8.4.1.1 Adjustment for uncertainty

Estimated greenhouse gas emissions and emission reductions from IFM activities have uncertainties associated with parameters and coefficients including estimates of area, carbon stocks, regrowth and expansion factors. It is assumed that the uncertainties associated with input data are available, either as default uncertainty values given in most recent IPCC guidelines, or as statistical estimates based on sampling.

Uncertainty at all times is defined at the 95% confidence interval where the estimated variance exceeds +/- 15 percent from the mean. Procedures including stratification and the allocation of sufficient measurement plots will help ensure that low uncertainty results and ultimately full crediting can result.

It is good practice to consider uncertainty at an early stage to identify the data sources with the highest uncertainty to allow the opportunity to conduct further work to diminish uncertainty.

Uncertainties arising from the measurement and monitoring of carbon pools and greenhouse gases must always be quantified. Errors in each pool must be weighted by the size of the pool so that projects may reasonably target a lower precision level in pools that only form a small proportion of the total stock.

For both the baseline and the with-project case the total uncertainty is equal to the square root of the sum of the squares of each component uncertainty and is calculated at the time of reporting through propagating the error in the baseline stocks and the error in the project stocks.

Therefore, total uncertainty for LtPF project is calculated as:

$$U_{TOTAL|LtPF} = \sqrt{U^2{}_{|PRJ} + U^2{}_{|BSL}} \quad \textbf{(42)}$$

Where:

$U_{total|LtPF}$	Total uncertainty for LtPF Project, dimensionless;
$U_{|PRJ}$	Total uncertainty for the improved forest management activities in the project scenario, dimensionless; and
$U_{|BSL}$	Total uncertainty for the baseline scenario, dimensionless.

The project proponent must justify the selection of uncertainty propagation in the project documents. If $U_{total|LtPF} \leq 0.15$ then no deduction will result for uncertainty.

If $U_{total|LtPF}>0.15$ then the amount of greenhouse gas emission credits associated with IFM activities will be deducted as follows:

$$Credits_{total|LtPF} = GHG_{credits|LtPF} * \left(1 - U_{total|LtPF}\right) \quad \textbf{(43)}$$

Where:

$Credits_{total|LtPF}$	Total greenhouse gas credits adjusted for uncertainty for each year *t* in the project crediting period;
$GHG_{credits|LtPF}$	Project greenhouse gas credits associated with the implementation of improved forest management (IFM) activities in the project scenario, $tCO_2e \cdot year^{-1}$; and
$U_{total|LtPF}$	Total uncertainty for LtPF Project, dimensionless.

8.4.1.2 Calculation of verified carbon units

The amount of greenhouse gas emission reductions estimated under Section 8.4.1.1 above must be adjusted to account for risk, following application of the most recent version of the VCS *AFOLU Non-Permanence Risk Tool*.

Therefore, the amount of VCU's that can be issued at time t=t2 (the date of verification) for monitoring period T=t2-t1, is calculated as:

$$VCU_{net|LtPF} = \left(Credits_{total,t2|LtPF} - Credits_{total,t1|LtPF}\right) - Bu_{|IFM-VCS} \quad \textbf{(44)}$$

Where:

$VCU_{net\,|\,LtPF}$	Number of verified carbon units; dimensionless;
$Credits_{total.t1\,|\,LtPF}$	Net anthropogenic greenhouse gas removals by sinks, as estimated for t*=t1 in tCO_2e;
$Credits_{total.t2\,|\,LtPF}$	Net anthropogenic greenhouse gas removals by sinks, as estimated for t*=t2 in tCO_2e; and
$Bu_{|IFM\text{-}VCS}$	Total number of credits withheld in VCS AFOLU pooled buffer account

9 MONITORING

9.1 Data and Parameters Available at Validation

In addition to the parameters listed in the tables presented in the following sections, the provisions on data and parameters not monitored in the tools referred to in this methodology apply. In choosing key parameters or making important assumptions based on information that is not specific to project circumstances, such as in use of existing published data, the project proponent must follow a conservative approach. That is, if different values for a parameter are equally plausible, a value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.

Note that the calculation of baseline emissions from fossil fuel combustion requires the determination of a set of parameters (eg, specific fuel consumption of a harvester, in kL/m3). As a general procedure, the determination of all parameters must follow one of the subsequent pathways:

1. Historic Data Pathway: Where the project proponent has a history of logging operations, the equipment type and fuel consumption data from the project proponent's operation must be considered.

2. Common Practice Pathway: Where the project proponent has no history of logging operations, regional or national standards and typical machinery (ie, default values) must be considered. This includes:

   - Identification of equipment type (eg, harvester or chain saw);

   - Identification of the specific fuel consumption (ie, in kL/m3) of equipment type.

   The following sources of information are permitted for the common practice pathway:

   - Data from other forest management companies in the region; or

- Data from peer reviewed literature (ie, available from a recognized, credible source and must be reviewed for publication by an appropriately qualified, independent organization or an appropriate peer review group, or published by a government agency).

Further, the source of all data must be appropriate to the methodology's geographic scope and eligible project activities.

Data / Parameter	$F_{V,INF,HWP}$
Data unit	%
Description	The fraction of merchantable timber volume from clearing of forest roads, skidtrails and log landings that is to be processed into wood products .Based on this fraction as well as forest inventory or sample plot data and forestry infrastructure data, $V_{EX,INF,j,i\|BSL}$ and $V_{notEX,INF,j,i\|BSL}$ will be calculated.
Equations	To be applied in the timber harvest plan
Source of data	A credible and conservative value for $F_{V,INF,HWP}$ must be set based on one of the following sources in order of their appearance: Forest management records of the baseline agent or other similar forestry companies Peer-reviewed literature Government statistics from the region If the project proponent cannot provide such a credible estimate, then it is conservatively assumed that all timber cleared for the purpose of forestry infrastructure is processed into sawnwood and hence must be accounted for under the harvested wood products section.

Purpose of Data	Determination of baseline scenario
Comments	Parameter needs to be re-assessed and updated (if appropriate) as part of the baseline re-evaluation.

Data/ Parameter:	$V_{l,j,i,sp}$

Data unit:	m^3
Used in equations:	(1)
Description:	Merchantable volume for tree *l* of species *j* in sample plots *p* in stratum *i*
Source of data:	Calculated from volume tables or equations linking diameter at breast height (DBH, at typically 1.3 m aboveground level), and/or merchantable height (MH), to commercial (merchantable) volume of trees in the sample plots above the minimum DBH set in the timber harvest plan. If locally derived equations or yield tables are not available use relevant regional, national or default equations from IPCC literature, national inventory reports or published peer-reviewed studies– such as those provided in Tables 4.A.1 to 4.A.3 of the GPG-LULUCF (IPCC 2003).
Measurement procedures (if any):	N/A
Any comment:	It is necessary to verify the applicability of equations used. Allometric equations can be verified by both: 1. Verification of equation conditions Justification should be provided for the applicability of the equation to the project locations. Such justification should include identification of climatic, edaphic, geographical and taxonomic similarities between the project location and the location in which the equation was derived. Any equation used should have an r2 value of greater than 0.5 (50%) and a p value that is significant (<0.05 at the 95% confidence level). 2. Additional field verification The following limited measures method must be used for field verification: select at least 10 trees per species distributed across the age range (but excluding trees less than 15 years old for which there is rarely a great relative inaccuracy in equations) ; measure DBH, and height to a 10 cm diameter top or to the first branch; calculate stem volume from measurements; and plot the estimated volume of all the measured trees along with the curve of volume against diameter as predicted by the allometric equation. If the estimated volume of the measured trees are distributed both

	above and below the curve (as predicted by the allometric equation) the equation may be used. The equation may also be used if the measured individuals have a volume consistently higher than predicted by the equation. The equation may not be used if >75% of the measured trees have a volume lower than the predicted curve. In this instance another equation must be selected.

Data/ parameter:	CF_j
Data unit:	$tC·td.m.^{-1}$
Used in equations:	(3),(4),(17)
Description:	Carbon fraction of dry matter for species j
Source of data:	Either the default value $0.5tC·td.m.^{-1}$ or species specific values from the literature must be used. The same value, however, must be used in all instances where this parameter is used.
Measurement procedures (if any):	N/A
Any comment:	Parameter needs to be re-assessed and updated (if appropriate) as part of the baseline re-evaluation.

