Carbon Pool	Status for IFM-LtPF Methodology	Justification
Harvested Wood Products	Included	Anticipated to significantly decrease under IFM-LtPF

Trees are perennial plants and primarily constitute forest biomass. The FAO considers all living trees with a minimum diameter of 10 cm (over bark) when estimating the biomass in a tropical forest (Brown, 1997). This Methodology applies to all trees with a minimum diameter at breast height as specified by the relevant authority in the host country.

2.2.4 GHG Sources and Sinks

2.2.4.1 Consideration of GHGs

The six primary GHGs that contribute to climate change (WBCSD and WRI, 2004) and their global warming potentials (Forster et al., 2007) are listed in Table 2-4. Forster et al. (2007) present global warming potentials (GWPs) for three given time horizons: 20-year, 100-year and 500-year in the IPCC's Fourth Assessment Report (AR4) (IPCC, 2007).

The Project Developer shall use GWP of the 100-year time horizon as specified in the VCS rules. Table 2-4 presents the GWPs for the six primary GHGs for 100-year time horizon in accordance to the IPCC's Second Assessment Report. However, hydrofluorocarbons, perfluorocarbons and sulphur hexafluoride are synthetic industrial gases and therefore not included under Agriculture, Forestry and Other Land Use (AFOLU) methodologies.

Methane and nitrous oxide gases are not included for soil fluxes since soil is not included as a carbon pool in this Methodology. However, methane and nitrous oxide gases are included for calculating emissions from fossil fuel use in machinery, subject to significance (see Section 1.2.3). This significance accounting approach is in line with IPCC's definition of good practice (Penman et al., 2003) and the CDM "Tool for testing significance of GHG emissions in A/R CDM project activities" (CDM-EB, 2007a).

Carbon dioxide is included since it is intuitively present in both sources and sinks. Tables 2-5 and 2-6 present potential sources and sinks for CO_2, CH_4 and N_2O and whether or not a source/sink is included in the baseline and actual project implementation, respectively.

Table 2-4. The six primary greenhouse gases that contribute to climate change (WBCSD and WRI, 2004) and their associated global warming potentials for a 100-year time horizon

Greenhouse Gas	Chemical Formula	Global Warming Potential (100-year horizon)	Consideration
carbon dioxide*	CO_2	1	included

Greenhouse Gas	Chemical Formula	Global Warming Potential (100-year horizon)	Consideration
methane	CH_4	21	not included for soil fluxes; included for fossil fuel use in machinery but subject to significance. It is also included to calculate emissions from natural disturbances such as forest fires, subject to significance (see Section 1.2.3).
nitrous oxide	N_2O	310	not included for soil fluxes; included for fossil fuel use in machinery but subject to significance. It is also included to calculate emissions from natural disturbances such as forest fires, subject to significance (see Section 1.2.3).
hydrofluorocarbons	HFCs	see Forster et al. (2007) for list of HFCs	not included
perfluorocarbons	PFCs	see Forster et al. (2007) for list of PFCs	not included
sulphur hexafluoride	SF_6	23,900	not included

* Where CH_4 and N_2O are determined to be insignificant (determined from Section 1.2.3) to the overall calculations, and HFCs, PFCs and SF_6 are not included, then CO_2 becomes the sole contributor. Throughout this Methodology, even if CO_2 becomes the sole contributor toward GHG emissions, it is expressed as CO_2-e.

Table 2-5. Sources and sinks for the three primary greenhouse gases (further to consideration stated in Table 2-3), carbon dioxide, methane and nitrous oxide for baseline consideration in the Project Area

Greenhouse Gas	Source (S) / Sink (CS)	Project Area Baseline Consideration and Justification
carbon dioxide	Forest degradation (S)	included; carbon stock determination
	Fossil fuel use in machinery (S)	included; since logging is the baseline activity
	Electricity consumption (S)	included
	Forest fires (S)	not included
	Commercially harvested fuelwood (S)	included
	Fuelwood gathered for domestic use (S)	not included
	Biomass burning in the course of land use conversion (S)	not included
	Embodied carbon in AGB (CS)	included, carbon stock determination
	Forest regrowth (CS)	included
	Harvested wood products (S and CS)	included
	Deadwood (S and CS)	included
methane	Pestilence (S)	not included; unlikely scenario
	Biomass burning in the course of land use conversion (S)	not included; unlikely scenario
	Fossil fuel use in machinery (S)	included but subject to significance; since logging is the most likely scenario
	Deadwood (S and CS)	not included
nitrous oxide	Biomass burning in the course of land use conversion (S)	not included; unlikely scenario
	Fossil fuel use in machinery (S)	included but subject to significance; since logging is the most likely scenario

Table 2-6. Sources for the three primary greenhouse gases (further to consideration stated in Table 2-3), carbon dioxide, methane and nitrous oxide for the actual project implementation

Greenhouse Gas	Source^	Actual Project Activity Consideration and Justification
carbon dioxide	Electricity consumption	included
	Flights	included
	Ground travel	included
	Aerial surveillance	included
	Natural disturbances such as forest fires	included
methane	Electricity consumption	included but subject to significance
	Flights	included but subject to significance
	Ground travel	included but subject to significance
	Aerial surveillance	included but subject to significance
	Natural disturbances such as forest fires	included but subject to significance
nitrous oxide	Electricity consumption	included but subject to significance
	Flights	included but subject to significance
	Ground travel	included but subject to significance
	Aerial surveillance	included but subject to significance
	Natural disturbances such as forest fires	included but subject to significance

^ Note that for the actual project implementation, there are no sinks for GHG emissions and as such, the term 'sink (CS)' is not stated.

3 Baseline Accounting

3.1 Estimation of Emissions from Degradation

Section 3 of the Methodology provides the method for calculating emissions for the baseline activity. As the Methodology is developed for a baseline activity of legally sanctioned selective logging, the annual GHG emissions resulting will be due to degradation of the Project Area ($C'_{degradation,t}$), as well as annual emissions due to the selective logging operations ($C'_{emissions,t}$):

Equation 3-1

$$C'_{baseline,t} = C'_{degradation,t} + C'_{emissions,t}$$

Parameter	Description	Unit
$C'_{baseline,t}$	Annual total carbon emissions associated with the baseline scenario in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C'_{degradation,t}$	Annual total carbon emissions associated with degradation as a result of the baseline activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C'_{emissions,t}$	Annual total carbon emissions associated with the baseline activity of selective logging operations in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

For an IFM-LtPF project, determination of GHG emission reductions relies on comparing a baseline scenario of selective logging to a “with GHG project” scenario that assumes all the selective logging will cease. Emissions from degradation due to the baseline selective logging operations are determined by conducting a carbon mass balance over the entire Project Area.

In the baseline scenario described by this Methodology, selective logging involves the harvesting of merchantable trees larger than the minimum diameter at breast height as specified by the relevant authority in the host country. The selective logging operations have been treated as an annual event resulting in the removal of a specified volume of merchantable logs from the harvested merchantable trees in the Project Area. The annual harvest volume, i.e. the merchantable logs’ volume, is obtained from the inventoried growing stock of the forest by employing a sustainable and commonly used method in the host country. Here the term “growing stock” implies the total volume (over bark) of all the living trees as defined by the relevant authority in the host country. The growing stock data for the Project Area is either available from the Existing Inventory Data pathway or Measured Data pathway before the start date of the IFM-LtPF project.

At the site of the logging operations, the felled trees are converted to merchantable logs. The branches, bark and foliage are trimmed off the felled trees and left on the forest floor, becoming part of the deadwood (DW) pool and decaying slowly over time. Trees that are damaged during the logging operations are considered as residual stand damage, and are also included as carbon input to the DW pool. Carbon emissions from the DW pool into the atmosphere are accounted for by considering the net accumulation per year into the pool, multiplied by the rate of decay of the dry matter.

The subsequent processing of merchantable logs is dependent upon their species type, diameter class and end-product use. Some merchantable logs are taken to an on-site processing plant (i.e. a sawmill) resulting in sawn timber. With further value-added processing, these sawn timbers are converted into long-term harvested wood products (ltHWPs). Other merchantable logs are removed directly from the Project Area, for example commercially harvested fuelwood, and are converted into short-term harvested wood products (stHWPs). Long-term HWPs are defined as those with a half-life of over 30 years, while short-term HWPs are those with a half-life of approximately 2 years (IPCC, 2006, Vol 4, Table 12-2). It is possible for a Project Area to have a combination of both ltHWPs and stHWPs.

In the case of merchantable logs intended to be used in the manufacture of ltHWPs, the proportion of log converted to sawn timber is known as the lumber recovery factor. The remaining proportion of the merchantable log (residues that include sawdust and wood chips) is set aside within the project boundary and can either decay in the stockpile or be utilised as an energy source for processing. The emissions from ltHWPs are then accounted for by applying a (delayed) rate of oxidation of the ltHWP pool.

In the case of merchantable logs intended to be used in the manufacture of stHWPs, the stHWPs are further classified into commercially harvested fuelwood and paper products. For commercially harvested fuelwood, immediate oxidation occurs when the fuelwood is consumed. For paper products, emissions due to paper products are accounted for by applying a (delayed) rate of oxidation of the stHWP (to be converted into paper products only) pool.

Over the lifetime of logging operations, the previously harvested areas will experience regrowth. The carbon increase in the forest due to regrowth must be subtracted from the carbon lost due to degradation. Conversely, the logging operations remove trees every year which would otherwise experience growth. This loss in growth, defined as the amount of growth foregone, must be determined and added to the overall carbon lost due to degradation. The total carbon emissions associated with degradation as a result of the baseline activity accounts for all of these processes and is calculated as follows:

Equation 3-2

$$C'_{degradation,t} = \left[\left(C_{DW_{decay},t} + C_{ltHWP_{oxidation},t} + C_{stHWP_{oxidation},t} + C_{growth\_foregone,t} - C_{regrowth,t} \right) \times \frac{44}{12} \right]$$

Parameter	Description	Unit
$C'_{degradation,t}$	Annual total carbon emissions associated with degradation as a result of the baseline activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C_{DW_{decay},t}$	Annual carbon leaving the deadwood pool due to the decay of deadwood in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{oxidation},t}$	Annual carbon due to the combined delayed oxidation of long-term harvested wood products and immediate oxidation of long-term harvested wood products residues in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{stHWP_{oxidation},t}$	Annual carbon due to immediate oxidation of short-term harvested wood products (commercially harvested fuelwood) and delayed oxidation of short-term harvested wood products (paper products) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{growth\_foregone,t}$	Annual carbon lost due to growth foregone in the aboveground biomass in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{regrowth,t}$	Annual carbon increase in the biomass due to regrowth following logging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
44/12	The ratio of molecular weight of carbon dioxide to carbon, *see* Appendix C	tCO_2-e tC^{-1}

Ex ante estimations of $C'_{degradation,t}$ will be made using data from Forest Inventory Report (FIR) or an equivalent document, or measured data using the sequence of equations in Section 3.2.

Figure 3-1 presents a schematic of the dual-pathway for data availability in determining a suitable method to apply. As the baseline refers to selective logging that has been sanctioned by the host country's authority, it is most likely that a Forest Inventory Report (FIR) or an equivalent document, is available: the Existing Inventory Data pathway.

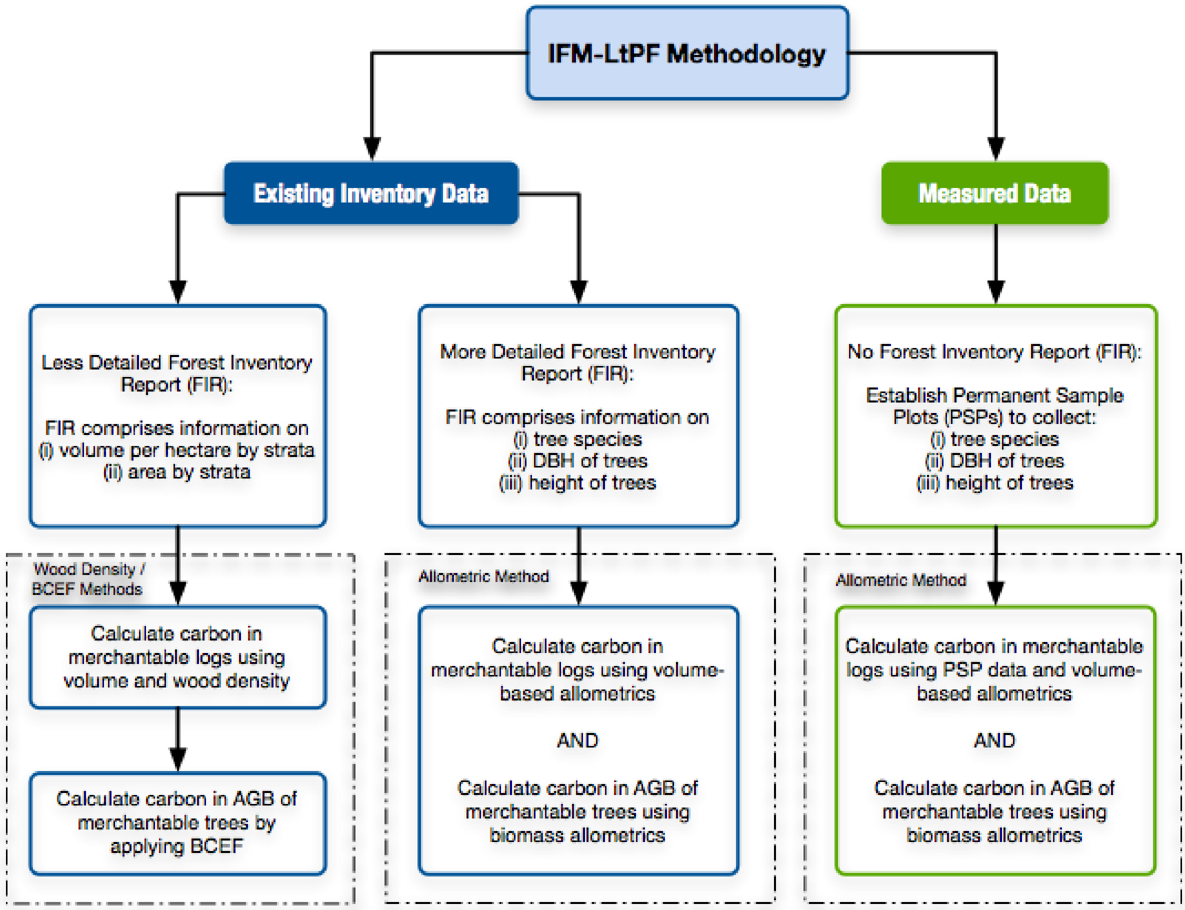

Figure 3-1. Schematic of accounting approach based on available data

There are two methods for determining the quantity of carbon in merchantable logs and the growing stock within the Existing Inventory Data pathway, depending on the detail of data in the FIR: Wood density plus the Biomass Conversion and Expansion Factor (BCEF) methods, or the use of the allometric method (see Section 3.2.1). The methods are selected based on the level of information provided in the FIR or equivalent document. For a less detailed FIR, where only stratified volume per hectare and area data is provided, the wood density plus BCEF methods must be applied. For a more detailed FIR, where information on tree species, diameter at breast height (DBH) and height of trees is provided, carbon is calculated using volume and biomass allometric equations. For the Existing Inventory Data pathway, prior to applying either the wood density and BCEF or allometric methods, the FIR must be validated conservatively according to Section 3.2.1.1.

In the case where there is legal approval for selective logging in the Project Area and the FIR or an equivalent document is under preparation by the relevant authority in the host country, there is only one pathway for determining the quantity of carbon in merchantable logs and the growing stock: the Measured Data pathway. This pathway is based on the data obtained from measurements in Permanent Sample Plots (PSPs) in the Project Area (see Section 7.1.2).

3.2 CALCULATION OF PRIMARY PARAMETERS IN THE PROJECT AREA

This section first presents the method to validate the existing inventory data. Then, the calculations to obtain the primary parameters: annual carbon in merchantable logs, $C_{merch,t}$, annual carbon in the AGB of the growing stock, $C_{AGB\_gstock,t}$ and annual net harvest area, $A_{NHA\_annual,t}$ are presented.

3.2.1 EXISTING INVENTORY DATA PATHWAY

3.2.1.1 Validation of existing forest inventory data

The Existing Inventory Data pathway applies where an existing legally approved FIR or an equivalent document, presents inventory data not more than five years old. According to Pearson et al. (2005), carbon in the aboveground biomass (AGB) is likely to change at a much faster rate than the carbon stock in the soil. It is thus appropriate that monitoring of the AGB in the forest be carried out at five-yearly intervals. This monitoring period also complies with the carbon verification and certification of the projects under the Clean Development Mechanism (CDM) policy (Pearson et al., 2005). Furthermore, the data in the FIR must have been obtained from an adequate number of representative sample plots in strata similar to the Project Area. The data in the FIR, or equivalent document, should only be employed after validation by the Project Proponent using the following procedure:

Step 1: Stratify the Project Area by following the procedure described in Section 2.2.1.1.1 and check with the existing stratification to verify whether it is similar to the Project Area stratification or not.

Step 2: If the existing stratification is not similar to the Project Area stratification, the existing inventory data must not be used. Apply the Measured Data pathway.

Step 3: If the existing stratification is similar to the Project Area stratification, randomly establish 6 to 10 preliminary sample plots in each stratum as suggested for measuring the variance (Pearson et al., 2005) and measure the trees in the sample plots for their diameter at breast height and tree height. Guidance on the size and shape of the sample plots to be established is described in Section 7.1.2.2.

Step 4: Estimate the carbon in the AGB for each forest product type (if specified) for each stratum using the biomass allometric method as presented in Section 3.2.1.2.

Step 5: Calculate the carbon in the AGB per hectare and the 95 percent confidence interval for each stratum from the measured data. A 95 percent confidence interval is considered an appropriate measure for carbon stock (Pearson et al., 2005; Brown, 2002).

Step 6: Estimate the carbon in the AGB per hectare for each forest product type (if specified) for each stratum from the existing data in the FIR or equivalent document, as stated in Section 3.2.1. The specific method chosen in Section 3.2.1 depends on the type of data presented in the FIR or equivalent document.

Step 7: Compare the mean values between the measured and existing data:

If the mean value for the existing data is within the 95 percent confidence interval of the measured data, use the lower bound of the 95 percent confidence interval. This is a conservative estimate of carbon stock for the baseline scenario.

If the mean value for the existing data is greater than the 95 percent confidence interval, use the mean value of the measured data as a conservative estimate of carbon stock for the baseline scenario.

If the mean value for the existing data is lower than the 95 percent confidence interval, use the existing data, which is a conservative estimate of carbon stock for the baseline scenario.

If the FIR or an equivalent document contains inventory data collected more than five years ago, or the inventory data has been obtained without proper stratification and sampling of the Project Area, then the Project Proponent must take the Measured Data pathway for calculating carbon emissions for the baseline scenario.

3.2.1.2 Where a less detailed FIR is available

For a less detailed FIR, only stratified volume per hectare and area data is provided. Thus, the wood density and BCEF methods must be applied to calculate carbon in merchantable logs and growing stock.

3.2.1.2.1 Carbon in the merchantable logs using wood density method

A. Where inventory data does not distinguish between different forest product types

Step 1: Select a sustainable and commonly employed method of the host country to convert growing stock data to merchantable logs' volume to be removed. The Project Proponent must justify in the PD that the chosen method is appropriate, and demonstrate that the method is commonly employed in the host country.

Step 2: Apply the method selected and justified in Step 1 to strata level growing stock data ($\bar{V}_{gstock,j,t=0}$), to obtain merchantable logs' volume per hectare in stratum, j ($\bar{V}_{merch,j,t=0}$).

Step 3: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone[3] (see Appendix B, Section B.1, Table B-1).

Step 4: Choose the most applicable carbon fraction[4] of wood from the following data sources:

(i) National carbon fraction (e.g. from National GHG Inventory)

(ii) Default IPCC carbon fraction of wood for a forest with corresponding climate domain (see Appendix B, Section B.2, Table B-2).

[3] As defined in IPCC (2006) Table 4-1, p 4.46, for climate region and ecological zone of forests.

[4] Throughout the Methodology, when determining carbon fraction, where merchantable logs are referred to, the carbon fraction of wood applies. Where aboveground biomass is referred to, the carbon fraction of aboveground biomass applies.

Step 5: Apply the following equation to convert the merchantable logs' volume to carbon per hectare in the stratum, *j*, using the wood density and carbon fraction:

Equation 3-3

$$\overline{C}_{merch,j,t=0} = D \times CF_{wood} \times \overline{V}_{merch,j,t=0}$$

Parameter	Description	Unit
$\overline{C}_{merch,j,t=0}$	Average carbon per hectare in merchantable logs in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$tC\ ha^{-1}$
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	$(t\ d.m.)\ m^{-3}$
CF_{wood}	Carbon fraction of wood for the tropical forest (see Appendix B)	$tC\ (t\ d.m.)^{-1}$
$\overline{V}_{merch,j,t=0}$	Average merchantable logs' volume per hectare in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ ha^{-1}$

Step 6: Convert the strata level average carbon per hectare to the average carbon per hectare in the merchantable logs for the entire Project Area:

Equation 3-4

$$\overline{C}_{merch,t=0} = \frac{\sum_{j=1}^{J}\left(\overline{C}_{merch,j,t=0} \times A_{project,j,t=0}\right)}{A_{project,t=0}}$$

Parameter	Description	Unit
$\overline{C}_{merch,t=0}$	Average carbon per hectare in merchantable logs in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$tC\ ha^{-1}$
$\overline{C}_{merch,j,t=0}$	Average carbon per hectare in merchantable logs in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$tC\ ha^{-1}$
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Parameter	Description	Unit
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

B. Where inventory data distinguish between different forest product types

This Methodology accounts for three forest product types: sawlog, pulplog and commercially harvested fuelwood. These can be categorised into long-term and short-term harvested wood products as presented in Appendix B, Section B.9, Figure B-1. If the growing stock of different forest product types *p*, per hectare at the strata level *j*, is available, calculate the average carbon in the merchantable logs per hectare for these forest product types using the following procedure:

Step 1: Select a sustainable and commonly employed method of the host country to convert growing stock data to the merchantable logs' volume to be removed, for the different forest product types. The Project Proponent must justify that the chosen method is appropriate and demonstrate that the method is commonly employed in the host country.