Data/ parameter:	D_j
Data unit:	$t.d.m.\ m^{-3}$
Used in equations:	(4)
Description:	Basic wood density of species *j* in $t\ d.m.\ m^{-3}$
Source of data:	Must be chosen with priority from higher to lower preference as follows: National species-specific or group of species-specific values (eg, from National GHG inventory); Species-specific or group of species-specific values from neighboring countries with similar conditions. When species-specific data from neighboring countries is of higher quality, being more representative of the species in the project scenario, it may be preferable to use these values than lower quality national data; Global species-specific or group of species-specific (eg, IPCC 2006 AFOLU Chapter 4 Tables 4.13 and 4.14). Species-specific wood densities may not always be available, and

	may be difficult to apply with certainty in the typically species rich forests of the humid tropics, hence it is acceptable practice to use wood densities developed for forest types or plant families or species groups.
Measurement procedures (if any):	N/A
Any comment:	Default values must be updated whenever new guidelines are produced by the IPCC

Data/ parameter:	$f_j(X,Y...)$
Data unit:	t d.m. tree^{-1}
Used in equations:	17
Description:	Allometric equation(s) for species *j* linking measured tree variable(s) to aboveground biomass of living trees
Source of data:	Equations must have been derived using a wide range of measured variables (eg, DBH, Height, etc.) based on datasets that comprise at least 30 trees. Equations must be based on statistically significant regressions and must have an r2 that is ≥ 0.8. The source of equation(s) must be chosen with priority from higher to lower preference, as available, as follows: National species-, genus-, family-specific; Species-, genus-, family-specific from neighboring countries with similar conditions (ie, broad continental regions); National forest-type specific; Forest-type specific from neighboring countries with similar conditions (ie, broad continental regions); Forest type-specific such as those provided Tables 4.A.1 to 4.A.3 of the GPG-LULUCF (IPCC 2003); or in Pearson, T., Walker, S. and Brown, S. 2005. Sourcebook for Land Use, Land-Use Change and Forestry Projects. Winrock International and the World Bank Biocarbon Fund. 57pp.; or in Chave, J., C. Andalo, S. Brown, M. A. Cairns, J. Q. Chambers, D. Eamus, H. Folster, F. Fromard, N. Higuchi, T. Kira, J.-P. Lescure, B. W. Nelson, H. Ogawa, H. Puig, B. Riera, T. Yamakura. 2005. Tree allometry and improved estimation of carbon stocks and balance in tropical forests. Oecologia 145: 87-99. Species-, genus- and family-specific allometric equations may not always be available, and may be difficult to apply with certainty in the typically species rich forests of the humid tropics. Hence it is

	acceptable practice to use equations developed for regional forest types, provided that their accuracy has been validated with direct site-specific data following guidance given below. If a forest-type specific equation is used, it should not be used in combination with species-specific equation(s) (ie, it must be used for all tree species[36]).
Measurement procedures (if any):	N/A
Any comment:	It is necessary to validate the applicability of equations used. Source data from which equation(s) was derived should be reviewed and confirmed to be representative of the forest type/species and conditions in the project and covering the range of potential independent variable values. Allometric equations can be validated either by: 1. Limited Measurements select at least 30 trees (if validating forest type-specific equation, selection should be representative of the species composition in the project area, ie, species representation in roughly in proportion to relative basal area). Minimum diameter of measured trees must be 20cm and maximum diameter must reflect the largest trees present or potentially present in the future in the project area (and/or leakage belt); measure DBH, and height to a 10 cm diameter top or to the first branch; calculate stem volume from measurements and multiplying by species-specific density to gain biomass of bole; apply a biomass expansion factor to estimate total aboveground biomass from stem biomass[37]; and plot the estimated biomass of all the measured trees along with the curve of biomass against diameter as predicted by the allometric equation. If the estimated volume of the measured trees are distributed both above and below the curve (as predicted by the allometric equation)

[36]Note that forest type specific and pantropical equations will typically not include palm species or hollow-stem species (e.g. Cecropia) and so specific equations for these growth forms will be needed

[37] See IPCC 2006 INVGLs AFOLU Chapter4 Table 4.5

	the equation may be used. The equation may also be used if the measured individuals have a biomass consistently higher than predicted by the equation. If >75% of the measured trees have a biomass lower than the predicted curve, destructive sampling must be undertaken or another equation must be selected. 2. Destructive Sampling select at least 5 trees (if validating forest type-specific equation, selection should be representative of the species composition in the project area, ie, species representation in roughly in proportion to relative basal area) at the upper end of the range of independent variable values existing in the project area; measure DBH and commercial height and calculate volume using the same procedures/equations used to generate commercial volumes to which BCEFs will be applied; fell and weigh the aboveground biomass to determine the total (wet) mass of the stem, branch, twig, leaves, etc. Extract and immediately weigh subsamples from each of the wet stem and branch components, followed by oven drying at 70 degrees C to determine dry biomass; determine the total dry weight of each tree from the wet weights and the averaged ratios of wet and dry weights of the stem and branch components; and plot the estimated biomass of all the measured trees along with the curve of biomass against diameter as predicted by the allometric equation. If the estimated volume of the measured trees are distributed both above and below the curve (as predicted by the allometric equation) the equation may be used. The equation may also be used if the measured individuals have a biomass consistently higher than predicted by the equation. If >75% of the measured trees have a biomass lower than the predicted curve another equation must be selected. Details of destructive sampling measurements are given in: Brown, S. 1997. Estimating biomass and biomass change of tropical forests: a primer. FAO Forestry Paper 134, Rome, Italy. Available at http://www.fao.org/docrep/W4095E/W4095E00.htm If using species-specific equations, and new species are encountered in the course of monitoring, new allometric equations must be sourced from the literature and validated, if necessary, as per requirements and procedures above.

	Default values must be updated whenever new guidelines are produced by the IPCC

Data/ parameter:	$BCEF_R$
Data unit:	$t.d.mm^{-3}$
Used in equations:	3, 22
Description:	Biomass conversion and expansion factor applicable to wood removals in the project area
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: Existing local forest type-specific; National forest type-specific or eco-region-specific (eg, from national GHG inventory); Forest type-specific or eco-region-specific from neighboring countries with similar conditions. Sometimes (c) might be preferable to (b); Global forest type or eco-region-specific (eg, IPCC 2006 INV GLs AFOLU Chapter 4 Table 4.5). Alternatively: BCEFR = BEFR * D Where BCEF values are not directly available, they can be calculated as Biomass Expansion Factor (BEF)* basic wood density (D). Application of this equation requires caution because basic wood density and biomass expansion factors tend to be correlated. If the same sample of trees was used to determine D, BEF or BCEF, conversion will not introduce error, therefore, it is acceptable to use this equation. If, however, basic wood density is not known with certainty, transforming one into the other might introduce error, as BCEF implies a specific but unknown basic wood density, therefore, all conversion and expansion factors must be derived or their applicability checked locally.
Measurement procedures (if any):	N/A
Any comment:	The combustion factor is a measure of the proportion of the fuel that is actually combusted, which varies as a function of the size and architecture of the fuel load (ie, a smaller proportion of large, coarse fuel such as tree stems will be burnt compared to fine fuels, such as

	grass leaves), the moisture content of the fuel and the type of fire (ie, intensity and rate of spread). Default values must be updated whenever new guidelines are produced by the IPCC

Data/ parameter:	G_{gi}
Data unit:	g kg^{-1}dry matter burnt
Used in equations:	(21)
Description:	Emission factor for stratum *i* for gas *g*
Source of data:	Defaults can be found in Volume 4, Chapter 2, of the IPCC 2006 Inventory Guidelines in table 2.5
Measurement procedures (if any):	N/A
Any comment:	Default values must be updated whenever new guidelines are produced by the IPCC

Data/ parameter:	*OF, SLF, WW*
Data unit:	Kg kg^{-1}
Used in equations:	7, 9
Description:	*OF* = Fraction of wood products that will be emitted to the atmosphere between3and100yearsafterproduction; *SLF* = Fraction of wood products that will be emitted to the atmosphere within 3 years of production; and *WW* = Fraction of extracted biomass effectively emitted to the atmosphere during production Wood waste fraction(WW): Winjum et al. 1998indicatethattheproportionofextracted biomass that is oxidized (burning or decaying) from the production of commodities to be equal to19%fordevelopedcountries, 24% for developing countries. Short-lived fraction (SLF) Winjumetal1998 give decay rates for proportions of wood products, which were converted to with short-term (<3yr) uses (applicable internationally) as below: Sawnwood 0.12 Woodbase panels 0.06

	Other industrial roundwood 0.18 Paper and Paperboard 0.24 Additional oxidized fraction (OF) Winjum et al 1998 gives annual oxidation fractions for each class of wood products split by forest region (boreal, temperate and tropical). This methodology projects these fractions over 95 years to give the additional proportion that is oxidized between the 3rd and the 100th year after initial harvest:
Source of data:	The source of data is the published paper of Winjum et al.1998[38]
Measurement procedures (if any):	N/A
Any comment:	Parameter needs to be reviewed as part of the baseline re-evaluation.

Wood Product Class	OF		
	Boreal	Temperate	Tropical
Sawnwood	0.39	0.62	0.86
Woodbase panels	0.62	0.86	0.98
Other industrial roundwood	0.86	0.98	0.99
Paper and paperboard	0.39	0.62	0.99

Data/ parameter:	PML_{FT}
Data unit:	%
Used in equations:	Section 8.3.2, Leakage, Box 2.
Description:	Mean merchantable biomass as a proportion of total aboveground tree biomass for each forest type.
Source of data:	The source of data must be chosen with priority from higher to lower preference as follows: peer-reviewed published sources (including carbon/biomass maps or growing stock volume[39] maps with a scale of at least 1km);

[38] Winjum ,J.K., Brown,S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. ForestScience44:272-28431

[39] Volumes shall be converted to merchantable biomass using wood densities / specific gravities. A weighted

Wood density shall be used to convert multi-species data on growing stock volume to merchantable biomass

	official Government data and statistics ;or original field measurements. The forest types considered must be only those relevant for the specific market effects leakage, that is, only forest types with active timber production. An appropriate source of data will be Government records on annual allowable cuts for the areas of commercial forests. Where volumes are used the source of data wood density is required to convert to merchantable biomass. The source of data on wood densities must be chosen as per the species specific density parameter, D_j.
Measurement procedures (if any):	
Any comment:	Parameter needs to be re-assessed and updated (if appropriate) as part of the baseline re-evaluation.

Data/ parameter:	RGR_i
Data unit:	$tC.ha^{-1}.yr^{-1}$
Used in equations:	10
Description:	Forest regrowth rate post timber harvest for stratum *i*
Source of data:	Regrowth rate must be calculated from either data generated in a reference area using measurements of timber volume in a chronosequence of replicated sample plots; or published data on forest growth after timber harvest of the same forest type within the same region as the project; or the IPCC default values for aboveground net biomass growth in natural forests[40].
Measurement procedures (if any):	
Any comment:	Default values must be updated whenever new guidelines are produced by the IPCC

Data/ parameter:	$V_{EX,j,i\|BSL}$

[40] IPCC Guidelines for National Greenhouse Gas Inventories(2006),Table4.9

Data unit:	$m^3 \cdot ha^{-1}$
Used in equations:	3, 4, 22, 27
Description:	Mean volume of extracted timber per unit area for species *j* in stratum *i*
Source of data:	The timber harvest plan sets the allowable mean extracted volume from the merchantable volume of timber in the forest inventory ($V_{j,i\|BSL}$),based on legal limits.
Measurement procedures (if any):	N/A
Any comment:	

Data/ parameter:	$TH_{i,p}$
Data unit:	Years
Used in equations:	
Description:	Number of years since timber harvest in stratum *i* in land parcel *p*
Source of data:	The timber harvest schedule specifies the year (*1,2,3...*) timber harvest in each land parcel is scheduled to occur and the number of years each land parcel is in a post harvest state during the project crediting period.
Measurement procedures (if any):	
Any comment:	

Data/ parameter:	$A_{i,p}$
Data unit:	Ha
Used in equations:	20
Description:	Area covered by stratum *i* over land parcel *p*
Source of data:	Geodetic coordinates and/or Remote Sensing data and/or legal parcel records
Measurement procedures (if any):	
Any comment:	It must be assumed ex-ante that land parcel boundaries and strata areas must not change through time

Data/ parameter:	$A_{1,i,p}$

Data unit:	Ha
Used in equations:	(11)
Description:	The area of stratum *i* in land parcel *p* that was harvested 1 year ago
Source of data:	Geodetic coordinates, GIS Files or legal parcel records
Measurement procedures (if any):	
Any comment:	

Data/ parameter:	$A_{2-10,i,p}$
Dataunit:	Ha
Usedin equations:	(12)
Description:	The area of stratum *i* in land parcel *p* that was harvested between 2 and 10 year ago
Sourceof data:	Geodetic coordinates, GIS Files or legal parcel records
Measurement procedures (if any):	
Any comment:	

Data/ parameter:	$A_{11-20,i,p}$
Data unit:	Ha
Used in equations:	13
Description:	The area of stratum *i* in land parcel *p* that was harvested between 11 and 20 years ago
Source of data:	Geodetic coordinates, GIS Files or legal parcel records
Measurement procedures (if any):	
Any comment:	

Data/ parameter:	A_{t+}
Data unit:	Ha
Used in equations:	14
Description:	Cumulative area harvested until time t*
Source of data:	Geodetic coordinates, GIS Files or legal parcel records

Measurement procedures (if any):	
Any comment:	

Data/ parameter:	A_{sp}
Data unit:	Ha
Used in equations:	2, 19
Description:	Area of sample plots *p*
Source of data:	Recording and archiving of size of sample plots
Measurement procedures (if any):	Standard procedures for plot delineation in forest timber inventory surveys must be used (see references in Box 3 for example procedures)
Any comment:	*Ex-ante* the size of the plots must be defined and recorded in the monitoring plan.

9.2 Data and Parameters Monitored

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply. In choosing key parameters or making important assumptions based on information that is not specific to the project circumstances, such as in use of existing published data, the project proponent must retain a conservative approach. That is, if different values for a parameter are equally plausible, a value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.

Data/ parameter:	Illegal Logging PRA Results
Data unit:	Dimensionless
Used in equations:	Used in Section 8.2.2.2a
Description:	
Source of data:	PRA
Measurement procedures (if any):	The PRA must evaluate whether timber harvest may be occurring in the project area and must consist of semi-structured interviews / questionnaires. If ≥10% of those interviewed / surveyed believe that illegal logging may be occurring within the project boundary then the limited on-the-ground illegal logging survey must be triggered. An additional output of the PRA must be a depth of penetration of illegal logging pressure. A maximum distance must be recorded for

	penetration into the forest from access points (such as roads, rivers, already cleared areas) for the purpose of harvesting timber.
Measurement Frequency	Every two years
QA/QC Procedures	
Any comment:	Ex ante estimation must be made of illegal logging in the with-project case. If the belief is that zero illegal logging will occur within the project boundaries then this parameter may be set to zero if clear infrastructure, hiring and policies are in place to prevent illegal logging.

Data/ parameter:	Result of Limited Illegal Logging Survey
Data unit:	Dimensionless
Used in equations:	Section 8.2.2.2b
Description:	
Source of data:	Limited on-the-ground illegal logging survey
Measurement procedures (if any):	Sampled by surveying multiple transects of known length and width across the access-buffer area to check whether new tree stumps are evident or not. The access-buffer area must be equal in area to at least 1% of ADIST_IL,i
Measurement Frequency	Must to be repeated each time the PRA indicates a potential for illegal logging.
QA/QC Procedures	
Any comment:	Ex ante an estimation must be made of illegal logging in the with-project case. If the belief is that zero illegal logging will occur within the project boundaries then this parameter may be set to zero if clear infrastructure, hiring and policies are in place to prevent illegal logging.