Step 2: Apply the method selected and justified in Step 1, to strata level growing stock data ($\bar{V}_{gstock,p,j,t=0}$) to obtain the merchantable logs' volume per hectare at the strata level *j* ($\bar{V}_{merch,p,j,t=0}$).

Step 3: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone[4] (see Appendix B, section B.1, Table B-1).

Step 4: Choose the most applicable carbon fraction of wood from the data sources presented in Step 4 of Section 3.2.1.2.1,A.

Step 5: Apply the following equation to estimate average carbon per hectare of the forest product types at the strata level:

Equation 3-5

$$\bar{C}_{merch,p,j,t=0} = D \times CF_{wood} \times \bar{V}_{merch,p,j,t=0}$$

Parameter	Description	Unit
$\bar{C}_{merch,p,j,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*, in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}
CF_{wood}	Carbon fraction of wood for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

Parameter	Description	Unit
$\bar{V}_{merch,p,j,t=0}$	Average merchantable logs' volume per hectare of forest product type *p*, in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ ha^{-1}$

Step 6: The average carbon per hectare in the merchantable logs for different forest product types in the Project Area is calculated as follows:

Equation 3-6

$$\overline{C}_{merch,p,t=0} = \frac{\sum_{j=1}^{J}\left(\overline{C}_{merch,p,j,t=0} \times A_{project,j,t=0}\right)}{A_{project,t=0}}$$

Parameter	Description	Unit
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$tC\ ha^{-1}$
$\overline{C}_{merch,p,j,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*, in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$tC\ ha^{-1}$
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Step 7: The average carbon per hectare in all the merchantable logs including the different forest product types in the Project Area, is calculated as follows:

Equation 3-7

$$\overline{C}_{merch,t=0} = \sum_{p=1}^{P}\overline{C}_{merch,p,t=0}$$

Parameter	Description	Unit
$\overline{C}_{merch,t=0}$	Average carbon per hectare in merchantable logs in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}

3.2.1.2.2 Carbon in the AGB of the growing stock using BCEF method

The carbon in the AGB of the growing stock can be calculated by applying the stratum-level BCEF method as presented in Figure 3-1 using the following procedure:

Step 1: Choose the most applicable BCEF value for each stratum in the Project Area from the following data sources:

(i) National factor (e.g. from National GHG Inventory)

(ii) Default IPCC BCEF for the corresponding forest, climate and growing stock in the Project Area (see IPCC, 2006, Chapter 4, Table 4.5, pp. 4.51-4.52).

If a factor for the forest type and the climatic region of the Project Area is not found, select the factor with the closest corresponding information.

Step 2: Choose the most applicable carbon fraction in the AGB of trees from the data sources presented in Step 4 of Section 3.2.1.2.1,A.

Step 3: Apply the following equation to convert the average growing stock per hectare to average carbon per hectare in the AGB in the growing stock in stratum *j*, using the values for BCEF and carbon fraction:

Equation 3-8

$$\overline{C}_{AGB\_gstock,j,t=0} = BCEF_j \times CF_{AGB} \times \overline{V}_{gstock,j,t=0}$$

Parameter	Description	Unit
$\overline{C}_{AGB\_gstock,j,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$BCEF_j$	Biomass conversion and expansion factor for converting average growing stock per hectare to carbon in the aboveground biomass for stratum *j*, (where *j*=1,2,3 … *J* strata)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

Parameter	Description	Unit
$\overline{V}_{gstock,j,t=0}$	Average growing stock per hectare for stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m^3 ha^{-1}

Step 4: Convert the average carbon per hectare in the AGB of the strata level to the whole forest level:

Equation 3-9

$$\overline{C}_{AGB\_gstock,t=0} = \frac{\sum_{j=1}^{J}\left(\overline{C}_{AGB\_gstock,j,t=0} \times A_{project,j,t=0}\right)}{A_{project,t=0}}$$

Parameter	Description	Unit
$\overline{C}_{AGB\_gstock,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$\overline{C}_{AGB\_gstock,j,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

3.2.1.3 Where a detailed FIR is available

If the FIR or an equivalent document provides field inventory data on tree species, diameter at breast height (DBH) and tree height (H) of the growing stock at the sample plot level *s*, in each stratum *j*, the volume allometric method can be used for estimating the carbon in the merchantable logs and in the AGB of the growing stock.

3.2.1.3.1 Carbon in the merchantable logs using volume allometric method

Use the following steps to calculate the carbon in the merchantable logs applying the volume allometric method:

A. Where inventory data does not distinguish between different forest product types

Step 1: To estimate the growing stock per hectare using DBH and tree height for each tree, select species-specific or group of species-specific volume allometric equations from the following data sources:

(i) Published peer reviewed studies for equations from tropical forests with corresponding climate region and ecological zone (e.g. Akindele and Lemay, 2006; Segura and Kanninen, 2005)

(ii) Published documents from the relevant forestry authority of the host country, e.g. National Inventory Report.

If species-specific or group of species-specific volume allometric equations are not available, general volume equations can be obtained from the relevant forestry authority of the host country. For this case, the Project Proponent is required to verify the applicability of this equation in the first monitoring event (see Section 7.2.4.2). If the equation is not applicable, derive a Project Area-specific equation (see specifically Step 5 of Section 7.2.4.2 for guidelines).

Step 2: Apply the following equation to sum the volume of each tree *n*, of species *i*, in sample plot *s*, to obtain the average growing stock in all the sample plots within a stratum *j*:

Equation 3-10

$$\overline{V}_{gstock,j,t=0} = \frac{1}{A_{s,j,t=0}} \times \sum_{s=1}^{S} \left\{ \sum_{i=1}^{I} \left[\sum_{n=1}^{N_i} f_V(DBH_{n,i,s,j,t=0}, H_{n,i,s,j,t=0}) \right] \right\}$$

Parameter	Description	Unit
$\overline{V}_{gstock,j,t=0}$	Average growing stock per hectare for stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ ha^{-1}$
$f_V(DBH_{n,i,s,j,t=0}, H_{n,i,s,j,t=0})$	Volume allometric equation as a function of diameter at breast height and height; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	dimensionless
$DBH_{n,i,s,j,t=0}$	Diameter at breast height for individual tree *n* (where *n*=1,2,3 … N_i for species, *i*), of species *i* (where *i*=1,2,3 … *I* species) in sample plot *s* (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	cm
$H_{n,i,s,j,t=0}$	Height for individual tree *n*, (where *n*=1,2,3 … N_i for species, *i*), of species *i*, (where *i*=1,2,3 … *I* species) in sample plot *s*, (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m
$A_{s,j,t=0}$	Total area of sample plots *s*, (where *s*=1,2,3 … *S* sample plot), in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Step 3: After estimating growing stock per hectare at the strata level, to calculate the carbon in the merchantable logs ($\overline{C}_{merch,t=0}$), apply Steps 2 to 6 as shown in the Section 3.2.1.2.1,A.

B. Where inventory data distinguish between different forest product types

If the different forest product types are distinguished based on the DBH of the tree, and are to be accounted for in GHG emissions calculations, apply the following steps:

Step 1: To estimate growing stock per hectare for each product type using DBH and tree height for each tree, select species-specific or group of species-specific volume allometric equations from the data sources presented in Step 1 of Section 3.2.1.3.1,A.

If species-specific or group of species-specific volume allometric equations are not available, general volume equations can be obtained from the relevant forestry authority of the host country. For this case, the Project Proponent is required to verify the applicability of this equation in the first monitoring event (see Section 7.2.4.2). If the equation is not applicable, derive a Project Area-specific equation (see specifically Step 5 of Section 7.2.4.2 for guidelines).

Step 2: Apply the allometric equations to individual tree *n*, of species *i*, to determine the average growing stock per hectare of the forest product type *p*, in a stratum *j*, as follows:

Equation 3-11

$$\overline{V}_{gstock,p,j,t=0} = \frac{1}{A_{s,j,t=0}} \times \sum_{s=1}^{S}\left\{\sum_{i=1}^{I}\left[\sum_{n=1}^{N_i} f_V(DBH_{n,i,s,j,t=0}, H_{n,i,s,j,t=0})_p\right]\right\}$$

Parameter	Description	Unit
$\overline{V}_{gstock,p,j,t=0}$	Average growing stock per hectare for product type *p,* in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m^3 ha^{-1}
$f_V(DBH_{n,i,s,j,t=0}, H_{n,i,s,j,t=0})_p$	Volume allometric equation as a function of diameter at breast height and height for the forest product type *p*; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	dimensionless
$DBH_{n,i,s,j,t=0}$	Diameter at breast height for individual tree *n* (where *n*=1,2,3 … N_i for species, *i*), of species *i,* (where *i*=1,2,3 … *I* species) in sample plot *s* (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	cm
$H_{n,i,s,j,t=0}$	Height for individual tree *n,* (where *n*=1,2,3 … N_i for species, *i*), of species *i*, (where *i*=1,2,3 … *I* species) in sample plot *s*, (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m

Parameter	Description	Unit
$A_{s,j,t=0}$	Total area of sample plots *s*, (where *s*=1,2,3 … *S* sample plot) in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Step 3: After estimating growing stock per hectare for different forest product types *p*, at the strata level, to calculate the average carbon per hectare in the merchantable logs ($\overline{C}_{merch,t=0}$), apply Steps 1 to 7 as shown in the Section 3.2.1.2.1,B.

3.2.1.3.2 Carbon in the AGB of the growing stock using biomass allometric method

The carbon in the AGB of the growing stock per hectare can be calculated based on the carbon fraction and growing stock. The growing stock is calculated by applying biomass allometric equations as a function of DBH, tree height, and wood density. This method of carbon estimation in the AGB of the growing stock is also used for estimating the carbon in the growth foregone due to selective logging as described in Section 3.3.4. The data on DBH and tree height are obtained from measurement of trees in the PSPs using the method presented in Section 7.1.2.

Calculate the carbon in the AGB of the growing stock applying the biomass allometric method by using the following procedure:

Step 1: Select species-specific or group of species-specific biomass allometric equations for estimating the AGB using the tree measurements from the following data sources:

(i) Published peer reviewed studies for equations from tropical forests with corresponding climate region and ecological zone (e.g. Pearson et al., 2005)

(ii) Published documents from the relevant authority of the host country, e.g. National Inventory Report.

If species-specific or group of species-specific biomass allometric equations are not available, general biomass allometric equations can be obtained from literature such as the IPCC GPG LULUCF (2003), Chapter 4, Annex 4A.1, Table 4.A.1, p. 4.114, or Pearson et. al. (2005), Appendix C, p. 43. For this case, select the most applicable allometric equation for a tropical forest with corresponding climate region and ecological zone and verify the applicability of this equation in the first monitoring event (see Section 7.2.4.2). If the equation is not applicable, derive a Project Area-specific equation (see specifically Steps 1 and 5 in Section 7.2.4.2 for guidelines).

Step 2: Find species-specific or group of species-specific wood densities from the data sources presented in Appendix B, Section B.1.

Step 3: Apply the biomass allometric equation to convert the DBH, tree height and wood density to the AGB of all the individual trees *n*, of species *i*, in the sample plot *s*, of the stratum *j*:

Equation 3-12

$$\overline{B}_{AGB\_gstock,j,t=0} = \frac{1}{A_{s,j,t=0}} \times \sum_{s=1}^{S}\left\{\sum_{i=1}^{I}\left[\sum_{n=1}^{N_i} f_B(DBH_{n,i,s,j,t=0}, H_{n,s,i,j,t=0}, D_i)\right]\right\}$$

Parameter	Description	Unit
$\overline{B}_{AGB\_gstock,j,t=0}$	Average aboveground biomass of the growing stock in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	(t d.m.) ha^{-1}
$f_B(DBH_{n,i,s,j,t=0}, H_{n,s,i,j,t=0}, D_i)$	Biomass allometric equation as a function of diameter at breast height, height determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year, and wood density	dimensionless
$DBH_{n,i,s,j,t=0}$	Diameter at breast height for individual tree *n*, (where *n*=1,2,3 … N_i for species, *i*), of species *i*, (where *i*=1,2,3 … *I* species) in sample plot *s*, (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	cm
$H_{n,i,s,j,t=0}$	Height for individual tree *n*, (where *n*=1,2,3 … N_i for species, *i*), of species *i* (where *i*=1,2,3 … *I* species) in sample plot *s*, (where *s*=1,2,3 … *S* sample plot), of stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m
D_i	Wood density for species, *i*, if D_i is not available, the density (D) for the tropical forest with the corresponding climate region and ecological zone	(t d.m.) m^{-3}
$A_{s,j,t=0}$	Total area of sample plots *s*, (where *s*=1,2,3 … *S* sample plot), in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Note that for estimating the annual average growth foregone in the Project Area due to selective logging, the AGB of the merchantable trees ($\overline{B}_{AGB\_merch,j.m_1}$ and $\overline{B}_{AGB\_merch,j.m_2}$, see Equation 3-36a) are obtained by applying the DBH and height of the merchantable trees at the stratum level, $DBH_{n,i,s,j,t}$ and $H_{n,i,s,j,t}$, respectively, to Equation 3-12 in monitoring events m_1 and m_2. Similarly, the annual average regrowth of the AGB in the naturally disturbed area ($\overline{B}_{AGB\_nd,j.m_1}$ and $\overline{B}_{AGB\_nd,j.m_2}$, see Equation 4-17b) is estimated by applying the DBH and height of all trees $DBH_{tree\_nd,n,i,s_{nd},j,t}$ and $H_{tree\_nd,n,i,s_{nd},j,t}$, respectively, in the sample plot established in the naturally disturbed areas, s_{nd}, to Equation 3-12 (see Step 5 of Section 4.4). Note that the subscript *s* in Equation 3-12 must consequently be replaced with the subscript s_{nd}.

Step 4: Convert the average AGB for the strata level to average AGB in the Project Area:

Equation 3-13
$$\overline{B}_{AGB\_gstock,t=0} = \frac{\sum_{j=1}^{J}\left(\overline{B}_{AGB\_gstock,j,t=0} \times A_{project,j,t=0}\right)}{A_{project,t=0}}$$

Parameter	Description	Unit
$\overline{B}_{AGB\_gstock,t=0}$	Average aboveground biomass per hectare of the growing stock in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	(t d.m.) ha^{-1}
$\overline{B}_{AGB\_gstock,j,t=0}$	Average aboveground biomass of the growing stock in stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	(t d.m.) ha^{-1}
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Step 5: Choose the carbon fraction of the AGB from the data sources presented in Step 4 of Section 3.2.1.2.1,A.

Step 6: Convert the average AGB to average carbon per hectare in the AGB in the Project Area:

Equation 3-14
$$\overline{C}_{AGB\_gstock,t=0} = \overline{B}_{AGB\_gstock,t=0} \times CF_{AGB}$$

Parameter	Description	Unit
$\overline{C}_{AGB\_gstock,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$\overline{B}_{AGB\_gstock,t=0}$	Average aboveground biomass per hectare of the growing stock in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	(t d.m.) ha^{-1}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

3.2.2 MEASURED DATA PATHWAY

If the Project Proponent has obtained approval for selective logging from the relevant authority of the host country and also provides evidence of preparation of the FIR or an equivalent document, then data collection through field measurements in PSPs (see Section 7.1.2) after proper stratification (see Section 2.2.1.1.1) is required. This approach has been termed as Measured Data pathway in this Methodology.

The data collected through the measurement in the PSPs provides the diameter at breast height (DBH) and tree height (H) of the growing stock at the sample plot level *s*, in each stratum *j*. The volume and biomass allometric methods described for the Existing Inventory Data pathway where the detailed FIR is available, Sections 3.2.1.3.1 and 3.2.1.3.2, respectively, will be used for calculating the carbon in the merchantable logs and the AGB in the growing stock.

3.2.3 DETERMINATION OF ANNUAL HARVEST VOLUME AND NET HARVEST AREA

3.2.3.1 Where the FIR or equivalent document contains a detailed harvesting plan

In the case where the FIR or equivalent document, contains a detailed harvesting plan, the plan must provide a detailed prescription for selective logging, clearly stating the total volume of wood to be harvested, the annual net harvest area, as well as a specification of the period when selective logging operations are to be carried out in the Project Area. Since the document is legally approved by the relevant authority in the host country, the total volume of wood to be harvested must be converted to an annual harvest volume ($V_{merch,t}$) based on the growing stock ($V_{gstock,t=0}$) and the area where the selective logging occurs, i.e., the annual net harvest area ($A_{NHA\_annual,t}$). The latter, if known, is the summation of the annual net harvest area at the stratum level ($A_{NHA\_annual,j,t}$). These parameters must be used in calculating the net GHG emission reductions for the baseline scenario.

3.2.3.2 Where a detailed harvesting plan is not available

In the case where the Project Proponent has obtained the approval for selective logging and also provides evidence of the preparation of the FIR or equivalent document, but this document is not complete, the annual harvest volume and annual net harvest area (at the stratum level) are calculated from the growing stock data obtained from field measurements in the PSPs (i.e. the Measured Data pathway) using the following procedure:

Step 1: The Project Proponent must select a sustainable and commonly employed method in the host country and prepare a timber harvesting plan for the selective logging in the Project Area. The Project Proponent must demonstrate that the plan is realistic and sustainable and will be implemented for selective logging if the IFM-LtPF project does not go ahead. This timber harvesting plan must provide the annual harvest volume (volume of merchantable logs to be removed) ($V_{merch,t}$) and the annual net harvest area ($A_{NHA\_annual,t}$), which, if known, is the summation of the annual net harvest area at the stratum level ($A_{NHA\_annual,j,t}$), where the harvesting would occur.

Step 2: Since the annual harvest volume and annual net harvest area are based on the measured data, the Project Proponent must obtain approval from the relevant authority in the host country and also provide the documentary evidence in the PD.

The Project Proponent must also provide evidence or documentation that the chosen method for preparing the timber harvesting plan is sustainable and a commonly employed method in the host country.

3.2.4 ANNUAL TOTAL CARBON IN THE MERCHANTABLE LOGS

The annual total carbon in the merchantable logs, $C_{merch,t}$ is calculated by multiplying the average carbon per hectare in the merchantable logs by the annual net harvest area applying Equation 3-15a. In the case where the annual net harvest area at the stratum level is known, apply Equation 3-15b:

Equation 3-15a
$$C_{merch,t} = \bar{C}_{merch,t=0} \times A_{NHA\_annual,t}$$

Equation 3-15b
$$C_{merch,t} = \sum_{j=1}^{J} \left(\bar{C}_{merch,j,t=0} \times A_{NHA\_annual,j,t} \right)$$

Parameter	Description	Unit
$C_{merch,t}$	Annual total carbon in the merchantable logs harvested in the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\bar{C}_{merch,t=0}$	Average carbon per hectare in the merchantable logs determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$\bar{C}_{merch,j,t=0}$	Average carbon per hectare in the merchantable logs in stratum *j,* (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha
$A_{NHA\_annual,j,t}$	Annual net harvest area for the Project Area in stratum *j,* (where *j*=1,2,3 … *J* strata) in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

3.2.5 ANNUAL TOTAL CARBON IN THE ABOVEGROUND BIOMASS OF THE GROWING STOCK

The annual total carbon in the AGB of the growing stock, $C_{AGB\_gstock,t}$ is calculated by multiplying the average carbon per hectare in the AGB of the growing stock by the annual net harvest area applying Equation 3-16a. In the case where the annual net harvest area at the stratum level is known, apply Equation 3-16b.

Equation 3-16a
$$C_{AGB\_gstock,t} = \bar{C}_{AGB\_gstock,t=0} \times A_{NHA\_annual,t}$$

Equation 3-16b $$C_{AGB\_gstock,t} = \sum_{j=1}^{J} \left(\bar{C}_{AGB\_gstock,j,t=0} \times A_{NHA\_annual,j,t} \right)$$

Parameter	Description	Unit
$C_{AGB\_gstock,t}$	Annual total carbon in the aboveground biomass of the growing stock harvested every year in the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\bar{C}_{AGB\_gstock,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$\bar{C}_{AGB\_gstock,j,t=0}$	Average carbon per hectare in the aboveground biomass of the growing stock in stratum *j,* (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha
$A_{NHA\_annual,j,t}$	Annual net harvest area for the Project Area in stratum *j,* (where *j*=1,2,3 … *J* strata) in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

3.3 CARBON CHANGES DUE TO DEGRADATION UNDER THE BASELINE SCENARIO

The primary parameters, annual net harvest area, $A_{NHA\_annual,t}$, annual total carbon in the merchantable logs, $C_{merch,t}$,and annual total carbon in the AGB of the growing stock, $C_{AGB\_gstock,t}$, calculated in Section 3.2, are then used to calculate each of the five parameters of Equation 3-2 to determine the annual carbon lost from degradation. The procedures for calculating these five parameters are provided in the subsequent sections.

3.3.1 NET CARBON FROM THE DEADWOOD POOL

The DW pool contains carbon in coarse woody debris, standing dead trees and other dead material not included in the litter or soil carbon pools (IPCC, 2006, p. 4.73). The Methodology assumes that the proportion of DW accumulation to the DW pool and rate of decay from the pool due to natural mortality and disturbance will be the same for both the baseline and with-project scenarios, and is therefore not included.

In this Methodology, for the baseline scenario of selective logging, the additions (also referred to as inputs) to the carbon in the DW pool are:

(i) Carbon from residual stand damage

(ii) Carbon in branches and trimmings.

The carbon from DW is a function of the (delayed) decay of the combined inputs to the DW pool and is given by:

Equation 3-17

$$C_{DW_{decay},t} = f(C_{DW_{in}t}, k_{decay})$$

Parameter	Description	Unit
$C_{DW_{decay},t}$	Annual carbon leaving the deadwood pool due to the decay of deadwood in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{DW_{in},t}$	Annual total carbon input to the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
k_{decay}	Rate of decay of the deadwood pool	yr^{-1}

The annual total carbon input into the deadwood pool is calculated as follows:

Equation 3-18

$$C_{DW_{in},t} = C_{RSD,t} + C_{branch\_trim,t}$$

Parameter	Description	Unit
$C_{DW_{in},t}$	Annual total carbon input to the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{RSD,t}$	Annual carbon in the residual stand damage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{branch\_trim,t}$	Annual carbon in branches and trimmings left over from harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

3.3.1.1 Carbon from residual stand damage

In the process of selective logging, the residual stand is damaged either by being knocked down, snapped off, or due to limb breakage. The fraction of residual stand that is damaged over the amount of timber that is extracted, is denoted as the factor for residual stand damage, f_{RSD}. Data on carbon impact from damage to residual stand by selective logging is very limited (Brown et. al., 2005).

Brown et al. (2005) compiled the factor for residual stand damage (damage over extracted) for various countries and revealed a strong relationship with commercial log length (Brown et al., 2005, Figure 11, p. 16). The results have been summarised in this Methodology in Table B-3 in Appendix B. The carbon from residual stand damage can be determined using the following procedure:

Step 1: Determine the average commercial log length based on the inventory data for the Project Area.

Step 2: Select an appropriate and conservative value for f_{RSD} from publications specific to the host country. Table B-3, Section B.3, Appendix B is provided as a guidance to determine a suitable f_{RSD}.

Step 3: Apply the following equation to calculate carbon in the residual stand damage:

Equation 3-19 $$C_{RSD,t} = f_{RSD} \times C_{merch,t}$$

Parameter	Description	Unit
$C_{RSD,t}$	Annual carbon in the residual stand damage in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
f_{RSD}	Factor for residual stand damage, based on the fraction of quantity of carbon damaged in the residual stand to the quantity of carbon in total merchantable logs harvested	dimensionless
$C_{merch,t}$	Annual total carbon in merchantable logs harvested in the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) (See Equations 3-15a and 3-15b)	tC

3.3.1.2 Carbon in branches and trimmings

In the baseline scenario where selective logging occurs, trees are trimmed of their branches, twigs, and foliage to produce the merchantable logs intended for processing. Branches and trimmings is the term used to denote the trimmed components such as large and small branches, whose carbon will be transferred into the DW pool. Biomass from the twigs, foliage and bark are transferred into the litter pool. In accordance with the VCS rules, litter is not included as a carbon pool in this Methodology. Hence, only the fraction of branches and trimmings are accounted for in the dead wood pool.

To determine this fraction, a branch-trim factor, f_{branch_trim}, is employed (see Appendix A). The factor can be derived from the ratio of biomass of large branches and coarse woody debris over the total AGB of trees.

Determine the carbon in branches and trimmings using the following procedure:

Step 1: Find a branch-trim factor, f_{branch_trim}, from published peer reviewed literature for tropical forests of corresponding climate domain and ecological zone. If the branch-trim factor obtained from the literature does not match the forest type and climatic region of the Project Area, it will require validation via the steps outlined in Section 7.2.4.3. If a branch-trim factor can be obtained from the literature, proceed to Step 2. If a branch-trim factor cannot be obtained from the literature, it is conservative to set $C_{branch\_trim,t}$ equal to zero in Equation 3-20. Carbon from branches and trimmings is thus omitted in the ex ante calculation and must be included when a project-specific f_{branch_trim} can be derived from measurements in the first monitoring event (Section 7.2.4.3).

Step 2: Apply f_{branch_trim} in the following equation to estimate the carbon from branches and trimmings transferring into the DW pool:

Equation 3-20

$$C_{branch\_trim,t} = f_{branch\_trim} \times C_{merch,t}$$

Parameter	Description	Unit
$C_{branch\_trim,t}$	Annual carbon in branches and trimmings left over from harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{merch,t}$	Annual total carbon in the merchantable logs harvested in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
f_{branch_trim}	The fraction of branches and trimmings in the aboveground biomass remaining after trimming of the merchantable logs transferred to the DW pool	dimensionless

Note: it is conservative to use $C_{merch,t}$ to determine $C_{branch\_trim,t}$.

3.3.1.3 Carbon emissions due to decay of the DW pool

Step 1: Select a value for the rate of decay, k_{decay}, from published peer reviewed literature, verified publication or equivalent document, for tropical forests of corresponding climate domain and ecological zone (e.g. Delaney et al., 1998) for the first year of the project.

If a range of values for the rate of decay is provided in the literature, the Project Proponent is required to provide justification for the choice of the rate of decay in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

If in the subsequent monitoring events, the Project Proponent decides to estimate the project specific rate of decay, then refer to the guidance proposed by Scott and Brown (2008).

Step 2: Determine the annual fraction of DW that would remain in the DW pool in year *t* (years elapsed since the start of the IFM-LtPF project activity) by applying the rate of decay in the following equation:

Equation 3-21

$$F_{DW\_remain,t} = e^{-k_{decay} \times t}$$

Parameter	Description	Unit
$F_{DW\_remain,t}$	Annual fraction of carbon in the deadwood pool that would remain in the deadwood pool in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of decay	dimensionless
k_{decay}	Rate of decay of the deadwood pool	yr^{-1}
t	1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity	yr

Step 3: Calculate the carbon remaining and accumulating in the DW pool in year t (years elapsed since the start of the IFM-LtPF project activity). For a fixed annual harvest volume as set out in the harvesting plan or equivalent document, implying a fixed input into the deadwood pool, use Equation 3-22a. For a variable annual harvest volume as set out in the harvesting plan or equivalent document, implying a variable input into the deadwood pool, use Equation 3-22b. Where Equation 3-22b is to be used, see Appendix D for an example application.

Equation 3-22a

$$C_{DW_{pool},t} = \sum_{t=1}^{t*}\left(F_{DW\_remain,t} \times C_{DW_{in},t}\right)$$

Equation 3-22b

$$C_{DW_{pool,t}} = \left(F_{DW\_remain,t-(t-1)} \times C_{DW_{in},t}\right) + \left(F_{DW\_remain,t-(t-2)} \times C_{DW_{in},t-1}\right) + \left(F_{DW\_remain,t-(t-3)} \times C_{DW_{in},t-2}\right) + \ldots + \left(F_{DW\_remain,t-(t-t*)} \times C_{DW_{in},t-(t*-1)}\right)$$

Parameter	Description	Unit
$C_{DW_{pool},t}$	Cumulative carbon remaining in the deadwood pool in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$F_{DW\_remain,t}$	Annual fraction of carbon in the deadwood pool that would remain in the deadwood pool in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of decay	dimensionless
$C_{DW_{in},t}$	Annual total carbon input to the deadwood pool in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Step 4: Calculate the cumulative overall emissions leaving the DW pool in year *t* (years elapsed since the start of the IFM-LtPF project activity):

Equation 3-23

$$C_{DW_{out},t} = \sum_{t=1}^{t*} C_{DW_{in},t} - C_{DW_{pool},t}$$

Parameter	Description	Unit
$C_{DW_{out},t}$	Cumulative carbon leaving the deadwood pool and emitted into the atmosphere in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{DW_{in},t}$	Annual total carbon input to the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{DW_{pool},t}$	Cumulative carbon remaining in the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Step 5: To calculate the annual emissions leaving the DW pool in year *t* (years elapsed since the start of the IFM-LtPF project activity), apply the following equation:

Equation 3-24

$$C_{DW_{decay},t} = C_{DW_{out},t} - C_{DW_{out},t-1}$$

Parameter	Description	Unit
$C_{DW_{decay},t}$	Annual carbon leaving the deadwood pool due to the decay of deadwood in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{DW_{out},t}$	Cumulative carbon leaving the deadwood pool and emitted into the atmosphere in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{DW_{out},t-1}$	Cumulative carbon leaving the deadwood pool and emitted into the atmosphere in year *t*-1, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Note that for the first year of the project where *t*=1, Equation 3-24 shows that the annual carbon leaving the DW pool ($C_{DW_{decay},t}$) is equal to the cumulative carbon leaving the DW pool ($C_{DW_{out},t}$).

3.3.2 Net Carbon from the Long-term HWP Pool

Long-term HWPs (ltHWPs) are those with a half-life of over 30 years while products with a half-life of two years or less are known as short-term HWPs (stHWPs) (IPCC, 2006, Chapter 12, Section 12.2.2, Table 12-2).

The approach taken for ltHWPs is for analysis to be based on domestic harvest volume and not domestic consumption volume. In the case where a FIR is not available (see Figure 3-1) and where no other information is available to determine what quantity or ratio of the total merchantable logs' volume is classed as stHWPs, then it is conservative to assume that all the merchantable logs' volume goes into the ltHWP pool.

In order to apply this Methodology, data availability with respect to the following parameters must be determined:

- average carbon in the ltHWPs
- lumber recovery factor (see Appendix B)
- ltHWP rate of oxidation (see Appendix B).

The carbon from ltHWPs is a combination of the immediate oxidation of ltHWP residues as a result of timber processing, and the delayed oxidation of ltHWPs, as given by:

Equation 3-25

$$C_{ltHWP_{oxidation},t} = C_{ltHWP_{residues},t} + C_{ltHWP_{net\_out},t}$$

Parameter	Description	Unit
$C_{ltHWP_{oxidation},t}$	Annual carbon due to the combined delayed oxidation of long-term harvested wood products and immediate oxidation of long-term harvested wood products residues in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{residues},t}$	Annual carbon due to the immediate oxidation of long-term harvested wood products residues in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{net\_out},t}$	Annual net carbon due to the delayed oxidation of the long-term harvested wood products, leaving the long-term harvested wood products pool in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

3.3.2.1 Carbon due to long-term HWP residues

Long-term HWP residues are known to be comprised of saw dust, trimmings and other conversion losses (Enters, 2001). The lumber recovery factor for merchantable log processing is required in order to determine the carbon associated with sawmill residues. This can be determined using the following procedure:

Step 1: Select a lumber recovery factor from the following data sources:

(i) National lumber recovery factors in relevant literature such as FAO (2004). Various country specific lumber recovery factors have been compiled in Table B-4 in Appendix B; or

(ii) If a national lumber recovery factor is not available, select a lumber recovery factor from a country that uses similar timber processing technology to that of the project's host country.

If a range for the lumber recovery factor is provided, the Project Proponent is required to provide justification for the choice of lumber recovery factor in the PD. If no justification can be derived, it is conservative to select the upper end of the range.

Step 2: Assuming that the sawmill residues undergo oxidation in the same year of processing, annual emissions due to ltHWP residues are determined by:

Equation 3-26

$$C_{ltHWP_{residues},t} = \overline{C}_{merch,p,t=0} \times (1 - f_{lumber\_recovery}) \times A_{NHA\_annual,t}$$

Parameter	Description	Unit
$C_{ltHWP_{residues},t}$	Annual carbon due to the immediate oxidation of long-term harvested wood products residues in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*=sawlog, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$f_{lumber\_recovery}$	Lumber recovery factor for proportion of merchantable log converted to harvested wood product	dimensionless
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

3.3.2.2 Carbon due to oxidation of the long-term HWP pool

Calculate the average amount of carbon expected to be transferred into the HWP pool each year and stored over the long term. Wood harvested for production of paper products (and the like) and commercially harvested fuelwood, such as from pulplog (see HWPs - stHWPs in Appendix A), are not considered to be ltHWPs and are therefore accounted in Section 3.3.3 instead.

According to the IPCC's default values for oxidation of specific ltHWPs (IPCC, 2006, Chapter 12) it is noteworthy that the oxidation factors among these ltHWPs do not vary greatly. Hence, it is assumed that a single oxidation factor applied to ltHWPs would suffice.

Step 1: Select a lumber recovery factor from the data sources presented in Step 1 of Section 3.3.2.1.

Step 2: Multiply the carbon in the forest product type such as sawlog that contributes to the ltHWPs (derived in Equation 3-6) by the lumber recovery factor and annual net harvest area, as given by:

Equation 3-27

$$C_{ltHWP_{in},t} = \overline{C}_{merch,p,t=0} \times f_{lumber\_recovery} \times A_{NHA\_annual,t}$$

Parameter	Description	Unit
$C_{ltHWP_{in},t}$	Annual carbon input to the long-term harvested wood products pool from sawlog in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC
$f_{lumber\_recovery}$	Lumber recovery factor for proportion of merchantable log converted to harvested wood product	dimensionless
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

Step 3: Find an appropriate rate of carbon oxidation[5] (k_{ltHWP_ox}) specific to ltHWPs. For example, if it is known that the ltHWPs are to be made into sawnwood furniture (i.e. solidwood products from sawlogs), then the rate of carbon oxidation should (closely) reflect solidwood products. The IPCC (2006) have default rates of oxidation for HWP categories (see Appendix B, Section B.5, Table B-5).

If a range of values for the carbon rate of oxidation is provided in the literature, the Project Proponent is required to provide justification for the rate of carbon oxidation in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

Step 4: Determine the annual fraction of ltHWP that would remain in the ltHWP pool in year *t* (years elapsed since the start of the IFM-LtPF project activity) by applying the rate of oxidation in the following equation:

Equation 3-28

$$F_{ltHWP\_remain,t} = e^{-k_{ltHWP\_ox} \times t}$$

Parameter	Description	Unit
$F_{ltHWP\_remain,t}$	Annual fraction of ltHWP that would remain in the ltHWP pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of oxidation	dimensionless

[5] The term "rate of carbon oxidation" is synonymous with "rate of decay". However in this Methodology, for improved clarity to differentiate between the rates used between long-term harvested wood products (ltHWPs) and deadwood (DW), "rate of carbon oxidation" is used in association with ltHWPs while "rate of decay" is used in associated with DW.

Parameter	Description	Unit
k_{ltHWP_ox}	Rate of oxidation for long-term harvested wood products	yr^{-1}
t	1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity	yr

Step 5: Calculate the carbon remaining and accumulating in the ltHWP pool in year *t* (years elapsed since the start of the IFM-LtPF project activity). For a fixed annual harvest volume as set out in the harvesting plan or equivalent document, implying a fixed input into the ltHWP pool, use Equation 3-29a. For a variable harvest volume as set out in the harvesting plan or equivalent document, implying a variable input into the ltHWP pool, use Equation 3-29b. Where Equation 3-29b is to be used, see Appendix D for an example application:

Equation 3-29a

$$C_{ltHWP_{pool},t} = \sum_{t=1}^{t*}\left(F_{ltHWP\_remain,t} \times C_{ltHWP_{in},t}\right)$$

Equation 3-29b

$$C_{ltHWP_{pool,t}} = \left(F_{ltHWP\_remain,t-(t-1)} \times C_{ltHWP_{in},t}\right) + \left(F_{ltHWP\_remain,t-(t-2)} \times C_{ltHWP_{in},t-1}\right) + \left(F_{ltHWP\_remain,t-(t-3)} \times C_{ltHWP_{in},t-2}\right) + \ldots + \left(F_{lHWP\_remain,t-(t-t*)} \times C_{ltHWP_{in},t-(t*-1)}\right)$$

Parameter	Description	Unit
$C_{ltHWP_{pool},t}$	Cumulative carbon remaining in the ltHWP pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$F_{ltHWP\_remain,t}$	Annual fraction of ltHWP that would remain in the ltHWP pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of oxidation	dimensionless
$C_{ltHWP_{in},t}$	Annual carbon input to the long-term harvested wood products pool from sawlog in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Step 6: Calculate the cumulative overall emissions leaving the ltHWP pool in year t (years elapsed since the start of the IFM-LtPF project activity):

Equation 3-30

$$C_{ltHWP_{out},t} = \sum_{t=1}^{t*} C_{ltHWP_{in},t} - C_{ltHWP_{pool},t}$$

Parameter	Description	Unit
$C_{ltHWP_{out},t}$	Cumulative carbon leaving the ltHWP pool and emitted into the atmosphere from year *t*=1 to year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{in},t}$	Annual carbon input to the long-term harvested wood products pool from sawlog in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{pool},t}$	Cumulative carbon remaining in the ltHWP pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Step 7: To calculate the annual emissions leaving the ltHWP pool in *t* years elapsed since the start of the IFM-LtPF project activity, apply the following equation:

Equation 3-31
$$C_{ltHWP_{net\_out},t} = C_{ltHWP_{out},t} - C_{ltHWP_{out},t-1}$$

Parameter	Description	Unit
$C_{ltHWP_{net\_out},t}$	Annual net carbon due to the delayed oxidation of the long-term harvested wood products, leaving the long-term harvested wood products pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{out},t}$	Cumulative carbon leaving the ltHWP pool and emitted into the atmosphere in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{ltHWP_{out},t-1}$	Cumulative carbon leaving the ltHWP pool and emitted into the atmosphere in year *t*-1, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Note, that for the first year of the project where *t*=1, Equation 3-31 shows that the annual carbon leaving the ltHWP pool ($C_{ltHWP_{net\_out},t}$) is equal to the cumulative carbon leaving the ltHWP pool ($C_{ltHWP_{out},t}$).

3.3.3 Net Carbon from the Short-term HWP Pool

Certain merchantable logs are destined to be converted into HWPs with a half-life of two years or less. These are referred to here as short-term HWPs (stHWPs; IPCC, 2006, Chapter 12, Section 12.2.2, p. 12.17). In this Methodology, the two forest product types contributing to stHWPs are pulplog (for paper products) and commercially harvested fuelwood. Similar to ltHWPs, the approach taken for stHWPs is for analysis to be based on domestic harvest volume and not domestic consumption volume.

In the case where inventory data do not distinguish the forest product types and/or where no other information is available to determine what quantity or ratio of the total merchantable logs' volume is classed into stHWPs, then it is conservative to assume that all the merchantable logs' volume goes into the ltHWP pool.

The annual carbon from stHWPs is a combination of the immediate oxidation of commercially harvested fuelwood and delayed oxidation of paper products, or solely from commercially harvested fuelwood, or solely from paper products. Equation 3-32 provides the annual carbon from the combination of both stHWPs. In the case where oxidation is attributable to only commercially harvested fuelwood, the parameter for paper products becomes zero - and vice versa.

Equation 3-32
$$C_{stHWP_{oxidation},t} = C_{stHWP_{comm\_FW},t} + C_{stHWP_{net\_out},t}$$

Parameter	Description	Unit
$C_{stHWP_{oxidation},t}$	Annual carbon due to immediate oxidation of short-term harvested wood products (commercially harvested fuelwood) and delayed oxidation of short-term harvested wood products (paper products) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{stHWP_{comm\_FW},t}$	Annual carbon due to immediate oxidation of short-term harvested wood products (commercially harvested fuelwood) leaving the project boundary in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{stHWP_{net\_out},t}$	Annual net carbon due to the delayed oxidation of short-term harvested wood products (paper products), leaving the short-term harvested wood products pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

3.3.3.1 Carbon in short-term HWPs - commercially harvested fuelwood

For commercially harvested fuelwood, immediate oxidation occurs upon consumption - and therefore is regarded as an (immediate) emission in the year of harvest. The carbon from stHWPs is thus considered from the immediate oxidation of the stHWP merchantable logs.

The annual carbon from stHWPs - commercially harvested fuelwood, is calculated by multiplying the average carbon per hectare in the commercially harvested fuelwood with the annual net harvest area:

Equation 3-33
$$C_{stHWP_{comm\_FW},t} = \overline{C}_{merch,p,t=0} \times A_{NHA\_annual,t}$$

Parameter	Description	Unit
$C_{stHWP_{comm\_FW},t}$	Annual carbon due to immediate oxidation of short-term harvested wood products (commercially harvested fuelwood) leaving the project boundary in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type p=pulplog, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

3.3.3.2 Carbon in short-term HWPs - pulplog

Pulplogs are mainly used for paper products. For paper products, the IPCC (2006) suggests to use a (delayed) rate of oxidation (see Appendix B). Hence, use the following procedure:

Step 1: Find an appropriate rate of carbon oxidation (k_{stHWP_ox}) specific to paper products (or see Appendix B). If a range of values for the rate of oxidation is provided in the literature, the Project Proponent is required to provide justification for the choice of the rate of oxidation in the PD. If no justification can be derived, it is conservative to select the lower end of the range. Then apply the following equation:

Equation 3-34

$$F_{stHWP\_remain,t} = e^{-k_{stHWP\_ox} \times t}$$

Parameter	Description	Unit
$F_{stHWP\_remain,t}$	Annual fraction of stHWP that would remain in the stHWP pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of oxidation	dimensionless
k_{stHWP_ox}	Rate of oxidation for short-term harvested wood products	yr^{-1}
t	1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity	yr

Step 2: Apply the following equation (note this is modified from Equation 3-33 because paper products are not immediately oxidized, these go into the stHWP pool).