Data/ parameter:	$A_{burn,i,t}$
Data unit:	Ha
Used in equations:	21
Description:	Area burnt in stratum *i* at time *t*
Source of data:	Geodetic coordinates and / or Remote Sensing data
Measurement procedures (if any):	N/A
Measurement Frequency	Areas burnt must be monitored at least every five years
QA/QC Procedures	Standard quality control / quality assurance (QA/QC) procedures for forest inventory including field data collection and data management

	must be applied. Use or adaptation of QA/QCs already applied in national forest monitoring, or available from published handbooks, or form the IPCC GPG LULUCF 2003, is recommended.
Any comment:	Ex ante estimations of areas burned must be based on historic incidence of fire in the Project region

Data/ parameter:	*Adist,i,t*
Data unit:	Ha
Used in equations:	23
Description:	Area disturbed in stratum *i* at time *t*
Source of data:	Geodetic coordinates and / or Remote Sensing data
Measurement procedures (if any):	N/A
Measurement Frequency	Areas disturbed must be monitored at least every five years
QA/QC Procedures	Standard quality control / quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of QA/QCs already applied in national forest monitoring, or available from published handbooks, or form the IPCC GPG LULUCF 2003, is recommended.
Any comment:	Ex ante estimations of areas disturbed must be based on historic incidence of natural disturbance in the Project region

Data/ parameter:	$A_{DIST\_IL,i}$
Data unit:	Ha
Used in equations:	24
Description:	Area potentially impacted by illegal logging in stratum *i*
Source of data:	GIS delineation and ground-truthing
Measurement procedures (if any):	ADIST_IL,i must be composed of a buffer from all access points (access buffer), such as roads and rivers or previously cleared areas. The width of the buffer must be determined by the depth of degradation penetration as defined as a PRA output
Measurement Frequency	Repeated each time the PRA indicates a potential for degradation
QA/QC Procedures	
Any comment:	Ex ante a limited survey can be used to determine a likely depth of degradation penetration

Data/ parameter:	$C_{DIST\_IL,i,t\|PRJ}$
Data unit:	tCO_2e
Used in equations:	24, 25
Description:	biomass carbon of trees cut and removed through illegal logging in stratum i at time t
Source of data:	Field measurements in sample plots
Measurement procedures (if any):	The sampling plan must be designed using plots systematically placed over the buffer zone so that they sample at least 3% of the area of the buffer zone (ADIST_IL,i). The diameter of all tree stumps will be measured and conservatively assumed to be the same as the DBH. Where the stump is a large buttress, several individuals of the same species nearby must be located and a ratio of the diameter at DBH to the diameter of buttress at the same height above ground as the measured stumps must be determined. This ratio will be applied to the measured stumps to estimate the likely DBH of the cut tree. The aboveground carbon stock of each harvested tree will be estimated using the allometric regression equations chosen for forest growth in the project scenario. The mean aboveground carbon stock of the harvested trees is conservatively estimated to be the total emissions and to all enter the atmosphere
Measurement Frequency	Repeated each time limited sampling of ADIST_IL, indicates illegal logging
QA/QC Procedures	Standard quality control / quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of QA/QCs already applied in national forest monitoring, or available from published handbooks, or form the IPCC GPG LULUCF 2003, is recommended.
Any comment:	If species-specific equations are used and species cannot be identified from stumps then it must be assumed that the harvested species is the species most commonly harvested. A PRA must be used to determine the most commonly harvested species.

Data/ parameter:	AP_i
Data unit:	Ha
Used in equations:	24

Description:	Total area of illegal logging sample plots in stratum *i*
Source of data:	Ground measurement
Measurement procedures (if any):	A sampling plan must be designed using multiple sample plots systematically placed across the buffer zone so that they sample at least 3% of the area of the buffer zone.
Measurement Frequency	Not more than five years
QA/QC Procedures	Standard quality control / quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of QA/QCs already applied in national forest monitoring, or available from published handbooks, or form the IPCC GPG LULUCF 2003, is recommended.
Any comment:	Ex ante estimation should be made of area of plots. This should be set to exactly 3% of the buffer zone ADIST_IL,i

Data/ parameter:	PMP_i
Data unit:	%
Used in equations:	Section 8.3.2, Box 2: 'Leakage Factor Calculation'
Description:	Merchantable biomass as a proportion of total aboveground tree biomass for stratum *i* within the project boundaries
Source of data:	Within each stratum divide the summed merchantable biomass (defined as total gross biomass of a tree15cm DBH or larger) by the summed total of aboveground tree biomass.
Measurement procedures (if any):	
Measurement Frequency	Not more than five years
QA/QC Procedures	Standard quality control /quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of QA/QCs already applied in national forest monitoring, or available from published handbooks, or form the *IPCC GPGLULUCF 2003*, is recommended.
Any comment:	Ex-ante a time zero measurement must be made of this factor. The timber harvest plan sets the allowable mean extracted volume from the merchantable volume of timber in the forest inventory (Vj,i|BSL), based on legal limits.

Data/ parameter:	$A_{i,}$
Data unit:	Ha
Used in equations:	20
Description:	Area covered by stratum *i*
Source of data:	Geodetic coordinates and/or Remote Sensing data and/or legal parcel records
Measurement procedures (if any):	
Measurement Frequency	
QA/QC Procedures	
Any comment:	In the baseline scenario strata areas must not change through time. In the project scenario it must be assumed *ex-ante* that stand boundaries and strata areas must not change through time. *Ex post* adjustments of the project scenario strata may be needed if unexpected disturbances occur during the project crediting period, severely affecting different parts of an originally homogenous stratum. This disturbance will be delineated as a separate stratum for the purpose of monitoring the carbon stock changes.

9.3 Description of the Monitoring Plan

The following parameters must be monitored in this methodology:

- Illegal logging PRA
- Result of limited illegal logging survey
- Area burnt in stratum *i* at time *t* ($A_{burn,i,t}$)
- Area potentially impacted by illegal logging in stratum *i* ($A_{DIST\_IL,\ i}$)
- Total area of illegal logging sample plots in stratum *i* (AP_i)
- Merchantable biomass as a proportion of total aboveground tree biomass for stratum *i* (PMP_i)
- Area covered by stratum *i* (A_i)
- Diameter at breast height of tree (*DBH*)

These parameters will be required at each verification and are used in equations 20, 21 and 23.

9.3.1 Scope of monitoring and the monitoring plan

Monitoring is required to:

a) Determine changes in forest carbon stocks and greenhouse gas emissions from project activity;

b) Confirm project activity; and

c) Determine changes in forest carbon stocks and greenhouse gas emissions from disturbance and illegal logging.

In some project cases monitoring may also be implemented to update stratification.

It is a requirement that the monitoring plan presented in the project documents must address the monitoring of project implementation, the monitoring of actual carbon stock changes from project activity, and estimation of ex-post net carbon stock changes from disturbance and illegal logging.

The description of the monitoring plan in the project documents will include the following for each of these monitoring tasks:

a) Technical description of the monitoring task;

b) A list of data and parameters to be collected;

c) Overview of data collection procedures;

d) Quality control and quality assurance procedure;

e) Data archiving; and

f) Organization and responsibilities of the parties involved in all the above.

9.3.2 General requirements for monitoring

All data collected as part of monitoring will be archived electronically and be kept at least for 2 years after the end of the project crediting period. All measurements will be conducted according to relevant standards.

Data archiving must take both electronic and paper forms, and copies of all data must be provided to each project proponent.

All electronic data and reports must also be copied on durable media such as CDs and copies of the CDs are to be stored in multiple locations.

The archives must include:

- Copies of all original field measurement data, laboratory data, data analysis spreadsheets;
- Estimates of the carbon stock changes in all pools and non-CO2 GHG and corresponding calculation spreadsheets;
- GIS products; and
- Copies of the measuring and monitoring reports.

9.3.3 Monitoring of project implementation

Information must be provided, and recorded in the project documents, to establish that:

- Geographic position of the project boundary is recorded for all areas of land;
- Geographic coordinates of the project boundary (and any stratification inside the boundary) are established, recorded and archived. This will be achieved by field survey (eg, using Geodetic coordinates) or by using georeferenced spatial data (eg, maps, GIS datasets, aerial photography, or georeferenced remote sensing images);
- Commonly accepted principles of forest inventory and management are implemented;
- Standard operating procedures (SOPs) and quality control/quality assurance (QA/QC) procedures for forest inventory including field data collection and data management must be applied. Use or adaptation of SOPs already applied in national forest monitoring or available from published handbooks or from the IPCC GPG LULUCF 2003 is recommended; and
- Project plan, together with a record of the plan as actually implemented during the project, must be available for validation or verification as appropriate.

9.3.4 Stratification

This methodology requires that an ex ante stratification of the project area in the project scenario is described in the project documents as documented in the timber harvest plan, or developed by the project proponent through sampling in the project area.

The monitoring plan may include sampling to adjust the number and boundaries of the strata defined ex ante where an update is required because of:

a) Unexpected disturbances occurring during the project crediting period affecting differently various parts of an originally homogeneous stratum and/or

b) Forest management activities that are implemented in a way that affects the existing stratification in the project scenario.