Equation 3-35

$$C_{stHWP_{in},t} = \overline{C}_{merch,p,t=0} \times A_{NHA\_annual,t}$$

Parameter	Description	Unit
$C_{stHWP_{in},t}$	Annual carbon input to the short-term harvested wood products pool, for the specific forest product type, pulplog,in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{C}_{merch,p,t=0}$	Average carbon per hectare in merchantable logs of forest product type *p*=pulplog, in the Project Area determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	tC ha^{-1}
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

Step 3: Apply Equations 3-29a or 3-29b through to 3-31, changing the descriptions (and subscripts) from ltHWP to stHWP to calculate the annual net carbon due to the delayed oxidation of the stHWPs, leaving the stHWP pool in t years elapsed since start of the IFM-LtPF project activity.

3.3.4 CARBON IN THE GROWTH FOREGONE DUE TO SELECTIVE LOGGING

The selective logging operations removes a prescribed amount of merchantable logs after harvesting of the selected merchantable trees from the Project Area under the baseline scenario. Consequently, the carbon that would have been stored from the annual growth in these trees is forfeited. The carbon lost here is denoted as carbon in the growth foregone, $C_{growth\_foregone,t}$, and this can be calculated using the following procedure:

Step 1: Calculate the AGB in merchantable trees from height and diameter measurements of all the merchantable trees in the PSPs at the stratum level for two consecutive monitoring events using the method presented in Section 3.2.1.3.2. The procedure for establishing PSPs and tree measurements are described in Section 7.1.2.

The method to determine the annual growth parameter is based on the stock change method presented in the approved CDM Methodology for Afforestation and Reforestation project activities (CDM-EB, 2009, p. 8). The difference between the AGB of merchantable trees from data obtained in the PSP measurements at the stratum level for two consecutive monitoring events is determined and divided by the monitoring period, i.e. the time interval taken between the two monitoring events (in years), at the stratum level using Equation 3-36a and, for the Project Area using Equation 3-36b:

Equation 3-36a

$$\bar{G}_{growth\_foregone,j,t} = \frac{\bar{B}_{AGB\_merch,j,m_2} - \bar{B}_{AGB\_merch,j,m_1}}{\Delta m}$$

Equation 3-36b

$$\bar{G}_{growth\_foregone,t} = \frac{\sum_{j=1}^{J}\left(\bar{G}_{growth\_foregone,j,t} \times A_{project,j,t=0}\right)}{A_{project,t=0}}$$

Parameter	Description	Unit
$\bar{G}_{growth\_foregone,j,t}$	Average growth per hectare per year in the aboveground biomass in the merchantable trees in the Project Area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}
$\bar{B}_{AGB\_merch,j,m_2}$	Average aboveground biomass of the merchantable trees in the Project Area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year, m_2 - when current monitoring event occurs	(t d.m.) ha^{-1}
$\bar{B}_{AGB\_merch,j,m_1}$	Average aboveground biomass of the merchantable trees in the Project Area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year, m_1- when preceding monitoring event occurred	(t d.m.) ha^{-1}

Parameter	Description	Unit
Δm	Monitoring period, the time taken between two consecutive monitoring events	yr
$\bar{G}_{growth\_foregone,t}$	Average growth per hectare per year in the aboveground biomass in the merchantable trees in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}
$A_{project,j,t=0}$	Project Area within each stratum *j*, (where *j*=1,2,3 … *J* strata) where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha
$A_{project,t=0}$	Project Area where the IFM-LtPF project activity will be implemented; determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	ha

Step 2: Calculate the carbon in the growth foregone due to the selective logging using Equation 3-37a. In the case where the annual net harvest area at the stratum level is known, apply Equation 3-37b:

Equation 3-37a

$$C_{growth\_foregone,t} = CF_{AGB} \times \bar{G}_{growth\_foregone,t} \times \sum_{t=1}^{t*} A_{NHA\_annual,t}$$

Equation 3-37b

$$C_{growth\_foregone,t} = CF_{AGB} \times \sum_{j=1}^{J} \left(\bar{G}_{growth\_foregone,j,t} \times \sum_{t=1}^{t*} A_{NHA\_annual,j,t} \right)$$

Parameter	Description	Unit
$C_{growth\_foregone,t}$	Annual carbon lost due to growth foregone in the aboveground biomass in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\bar{G}_{growth\_foregone,t}$	Average growth per hectare per year in the aboveground biomass in the merchantable trees in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}
$\bar{G}_{growth\_foregone,j,t}$	Average growth per hectare per year in the aboveground biomass in the merchantable trees in the Project Area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}

Parameter	Description	Unit
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$
$A_{NHA\_annual,j,t}$	Annual net harvest area for the Project Area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

3.3.5 Carbon in the Regrowth after Selective Logging

It is good practice to account for regrowth in the gaps following logging. The IPCC (2006) suggested approach for estimating the regrowth is based on the mean annual growth in the AGB after logging, denoted here as $\bar{G}_{regrowth,t}$.

This Methodology applies a conservative approach for area of regrowth by considering that the entire annual net harvest area would permit regrowth each year. The annual net harvest area for the selective logging is calculated in Section 3.2.3.

Determine carbon in the regrowth after selective logging using the following procedure:

Step 1: Select the factor for the annual average growth in the aboveground biomass after selective logging, or a time-dependent growth model from the following sources:

(i) Local growth tables or growth models

(ii) National growth tables or growth models (e.g., from National GHG Inventory)

(iii) Published peer reviewed studies for growth models/tables from previous logged tropical forests with corresponding age, climate region and ecological zone.

Step 2: Determine the carbon due to regrowth by multiplying the annual net harvest area(s) and the average growth rate per hectare per year by the carbon fraction:

Equation 3-38

$$C_{regrowth,t} = \left(\bar{G}_{regrowth,t} \times CF_{AGB}\right) \times \sum_{t=1}^{t*} A_{NHA\_annual,t}$$

Parameter	Description	Unit
$C_{regrowth,t}$	Annual carbon increase in the biomass due to regrowth following logging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\bar{G}_{regrowth,t}$	Average regrowth per hectare per year of the aboveground biomass after logging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}

Parameter	Description	Unit
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)^^	ha

3.4 Baseline Activity Emissions

A number of emission sources are associated with the implementation of the baseline (selective logging) activity. Omission of any or all of the associated emission sources is conservative. The Project Proponent intending to calculate baseline activity emissions must select data required in the calculations on a conservative basis.

The stages of operation for timber harvesting include, but are not limited to, the process steps outlined in Figure 3-2 below:

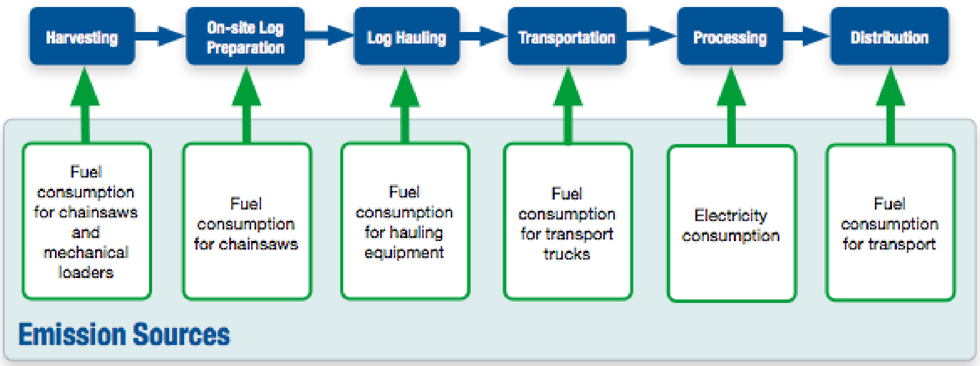

Figure 3-2. An outline of timber harvesting operations and the associated emission sources

The total emissions due to the baseline activity ($C'_{emissions,t}$) is determined from the summation of all the emission sources presented in Figure 3-2 using the following equation:

Equation 3-39

$$C'_{emissions,t} = E_{harvest,t} + E_{onsiteprep,t} + E_{hauling,t} + E_{transport,t} + E_{processing,t} + E_{distribution,t}$$

Parameter	Description	Unit
$C'_{emissions,t}$	Annual total carbon emissions associated with the baseline activity of selective logging operations in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{harvest,t}$	Annual emissions due to harvesting operations such as felling and snigging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

Parameter	Description	Unit
$E_{onsiteprep,t}$	Annual emissions due to on-site preparation such as trimming of tree heads, butts, branches and defective components in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{hauling,t}$	Annual emissions due to log hauling in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{transport,t}$	Annual emissions due to log transport from collection depot to processing plant in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{processing,t}$	Annual emissions due to electricity consumption in sawmill in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{distribution,t}$	Annual emissions due to transport of the sawn product from the mill to the wharf for export or to the depot for local usage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

Ex ante baseline activity emissions $C'_{emissions,t}$ will be made using default emission factor data and activity data based on common practice in the area. The Project Proponent must ensure that the default values and activity data used are conservative.

3.4.1 Emissions Due to Harvesting Operations

Mechanical harvesting operations ($E_{harvest,t}$) of merchantable logs contributes to GHG emissions. This operation in countries containing tropical forests commonly employs chainsaws, while in other regions harvesters are commonly employed. Emissions from log harvesting are determined using the following procedure:

Step 1: For the common practice in the host country, select the typical equipment type, size and type of fuel consumed that is employed for harvesting. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.

Step 2: Find the fuel consumption (kL m^{-3}) of the selected equipment from the following data sources:

Reports on common practice for harvesting in the host country and/or manufacturers specifications

Published peer reviewed studies on harvesting operations (e.g. Klvac and Skoupy (2009) in Table B-6, Appendix B).

If a range for fuel consumption is provided, the Project Proponent is required to provide justification for their choice of fuel consumption in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

Step 3: Select the emission factor associated with the fuel employed for harvesting from IPCC default emission factors for CO_2, CH_4 and N_2O emissions for Off-Road Mobile Sources and Machinery for the Forestry Sector (IPCC, 2006, Volume 2, Chapter 3, Section 3.3.1, Table 3.3.1, p. 3.36). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 4: Emissions from harvesting of $V_{merch,t}$ are then determined by applying the following equation:

Equation 3-40

$$E_{harvest,t} = FC_{harvest} \times EF_{fuel} \times V_{merch,t}$$

Parameter	Description	Unit
$E_{harvest,t}$	Annual emissions due to harvesting operations such as felling and snigging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$FC_{harvest}$	Fuel consumption of equipment employed for felling and snigging per m^3 of merchantable log harvested	$kL\ m^{-3}$
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}
$V_{merch,t}$	Annual volume of merchantable logs in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) (see Section 3.2.3)	m^3

3.4.2 Emissions Due to On-site Preparation

Emissions due to on-site preparation ($E_{onsiteprep,t}$) such as trimming of tree heads, butts, branches and defective components are estimated using the following procedure:

Step 1: Select the typical equipment type, size and type of fuel consumed that is employed for trimming based on common practice for harvesting in the host country. For example, in tropical countries, chainsaws are commonly employed. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.

Step 2: Find the fuel consumption (kL m^{-3}) of the selected equipment from reports on common practice for harvesting in the host country and/or manufacturers specifications.

If a range for fuel consumption is provided, the Project Proponent is required to provide justification for their choice of fuel consumption factor in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

Step 3: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Off-Road Mobile Sources and Machinery for the Forestry Sector (IPCC, 2006, Volume 2, Chapter 3, Section 3.3.1, Table 3.3.1, p 3.36). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 4: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone, and choose the most applicable carbon fraction of wood from the data sources presented in Step 4 of Section 3.2.1.2.1,A. Then determine the volume of trimmings and branches using the following equation:

Equation 3-41

$$V_{branch\_trim,t} = \frac{C_{branch\_trim,t}}{CF_{wood} \times D}$$

Parameter	Description	Unit
$V_{branch\_trim,t}$	Annual volume of the trimmings and branches produced from harvesting in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
$C_{branch\_trim,t}$	Annual carbon in branches and trimmings left over from harvesting in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
CF_{wood}	Carbon fraction of wood for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}

Step 5: Emissions from on-site preparation is then determined by applying the following equation:

Equation 3-42 $$E_{onsiteprep,t} = FC_{trim\_equip} \times EF_{fuel} \times V_{branch\_trim,t}$$

Parameter	Description	Unit
$E_{onsiteprep,t}$	Annual emissions due to on-site preparation such as trimming of tree heads, butts, branches and defective components in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
FC_{trim_equip}	Fuel consumption of equipment employed for trimming per m^3 of trimmed material	kL m^{-3}
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}
$V_{branch\_trim,t}$	Annual volume of the trimmings and branches produced from harvesting in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3

3.4.3 Emissions Due to Log Hauling

Emissions associated with log hauling ($E_{hauling,t}$) to the collection depot are calculated using the following procedure:

Step 1: Select the typical equipment type, size and type of fuel consumed that is employed for hauling based on common practice for harvesting in the host country. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.

Step 2: Find the fuel consumption (kL m^{-3}) of the selected equipment from reports on common practice for harvesting in the host country and/or manufacturers specifications.

If a range for fuel consumption is provided, the Project Proponent is required to provide justification for the choice of fuel consumption factor in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

Step 3: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Off-Road Mobile Sources and Machinery for the Forestry Sector (IPCC, 2006, Volume 2, Chapter 3, Section 3.3.1, Table 3.3.1, p. 3.36). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 4: Emissions from log hauling are then determined by applying the following equation:

Equation 3-43

$$E_{hauling,t} = FC_{hauling} \times EF_{fuel} \times V_{merch,t}$$

Parameter	Description	Unit
$E_{hauling,t}$	Annual emissions due to log hauling in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$FC_{hauling}$	Fuel consumption of equipment for hauling one m^3 of merchantable log	kL m^{-3}
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}
$V_{merch,t}$	Annual volume of merchantable logs in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) (see Section 3.2.3)	m^3

3.4.4 Emissions Due to Log Transport

Emissions associated with log transport ($E_{transport,t}$) from the collection depot to the processing plant are calculated using the following procedure:

Step 1: Select the vehicle: type, load capacity (m^3 $truck^{-1}$) and type of fuel consumed for log transport based on common practice for transport in the host country. Information on harvesting practices can be found from reports on previous and existing harvesting practices in the host country.

Step 2: Determine the number of trucks required using the following equation:

Equation 3-44

$$N_{trucks\_transport,t} = \frac{V_{merch,t}}{Cap_{truck}}$$

Parameter	Description	Unit
$N_{trucks\_transport,t}$	Number of truck trips required for log transport from collection depot to processing plant in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	truck
$V_{merch,t}$	Annual volume of merchantable logs in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) (see Section 3.2.3)	m^3
Cap_{truck}	Truck load capacity	m^3 $truck^{-1}$

Step 3: Find the fuel efficiency (km kL^{-1}) of the selected vehicle from the following data sources:

(i) Manufacturers specifications

(ii) Published peer reviewed studies on harvesting operations (e.g. Kinjo et al., 2005).

If a range for fuel efficiency is provided, the Project Proponent is required to provide justification for the choice of fuel efficiency factor in the PD. If no justification can be derived, it is conservative to select the upper end of the range.

Step 4: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Road Transport (IPCC, 2006, Volume 2, Chapter 3, Section 3.2.1.2, Table 3.2.1-2, p. 3.16-3.21). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 5: Estimate the transport distance from the collection depot to the processing plant ($KM_{transport,t}$) using the digital maps of the Project Area. If transport route(s) for the baseline scenario must be hypothesised, the Project Proponent is required to provide justification for their derivation of the transport route in the PD. In addition, to be conservative, the transport route proposed must be the minimum possible route.

The total log transport distance can be determined by the following:

Equation 3-45 $$KM_{transport\_total,t} = KM_{transport,t} \times N_{trucks\_transport,t} \times 2$$

Parameter	Description	Unit
$KM_{transport\_total,t}$	Annual total log transport distance in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km
$KM_{transport,t}$	Annual log transport distance from collection depot to processing plant in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km truck^{-1}
$N_{trucks\_transport,t}$	Number of truck trips required for log transport from collection depot to processing plant in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	truck
2	Constant, indicating return trip	dimensionless

Step 6: Emissions due to log transport are then determined by applying the following equation:

Equation 3-46 $$E_{transport,t} = \frac{KM_{transport\_total,t}}{Eff_{vehicle}} \times EF_{fuel}$$

Parameter	Description	Unit
$E_{transport,t}$	Annual emissions due to log transport haulage from felling location to the collection depot/ sawmill in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$KM_{transport\_total,t}$	Annual total log transport distance in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}

3.4.5 Emissions Due to Timber Processing

Emissions as a result of processing ($E_{processing,t}$), where the processing plant is situated in the Project Area, depend on the electricity source available at the processing site. Electricity can be supplied via the national grid, or where this is not available, supplied via on-site generators. In addition, mill residue/waste may also be used as an energy source during timber processing.

To avoid double accounting, if a processing plant utilises mill residue/waste as an electricity source, then the emissions from electricity generated by mill residue/waste must not be considered here - as these emissions have already been accounted for in Section 3.3.2.1.

3.4.5.1 Emissions from processing where grid electricity is available

If grid electricity is available, then emissions due to processing will be calculated using the following procedure:

Step 1: Select an electricity demand factor (e_{demand}) for the timber processing facility from the following data sources:

(i) National electricity demand factors in relevant literature for timber processing. Various country specific electricity demand factors have been compiled in Table B-7 in Appendix B

(ii) If a national electricity demand factor is not available, select an electricity demand factor from a country that uses similar timber processing technology to that of the project's host country.

If a range for the electricity demand factor is provided, the Project Proponent is required to provide justification for the choice of electricity demand factor in the PD. If no justification can be derived, it is conservative to select the lower end of the range.

Step 2: Using the volume of merchantable logs, determine the electricity consumption required for the processing mill:

Equation 3-47 $$Q_{processing,t} = V_{merch,t} \times e_{demand}$$

Parameter	Description	Unit
$Q_{processing,t}$	Annual quantity of electricity consumption for processing in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kWh
$V_{merch,t}$	Annual volume of merchantable logs in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) (see Section 3.2.3)	m^3
e_{demand}	Electricity demand for processing per volume processed	kWh m^{-3}

Step 3: Select an emission factor for electricity for the host country from IEA (2009), CO_2 emissions per kWh from electricity and heat generation, pp. 101-103.

Step 4: Apply the following equation to determine the emissions due to processing:

Equation 3-48 $$E_{processing,t} = Q_{processing,t} \times EF_{electricity}$$

Parameter	Description	Unit
$E_{processing,t}$	Annual emissions due to electricity consumption in sawmill in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$Q_{processing,t}$	Annual quantity of electricity consumption for processing in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kWh
$EF_{electricity}$	Electricity emission factor for the host country	tCO_2-e kWh^{-1}

3.4.5.2 Emissions from processing where a generator is required

If grid electricity is not available, and an on-site generator is required to power the processing facility, then calculation of processing emissions is determined from the emissions associated with fuel consumption of the generator. Apply Steps 1 and 2 of Section 3.4.5.1 to determine the electricity consumption involved for processing ($Q_{processing,t}$). Then use the following procedure:

Step 1: Select the typical load capacity (1/4, 1/2, full load), type of fuel consumed and operating time of the generator employed to power the processing facility. Such data can be obtained from the following data sources:

(i) National reports from the relevant national forestry authority

(ii) Published peer reviewed literature on timber processing for cases of equivalent volumes and processing modes and of a country that uses similar timber processing technology to that of the project's host country.

Step 2: Determine the power rating of the generator from the electricity required for processing and the operating hours required:

Equation 3-49

$$PR_{generator,t} = \frac{Q_{processing,t}}{t_{generator,t}}$$

Parameter	Description	Unit
$PR_{generator,t}$	Power rating of generator or generator size in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kW
$Q_{processing,t}$	Annual quantity of electricity consumption for processing in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kWh
$t_{generator,t}$	Annual operating time of generator in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	h

Step 3: Using a fuel consumption chart for the generator selected for the baseline case, apply the power rating (kW) and an appropriate load capacity (1/4, 1/2, full) to determine the fuel consumption

(kL h^{-1}) of the generator. Fuel consumption charts can be found from manufacturers of generators (see Table B-8, Appendix B for an example).

Step 4: Select an emissions factor for the fuel employed in the generator from IPCC (2006), Volume 2, Chapter 2 Stationary Combustion, Table 2.5, p. 2.22.

Step 5: Apply the following equation to determine emissions due to processing:

Equation 3-50
$$E_{processing,t} = FC_{generator} \times t_{generator,t} \times EF_{fuel}$$

Parameter	**Description**	**Unit**
$E_{processing,t}$	Annual emissions due to electricity consumption in sawmill in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$FC_{generator}$	Fuel consumption per hour of operation of generator	kL h^{-1}
$t_{generator,t}$	Annual operating time of generator in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	h
EF_{fuel}	Fuel emission factor	tCO_2-e kL $^{-1}$

3.4.6 Emissions Due to Log Distribution

Emissions due to distributing logs ($E_{distribution,t}$) are calculated using the following procedure:

Step 1: Select the vehicle type, load capacity (for e.g. m^3 $truck^{-1}$) and type of fuel consumed, for log distribution based on common practice in the host country.

Step 2: Calculate the annual total volume of ltHWP to be distributed per year from the input of carbon in ltHWP pool as determined from Equation 3-27 in Section 3.3.2.2, and the most applicable density and carbon fraction of wood for a forest with corresponding climate region and ecological zone (see Section B-1 and B-2 of Appendix B).

Equation 3-51
$$V_{ltHWP,t} = \frac{C_{ltHWP_{in},t}}{D \times CF_{wood}}$$

Parameter	**Description**	**Unit**
$V_{ltHWP,t}$	Annual volume of long-term harvested wood products in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
$C_{ltHWP_{in},t}$	Annual carbon input to the long-term harvested wood products pool from sawlog in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Parameter	Description	Unit
CF_{wood}	Carbon fraction of wood for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}

Step 3: Determine the number of trucks required for distribution by dividing the long-term HWP volume by the load capacity of the vehicle:

Equation 3-52

$$N_{trucks\_distrib,t} = \frac{V_{ltHWP,t}}{Cap_{truck}}$$

Parameter	Description	Unit
$N_{trucks\_distrib,t}$	Annual number of truck trips required for log distribution from processing plant to distribution/export point in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	truck
$V_{ltHWP,t}$	Annual volume of long-term harvested wood products in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
Cap_{truck}	Truck load capacity	m^3 truck^{-1}

Step 4: Find the fuel efficiency (km kL^{-1}) of the selected vehicle from the following data sources:

(i) Manufacturers specifications

(ii) Published peer reviewed studies on harvesting operations (e.g. Kinjo et al., 2005).

If a range for fuel efficiency is provided, the Project Proponent is required to provide justification for the choice of fuel efficiency factor in the PD. If no justification can be derived, it is conservative to select the upper end of the range.

Step 5: Select the emission factor associated with CO_2, CH_4 and N_2O emissions for the fuel employed from IPCC default emission factors for Road Transport (IPCC, 2006, Volume 2, Chapter 3, Section 3.2.1.2, Table 3.2.1-2, p 3.16-3.21). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 6: Estimate the distance for distribution from the processing plant to the distribution/export point ($KM_{distrib,t}$) using digital maps. If distribution route(s) for the baseline scenario must be hypothesised, the Project Proponent is required to provide justification for the derivation of a distribution route in the PD. In addition, to be conservative, the distribution route proposed must be the minimum possible route.

The total distance for distribution can be determined by the following:

Equation 3-53 $$KM_{distribtotal,t} = KM_{distrib,t} \times N_{trucks\_distrib,t} \times 2$$

Parameter	Description	Unit
$KM_{distribtotal,t}$	Annual total distribution distance in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km
$KM_{distrib,t}$	Annual distance of transport from point of processing to distribution/export point in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km $truck^{-1}$
$N_{trucks\_distrib,t}$	Annual number of truck trips required for log distribution from processing plant to distribution/export point in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	truck
2	Constant, indicating return trip	dimensionless

Step 7: Apply the following equation to determine the emissions due to log distribution:

Equation 3-54 $$E_{distribution,t} = \frac{KM_{distribtotal,t}}{Eff_{vehicle}} \times EF_{fuel}$$

Parameter	Description	Unit
$E_{distribution,t}$	Annual emissions due to transport of the sawn product from the mill to the wharf for export or to the depot for local usage in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$KM_{distribtotal,t}$	Annual total distribution distance in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}

4 Actual Project Activity Emissions

The project activity is the introduction of forest protection without selective logging (i.e. no emissions from harvesting) - Improved Forest Management (Logged Forest to Protected Forest). However, implementing the IFM-LtPF project activity will incur quantifiable emissions. In addition, the forest in the Project Area is likely to be disturbed by natural causes such as fires, landslides, volcanoes etc. and may also be harvested illegally. The Project Proponent must take all possible measures to prevent carbon emissions from such causes and must keep detail and accurate records of emissions associated with the project activities including the monitoring of the Project Area for natural disturbances. Such records and data must be submitted along with the monitoring report to the Verifier.

Emissions associated with the actual project implementation is given by Equation 4-1, and include, but are not limited to:

- administration and planning (electricity and fuel consumption) ($E_{projplan,t}$)
- travel for design and set up (e.g. consultation and education) (fuel consumption) ($E_{design,t}$)
- travel for implementing monitoring plan (e.g. from on-the-ground forest surveillance) ($E_{monitoring,t}$)
- natural disturbances such as forest fires ($C_{natdisturb,t}$)
- illegal harvesting ($C_{illegal\_harvest,t}$) .

Equation 4-1 $$C'_{actual,t} = E_{projplan,t} + E_{design,t} + E_{monitoring,t} + \left[\left(C_{natdisturb,t} + C_{illegal\_harvest,t} \right) \times \frac{44}{12} \right]$$

Parameter	Description	Unit
$C'_{actual,t}$	Annual total carbon emissions associated with the project activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{projplan,t}$	Annual emissions due to administration and project planning in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{design,t}$	Annual emissions from travel for design and set up in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{monitoring,t}$	Annual emissions due to monitoring for field work in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C_{natdisturb,t}$	Annual carbon losses due to natural disturbance(s) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Parameter	Description	Unit
$C_{illegal\_harvest,t}$	Annual carbon losses due to illegal harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
44/12	The ratio of molecular weight of carbon dioxide to carbon, *see* Appendix C	tCO_{2}-e tC^{-1}

The Project Proponent must use the guidelines established by The Greenhouse Gas Protocol (WBCSD and WRI, 2005) to determine the boundary for accounting of the activities of the above emission sources.

Omission of any of the above emissions sources must follow the significance guidelines outlined in Section 1.2.3.

Ex ante actual project activity emissions $C'_{actual,t}$ will be made using default emission factor data and projected activity data for planning, design and monitoring based on the project implementation requirements. The Project Proponent must ensure that the default values and activity data used are conservative.

4.1 Emissions Due to Project Planning

Project planning involves administrative activities and travel. Emissions associated with project planning are calculated as follows:

Equation 4-2

$$E_{projplan,t} = E_{admin,t} + E_{plan\_travel,t}$$

Parameter	Description	Unit
$E_{projplan,t}$	Annual emissions due to administration and project planning in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{admin,t}$	Annual emissions due to electricity consumption required for administration of the project activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{plan\_travel,t}$	Annual emissions due to travel for project planning in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

4.1.1 Emissions Due to Administration

Where administration and planning operations are conducted in the project's host country, emissions from these operations will be accounted for. Emissions from such activities including data processing are estimated using the following procedure:

Step 1: Determine annual electricity consumption from the following:

(i) Electricity bills summated to determine the annual electricity consumption

(ii) Derived from logged hours of operation for electrical equipment employed for administration and planning multiplied by the power rating of the equipment, as per the following equation:

Equation 4-3

$$Q_{admin,t} = \sum_{ee=1}^{EE} PR_{equip,ee,t} \times t_{op\_equip,ee,t}$$

Parameter	Description	Unit
$Q_{admin,t}$	Annual electricity consumption due to administration of the project activity in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kWh
$PR_{equip,ee,t}$	Power rating for electrical equipment, *ee* (where e*e*=1,2,3 … *EE* pieces of equipment), in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kW
$t_{op\_equip,ee,t}$	Annual hours of operation per year of electrical equipment, e*e* (where *ee*=1,2,3 … *EE* pieces of equipment) in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	h

If administration activities occur outside the host country, they are not considered in the project accounting.

Step 2: Select an emission factor for electricity for the project's host country from data sources such as IEA (2009), CO_2 emissions per kWh from electricity and heat generation, pp. 101-103.

Step 3: Determine the emissions due to electricity consumption required for administration and planning by the following equation:

Equation 4-4

$$E_{admin,t} = Q_{admin,t} \times EF_{electricity}$$

Parameter	Description	Unit
$E_{admin,t}$	Annual emissions due to electricity consumption required for administration of the project activity in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$Q_{admin,t}$	Annual electricity consumption due to administration of the project activity in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kWh

Parameter	Description	Unit
$EF_{electricity}$	Electricity emission factor for the host country	tCO_2-e kWh^{-1}

4.1.2 Emissions Due to Travel

Emissions as a result of travel depend on the mode of transport. For project planning this will typically and principally be either aircraft or ground transportation in the equation below.

Equation 4-5

$$E_{plan\_travel,t} = E_{plan\_flight,t} + E_{plan\_ground,t}$$

Parameter	Description	Unit
$E_{plan\_travel,t}$	Annual emissions due to travel for project planning in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{plan\_flight,t}$	Annual emissions due to flights in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{plan\_ground,t}$	Annual emissions due to ground transportation in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

Note: If transportation occurs outside the host country, it will not be considered in the project accounting.

4.1.2.1 Emissions due to flights

A flight log must be maintained throughout the project lifetime to provide the information required for the emission calculations. A flight log must have the following information:

(i) Departure and destination location, or airport codes for arrival and departure

(ii) Number of passengers per trip

(iii) Type of aircraft

(iv) Date of travel.

Emissions due to flights are calculated using the following procedure:

Step 1: From the travel log, determine in year *t*, for each trip *y*, the distance required for each trip and the number of passengers.

Step 2: Using distance and/or aircraft information, select an appropriate flight emission factor from the following data sources:

(i) Published peer-reviewed studies for air transportation (e.g. Miyoshi and Mason, 2009; Babikian et al., 2002)

(ii) Relevant studies from international industry experts (e.g. Ross, 2009; DEFRA, 2008).

Step 3: Calculate the total emissions due to flights for project planning using the emission factor (with units of tCO_2-e per passenger.km) by the following equation:

Equation 4-6

$$E_{plan\_flight,t} = \sum_{y=1}^{Y} \left(KM_{plan\_flight,y,t} \times N_{plan\_flight,y,t} \times EF_{flight,y} \right)$$

Parameter	Description	Unit
$E_{plan\_flight,t}$	Annual emissions due to flights in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$N_{plan\_flight,y,t}$	Annual number of passengers per trip *y,* (where *y=1*,2,3 … *Y* trips) in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	passenger
$EF_{flight,y}$	Flight emission factor for trip, *y* (where *y*=1,2,3 … *Y* trips)	tCO_2-e (passenger.km)$^{-1}$
$KM_{plan\_flight,y,t}$	Annual distance travelled per trip *y,* (where *y*=1,2,3 … *Y* trips), in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km

4.1.2.2 Emissions due to ground transport

A ground transport log must be maintained throughout the project lifetime to provide the information required for the emission calculations. A ground travel log must have the following information for each trip taken:

(i) Departure and arrival points, or volume of fuel consumed

(ii) Type of vehicle employed

(iii) Type of fuel consumed

(iv) Date of travel.

Emissions due to ground transport are calculated using the following procedure:

Step 1: If volume of fuel consumed per trip has been recorded in the travel log, go to Step 4. If the departure and arrival destinations have been provided, determine the distance travelled for each trip, *y* ($KM_{plan\_ground,y,t}$).

Step 2: For the vehicle employed and fuel consumed, select the fuel efficiency of the vehicle from the following data sources:

(i) Manufacturers' specifications for vehicle employed

(ii) National database for vehicle specifications (e.g. Greenvehicle Guide, Australia, 2010)

Step 3: Calculate the volume of fuel consumed per trip by the following equation:

Equation 4-7

$$V_{fuel\_plan\_ground,y,t} = \frac{KM_{plan\_ground,y,t}}{Eff_{vehicle}}$$

Parameter	Description	Unit
$V_{fuel\_plan\_ground,y,t}$	Annual volume of fuel consumed per trip *y*, (where *y*=1,2,3 … *Y* trips), in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kL
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}
$KM_{plan\_ground,y,t}$	Annual distance travelled per trip *y*, (where *y*=1,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km

Step 4: From the type of fuel consumed, select the fuel emission factor(s) from the following sources:

(i) National country-specific fuel emission factors

(ii) Global fuel emission factors (e.g. IPCC (2006), Volume 2, Chapter 3, Table 3.2.1, p. 3.16 for CO_2 and Table 3.2.2, p. 3.21 for CH_4 and N_2O). Guidance for converting the emission factors to a CO_2 equivalent (CO_2-e) emission factor (EF_{fuel}) is provided in Appendix C.2. Guidance for unit conversions of fuel emission factors is provided in Appendix C.3.

Step 5: Calculate the total emissions due to ground transport for project planning by the following equations:

Equation 4-8

$$E_{plan\_ground,t} = \sum_{y=1}^{Y} \left(V_{fuel\_plan\_ground,y,t} \times EF_{fuel} \right)$$

Parameter	Description	Unit
$E_{plan\_ground,t}$	Annual emissions due to ground transportation in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$V_{fuel\_plan\_ground,y,t}$	Annual volume of fuel consumed per trip *y*, (where *y*=1,2,3 … *Y* trips), in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	kL
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}

4.2 Emissions Due to Design

Project design involves travel to the host country for stakeholder consultation(s), thus emissions associated with project design are calculated from both ground and air travel emissions:

Equation 4-9

$$E_{design,t} = E_{design\_ground,t} + E_{design\_flight,t}$$

Parameter	Description	Unit
$E_{design,t}$	Annual emissions from travel for design and set up in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{design\_ground,t}$	Annual emissions due to ground travel for the design stage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$E_{design\_flight,t}$	Annual emissions due to air travel for the design stage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

4.2.1 Emissions Due to Flights

Determine the distance, number of passengers and emission factor per trip for project design using Steps 1 to 3 in Section 4.1.2.1. Emissions from flights for project design and aerial surveillance for monitoring the Project Area can be determined as below:

Equation 4-10

$$E_{design\_flight,t} = \sum_{y=1}^{Y}\left(KM_{design\_flight,y,t} \times N_{design\_flight,y,t} \times EF_{flight,y}\right)$$

Parameter	Description	Unit
$E_{design\_flight,t}$	Annual emissions due to air travel for the design stage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$N_{design\_flight,y,t}$	Annual number of passengers per trip *y*, (where *y=1*,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	passenger
$EF_{flight,y}$	Flight emission factor for trip, *y* (where *y*=1,2,3 … *Y* trips)	tCO_2-e (passenger.km)$^{-1}$
$KM_{design\_flight,y,t}$	Annual distance travelled per trip *y*, (where *y*=1,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km

4.2.2 Emissions Due to Ground Transport

Determine the distance, vehicle fuel efficiency and fuel emission factor per trip for project design using Steps 1 to 3 in Section 4.1.2.2. Emissions from ground transport for project design and ground patrolling for monitoring the Project Area can be determine as below:

Equation 4-11 $$E_{design\_ground,t} = \sum_{y=1}^{Y}\left(\frac{KM_{design\_ground,y,t}}{Eff_{vehicle}} \times EF_{fuel}\right)$$

Parameter	Description	Unit
$E_{design\_ground,t}$	Annual emissions due to ground travel for the design stage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}
$KM_{design\_ground,y,t}$	Annual distance travelled per trip *y*, (where *y*=1,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km

4.3 Emissions Due to Monitoring

Project monitoring requires travel to the Project Area for field work, thus emissions associated with project monitoring including the aerial surveillance and ground patrolling are deduced from travel emissions:

Equation 4-12 $$E_{monitoring,t} = KM_{monitoring\_ground,t} + KM_{monitoring\_flight,t}$$

Parameter	Description	Unit
$E_{monitoring,t}$	Annual emissions due to monitoring for field work in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$KM_{monitoring\_ground,t}$	Annual emissions due to ground travel for monitoring team in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$KM_{monitoring\_flight,t}$	Annual emissions due to air travel for monitoring team in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

4.3.1 Emissions Due to Flights

Determine the distance, number of passengers and emission factor per trip for monitoring using Steps 1 to 3 in Section 4.1.2.1. Emissions from flights including aerial surveillance for monitoring can be determined as below:

Equation 4-13 $$E_{monitoring\_flight,t} = \sum_{y=1}^{Y}\left(KM_{monitoring\_flight,y,t} \times N_{monitoring\_flight,y,t} \times EF_{flight,y}\right)$$

Parameter	Description	Unit
$E_{monitoring\_flight,t}$	Annual emissions due to air travel for monitoring team in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$N_{monitoring\_flight,y,t}$	Annual number of passengers per trip *y*, (where *y*=*1*,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	passenger
$EF_{flight,y}$	Flight emission factor for trip, *y* (where *y*=1,2,3 … *Y* trips)	tCO_2-e $(passenger.km)^{-1}$
$KM_{monitoring\_flight,y,t}$	Annual distance travelled per trip *y*, (where *y*=1,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km

4.3.2 Emissions Due to Ground Transport

Determine the distance, vehicle fuel efficiency and fuel emission factor per trip for monitoring using Steps 1 to 3 in Section 4.1.2.2. Emissions from ground transport including ground patrolling for monitoring can be determined as below:

Equation 4-14

$$E_{monitoring\_ground,t} = \sum_{y=1}^{Y}\left(\frac{KM_{monitoring\_ground,y,t}}{Eff_{vehicle}} \times EF_{fuel}\right)$$

Parameter	Description	Unit
$E_{monitoring\_ground,t}$	Annual emissions due to ground travel for monitoring team in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$KM_{monitoring\_ground,y,t}$	Annual distance travelled per trip *y*, (where *y*=1,2,3 … *Y* trips) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	km
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}

4.4 Emissions Due to Natural Disturbances

Natural disturbances caused by fire (including human induced), windstorms, landslides or volcanoes can have impacts on both the extent of the forest area and the carbon. As a consequence, emissions from such disturbance must be measured and factored out of the estimation of the ex post net anthropogenic GHG emission reductions. Events due to natural disturbances will be identified using the following procedures:

- Regular familiarisation with meteorological reports of the Project Area - the frequency of monitoring is dependent on the susceptibility of the region to natural disturbances
- Analysis of best available satellite imagery to monitor the Project Area, specifically to identify and estimate the areas that have been disturbed within the Project Area
- Aerial surveillance and/or ground patrolling followed by field checking to verify the extent (area) of the damage and quantification of the GHG emissions.

Once an event has been identified, emissions attributed to that naturally disturbed area must be monitored annually over the project crediting period and must be estimated using the following procedure:

Step 1: Identify the naturally disturbed areas, $A_{nd,t}$, using satellite data and locate them at the strata level. The satellite data analysis must follow a standard procedure for remote sensing, and must be verified by a field team (e.g. Fagan and DeFries, 2009).

Step 2: Calculate the area of natural disturbance in each stratum, $A_{nd,j,t}$, using satellite data and employ a field team to conduct on-ground verification of the damaged areas by measuring the area and extent of damage.

Step 3: Obtain the growing stock per hectare for the respective stratum, *j*, where the natural disturbance has occurred and also select appropriate BCEF at the stratum level (see Step 1 of Section 3.2.1.2.2) and carbon fraction (see Step 4 of Section 3.2.1.2.1,A) and then apply the following equation to obtain the annual carbon in the naturally disturbed area(s):

Equation 4-15

$$C_{AGB\_nd,j,t} = \left[\overline{V}_{gstock,j,t=0} \times BCEF_j \times \left(\sum_{nd=1}^{ND} A_{nd,j,t} \right) \right] \times CF_{AGB}$$

Parameter	Description	Unit
$C_{AGB\_nd,j,t}$	Annual carbon in the aboveground biomass of the growing stock in the naturally disturbed area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{V}_{gstock,j,t=0}$	Average growing stock per hectare for stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m^3 ha^{-1}
$A_{nd,j,t}$	Annual area of natural disturbance *nd*, (where *nd*=1,2,3 … *ND* naturally disturbed areas) in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha

Parameter	Description	Unit
$BCEF_j$	Biomass conversion and expansion factor for converting growing stock to carbon in the aboveground biomass for stratum *j*, (where *j*=1,2,3 … *J* strata)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the forest (see Appendix B)	tC (t d.m.)$^{-1}$

Step 4: Using direct observations of the area(s) damaged, the field team must provide an estimate of the fraction of the growing stock naturally disturbed based on a comparison with an adjacent representative undisturbed forest ($f_{natdisturb,j,t}$) within the stratum, then apply the following equation:

Equation 4-16

$$C_{AGB\_nd,t} = \sum_{j=1}^{J}\left(C_{AGB\_nd,j,t} \times f_{natdisturb,j,t}\right)$$

Parameter	Description	Unit
$C_{AGB\_nd,t}$	Annual carbon losses in the aboveground biomass of the growing stock due to natural disturbance(s) in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{AGB\_nd,j,t}$	Annual carbon in the aboveground biomass of the growing stock in the naturally disturbed area in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$f_{natdisturb,j,t}$	Fraction of the growing stock naturally damaged in stratum *j* (where *j* = 1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	dimensionless

Step 5: After a natural disturbance, regrowth is likely to occur in the naturally disturbed area and hence, acts as a carbon sink. Note that the rate of regrowth in the naturally disturbed area is not the same as the rate of regrowth in the gaps created after selective harvesting under the baseline scenario. The annual carbon increase due to the regrowth in the naturally disturbed area will be calculated via Equation 4-17a.

This Methodology has accounted for the carbon in the AGB of trees (see Table 2-3 in Section 2.2.3) which conservatively estimates the carbon due to regrowth. The annual average regrowth in the AGB in the naturally disturbed area is derived by direct measurement of all trees, i.e. trees with a minimum diameter at breast height as specified by the relevant authority in the host country (see footnote ## under Table 2-3 in Section 2.2.3 of this Methodology), in the sample plots, s_{nd}, established in the naturally disturbed stratum during the monitoring event. The procedure for establishing the sample plots and the measurement techniques are described in Section 7.1.2. Number of sample plots within a stratum for regrowth measurement is determined in accordance with Pearson et al (2005) (see pp. 15-17).