Established strata may also be merged if the reasons for their establishment have disappeared.

9.3.5 Monitoring of actual carbon stock changes

Carbon stocks will be measured according to the stock assessment equations in this methodology with field sampling based on forest inventory methods. Various sources exist to assist with the design of a verifiable forest field inventory based on best practice for sampling, data management and analysis (Box 3).

In the project area (or areas) the inventory plan must be specified in the project documents and include:

a) Adequate forest stratification, sample size estimation methods and consider uncertainty; and

b) Sampling framework including sample size, plot size, plot shape and information to determine plot location.

To determine the sample size and allocation among strata, this methodology uses the most recent version of the tool for the “Calculation of the number of sample plots for measurements within A/R CDM project activities”[41] approved by the CDM Executive Board.

Carbon stock changes over time must be estimated by taking measurements in plots at each monitoring event. Monitoring events must take place at intervals of 5, or preferably 3 years. For intermittent years it is good practice to use extrapolations of trends as they have occurred up till that moment. Monitoring reports can use such extrapolated parameter values for the determination of net emissions by sources and removals resulting from the project.

The design of the sampling regime will be determined by the number of strata and timber harvest the baseline case.

9.3.6 Conservative approach and uncertainty

The project proponent must also apply all relevant equations for the ex-ante calculation of net anthropogenic GHG removals by sinks with care and provide transparent estimations for the parameters that are monitored during the project crediting period. These estimates must be based on measured or existing published data where possible and the project proponent should retain a conservative approach. That is, if different values for a parameter are equally plausible, a

[41] http://cdm.unfccc.int/methodologies/ARmethodologies/approved_ar.html

value that does not lead to over-estimation of net anthropogenic GHG removals by sinks must be selected.

An uncertainty analysis is required for all estimates from monitoring related to change in area, change in carbon stocks and emissions for both the baseline and project case.

APPENDIX 1: CONVERTING OTHER GHGS TO CO_2E

Other GHGs considered in this methodology (subject to significance as determined in Section 1.2.3) are methane (CH_4) and nitrous oxide (N_2O).

Non-CO_2 gas emission factors must be expressed in carbon dioxide equivalents by multiplying their emission factors by their corresponding global warming potentials (GWPs) and summating the results together to obtain an overall emission factor in terms of carbon dioxide equivalents:

$$EF = EF_{CH4} \, x \, GWP_{CH4} + EF_{N2O} \, x \, GWP_{N2O} \qquad \textbf{(45)}$$

Where:

EF_{CH4}	Emission factor for methane gas, activity data-specic, tCH_4/activity data unit;
GWP_{CH4}	Global warming potential of methane, tCO_2e/tCH_4;
EF_{N2O}	Emission factor for nitrous oxide gas, activity data-specific, tN_2O//activity data unit;
GWP_{N2O}	Global warming potential of nitrous oxide, in tCO_2e/tN_2O;

Where CH_4 and N_2O are determined to be insignificant to the overall calculations, and HFCs, PFCs and SF_6 are not included, then CO_2 becomes the sole greenhouse gas quantified. Throughout this methodology, even where CO_2 becomes the sole GHG emission quantified, it is expressed as CO_2-e.

APPENDIX 2: CONVERTING UNITS FOR FUEL EMISSION FACTOR

IPCC (2006) emission factors for GHGs (CO_2, CH_4 and N_2O) are recorded in units of kg of GHG (TJ of fuel)$^{-1}$. As such, for each GHG, the emission factor must be multiplied by the fuel heating value (in TJ kg^{-1}) and density (kg kL^{-1}) to obtain an emission factor in tGHG kL^{-1}. (eg, tCO_2-e kL^{-1}, tCH_4 kL^{-1} and tN_2O kL^{-1}).

$$EF_{FUEL-GHG} = \frac{EF_{IPCC-FUEL}\ x\ HV_{FUEL}\ x\ \rho_{FUEL}}{1000} \quad \textbf{(46)}$$

Where:

$EF_{FUEL-GHG}$	Fuel emission factor for the greenhouse gas (CO_2, CH_4 or N_2O), in tGHG/kL;
$EF_{IPCC-FUEL}$	IPCC fuel emission factor for greenhouse gas (CO_2, CH_4 or N_2O), in kgGHG/TJ;
HV_{FUEL}	Heating value of fuel, in TJ/kg;
ρ_{FUEL}	Density of fuel, in kg/kL;

APPENDIX 3: FUEL CONSUMPTION CHARTS

As referenced in Section 8.1.5.4, the fuel consumption rate of a generator can be derived from fuel consumption charts for generators. Table A3 offers default factors depending on the generator size (kW) and on the anticipated load (Diesel Service and Supply, 2009).

Table A3: Fuel Consumption Chart for a Diesel Generator

Generator Size (kW)	1/4 Load (kL h^{-1})	Full Load (kL h^{-1})	Generator Size (kW)	1/4 Load (kL h^{-1})	Full Load (kL h^{-1})
20	0.002	0.006	500	0.042	0.135
40	0.006	0.015	750	0.062	0.202
60	0.007	0.018	1000	0.082	0.269
100	0.01	0.028	1250	0.102	0.336
125	0.012	0.034	1500	0.122	0.403
150	0.014	0.041	1750	0.142	0.47
200	0.018	0.055	2000	0.162	0.537
300	0.026	0.081	2250	0.182	0.604

APPENDIX 4: HARVESTER FUEL CONSUMPTION FACTOR

As referenced in Section 8.1.5.1, the emission factors for equipment required for harvesting operations derived from from Klvac and Skoupy (2009) are listed in Table A4.

Table A4: Equipment Types and Fuel Consumption for Harvesting Operations

Operation	Equipment	Factor	Data	Unit
Felling	harvester	Fuel consumption, $FC_{harvest}$	1.28 - 1.73	L m^{-3}

APPENDIX 5: ELECTRICITY DEMAND OF SAWMILL PROCESSES

An electricity demand factor may be used to determine the electricity consumption (kWh) required for a particular volume of merchantable logs. As referenced in Section 8.1.5.4, the table below presents data from three international sawmill processes and shows that an approximate range for the electricity demand is 20-40 kWh/m^3.

Where a country specific-value for the electricity demand is available, it must be used. Where a country-specific value is not available, a factor from a country that uses similar timber processing technology to that of the project's host country must be used.

Table A5: Electricity Demand For Sawmill Processing In Various Countries

Country	Electricity (kWh day^{-1})	Harvest Volume (m^3 day^{-1})	e_{demand} (kWh m^{-3})	Data Source
Indonesia	600	20	30	Budiono (unknown)
Brazil	2756	136	20	Poole and Pinheiro (2003)
New Zealand	-	-	26-41	Li et al. (2006)

DOCUMENT HISTORY

Version	Date	Comment
v1.0	11 Feb 2011	Initial version released.
v1.1	10 Nov 2011	Updates: 1) In Equation 7 parameter CEX,i,k|BSL was clarified to be the mean carbon stock of extracted timber per unit area in stratum *I*, for wood product type *k*. 2) Section 4.1.2, was clarified that only individual trees, species and strata which were to be harvested in the baseline scenario may be modeled for on-going forest growth in the project scenario. 3) Equation 21 was modified to clarify that net greenhouse gas emissions in the project scenario are a result of the sum of emission from disturbance minus the annual carbon stock change in the aboveground biomass of trees due to forest growth. 4) Parameter BECFR was clarified to have the unit t.d.m m^{-3}.
v1.2	27 Mar 2013	Updates: The methodology was updated in order to comply with Section 4.5.3 of the VCS *AFOLU Requirements*, v3.2, which requires methodologies to set out criteria and procedures to reliably establish the pattern of carbon loss in the baseline scenario. Specifically, the methodology has been updated to account for a 10-year linear decay of the dead wood pool, an immediate release of the wood waste and short-term wood product pools and a 20-year linear decay of the medium-term wood product pool.
v1.3	28 Apr 2016	The methodology was revised to include emissions from: • Cleared biomass as a result of forestry infrastructure such as forestry roads, skidtrails and log landings • Residual stand damage • Fossil fuel combustion in forestry and wood processing machinery

Methodology for Improved Forest Management – Logged to Protected Forest:

Calculating GHG Benefits from Preventing Planned Degradation

Scope

This Methodology provides a procedure to determine the net greenhouse gas (GHG) emission reductions associated with an Improved Forest Management - Logged to Protected Forest (IFM-LtPF) activity where the baseline activity is selective logging.