The annual average regrowth post natural disturbance ($\bar{G}_{regrowth\_nd,j,t}$) is calculated based on the AGB in the naturally disturbed area estimated using Step 3 of Section 3.2.1.3.2, as follow:

(i) when the regrowth is measured for the first time in a monitoring event, the AGB at the stratum level obtained from the measurement is divided by the number of years of regrowth post natural disturbance

(ii) in subsequent monitoring events, the difference in the AGB at the stratum level between the two consecutive monitoring events are divided by the monitoring period as presented in Equation 4-17b.

Equation 4-17a

$$C_{regrowth\_nd,t} = CF_{AGB} \times \sum_{j=1}^{J} \left[\sum_{nd=1}^{ND} \left(A_{nd,j,t} \right) \times \bar{G}_{regrowth\_nd,j,t} \right]$$

Equation 4-17b

$$\bar{G}_{regrowth\_nd,j,t} = \frac{\bar{B}_{AGB\_nd,j,m_2} - \bar{B}_{AGB\_nd,j,m_1}}{\Delta m}$$

Parameter	Description	Unit
$C_{regrowth\_nd,t}$	Annual carbon increase due to the regrowth in the naturally disturbed area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\bar{G}_{regrowth\_nd,j,t}$	Average regrowth per hectare per year in the aboveground biomass after natural disturbance in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	(t d.m.) ha^{-1} yr^{-1}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the forest (see Appendix B)	tC (t d.m.)$^{-1}$
$A_{nd,j,t}$	Annual area of natural disturbance *nd*, (where *nd*=1,2,3 … *ND* naturally disturbed areas) in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)^^	ha
$\bar{B}_{AGB\_nd,j,m_2}$	Average aboveground biomass of the trees in the area of natural disturbance *nd*, (where *nd*=1,2,3 … *ND* naturally disturbed areas) in stratum *j*, (where *j*=1,2,3 … *J* strata) in year, m_2 - when current monitoring event occurs	(t d.m.) ha^{-1}

Parameter	Description	Unit
$\bar{B}_{AGB\_nd,j,m_1}$	Average aboveground biomass of the trees in the area of natural disturbance *nd*, (where *nd*=1,2,3 … *ND* naturally disturbed areas) in stratum *j*, (where *j*=1,2,3 … *J* strata) in year, m_1- when preceding monitoring event occurred	(t d.m.) ha^{-1}
Δm	Monitoring period, the time taken between two consecutive monitoring events	yr

Step 6: In the case of a natural disturbance such as fire, CH_4, N_2O and CO_2 gases are generated. The emissions of the non-CO_2 gases can be estimated based on the total carbon emitted, as suggested by the IPCC GPG for LULUCF (IPCC, 2003, Chapter 3, Equation 3.2.19, p. 3.49). Emission ratios for CH_4 and N_2O can be obtained from IPCC (2003) in Table 3A.1.15 and an appropriate ratio for nitrogen-to-carbon ($R_{N/C}$) for the material burnt must be used. If the specific $R_{N/C}$ cannot be found, a default value of 0.01 that applies to leaf litter can be used instead, noting that lower values would be appropriate for woody material (IPCC, 2003, Chapter 3, p. 3.50). The emissions of both CH_4 and N_2O are then estimated by applying the following equations:

Equation 4-18a $$E_{CH_4,t} = C_{AGB\_nd,t} \times R_{CH_4} \times \frac{16}{12}$$

Equation 4-18b $$E_{N_2O,t} = C_{AGB\_nd,t} \times R_{N/C} \times R_{N_2O} \times \frac{44}{28}$$

Parameter	Description	Unit
$E_{CH_4,t}$	Annual emissions due to CH_4 in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCH_4
$C_{AGB\_nd,t}$	Annual carbon losses in the aboveground biomass of the growing stock due to natural disturbance(s) in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
R_{CH_4}	Emission ratio for CH_4	dimensionless
$E_{N_2O,t}$	Annual emissions due to N_2O in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tN_2O
$R_{N/C}$	Ratio of nitrogen to carbon	tN tC^{-1}
R_{N_2O}	Emission ratio for N_2O	dimensionless

Parameter	Description	Unit
$16/12$	The ratio of molecular weight of CH_4 to carbon	tCH_4 tC^{-1}
$44/28$	The ratio of molecular weight of N_2O to N	tN_2O tN^{-1}

Step 7: Select the most current Global Warming Potentials (GWPs) for CH_4 and N_2O from UNFCCC documents and apply the GWPs in the following equation to aggregate the carbon emissions from the non-CO_2 gases. See also Section 2.2.4.1 Table 2.4 for more information. Then apply the following equation:

Equation 4-19

$$C_{CH_4N_2O,t} = \left(E_{CH_4,t} \times GWP_{CH_4} + E_{N_2O,t} \times GWP_{N_2O} \right) \times \frac{12}{44}$$

Parameter	Description	Unit
$C_{CH_4N_2O,t}$	Annual carbon from CH_4 and N_2O emissions in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$E_{CH_4,t}$	Annual emissions due to CH_4 in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCH_4
GWP_{CH_4}	Global warming potential of CH_4	tCO_2-e tCH_4^{-1}
$E_{N_2O,t}$	Annual emissions due to N_2O in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tN_2O
GWP_{N_2O}	Global warming potential of N_2O	tCO_2-e tN_2O^{-1}
$12/44$	The ratio of molecular weight of carbon to carbon carbon dioxide, see Appendix C	tC tCO_2-e^{-1}

Step 8: Calculate the total carbon emissions due to natural disturbances by using the outputs from Equations 4-16, 4-17a and 4-19. If natural disturbance is caused by an event other than fire, non-CO2 gases (CH_4 and N_2O) would not be produced. Hence the terms from Equations 4-17a and 4-19 would be zero. The regrowth in the naturally disturbed area is subtracted because it is considered as a carbon sink in this equation.

Equation 4-20

$$C_{natdisturb,t} = \sum_{t=1}^{t*} \left(C_{AGB\_nd,t} - C_{regrowth\_nd,t} + C_{CH_4N_2O,t} \right)$$

Parameter	Description	Unit
$C_{natdisturb,t}$	Annual total carbon losses due to natural disturbance(s) in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{AGB\_nd,t}$	Annual carbon losses in the aboveground biomass of the growing stock due to natural disturbance(s) in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{regrowth\_nd,t}$	Annual carbon increase due to the regrowth in the naturally disturbed area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$C_{CH_4N_2O,t}$	Annual carbon from CH_4 and N_2O emissions in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

Ex ante estimations for natural disturbances will be made based on the likely scenario in the Project Area. The Project Proponent must justify the likely scenario of natural disturbances using the historical data from satellite imagery or regional/local documentation from the relevant authority.

4.5 Emissions Due to Illegal Harvesting

Under the IFM-LtPF project scenario, the Project Area is completely protected and the Project Proponent must stop selective harvesting operation as well as harvesting by other agents of deforestation. All harvesting operations in the Project Area during the Project Crediting Period are considered as illegal harvesting. Ex ante estimations for illegal harvesting will be made based on the likely scenario in the Project Area. The Project Proponent must justify the likely scenario of illegal harvesting using the historical data from satellite imagery or regional/local documentation from the relevant authority. Ex post calculation for emissions due to illegal harvesting is described below for two different scenarios depending upon the method of data collected: the field inventory method or using satellite data must be used.

4.5.1 Field Inventory Method

Where field teams are able to collect data on the quantity of wood illegally harvested from the Project Area through observation or interviews based on Participatory Rural Appraisal techniques (e.g. see Surhone et al., 2010) carbon losses are quantified using the following procedure:

Step 1: Quantify the total volume of wood illegally harvested in the Project Area through field surveys ($V_{illegal\_harvest,t}$) by measuring the stump diameter and developing species specific model to predict tree volumes based on the relevant peer reviewed literature (e.g. Corral-Rival et al., 2007)

Step 2: Choose the most applicable biomass expansion factor (BEF) value from the following data sources:

(i) National factor (e.g. from National GHG Inventory)

(ii) Default IPCC factor (see IPCC, 2003, Table 3A.1.10; and IPCC, 2006, Table 4.5)

It is noteworthy that the BEF values in IPCC literature and national GHG inventory are usually applicable to closed canopy forest. If applied to individual trees growing in an open field, the selected BEF value be increased by a further 30 percent (CDM-EB, 2009, p. 24).

Step 3: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone (see Appendix B, Section B.1, Table B-1).

Step 4: Find the appropriate factor for residual stand damage (f_{RSD}), and carbon fraction (Step 4 of Section 3.2.1.2.1,A) and apply the following equation (which has been based on IPCC (2003), Equation 3.2.7, p. 3.27) to obtain the total carbon due to illegal harvesting in the Project Area:

Equation 4-21

$$C_{illegal\_harvest,t} = V_{illegal\_harvest,t} \times \left(1 + f_{RSD}\right) \times BEF \times D \times CF_{AGB}$$

Parameter	Description	Unit
$C_{illegal\_harvest,t}$	Annual carbon losses due to illegal harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$V_{illegal\_harvest,t}$	Annual volume of wood sold as determined from field surveys in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
BEF	Biomass expansion factor for converting volume of extracted roundwood to total aboveground biomass (including bark)	(t d.m.) m^{-3}
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$
f_{RSD}	Factor for residual stand damage, based on the fraction of quantity of carbon damaged in the residual stand to the quantity of carbon in the total merchantable logs harvested	dimensionless

4.5.2 Using Satellite Data

Where high resolution satellite data are used, carbon losses are quantified by:

Step 1: Identify and calculate the illegally harvested areas ($A_{illegal\_harvest,t}$) using satellite data and locate them at the strata level. The satellite data analysis must follow a standard procedure (e.g. Skole et al., 1998), and must be verified by a field team or teams.

Step 2: Verify the areas by sending a field team or teams.

Step 3: Obtain the growing stock per hectare for the respective stratum, *j*, where the illegal harvesting has occurred and also select appropriate BCEF (Step 1 of Section 3.2.1.2.2) and carbon fraction (Step 4 of Section 3.2.1.2.1,A) and then apply the following equation to obtain the total carbon per year due to illegal harvesting:

Equation 4-22

$$C_{illegal\_harvest,t} = \sum_{j=1}^{J}\left[\overline{V}_{gstock,j,t=0} \times BCEF_j \times \left(\sum_{il=1}^{IL} A_{illegal\_harvest,j,t}\right)\right] \times CF_{AGB}$$

Parameter	Description	Unit
$C_{illegal\_harvest,t}$	Annual carbon losses due to illegal harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\overline{V}_{gstock,j,t=0}$	Average growing stock per hectare for stratum *j*, (where *j*=1,2,3 … *J* strata) determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ ha^{-1}$
$A_{illegal\_harvest,j,t}$	Annual area of illegal harvest *il* (where *il*=1,2,3 … *IL* illegal harvested areas) in stratum *j*, (where *j*=1,2,3 … *J* strata) in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	ha
$BCEF_j$	Biomass conversion and expansion factor for converting growing stock to the aboveground biomass for stratum *j*, (where *j*=1,2,3 … *J* strata)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

5 Leakage Assessment and Management

5.1 Identifying Leakage

The objective of leakage assessment and management is to provide an ex post estimate of the actual decrease in carbon and increase in GHG emissions (other than carbon changes) that arise as a result of the implementation of the project activity. Where an increase in GHG emissions occurs outside a project's boundary but is measurable and attributable to the project activity, this is known as project leakage and the associated emissions in tonnes of CO_2-e per year are termed $C'_{leakage,t}$.

For an IFM-LtPF project activity, there are two sources of leakage that need to be considered and addressed in this Methodology:

(i) Carbon from degradation due to shifting of the baseline activity, $CL_{activityshifting,t}$ i.e. removal of harvested wood products including sawlog, pulplog and commercially harvested fuel wood and emissions from the associated activities outside the Project Area, $CL'_{emissions,t}$

(ii) Carbon from market leakage $CL_{market,t}$, due to shifts in supply and demand of the products and services affected by the project activity, which in this case is the supply and demand of timber.

On this basis, project leakage is the combined total of the above leakage parameters:

Equation 5-1

$$C'_{leakage,t} = (CL_{activityshifting,t} + CL_{market,t}) \times \frac{44}{12} + CL'_{emissions,t}$$

Parameter	Description	Unit
$C'_{leakage,t}$	Annual total carbon emissions associated with leakage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$CL_{activityshifting,t}$	Annual carbon losses due to baseline activity shifting in other lands managed or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$CL_{market,t}$	Annual carbon due to market leakage effects in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$CL'_{emissions,t}$	Annual emissions due to implementation of the shifted baseline activity in other lands managed or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
44/12	The ratio of molecular weight of carbon dioxide to carbon, *see* Appendix C	tCO_2-e tC^{-1}

The emissions determined in $C'_{leakage,t}$ are subsequently accounted for in the net anthropogenic GHG emissions for the IFM-LtPF project (Equation 1-1).

5.2 Leakage Due to Activity Shifting

Any activity shifting due to selective logging which includes removal of harvested wood projects comprising sawlog, pulplog and commercially harvested fuel wood by the Project Proponent must be assessed as a component of leakage.

Activity shifting leakage situations become evident where the Project Proponent has:

(i) Intensified operations for selective logging, i.e. has legal authorisation for selective logging and increase logging operations in other owned and/or operated lands to recover the harvesting loss due to the IFM-LtPF project; or

(ii) Shifted operations for selective logging from the Project Area to another forest area within the host country.

The Project Proponent must provide documentation for the potential leakage areas due to activity shifting i.e. other lands owned and/or operated by the Project Proponent, including geo-referenced or digital maps illustrating the physical location(s) and their boundaries, existing land uses and management plans at each verification period. When this documentation has been provided, the carbon losses from activity shifting, $CL_{activityshifting,t}$, can be assessed as described in the following sections.

Equation 5-2 $$CL_{activityshifting,t} = CL_{IH\_activityshifting,t} + CL_{SH\_activityshifting,t}$$

Parameter	Description	Unit
$CL_{activityshifting,t}$	Annual carbon losses due to baseline activity shifting in other lands managed or operated by the Project Proponent in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$CL_{IH\_activityshifting,t}$	Annual carbon losses from activity shifting due to intensification of harvest volumes in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$CL_{SH\_activityshifting,t}$	Annual carbon losses from activity shifting due to shifting of harvest to new area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

5.2.1 Intensification of Logging Operations

Activity shifting leakage through intensification of logging operations including removal of sawlog, pulplog and commercially harvested fuel wood is considered where the actual merchantable logs' volume in lands currently owned and/or operated by the Project Proponent (but not part of the Project Area) since the commencement date of the IFM-LtPF project activity, exceeds the common practice volumes. To identify and determine the carbon due to the intensification of logging operations, use the following procedure:

Step 1: Assign a historical reference period of five years (Refer to Section 2.2.2.3) where the harvesting operations have occurred over five years. In the case where harvesting operations have been conducted for less than five years, the harvest volume data from the forest with comparable situations and conditions at the local or regional or national level (with conservative value) shall be used. The Project Proponent shall provide the data source and collection method for the common harvest volume from the forest comparable situations and conditions to the Verifier along with the monitoring report for verification.

Step 2: Obtain the annual volume of harvest for each land *l*, currently owned and/or operated by the Project Proponent or the forest land with comparable situations and conditions at the local or regional or national level (with conservative value), for each historical reference year *k*, over the historical reference period *K*.

Step 3: Determine the average volume of harvest for each land *l*, currently owned and/or operated by the Project Proponent using the following equation:

Equation 5-3 $$V_{historical\_harvest,l,t=0} = \frac{\sum_{k=1}^{K} V'_{historical\_harvest,l,k}}{K}$$

Parameter	Description	Unit
$V_{historical\_harvest,l,t=0}$	Average volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent or the forest with comparable situations and conditions at local or regional or national level over the historical reference period *K*, determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	m^3 yr^{-1}
$V'_{historical\_harvest,l,k}$	Total volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent during the historical reference year *k*, (where *k*=1,2,3 … *K* historical reference years)	m^3
K	Historical reference period (see Section 2.2.2.3) or actual number of years of harvesting operation	yr

Step 4: Compare the annual actual volume of harvest in year *t* (years elapsed since the start of the IFM-LtPF project activity) with the average volume of harvest over the historical reference period determined ex ante, for each land *l*.

One of the following three situations would occur:

Equation 5-4 $V_{historical\_harvest,l,t=0} > V_{actual\_harvest,l,t}$ $\Rightarrow$ **No Leakage**

Equation 5-5 $V_{historical\_harvest,l,t=0} = V_{actual\_harvest,l,t}$ $\Rightarrow$ **No Leakage**

Equation 5-6 $V_{historical\_harvest,l,t=0} < V_{actual\_harvest,l,t}$ $\Rightarrow$ **Leakage**

Parameter	Description	Unit
$V_{historical\_harvest,l,t=0}$	Average volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent over the historical reference period *K*, determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ yr^{-1}$
$V_{actual\_harvest,l,t}$	Annual actual volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	$m^3\ yr^{-1}$

Step 5: If there is leakage (i.e. Equation 5-6 is true), the total leakage in terms of the merchantable logs' volume is calculated as follows:

Equation 5-7 $$V_{IH\_activityshifting,t} = \sum_{l=1}^{L}\left(V_{actual\_harvest,l,t} - V_{historical\_harvest,l,t=0}\right)$$

Parameter	Description	Unit
$V_{IH\_activityshifting,t}$	Annual total intensification of harvest volume per year in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
$V_{actual\_harvest,l,t}$	Annual actual volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	$m^3\ yr^{-1}$
$V_{historical\_harvest,l,t=0}$	Average volume of harvest for land *l*, (where *l*=1,2,3 … *L* lands), that is owned and/or operated by the Project Proponent over the historical reference period *K*, determined ex ante - before the start of the IFM-LtPF project activity, hence *t*=0 year	$m^3\ yr^{-1}$

Step 6: Choose the most applicable BEF value from the data sources presented in Step 2 of Section 4.5.1

Step 7: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone (see Appendix B, Section B.1, Table B-1).

Step 8: Select an appropriate factor for residual stand damage (f_{RSD}) (use Table B-3, section B.3, Appendix B) and carbon fraction (see Step 4 of Section 3.2.1.2.1,A) and apply the following equation to get the carbon loss due to intensification of harvest volumes:

Equation 5-8 $$CL_{IH\_activityshifting,t} = V_{IH\_activityshifting,t} \times \left(1 + f_{RSD}\right) \times BEF \times D \times CF_{AGB}$$

Parameter	Description	Unit
$CL_{IH\_activityshifting,t}$	Annual carbon losses from activity shifting due to intensification of harvest volumes in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$V_{IH\_activityshifting,t}$	Annual total intensification of harvest volume per year in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
f_{RSD}	Factor for residual stand damage, based on the fraction of quantity of carbon damaged in the residual stand to the quantity of carbon in the total merchantable logs harvested	dimensionless
BEF	Biomass expansion factor for converting volume of extracted roundwood to total aboveground biomass (including bark)	dimensionless

Parameter	Description	Unit
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

5.2.2 Shifted Logging Operations

Activity shifting leakage due to shifted harvesting to a new forest area can be confirmed where documentation of the management plans and/or land-use designations reveal that the Project Proponent has commenced harvesting operation in any new land logged during the crediting period after the start date of the IFM-LtPF project. When this is the case, the carbon losses due to harvest shifting can be determined using the following procedure:

Step 1: Obtain the volume of harvest in the new area from management plans ($V_{SH\_activityshifting,t}$)

Step 2: Choose the most applicable BEF value from the data sources presented in Step 2 of Section 4.5.1

Step 3: Choose the most applicable wood density for a forest with corresponding climate region and ecological zone (see Appendix B, Section B.1, Table B-1)

Step 4: Select an appropriate factor for residual stand damage (f_{RSD}) (use Table B-3, Section B.3, Appendix B) and carbon fraction (see Step 4 of Section 3.2.1.2.1,A) and apply the following equation to get the carbon loss due to shifted logging operations:

Equation 5-9

$$CL_{SH\_activityshifting,t} = V_{SH\_activityshifting,t} \times \left(1 + f_{RSD}\right) \times BEF \times D \times CF_{AGB}$$

Parameter	Description	Unit
$CL_{SH\_activityshifting,t}$	Annual carbon losses from activity shifting due to shifting of harvest to new area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$V_{SH\_activityshifting,t}$	Annual shifted harvest volume for new area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	m^3
f_{RSD}	Factor for residual stand damage, based on the fraction of quantity of carbon damaged in the residual stand to the quantity of carbon in the total merchantable logs harvested	dimensionless
BEF	Biomass expansion factor for converting volume of extracted roundwood to total aboveground biomass (including bark)	dimensionless
D	Wood density for the tropical forest with corresponding climate region and ecological zone (see Appendix B)	(t d.m.) m^{-3}
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest (see Appendix B)	tC (t d.m.)$^{-1}$

5.2.3 Shifted Baseline Activity Emissions

Following Section 5.2.1.1, if Equation 5-6 is true, implying that harvesting has intensified, and/or shifted operations for logging have been confirmed in Section 5.2.1.2, it implies leakage due to activity shifting of the baseline scenario has occurred. Consequently, emissions associated with implementation of the shifted baseline activity must be accounted for and determined using the same approach as presented in Section 3.4 for determining baseline activity emissions. In this case, the parameters *E* are replaced with *L* in Equation 3-54 to distinguish between the baseline and leakage scenarios:

Equation 5-10

$$CL'_{emissions,t} = L_{harvesting,t} + L_{onsiteprep,t} + L_{hauling,t} + L_{transport,t} + L_{processing,t} + L_{distribution,t}$$

Parameter	Description	Unit
$CL'_{emissions,t}$	Annual emissions due to implementation of the shifted baseline activity in other lands managed or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{harvesting,t}$	Annual shifted emissions due to harvesting operations such as felling and snigging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{onsiteprep,t}$	Annual shifted emissions due to on-site preparation such as trimming of tree heads, butts, branches and defective components in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{transport,t}$	Annual shifted emissions due to log transport from collection depot to processing plant in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{hauling,t}$	Annual shifted emissions due to log hauling in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{processing,t}$	Annual shifted emissions due to electricity consumption in sawmill in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$L_{distribution,t}$	Annual shifted emissions due to transport of the sawn product from the mill to the wharf for export or to the depot for local usage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

5.3 Market Leakage

Market effects due to the presence of an IFM-LtPF project could occur in two main ways:

(i) Intensification of existing harvest practices

(ii) Formation of new enterprises and hence new (or modified existing) FIRs for sanctioned selective logging.