Authors

Executive Summary

The Methodology provides a procedure to determine the net anthropogenic greenhouse gas (GHG) emission reductions associated with an Improved Forest Management - Logged to Protected Forest (IFM-LtPF) activity which prevents the degradation of a forest through the cessation of a baseline activity of selective logging.

The Methodology is written to be compliant with VCS 2007.1. The Methodology specifically applies to previously logged or intact tropical forests, where the baseline activity can be clearly demonstrated and substantiated to be selective logging.

The key components of the Methodology are:

(1) Applicability criteria and decision pathway for applying this Methodology based on the availability of data sources
(2) Justification for a baseline activity of selective logging, additionality and definition of project boundary
(3) Accounting for carbon changes of the baseline activity of selective logging
(4) Accounting for emissions due to implementation of the baseline and IFM-LtPF project activity
(5) Leakage assessment and management
(6) Uncertainty analysis
(7) Monitoring methodology

The application of this Methodology is based on the justification that selective logging is the most likely baseline activity above all other possible land use alternatives.

The Methodology calculates the net anthropogenic emission reductions by firstly estimating emissions due to forest degradation and the implementation of the baseline activity, selective logging. From this, GHG emissions associated with the implementation of the IFM-LtPF project activity, plus any emissions due to leakage of the baseline activity occurring outside the Project Area (as a result of the IFM-LtPF project activity), are subtracted from the baseline emissions to provide the net anthropogenic emission reductions of the IFM-LtPF project.

The baseline scenario, selective logging, as defined in the Methodology, involves the annual removal of merchantable trees with a minimum diameter at breast height as defined by the relevant authority in the host country. According to the data available, the Methodology provides guidance on determining the quantity and type of wood product that would be removed, as well as the nature of its fate as a result of the baseline scenario. In summary, emissions due to carbon lost from forest degradation from selective logging are attributable to (i) emissions from the oxidation of both short-term and long-term harvested wood products that are removed from the Project Area, (ii) emissions from the decay of the trimmings and branches, as well as any residual stand damage accumulating in the dead wood pool, and (iii) emissions from carbon that is forfeited due to forest growth that did not occur (foregone) as a result of the selective logging. These emissions are offset by (iv) regrowth in already harvested areas following logging.

The monitoring methodology provides guidance for the monitoring of the parameters employed to calculate carbon changes due to forest degradation, as well as emissions due to implementation of project and baseline activities. Following the implementation of the monitoring methodology, the results are applied to the above-mentioned accounting components (3) to (6) to revise the net anthropogenic GHG emission reductions for the subsequent reporting period.

The application of the Methodology is intended to not only mitigate GHGs, but to trigger a long term sustainable shift in the status of the forest in the covered region, hence aiding in the conservation of biodiversity. In addition, local communities will have new avenues for revenues that replace and exceed revenues to be derived from the removal of their forest.

Table of Contents

1 Introduction

The Methodology herein is applicable to a project activity that reduces greenhouse gas (GHG) emissions by preventing the degradation of a forest, either intact[1] or previously logged, that has been legally authorised by local, national or sub-national regulatory bodies to be harvested.

A common practice of IFM in tropical forests is selective logging. In selective logging operations (which is the baseline scenario of the Methodology), trees that meet the requirements as specified by the relevant authority in the host country of (i) minimum diameter at breast height, (ii) species, (iii) accessibility, and (iv) tree quality, are considered merchantable.

1.1 Methodology Applicability Criteria

The Methodology is applicable under the criteria and conditions presented in Table 1-1:

Table 1-1. Methodology applicability criteria

Criteria	Description
Project Type	Improved Forest Management - Logged to Protected Forest; with no removals (e.g. harvesting, planned biomass burning) occurring in the Project Area upon implementation of the actual project (with the exception of felling sample trees for validating or deriving project-specific parameters presented in Section 7.2.4).
Condition of the Forest	Intact forest or previously logged forest (also known as forest degraded due to logging) Land within the Project Area must have qualified as forest at least 10 years before the project start date.
Type of Forest	Tropical forests including evergreen tropical rainforests, moist deciduous forests, tropical dry forests and tropical upland forests (see Appendix A for definition), except peat swamp forests.
Forest Product Type	Harvested wood products i.e., sawlog, pulplog and commercially harvested fuelwood (See Appendices A and B.9).
Driver of Degradation	Legally sanctioned logging (timber and commercially harvested fuelwood) undertaken in accordance with the relevant laws, regulations and codes of practice of the country in which the Methodology is being applied.
Baseline Activities to be Displaced	Legally sanctioned selective logging for specific forest product types presented above.
Project Area	Must be designated, sanctioned or approved by the relevant authority in the host country for the selective logging

[1] Defined herein as forests that have not yet been logged.

Criteria	Description
Carbon Pools	Carbon Pools considered: • Aboveground biomass (AGB) of all trees as defined by the relevant authority in the host country • Harvested wood products (HWPs) based on domestic production not domestic consumption • Deadwood (DW). Carbon Pools not considered: • Aboveground biomass (non-trees) • Belowground biomass • Soil • Litter.

1.2 Methodology Overview

1.2.1 Net Anthropogenic GHG Emission Reductions

The Methodology estimates the net anthropogenic GHG emission reductions associated with an IFM-LtPF project ($C'_{IFM-LtPF,t}$) that replaces a baseline of selective logging in a tropical forest. It does this by estimating the annual total carbon emissions associated with the baseline scenario ($C'_{baseline,t}$) and by subtracting the emissions associated with project activity ($C'_{actual,t}$) and leakage ($C'_{leakage,t}$), in year, *t*, years elapsed since the start of the IFM-LtPF project activity. The parameters $C'_{baseline,t}$, $C'_{actual,t}$ and $C'_{leakage,t}$ are determined in Sections 3, 4 and 5, respectively.

The net anthropogenic GHG emission reductions in tonnes of carbon dioxide equivalents (tCO_2-e) of the IFM-LtPF project activity will be[2] calculated as follows:

Equation 1-1

$$C'_{IFM-LtPF,t} = C'_{baseline,t} - C'_{actual,t} - C'_{leakage,t}$$

Parameter	Description	Unit
$C'_{IFM-LtPF,t}$	Annual net anthropogenic GHG emission reductions in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C'_{baseline,t}$	Annual total carbon emissions associated with the baseline scenario in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

[2] Throughout, four main terms are used: "must be", "should be", "will be" and "can be". The term "must be" represents an action to be taken, according to a mandatory condition specified in the Standards or Guidelines; the term "should be" represents an action to be taken, according to a best practice condition; the term "will be" represents an action to be taken, as developed specifically in this Methodology; whilst the term "can be" is used to indicate possibility.

Parameter	Description	Unit
$C'_{actual,t}$	Annual total carbon emissions associated with the project activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C'_{leakage,t}$	Annual total carbon emissions associated with leakage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

The term "ex ante" is defined as the estimation of the net GHG emission reductions, before the start of the IFM-LtPF project activity, for the project crediting period. The term "ex post" is defined as the calculation of the actual net GHG emission reductions for the years elapsed since the start of the IFM-LtPF project activity. See Appendix A of the Methodology for a list of definitions of other terms.

For an ex ante estimation of annual net anthropogenic GHG emission reductions, $C'_{IFM-LtPF,t}$, equations in Sections 3 and 4 for baseline accounting and actual project activity emissions, respectively, must be applied. The ex ante estimation for leakage assessment will be zero. The Project Proponent must provide estimates of the values of those parameters that are not available before the start of the monitoring activities and must retain a conservative approach in making these estimates.

1.2.2 Data Sources Required

Due to the nature of IFM-LtPF projects, the emission reductions will be largely dependent on emissions arising from the baseline scenario ($C'_{baseline,t}$), which, in turn, is a function of emissions from the implementation of the baseline activity (i.e. selective logging) ($C'_{emissions,t}$) and primarily, the emissions arising from forest degradation due to the baseline activity ($C'_{degradation,t}$). The method to calculate $C'_{degradation,t}$ depends on the available data for the Project Area.