The Project Proponent must demonstrate how market leakage has been accounted for in accordance with the most recent version of applicable VCS rules.

6 Uncertainty Assessment

The assessment of uncertainty is a required component of quality management procedures for the management of data and information (see Section 7.3). It is considered necessary that the Project Proponent identify the parameters that significantly affect the accuracy of the calculated emission reductions in order to reduce uncertainties related to the quantification of GHG emission reductions or removal enhancements. A procedure for the estimation of uncertainty of the GHG emission reductions arising from an IFM-LtPF project is presented in this section.

6.1 Identifying Uncertainty

In general, estimations of emission reductions that are a result of emissions and removals from IFM activities have various sources of uncertainties. Typically these uncertainties are associated with sample data, such as height and diameter measurements from PSPs, biomass growth and rates of decay, activity data, emission factors, and other coefficients (e.g. lumber recovery factor).

The values of the uncertainties associated with these parameters are derived from a number of different sources:

(i) IPCC (2006) default data and guidelines

(ii) Statistical sampling

(iii) Expert judgement with justification.

Where the uncertainty of a parameter is not known, the value of the parameter will be assigned a value that is indisputably conservative, eliminating the corresponding uncertainty.

6.1.1 Calculating Uncertainty

In accordance with IPCC best practice, the methodology requires the use of 95% confidence interval for quantification of random errors (IPCC, 2006, Volume 1, Chapter 3, p. 3.6 and 3.9).

A simple approach to determine the uncertainty value of the overall emission reductions from the uncertainties of the individual components, is based on the basic error propagation rule set outlined below:

Rule 1

The uncertainty or absolute error for a function, z = x + y, where σ_x and σ_y represent the absolute error for x and y, respectively, is determined by the following:

Equation 6-1

$$\sigma_z = \sqrt{\sigma_x^2 + \sigma_y^2}$$

Rule 2

The uncertainty or absolute error for a function, $fn = x \times y \times z$, where σ_x, σ_y and σ_z represent the absolute error for x, y and z, respectively, is determined by the following:

Equation 6-2

$$\sigma_{fn} = \sqrt{\left[\frac{\partial f}{\partial x}\sigma_x\right]^2 + \left[\frac{\partial f}{\partial y}\sigma_y\right]^2 + \left[\frac{\partial f}{\partial z}\sigma_z\right]^2}$$

The relative error, or percentage error (U) is determined, for function, *fn*, as an example, via the following:

Equation 6-3

$$U_{fn} = \frac{\sigma_{fn}}{fn} \times 100$$

Project Proponents seeking more detailed guidance for combining uncertainties will find it provided in IPCC (2006), Volume 1, Chapter 3, Section 3.2.3, p. 3.27. The above method has been presented for the parameters specific to the IFM-LtPF project in the subsequent sections.

6.2 Overall IFM-LtPF Project Uncertainty

The net anthropogenic GHG emission reductions of the IFM-LtPF project activity, is deduced from the subtraction of the actual project emissions ($C'_{actual,t}$) and the leakage emissions ($C'_{leakage,t}$) from the proposed baseline emissions ($C'_{baseline,t}$), as presented in Equation 1-1 in Section 1.2.1.

An estimation of the overall uncertainty for the IFM-LtPF project is deduced by error propagation using the following equation:

Equation 6-4

$$\sigma_{IFM-LtPF,t} = \sqrt{(\sigma_{baseline,t})^2 + (\sigma_{actual,t})^2 + (\sigma_{leakage,t})^2}$$

Parameter	Description	Unit
$\sigma_{IFM-LtPF,t}$	Annual uncertainty (absolute error) for the overall IFM-LtPF project in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{baseline,t}$	Annual uncertainty in the annual total GHG emissions as a result of the baseline scenario in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{actual,t}$	Annual uncertainty in the actual (project) activity in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{leakage,t}$	Annual uncertainty in leakage in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

To track the changes in uncertainty associated with the IFM-LtPF activity, it is appropriate to use the relative uncertainty instead of the absolute. The relative error, or percentage error is expressed using the following equation:

Equation 6-5

$$U_{IFM-LtPF,t} = \frac{\sigma_{IFM-LtPF,t}}{C'_{IFM\_LtPF,t}} \times 100$$

Parameter	Description	Unit
$U_{IFM-LtPF,t}$	Annual uncertainty (relative error) for the overall IFM-LtPF project in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	%
$\sigma_{IFM-LtPF,t}$	Annual uncertainty (absolute error) for the overall IFM-LtPF project in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$C'_{IFM\_LtPF,t}$	Annual net anthropogenic GHG emission reductions in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

6.3 Uncertainty in Baseline Accounting

The total uncertainty related to the baseline scenario (see Equation 3-1) is a propagation of error associated with the uncertainty of the degradation plus the uncertainty in the estimation of emission sources due to the implementation of the baseline case, and is expressed using the following equation:

Equation 6-6

$$\sigma_{baseline,t} = \sqrt{\left(\sigma_{degradation,t}\right)^2 + \left(\sigma_{emissions,t}\right)^2}$$

Parameter	Description	Unit
$\sigma_{baseline,t}$	Annual uncertainty in the annual total GHG emissions as a result of the baseline scenario in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{degradation,t}$	Annual uncertainty in the annual emissions produced from degradation due to the baseline activity: selective logging in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{emissions,t}$	Annual uncertainty in the annual emissions from the baseline activity: selective logging operations in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

6.3.1 Degradation Uncertainty

The uncertainty associated with degradation in the baseline scenario (see Equation 3-2) is a propagation of errors of the individual components contributing to degradation and is expressed using the following equation:

Equation 6-7

$$\sigma_{degradation,t} = \left[\left(\sqrt{\left(\sigma_{DW_{decay},t}\right)^2 + \left(\sigma_{ltHWP_{oxidation},t}\right)^2 + \left(\sigma_{stHWP_{oxidation},t}\right)^2 + \left(\sigma_{growth\_foregone,t}\right)^2 + \left(\sigma_{regrowth,t}\right)^2} \right) \times \frac{44}{12} \right]$$

Parameter	Description	Unit
$\sigma_{degradation,t}$	Annual uncertainty in the annual emissions produced from degradation due to the baseline activity: selective logging in the Project Area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{DW_{decay},t}$	Annual uncertainty in carbon from the deadwood (DW) pool due to decay in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{ltHWP_{oxidation},t}$	Annual uncertainty in carbon from the long-term harvested wood products (ltHWP) pool due to oxidation in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{stHWP_{oxidation},t}$	Annual uncertainty in carbon from the short-term harvested wood products (stHWP) pool due to oxidation in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{growth\_foregone,t}$	Annual uncertainty in the carbon lost due to growth foregone in the annual net harvest area in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{regrowth,t}$	Annual uncertainty in the carbon increase in the biomass due to regrowth following logging in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
44/12	The ratio of molecular weight of carbon dioxide to carbon, *see* Appendix C	tCO_2-e tC^{-1}

6.3.2 Baseline Emission Sources Uncertainty

The uncertainty due to emissions from the implementation of the baseline case is determined as follows:

Equation 6-8 $$\sigma_{emissions,t} = \sqrt{\sum_{g=1}^{G} \sigma^2_{baseline\_source,g,t}}$$

Parameter	Description	Unit
$\sigma_{emissions,t}$	Annual uncertainty in the annual emissions from the baseline activity: selective logging operations in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{baseline\_source,g,t}$	Annual uncertainty in the greenhouse gas emissions sources *g*, (where *g*=1,2,3 … *G* emission sources) associated with the baseline activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

6.4 Uncertainty in Actual Project Accounting

The uncertainty associated with the emissions due to the implementation of the actual project activity can be tracked through error propagation related to the individual project activity emission sources as outlined by the following:

Equation 6-9 $$\sigma_{actual,t} = \sqrt{\sum_{g=1}^{G} \sigma^2_{proj\_source,g,t}}$$

Parameter	Description	Unit
$\sigma_{actual,t}$	Annual uncertainty in the actual project activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{proj\_source,g,t}$	Annual uncertainty in the greenhouse gas emissions sources *g*, (where *g*=1,2,3 … *G* emission sources) associated with the actual project activity in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

6.5 Uncertainty in Leakage Accounting

The uncertainty associated with leakage takes into account uncertainty in the estimations of emissions due to activity shifting ($CL_{activityshifting,t}$), illegal harvesting ($CL_{illegal\_harvest,t}$), natural disturbances ($CL_{natural\_disturb,t}$) implementation of the shifted baseline activity ($CL'_{emissions,t}$), and market effects ($CL_{market,t}$).

Equation 6-10

$$\sigma_{leakage,t} = \left(\sqrt{(\sigma_{activityshifting,t})^2 + (\sigma_{market,t})^2 + (\sigma_{illegal\_harvest,t})^2 + (\sigma_{natural\_disturb,t})^2 + \left(\sigma_{CL'\_emissions,t} \times \frac{12}{44}\right)^2} \right) \times \frac{44}{12}$$

Parameter	Description	Unit
$\sigma_{leakage,t}$	Annual uncertainty in leakage in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$\sigma_{activityshifting,t}$	Annual uncertainty associated with carbon due to activity shifting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{market,t}$	Annual uncertainty associated with carbon due to market effects in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{illegal\_harvest,t}$	Annual uncertainty associated with carbon due to illegal harvesting in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{natural\_disturb,t}$	Annual uncertainty associated with carbon due to natural disturbances in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$\sigma_{CL'\_emissions,t}$	Annual uncertainty associated with emissions due to implementation of the shifted baseline activity in other lands managed or operated by the Project Proponent in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity); this parameter has been multiplied by 12/44 for conversion into tC	tCO_2-e
44/12	The ratio of molecular weight of carbon dioxide to carbon, *see* Appendix C	tCO_2-e tC^{-1}

6.6 Uncertainty Deduction

Upon establishing the uncertainty percentage using Equation 6-5, apply the following procedure:

Step 1: If $U_{IFM-LtPF,t} \leq 10\%$, then no deduction will be applied for uncertainty. The Project Proponent shall proceed to Section 6.7 to further reduce uncertainty associated with parameters.

Step 2: If $U_{IFM-LtPF,t} > 10\%$, then apply the following equation:

Equation 6-11

$$CC_{IFM-LtPF,t} = \frac{100 - (U_{IFM-LtPF,t} - 10)}{100} \times C'_{IFM-LtPF,t}$$

Parameter	Description	Unit
$CC_{IFM-LtPF,t}$	Annual carbon credits post uncertainty deduction in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$U_{IFM-LtPF,t}$	Annual uncertainty (relative error) for the overall IFM-LtPF project in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	%
$C'_{IFM\_LtPF,t}$	Annual net anthropogenic GHG emission reductions in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

After applying Equation 6-11, the Project Proponent proceeds to Section 6.7 to further reduce uncertainty associated with parameters, so as to maximise the estimates of carbon credits.

6.7 Reducing Uncertainty

Reducing the uncertainty associated with the net anthropogenic GHG emission reductions of the IFM-LtPF project activity can be achieved by identifying the parameters contributing the greatest to the uncertainty and conducting appropriate procedures to reduce the uncertainty of these parameters. This will be achieved using the following procedure:

Step 1: For each parameter used to calculate the net anthropogenic GHG emission reductions, e.g. $C'_{baseline,t}$, $C'_{actual,t}$, and $C'_{leakage,t}$, derive the ratio of the uncertainty of each contributing parameter over the main parameter. For example, to determine the ratio of the uncertainty of the individual components of the baseline scenario: degradation and baseline activity emissions, the following ratios must be derived:

Equation 6-12

$$R_{degradation,t} = \frac{\sigma_{degradation,t}}{\sigma_{baseline,t}}$$

Equation 6-13

$$R_{emissions,t} = \frac{\sigma_{emissions,t}}{\sigma_{baseline,t}}$$

Parameter	Description	Unit
$R_{degradation,t}$	Annual ratio of uncertainty of emissions due to degradation over uncertainty of the annual total GHG emissions of the baseline scenario in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	dimensionless
$\sigma_{degradation,t}$	Annual uncertainty in the annual emissions produced from degradation due to the baseline activity: selective logging in the Project Area in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

Parameter	Description	Unit
$\sigma_{baseline,t}$	Annual uncertainty in the annual total GHG emissions as a result of the baseline scenario in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e
$R_{emissions,t}$	Annual ratio of uncertainty of emissions due to implementation of baseline activity over uncertainty of the annual total GHG emissions of the baseline scenario in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	dimensionless
$\sigma_{emissions,t}$	Annual uncertainty in the annual emissions from the baseline activity: selective logging operations in year *t,* (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tCO_2-e

Step 2: Identify the parameters with the highest ratios and using the same procedure as in Step 1, investigate the parameters contributing to the identified parameter. Continue this process for all calculated/derived parameters until only sourced/measured parameters remain.

Step 3: For the sourced parameters identified as the greatest contributors to uncertainty from Step 2, analyse the source of the parameter value and the associated uncertainty.

If the parameter is either a default IPCC value or sourced from literature:

(i) Can the accuracy of the parameter and hence the range of the uncertainty be reduced by selecting another appropriate data source? If yes, provide justification and new data source

(ii) If no, can a project-specific parameter be measured? If yes, provide a description of the procedure and incorporate into the Monitoring Plan

(iii) If no, summarise justification on why the uncertainty of the parameter cannot be improved upon.

If the parameter is a project-specific measured value:

(i) Can the accuracy of the parameter and hence the range of the uncertainty be reduced by increasing the statistical sampling? If yes, provide statistical requirements and incorporate into Monitoring Plan

(ii) If no, summarise justification on why the uncertainty of the parameter cannot be improved upon.

Step 4: Once uncertainty revisions have been conducted, re-calculate the net anthropogenic emission reductions, $C'_{IFM-LtPF}$, and follow Sections 6.2 to 6.5 to calculate the revised uncertainty for the net anthropogenic GHG emission reductions of the IFM-LtPF project activity using Equations 6-4 and 6-5. Compare revised percentage with the previous.

Step 5: Follow Steps 1 and 2 in Section 6.6 and where required, account for uncertainty deduction using Equation 6-11.

7 Monitoring

7.1 Monitoring Methodology

This section provides the methodology for monitoring the parameters employed to calculate carbon changes due to forest degradation, as well as emissions due to implementation of the project and baseline activities, plus emissions as a result of leakage.

In addition, the procedures for establishing Permanent Sample Plots (PSPs) and data collection presented herein also apply to the Measured Data pathway, i.e., the case where the preparation of FIR or equivalent document, is in progress (see Section 3.2.2).

After monitoring has been implemented, the results are consequently applied to revise the net anthropogenic GHG emission reductions for the subsequent reporting period.

7.1.1 Monitoring Plan

The Project Proponent is required to submit a detailed monitoring plan in accordance with the most recent version of applicable VCS rules.

Standard Operating Procedures (SOPs), training, and capacity building will be provided by the Project Proponent to the identified responsible entity as specified in the PD. This is to ensure that accurate data is collected as required. The data, its source, the entity responsible, the frequency of collection and the equation it applies to, is detailed in the monitoring tables provided in the following sections (Tables 7-1 to 7-3).

7.1.2 Procedure for Establishing the Permanent Sample Plots (PSPs) and Measurement

Forest inventory obtained in the PSPs that are established in the Project Area is required for:

(i) The Measured Data pathway, ex ante estimation for the baseline degradation calculations (see Section 3.2.2)

(ii) Monitoring of the carbon change throughout the crediting period to obtain ex post estimations of growth foregone (see Section 3.3.4) and emissions due to natural disturbances (see Section 4.4).

Sample plots are either permanent or temporary in nature. For measuring the carbon change under the IFM-LtPF project, Permanent Sample Plots (PSPs) are more suitable than Temporary Sample Plots, as they are statistically more accurate and efficient in estimating changes in forest carbon. The measurements collected within the same plots under the PSPs approach throughout the crediting period allows the monitoring of the growth of individual trees, survivors, mortality, and growth of new trees at specific time intervals. In addition, the PSPs also permit the verification body to find, measure at random, and to verify in quantitative terms, the design and implementation of the carbon monitoring plan. The following sections describe the procedures for establishing PSPs in the Project Area.

7.1.2.1 Stratification of the Project Area

To facilitate the field work and increase the accuracy and precision of the parameters that are to be measured, the Project Area is to be divided into sub-populations or "strata" that form relatively homogeneous units. This makes monitoring more cost effective because it decreases the sampling and monitoring efforts, whilst maintaining the same level of confidence. Stratification of the Project Area is presented in more detail Section 2.2.1.1.1.

7.1.2.2 Shape and size of plots

The measurement of tree parameters in a PSP requires the determination of the size and shape of the PSPs. Circular or rectangular plots with varying sizes can be used for measuring different diameter class trees. Nesting of plots is possible - a smaller size plot is established inside a larger plot for measuring small diameter class trees. Figure 7-1 shows an example of nested circular sample plots for measuring different diameter classes in a specified circular plot. The sample plot has three circular plots: a small plot with 4 m radius to measure trees with DBH between 5-20 cm, an intermediate plot with 14 m radius to measure trees with DBH between 20-50 cm, and a large plot with 20 m radius for measuring trees with DBH above 50 cm.

The Project Proponent must decide on the appropriate size and shape of the PSP based on the common practices employed for forest inventory in the host country.

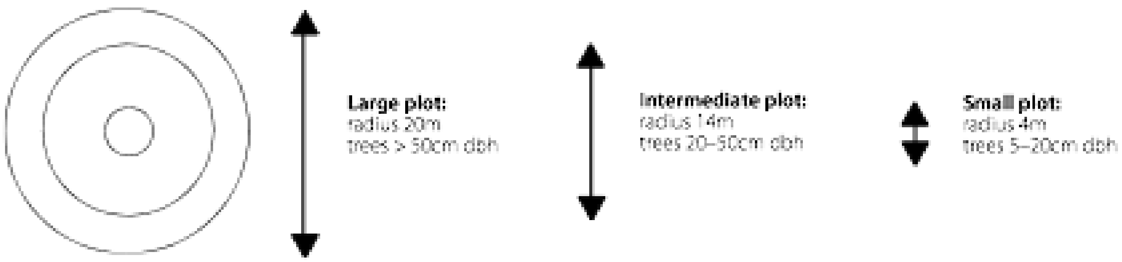

Figure 7-1 Circular three-nest sample plot sizes (Pearson et al. 2005)

7.1.2.3 Determining the number of PSPs

The number of PSPs in each stratum is determined by taking measurements in preliminary sample plots randomly laid in each stratum to achieve the desired level of precision using the following procedure:

Step 1: Select the number of preliminary sample plots (*sp*) to be established (between 6 and 10 for each stratum).

Step 2: Set the geographic location of the preliminary sample plots in each stratum by employing, for example, a random function available in the Geographic Information System (GIS) platform (e.g. ArcGIS).

Step 3: Locate the preliminary sample plot on the ground using GPS and maps.

Step 4: Establish the sample plot of specific size and shape as discussed in the Section 7.1.2.2.

Step 5: Measure the DBH and tree height of all trees as defined by the relevant authority of the host country. Use the standard forestry techniques and equipment such as DBH tape and clinometer for measuring DBH and tree height, respectively. See Pearson et al. (2005) for details.

Step 6: Use field data to calculate the carbon in the AGB in each preliminary sample plot and stratum as per the calculation in Section 3.2.1.2, and employ the following equation to estimate the standard deviation for each stratum (sd_j):

Equation 7-1

$$sd_j = \sqrt{\frac{\sum_{sp=1}^{SP} (\overline{C}_{AGB\_gstock,sp,j} - \overline{C}_{AGB\_gstock,j})}{N_j - 1}}$$

Parameter	Description	Unit
sd_j	Standard deviation for carbon in the aboveground biomass in the stratum *j*, (where *j*=1,2,3, … *J* strata)	tC ha^{-1}
$\overline{C}_{AGB\_gstock,sp,j}$	Average carbon per hectare in the aboveground biomass of the growing stock in the preliminary sample plot *sp (where sp*=1,2,3 … *SP* preliminary sample plots), of the stratum *j*, (where *j*=1,2,3, … *J* strata)	tC ha^{-1}
$\overline{C}_{AGB\_gstock,j}$	Average carbon per hectare in the aboveground biomass of the growing stock in the stratum *j*, (where *j*=1,2,3, … *J* strata)	tC ha^{-1}
N_j	Total number of sampling units in the stratum *j*, (where *j*=1,2,3, … *J* strata)	dimensionless

Step 7: Apply the precision level of 10% of the true value of the mean at the 95% confidence interval for accurate estimation of net change in the carbon stock (Pearson et al., 2005) in the project area.