This IFM-LtPF Methodology includes: (1) protecting currently logged or degraded forests from further logging and degradation; and (2) protecting unlogged forests that would be logged in the absence of carbon finance. For both, the Project Proponent must provide documentary evidence to prove that the Project Area will be legally harvested if the IFM-LtPF project is not implemented in the area and must include these documents Project Description (PD). The following documentary evidences are relevant, but not limited to:

(i) A legally authorised letter or a document that clearly demonstrates the area will be selectively logged in the absence of the IFM-LtPF project; and

(ii) An approved Forest Inventory Report (FIR) or an equivalent document including a forest management plan or a timber harvesting plan. This document must also include map(s) of the geographical extent of the Project Area where selective logging has occurred or would occur; or

(iii) Preparation of the FIR or an equivalent document (by the relevant authority in the host country) which specifies the geographical extent of the Project Area where selective logging would occur.

Figure 1-1 presents a schematic of the dual-pathway for data availability in determining a suitable method. The Existing Inventory Data pathway represents the case where a Forest Inventory Report (FIR) or an equivalent document, is available. Within this pathway, two methods exist for determining emissions due to degradation of the Project Area. These are: (i) combined methods of wood density and biomass conversion and expansion factor (BCEF) or (ii) allometric equations. The choice of method is based on the level of detail in the existing inventory data.

The Measured Data pathway must be applied for the following cases:

(i) where there is no Forest Inventory Report (FIR) or equivalent document available

(ii) where the FIR is still in preparation by the relevant authority in the host country

(iii) where the validation of existing data is not accepted (see Section 3.2.1.1).

In order to apply this pathway, upfront monitoring is required, and carbon emissions will be based on the data obtained from the measurements taken in the Permanent Sample Plots (PSPs) in the forest using allometric equations (see Section 7.1.2).

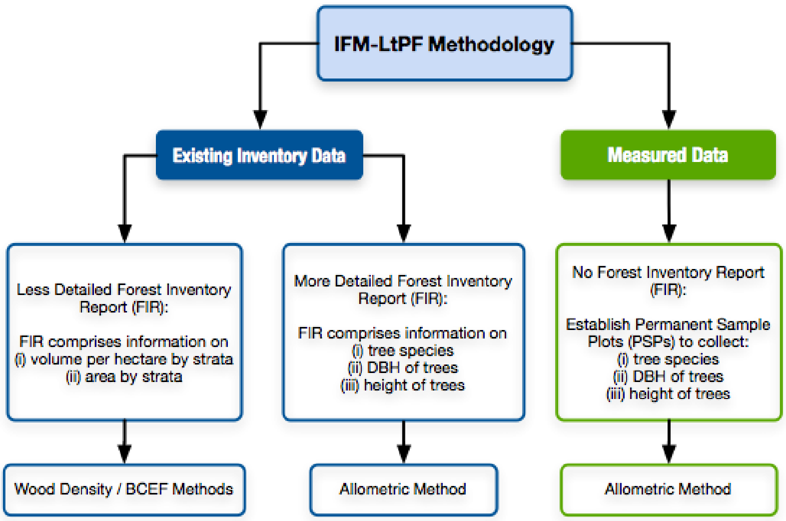

Figure 1-1. Schematic of data sources required for IFM-LtPF Methodology

1.2.3 Significance

To test for the significance of emission sources, the Project Proponent must use the most recent CDM Tool - "Tool for testing significance of GHG emissions in A/R CDM project activities" (see CDM-EB, 2007a).

1.2.4 VCUs and the Non-Permanence Risk Withholding Buffer Percentage

A procedure for determining the non-permanence risk rating (i.e., the potential reversibility of sequestered/protected carbon) is described in Section 7.2.5. The outcome of the risk rating is the determination of the non-permanence buffer withholding percentage ($NP_{buffer}\%$) required to calculate the number of carbon credits to be deposited in the VCS buffer withholding pool. The latter is calculated as follows:

Equation 1-2

$$CC_{NPbuffer,t} = NP_{buffer,t}\% \times C'_{degradation,t}$$

Parameter	Description	Unit
$CC_{NPbuffer,t}$	Annual carbon credits deposited in the VCS non-permanence buffer withholding account in year t, (where t=1,2,3 ... t* years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$NP_{buffer,t}\%$	Annual buffer withholding percentage required for the VCS buffer withholding pool in year *t,* (where *t*=1,2,3 ... *t** years elapsed since the start of the IFM-LtPF project activity)	%
$C'_{degradation,t}$	Annual total carbon emissions associated with degradation as a result of the baseline activity in year *t,* (where *t*=1,2,3 ... *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

The number of VCUs that can be traded annually from the IFM-LtPF project activity is determined by subtracting the carbon credits deposited in the buffer account from the carbon credits determined post uncertainty deduction issued in year *t*:

Equation 1-3

$$VCU_t = CC_{IFM-LtPF,t} - CC_{NPbuffer,t}$$

Parameter	Description	Unit
VCU_t	Annual total tradeable Verified Carbon Units in year *t,* (where *t*=1,2,3 ... *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$CC_{IFM-LtPF,t}$	Annual carbon credits post uncertainty deduction in year *t*, (where *t*=1,2,3 ... *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$CC_{NPbuffer,t}$	Annual carbon credits deposited in the VCS non-permanence buffer withholding account in year *t*, (where *t*=1,2,3 ... *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

2 Project Baseline, Additionality and Boundary

2.1 Project Baseline Justification and Additionality

Since the Methodology is limited to a baseline scenario of selective logging, it must therefore be demonstrated that selective logging is the most likely baseline scenario above all other possible scenarios.

2.1.1 Selection of Baseline Amongst Alternative Scenarios

The procedure to identify the baseline scenario as selective logging for a VCS IFM-LtPF project activity, has been adapted from Steps 1 and 2 of the "Combined tool to identify the baseline scenario and demonstrate additionality in A/R CDM project activities" (CDM-EB, 2007b, pp. 2-7).

Step 1: Identify credible alternative baseline scenarios to the proposed VCS IFM-LtPF project activity.

Sub-step 1a: Identify all realistic and credible alternative baseline scenarios to the proposed VCS IFM-LtPF project activity.

Realistic and credible baseline scenarios would be those that may have occurred in the Project Area in the absence of the VCS IFM-LtPF project activity. The scenarios must take into account relevant national and or sectoral policies and circumstances such as historical land use and practices, and economic trends and must at least include (CDM-EB, 2007b, p. 2):

- continuation of pre-project land use
- the protection of the land within the Project Area without being registered under the VCS as an IFM-LtPF project activity.

To identify realistic and credible baseline scenarios, data from the following sources must be applied:

(i) land use records

(ii) field surveys

(iii) data and feedback from stakeholders.

To establish that all identified baseline scenarios are credible, the Project Proponent must ascertain the following:

- all land uses within the Project Area of the proposed IFM-LtPF project activity that are currently existing, or have existed but no longer exist, are deemed credible
- for all other baseline scenarios, credibility must be justified and justification must include elements of spatial planning information, if applicable, or legal requirements. In the absence of adequate justification, an assessment of economic feasibility of the proposed alternative baseline scenario must be provided.

Sub-step 1b: Identify realistic and credible alternative baseline scenarios with enforced mandatory legislation and regulations.

For the alternative baseline scenarios identified in Sub-step 1a, the Project Proponent must demonstrate that these alternatives comply with mandatory applicable legislation and regulations in the host country.

In the case where an identified alternative does not comply with mandatory applicable legislation and regulations, the Project Proponent must demonstrate that non-compliance of such legislation and regulations are the current practices in the host country, to the extent that the legislation and regulations are systematically not enforced and that non-compliance of such legislation and regulations is widespread.

Alternative baseline scenarios that do not comply with mandatory applicable legislation and regulations in the host country, and where widespread non-compliance cannot be demonstrated, must be removed from the list of realistic and credible baseline scenarios.

Selective logging must be present in the list from Sub-steps 1a and 1b for the Methodology to be applicable.

Step 2: Determine alternative baseline scenarios.

Sub-step 2a: Identify barriers that would prevent the implementation of at least one alternative baseline scenario.

For the alternative baseline scenarios identified in Sub-step 1b, the Project Proponent must identify any barriers that prevent the implementation of at least one of the alternatives. The barriers must not be specific to the Project Proponent but must apply to the activity itself, regardless of the entity that is developing the project.

A list of potential barriers can be found in CDM-EB (2007b), pp. 4-5.

Sub-step 2b: Eliminate baseline scenarios that are prevented by the identified barriers.

Determine which baseline scenarios identified in the Sub-step 1b are prevented by at least one of the barriers listed in Sub-step 2a. Eliminate these scenarios from the list (of alternative baseline scenarios) produced in Sub-step 1b.

Selective logging must be present in the resultant list for the Methodology to be applicable.

In applying Sub-steps 2a and 2b, the Project Proponent must provide transparent and documented evidence, and offer conservative interpretations of this documented evidence, as to how it demonstrates the existence and significance of the identified barriers. Anecdotal evidence can be included, but this alone is not sufficient proof of barriers (CDM-EB, 2007b, point 17, p. 6).

A list of the types of evidence acceptable can be found in CDM-EB (2007b), pp. 6-7.

Sub-step 2c: Determine the baseline scenario.

From Sub-step 2b, the refined list of alternative baseline scenarios that are in compliance with mandatory applicable legislation and regulations (or for which widespread non-compliance can be demonstrated), and are not prevented by barriers, must contain selective logging as an alternative baseline for the current Methodology to be applied.

If selective logging is the only alternative scenario that is not prevented by any barrier, then this scenario is identified as the baseline activity.

If there are several alternative baseline scenarios in the list produced from Sub-step 2b (and this may include the proposed IFM-LtPF project activity undertaken without being registered as a VCS activity), then apply the Investment Analysis procedure (CDM-EB, 2007b, Step 3, pp. 7-11) to demonstrate that selective logging is the most economically and/or financially attractive baseline scenario amongst all the alternative baseline scenarios.

Selective logging must be demonstrated to be the most economically and/or financially attractive baseline scenario for the Methodology to be applicable.

2.1.2 Establishment of the Baseline Scenario: Selective Logging

Upon demonstrating that the most conservative baseline scenario is selective logging, and in order to establish this baseline, the Project Proponent must provide the following information:

(i) documented history of the operator (e.g., operator shall have five to 10 years of management records to show normal historical practices)

(ii) legal requirements for forest management and land use in the area; and

(iii) proof that operator’s environmental practices equal or exceed those commonly considered a minimum standard among similar landowners in the area.

If the Project Proponent is not a logging operator, but instead a new management entity with no history of logging practices in the project region and who takes over ownership of a property specifically to reduce forest emissions, then the baseline of selective logging is to be based on the projected management plans of the previous property owners. The established baseline must represent what would have most likely occurred in the absence of the IFM-LtPF project.

2.1.3 Additionality

For the specific case of demonstration and assessing additionality, the Project Proponent must use the latest version of the VCS tool for the Demonstration and Assessment of Additionality in VCS Agriculture Forestry and Other Land Use Project.

2.2 Project Boundaries

Project boundaries must be defined in terms of the following categories:

- Geographic boundary
- Temporal boundaries
- Carbon pools
- GHG sinks and sources.

2.2.1 Geographic Boundary

The Geographic Boundary includes the Project Area and the leakage area(s) and is described in the sections below. The land eligibility for the Project Area is discussed in Section 2.2.1.1.

2.2.1.1 Project Area and Land Eligibility

The Project Area is the forest area within the defined Geographic Boundary which would be degraded through selective logging under the baseline scenario. The term "forest area" must be appropriately defined in a way that is consistent with the thresholds used to define the term "forest" in the host country where the project activity will be implemented. Where the country has adopted a forest definition for the Kyoto Protocol, the minimum thresholds of the vegetation indicators used for defining "forest" will be used (see Appendix A). Otherwise, the definition used to define "forest" in the national GHG inventory will be used.

The Project Area must be designated, sanctioned or approved by the relevant authority in the host country.

The Project Proponent must provide sanctioned or approved document(s) which designates or specifies the geographical boundary of the Project Area. The Project Proponent must also provide the following information about the Project Area: name, local name, compartment number, harvesting blocks, identification number and area for each forest compartment in the Project Area, the geographic co-ordinates obtained from the Global Positioning System (GPS) or from the geo-referenced digital maps and, digital or GIS maps. In addition, the Project Proponent requires to provide digital map of the geographic boundary distinguishing the Project Area and the Leakage Area. In the case this Methodology is used for multiple discrete land parcels, each land parcel is treated as a separate Project Area and requires all the detail information/documentation as well as the digital maps as stated above.

If the Project Area has already been stratified, similar information must be provided for each stratum including stratified maps for the Project Area.

After the project has commenced, the Project Area will remain fixed throughout the crediting period.

2.2.1.1.1 Stratification of the Project Area

Stratification of the Project Area is required to divide the forest area into relatively homogeneous units or 'strata' in order to minimise variation among the strata. The stratification enhances the measuring precision and also minimises the cost of measurement. Where stratification of the Project Area has not been done, stratification is required before establishing PSPs for monitoring. Various criteria including forest parameters such as species, canopy density, tree height, age, etc., as well as physical parameters such as slope and drainage condition, are to be used to define the stratification. The most appropriate criteria for stratification are to be those which are directly related to the variables to be measured and monitored.

The forest stratification can be performed using forest type maps, topographic maps, interpretation of aerial photographs and satellite data with subsequent field verification. Remote sensing and GIS software is useful for spatial analysis and mapping for stratification.

The Project Area is a summation of the areas defining each stratum, j:

Equation 2-1

$$A_{project,t=0} = \sum_{j=1}^{J} A_{project,j,t=0}$$

Parameter	Description	Unit
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Both $A_{project,t=0}$ and $A_{project,j,t=0}$ are employed in both Sections 3.2 and 3.3 to calculate emissions from degradation due to selective logging.

In the case of existing stratification in the Project Area, the Project Proponent must review the strata using the latest available maps and data sources. If the existing stratification is not relevant for implementing the GHG project, the Project Proponent must update the strata, following the approach discussed above, and derive a Project Area map based on the revised stratification.

The Project Proponent must describe the approach used for stratifying the Project Area and also include GIS map(s) illustrating each stratum with specific detail. These maps must be revised if there is any update in the stratification in the event that there is a change in the carbon in the existing stratum.

2.2.1.2 Leakage area(s)

The leakage area(s) is defined as the area(s) to which the activity (i.e. selective logging) has shifted. This applies to lands owned and/or operated by the Project Proponent outside the Project Boundary, as well as to other areas within the host country (caused by market leakage effects), since both activity shifting and market leakage are considered in the IFM-LtPF Methodology. Section 5 addresses leakage accounting in more detail.

The Project Proponent must identify the strata in the leakage area similar to the Project Area through analysing the forest and topographical characteristics as described in Section 2.2.1.1.1. These areas must also be illustrated in the maps of the project.

2.2.2 Temporal Boundaries

2.2.2.1 Project crediting period

The project crediting period shall be determined in accordance with applicable VCS rules.

2.2.2.2 Monitoring and reporting periods

The monitoring period corresponds to the time taken between one monitoring event and the immediate next monitoring event for collecting measurements in the PSPs in the Project Area, and for reviewing non-monitored parameters. According to international industry practices for forest carbon assessment, the maximum interval between one monitoring event and the immediate next, should not exceed five years (Pearson et al., 2005).

The results of project monitoring must be used to re-calculate the emissions associated with the project and this must be included in a report submitted for independent verification by an accredited third party.

2.2.2.3 Historical reference period

The historical reference period is a predetermined amount of time before the project start date, from which data can be taken in order to make ex ante estimation of natural disturbances and illegal harvesting and also to analyse leakage due to implementation of the project. A five-year timeframe for a historical reference period as close as possible to the project start date shall be used so as to limit uncertainty of the data collected.

2.2.3 Carbon Pools

Table 2-3 presents the justification, for inclusion or exclusion of carbon pools in the present IFM-LtPF Methodology in accordance with applicable VCS rules.

Table 2-3. Summary of carbon pools eligible under the Methodology

Carbon Pool	Status for IFM-LtPF Methodology	Justification
Aboveground Biomass (tree[#])	Included	Anticipated to significantly increase under IFM-LtPF
Aboveground Biomass (non-tree)	Not included	Unlikely to decrease as a result of the project activities, or increase due to the baseline
Belowground Biomass	Not included	Unlikely to decrease as a result of the project activities, or increase due to the baseline
Deadwood	Included	Anticipated to significantly decrease under IFM-LtPF
Litter	Not included	Unlikely to decrease as a result of the project activities, or increase due to the baseline
Soil	Not included	Unlikely to decrease as a result of the project activities, or increase due to the baseline