Step 8: Apply the equation below to estimate the total number of PSPs, *N*, in all strata for the entire Project Area (Pearson et al., 2005):

Equation 7-2

$$N = \frac{\left(\sum_{j=1}^{J} N_j \times sd_j\right)^2}{\left(\frac{N_j^2 \times err^2}{t_{stat}^2}\right) + \left(\sum_{j=1}^{J} N_j \times sd_j^2\right)}$$

Parameter	Description	Unit
N	Total number of Permanent Sample Plots in the Project Area	Number
N_j	Number of sampling units in stratum *j* (where *j* = 1,2,3 … *J* strata)	Number
sd_j	Standard deviation of carbon density for the stratum *j*, (where *j*=1,2,3, … *J* strata)	tC ha^{-1}

Parameter	Description	Unit
t_{stat}	Sample statistic from the t-distribution for the 95% confidence level	dimensionless
err	Allowable error (calculated by mean carbon density by desired precision)	dimensionless

Step 9: The following equation is then used to calculate the number of PSPs in each individual stratum (Pearson et al. 2005):

Equation 7-3

$$n_j = N \times \frac{N_j \times sd_j}{\sum_{j=1}^{J} N_j \times sd_j}$$

Parameter	Description	Unit
n_j	Number of Permanent Sample Plots in stratum *j*, (where *j*=1,2,3, … *J* strata)	Number
N	Total number of Permanent Sample Plots in the Project Area	Number
N_j	Total number of sampling units in the stratum *j*, (where *j*=1,2,3, … *J* strata)	Number
sd_j	Standard deviation of carbon density for the stratum *j*, (where *j*=1,2,3, … *J* strata)	tC ha^{-1}

Equation 7-3 determines the number of PSPs for each stratum based on the variability in the stratum. A stratum with higher variability will require a higher number of sample plots than a stratum with less variability.

In the case of the natural disturbances, the sample plots, s_{nd}, are established in the naturally disturbed stratum during the monitoring event for estimating the carbon increased in the AGB pool due to regrowth in the naturally disturbed areas (see Step 5 of Section 4.4).

7.1.2.4 Sampling design for the PSPs

Different sampling design approaches are available for laying out the ground location of the PSPs in each stratum. Some of the commonly used sampling designs in forestry are random sampling, stratified sampling, stratified random sampling, stratified systematic sampling and cluster sampling. A suitable sampling design for establishing the PSPs is required and is important to avoid bias, such as locating PSPs along a road for example, in order to maintain the statistical rigour and validity of the calculations.

7.1.2.5 Parameter measurement in the PSPs

After determining the number of PSPs in each stratum, and the sampling design for on the ground location of the PSPs, field measurements will be conducted. The field team should have sound knowledge and experience in forest inventory, measurement procedures and equipment. Before the field work commences, the field team must prepare the following:

- A plan of the data collection procedures including the specification of merchantable tree in terms of species, minimum DBH and tree form, rules for borderline trees, locating trees during the following monitoring period, and measurement techniques for the DBH and tree height
- A plan of the data recording procedures and resources, such as paper forms or handheld PDAs
- Documentation of quality control and quality assurance procedures
- Documentation of data archiving methods
- Details of the responsibilities of the parties involved.

The Project Proponent will develop Standard Operating Procedures (SOPs) for each of the above steps and include these in the PD.

After establishing a PSP on the ground, all trees as defined by the relevant authority in the host country will be measured for their DBH and tree height (H) using appropriate equipment. The equipment employed must have been calibrated before taking to the field for measurements.

This Methodology has provided guidance on establishment of the PSPs and the measurement in the Section 7.1.2. However, the Project Proponent will be required to use methods that adhere to good practice internationally as well as locally in the host country. A detail of the chosen methods for the Project Area stratification, sampling design, intensity and the actual tree measurement must be provided in the PD. Some of the specific resource materials for monitoring the net GHG emissions are provided by the following literature: Pearson et al. (2005); Pearson et al. (2007); IPCC (2003); Hoover (2008).

7.1.3 Monitoring Frequency

Under this methodology, the Project Proponent should undertake measurement in the PSPs at intervals not exceeding five years. Parameters associated with the Project Area and leakage must be monitored annually.

7.2 Monitoring Implementation

The Project Proponent must prepare a monitoring plan for estimating carbon changes under the baseline scenario, project implementation and leakage. This section provides guidance on the specific parameters to be monitored under these scenarios, their reference in this Methodology, their sources, monitoring frequency and the relevant equation where the new value is to be applied for ex post calculations of net anthropogenic GHG emission reductions.

The data and the parameters associated with the calculation of the annual change in carbon due to degradation from selective logging ($C'_{degradation,t}$ in Equation 3-2) have been categorised into three groups:

(i) parameters obtained from the literature or reports (not monitored)

(ii) parameters measured once (not monitored)

(iii) parameters that require monitoring.

Tables 7-1 through 7-3 summarise the specific parameters, the source(s) of each data or parameter, and the equation(s) in which each of the parameters are applied.

7.2.1 Parameters Obtained from the Literature/Reports to be Reviewed/Verified (Not Monitored)

Table 7-1 provides a list of parameters to be monitored during the project lifetime and used for updating the net anthropogenic GHG emissions calculation. Section 7.3.2 provides QA/QC procedures for selecting the most appropriate value. The Project Proponent must select the value which does not lead to an over-estimation of the net anthropogenic GHG emission reductions.

Table 7-1 Parameters obtained from the literature or reports to be reviewed or verified

Parameter	Summary of Description	Unit	Source of the parameter	Review frequency or validation	Application of the Parameter in Equation(s)
$BCEF_j$	Biomass conversion and expansion factor in stratum *j*	(t d.m.) m^{-3}	literature value or derive a local value	Review the literature or where required, verify or derive local value	3-8; 4-15; 4-22
BEF	Biomass expansion factor for converting volume of extracted roundwood to total aboveground biomass (including bark)	dimensionless	literature value or derive a local value	Review the literature or where required, verify or derive local value	4-21; 5-8; 5-9
CF_{wood}	Carbon fraction of wood for the tropical forest	tC (t d.m.)$^{-1}$	literature value	Review the literature for appropriate value during the monitoring event	3-3; 3-5; 3-41; 3-51;
CF_{AGB}	Carbon fraction in the aboveground biomass of trees for the tropical forest	tC (t d.m.)$^{-1}$	literature value	Review the literature for appropriate value during the monitoring event	3-8; 3-14; 3-37a; 3-37b; 3-38; 4-15; 4-17a; 4-21; 4-22; 5-8; 5-9
D	Wood density for the tropical forest with corresponding climate region and ecological zone	(t d.m.) m^{-3}	literature value or derive a local value	Review the literature or where required, verify or derive local value	3-3; 3-5; 3-41; 3-51; 4-21; 5-8; 5-9
D_i	Species-specific density of wood,	(t d.m.) m^{-3}	literature value	Review the literature or where required, verify or derive local value	3-12

Parameter	Summary of Description	Unit	Source of the parameter	Review frequency or validation	Application of the Parameter in Equation(s)
$f_V(DBH_{n,i,s,j,t=0}, H_{n,i,s,j,t=0})$	Volume allometric equation as a function of diameter at breast height and height; t=0 year	dimensionless	obtained from literature	Review the literature or where required, verify or derive local value	3-10; 3-11
$f_B(DBH_{n,i,s,j,t=0}, H_{n,s,i,j,t=0}, D_i)$	Biomass allometric equation as a function of diameter at breast height and height; t=0 year	dimensionless	obtained from literature	Review the literature or where required, verify or derive local value	3-12
k_{decay}	Rate of decay of the deadwood pool	yr^{-1}	literature value	Review the literature for appropriate value during the monitoring event	3-17, 3-21
f_{RSD}	Factor for residual stand damage	dimensionless	literature value	Review the literature for appropriate value during the monitoring event	3-19; 4-21; 5-8, 5-9
f_{branch_trim}	Branch-trim factor	dimensionless	literature value or derive a local value	Review the literature or where required, verify or derive local value	3-20
$f_{lumber\_recovery}$	Lumber recovery factor	dimensionless	literature value	Review the literature for appropriate value during the monitoring event	3-26, 3-27
k_{ltHWP_ox}	Rate of oxidation for long-term harvested wood products	yr^{-1}	literature value	Review the literature for appropriate value during the monitoring event	3-28
k_{stHWP_ox}	Rate of oxidation for short-term harvested wood products	yr^{-1}	literature value	Review the literature for appropriate value during the monitoring event	3-34
$\bar{G}_{regrowth,t}$	Average regrowth per hectare per year of the aboveground biomass after logging in year, t	(t d.m.) ha^{-1} yr^{-1}	literature value	Review the literature for appropriate value during the monitoring event	3-38

Parameter	Summary of Description	Unit	Source of the parameter	Review frequency or validation	Application of the Parameter in Equation(s)
EF_{fuel}	Fuel emission factor	tCO_2-e kL^{-1}	literature value	Review the literature for appropriate value during the monitoring event	3-40; 3-42; 3-43; 3-46; 3-50; 3-54; 4-8; 4-11; 4-14
$FC_{harvest}$	Fuel consumption of equipment employed for felling and snigging per m^3 of merchantable log harvested	kL m^{-3}	Manufacturer's specification/literature value	Review the literature for appropriate value during the monitoring event	3-40
FC_{trim_equip}	Fuel consumption of equipment employed for trimming per m^3 of trimmed material	kL m^{-3}	Manufacturer's specification	Review the literature for appropriate value during the monitoring event	3-42
$FC_{hauling}$	Fuel consumption of equipment for hauling one m^3 of merchantable log	kL m^{-3}	Manufacturer's specification	Review the literature for appropriate value during the monitoring event	3-43
Cap_{truck}	Truck load capacity	m^3 $truck^{-1}$	literature value	Review the literature for appropriate value during the monitoring event	3-44; 3-52
$Eff_{vehicle}$	Fuel efficiency for vehicle type	km kL^{-1}	Manufacturer's specification/National Database	Review the literature for appropriate value during the monitoring event	3-46; 3-52; 3-54; 4-7; 4-11; 4-14
e_{demand}	Electricity demand for processing per volume processed	kWh m^{-3}	literature value	Review the literature for appropriate value during the monitoring event	3-47
$EF_{electricity}$	Emission factor for electricity in the host country	tCO_2-e kWh^{-1}	Country-specific data from International Energy Agency	Annually revised for the specific value	3-48; 4-4
$t_{generator,t}$	Total operating time of generator in year t	h	National reports on harvesting practice	Review the literature for appropriate value during the monitoring event	3-49; 3-50

Parameter	Summary of Description	Unit	Source of the parameter	Review frequency or validation	Application of the Parameter in Equation(s)
$FC_{generator}$	Fuel consumption per hour of operation of generator	kL h^{-1}	Manufacturer's fuel consumption chart	Review the literature for appropriate value during the monitoring event	3-50
$PR_{equip,ee,t}$	Power rating for electrical equipment, *ee*, in year *t*	kW	Manufacturer's power rating for the equipment	Review the value during the monitoring event	4-3
$EF_{flight,y}$	Flight emission factor for trip y	tCO_2-e (passenger.km)$^{-1}$	literature value	Annually revised for the specific value	4-6, 4-10; 4-13
R_{CH_4}	Emission ratio for CH_4	dimensionless	literature value	Review the literature for appropriate value during the monitoring event	4-18a
R_{N_2O}	Emission ratio for N_2O	dimensionless	literature value	Review the literature for appropriate value during the monitoring event	4-18b
$R_{N/C}$	Ratio of nitrogen to carbon	dimensionless	literature value	Review the literature for appropriate value during the monitoring event	4-18b
GWP_{CH_4}	Global warming potential of CH_4	tCO_2-e tCH_4^{-1}	literature value	Review the literature for appropriate value during the monitoring event	4-19
GWP_{N_2O}	Global warming potential of N_2O	tCO_2-e tN_2O^{-1}	literature value	Review the literature for appropriate value during the monitoring event	4-19

7.2.2 Parameters to be Measured Once (Not Monitored)

Table 7-2 provides a list of parameters measured ex ante and used in the calculation for the net anthropogenic GHG emission reductions. These parameters and data are validated or verified but not monitored.

Table 7-2 Parameters to be measured once but not monitored

Parameter	Summary of Description	Unit	Source of the parameter	Measurement Frequency	Application of the Parameter in Equation(s)
$A_{project,t=0}$	Project Area at time, *t*=0	ha	GPS data, GIS maps and satellite data	Validated/Verified before the IFM-LtPF project start date	2-1; 3-4; 3-6; 3-9; 3-13; 3-36b;
$A_{project,j,t=0}$	Project Area within each stratum, *j*, at time, *t*=0	ha	GPS data, GIS maps and satellite data	Validated/Verified before the IFM-LtPF project start date	2-1; 3-4; 3-6; 3-9; 3-13
$A_{s,j,t=0}$	Total area of sample plots, *s*, in stratum, *j*, *t*=0 year	ha	Ex ante field measurement in the sample plots	Validated/Verified before the IFM-LtPF project start date	3-10; 3-11; 3-12
$DBH_{n,i,s,j,t=0}$	Diameter at breast height *t*=0 year	cm	Ex ante field measurement in the sample plots	Validated/Verified before the IFM-LtPF project start date	3-10; 3-11; 3-12
$H_{n,i,s,j,t=0}$	Height for individual tree, *t*=0 year	m	Ex ante field measurement in the sample plots	Validated/Verified before the IFM-LtPF project start date	3-10; 3-11; 3-12
$A_{NHA\_annual,t}$	Annual net harvest area for the Project Area in year, *t*	ha	Ex ante, obtained from the harvesting plan	Validated/Verified before the IFM-LtPF project start date	3-15a; 3-16a; 3-26; 3-27; 3-33; 3-35; 3-37a; 3-38
$A_{NHA\_annual,j,t}$	Annual net harvest area at the stratum level in year, *t*	ha	Ex ante, obtained from the harvesting plan	Validated/Verified before the IFM-LtPF project start date	3-15b; 3-16b; 3-37b
$KM_{transport,t}$	Annual log transport distance from collection depot to processing plant	km $truck^{-1}$	Digital maps	Validated/Verified before the IFM-LtPF project start date	3-45
$KM_{distrib,t}$	Annual distance of transport from point of processing to distribution/export point	km $truck^{-1}$	Digital maps	Validated/Verified before the IFM-LtPF project start date	3-53
$V'_{historical\_harvest,l,k}$	Total volume of harvest for land *l* that is owned and/or operated by the Project Proponent over the historical reference period	m^3	Project Proponent records	Validated/Verified before the IFM-LtPF project start date	5-3

7.2.3 Parameters to be Monitored

Table 7-3 provides a list of parameters to be monitored during the project lifetime which are then employed to update the net anthropogenic GHG emission reductions calculation.

Table 7-3 Parameters to be monitored in the Project Area

Parameter	Summary of Description	Unit	Source of the parameter	Measurement Frequency	Application of the Parameter in Equation(s)
$DBH_{n,i,s,j,t}$	Diameter at breast height for individual tree *n*, of species *i*, in sample plot *s*, of stratum *j*, in year *t*	cm	Measured using DBH tape	At intervals not exceeding five years after the first monitoring event	3-12
$DBH_{tree\_nd,n,i,s_{nd},j,t}$	Diameter at breast height for individual tree *n*, of species *i*, in sample plot in the naturally disturbed area s_{nd}, of stratum *j*, in year *t*	cm	Measured using DBH tape	At intervals not exceeding five years after the first monitoring event	3-12
$H_{n,i,s,j,t}$	Height for individual tree *n*, of species *i*, in sample plot *s*, of stratum *j*, in year *t*	m	Measured using tree height measurement equipment	At intervals not exceeding five years after the first monitoring event	3-12
$H_{tree\_nd,n,i,s_{nd},j,t}$	Height for individual tree n, of species i, in sample plot in the naturally disturbed area s_{nd}, of stratum i, in year *t*	m	Measured using tree height measurement equipment	At intervals not exceeding five years after the first monitoring event	3-12
$t_{op\_equip,ee,t}$	Hours of operation of electrical equipment *ee*, in year *t*	h	Electrical equipment time log book	Annual	4-3
$KM_{plan\_flight,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Flight travel log	Annual	4-6
$N_{plan\_flight,y,t}$	Number of passengers per trip *y* in year *t*	Number	Flight travel log	Annual	4-6
$KM_{plan\_ground,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Vehicle travel log	Annual	4-7

Parameter	Summary of Description	Unit	Source of the parameter	Measurement Frequency	Application of the Parameter in Equation(s)
$V_{fuel\_plan\_ground,y,t}$	Annual volume of fuel consumed per trip *y* in year *t*	kL	Vehicle travel log	Annual	4-8
$KM_{design\_flight,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Flight travel log	Annual	4-10
$N_{design\_flight,y,t}$	Number of passengers per trip *y* in year *t*	Number	Flight travel log	Annual	4-10
$KM_{design\_ground,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Vehicle travel log	Annual	4-11
$KM_{monitoring\_flight,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Flight travel log	Annual	4-13
$N_{monitoring\_flight,y,t}$	Number of passengers per trip *y*, in year *t*	passenger	Flight travel log	Annual	4-13
$KM_{monitoring\_ground,y,t}$	Distance travelled per trip *y*, for a total of Y trips in year *t*	km	Vehicle travel log	Annual	4-14
$A_{nd,j,t}$	Area of natural disturbance *nd*, in stratum *j* in year *t*	ha	Satellite imagery and field measurement	Annual	4-15; 4-17a
$f_{natdisturb,j,t}$	Fraction of the forest naturally damaged in stratum *j*, in year *t*	dimensionless	Field survey	Annual	4-16
$V_{illegal\_harvest,t}$	Volume of wood sold as determined from field surveys in year *t*	m^3	Field survey	Annual	4-21
$A_{illegal\_harvest,j,t}$	Area of illegal harvest in stratum *j*, in year *t*	ha	Satellite data	Annual	4-22

Parameter	Summary of Description	Unit	Source of the parameter	Measurement Frequency	Application of the Parameter in Equation(s)
$V_{actual\_harvest,l,t}$	Annual actual volume of harvest for land l that is owned and/or operated by the Project Proponent or the forest with comparable situations and condition in local or regional or nation level in year t	m^3 yr^{-1}	Project Proponent records	Annual	5-4 to 5-7

7.2.4 Validating or Deriving the Parameters

To calculate the annual change in carbon due to degradation, the carbon in merchantable logs and AGB must be calculated. Good practice (IPCC, 2003) suggests the use of locally derived species-specific or group of species-specific default values for the net anthropogenic GHG emission reductions calculation. However, the application of default parameters available in the IPCC literature, national inventory reports or published peer-reviewed studies is acceptable if the parameter is applicable to a forest type and climatic region similar to the Project Area (CDM-EB, 2009, p. 26). Where the default parameter does not match the forest type and climatic region of the Project Area, it is required to validate the parameters using the destructive sampling approach described in the following section.

7.2.4.1 Validating or deriving the wood density

Where the default value for wood density is not obtained from the forest type and climatic region similar to the Project Area, validate or derive the wood density using the following procedures based on Pearson et al. (2005) and CDM-EB (2009):

Step 1: Select 20-30 trees[6] representing all DBH classes found in the Project Area during the first monitoring event (within five years from the project start date).

Step 2: Measure the DBH and height of all trees.

Step 3: Fell the trees and separate each tree into the following components: merchantable log, large branches, small branches (less than 10 cm diameter), and foliage.

Step 4: Cut the merchantable logs into at least five sections, and the large branches into at least three sections.

Step 5: To determine the total volume of the merchantable logs and large branches, measure the length and the diameter at both ends of each section of the logs/branches; and calculate the total volume as in Pearson et al. (2005), Appendix B, Method 1, step 6a, p. 40.

[6] According to the CDM at least five trees representing all DBH classes, is sufficient for the destructive sampling method for verifying default values or equations. However, this Methodology suggests using at least 20 trees, which provides a greater representation of the trees in the Project Area.

Step 6: Obtain a complete cross-sectional sample from each log and large branch and measure the fresh weight and calculate the volume of each sample. Oven-dry the samples at 70 degrees for 24 hours and measure the dry weight. Estimate the wood density (D) for the forest types as well as species-specific wood density (D_j) by dividing the dry weight by the volume.

Step 7: Select the wood density.

If the wood density for the forest types and the species-specific wood density in the Project Area derived from the direct measurement are within ± 10% (CDM-EB, 2009, p. 26) of the corresponding default wood densities or lower than the measured value, it is conservative to use the selected default values for wood densities.

If the default wood densities are greater than the measured wood densities by 10% or more, it is conservative to use the wood densities derived from the samples.

If the default wood densities are lower than the measured wood densities by 10% or more, it is conservative to use the default wood densities.

7.2.4.2 Validating or deriving the volume and biomass allometric equations

Where the default volume and biomass allometric equations do not match the forest type and climatic region of the Project Area, it is required to validate or derive the allometric equations using the following destructive sampling procedure:

Step 1: Follow Steps 1 to 5 in Section 7.2.4.1 to calculate the total volume of the merchantable logs and large branches.

Step 2: Measure the fresh weight and oven dry weight of the small branches and foliage of all the felled trees.

Step 3: Estimate the biomass of the logs and large branches using the total volume and wood density (see Section 7.2.4.1) (biomass = volume x wood density). Derive the total AGB by adding the oven dry biomass of the leaves and small branches to the biomass of the large branches and logs.

Step 4: Apply the volume and biomass allometric equations to the measured data for 20-30 trees and obtain the mean volume and AGB for these trees.

Step 5: Select the equations.

If the volumes and AGB of the harvested trees derived from the direct measurement are within ± 10% of the mean values predicted by the default allometric equations, or the prediction is lower than the measured value, it is conservative to use the selected default allometric equation.

If the default allometric equations overestimate the prediction compared with the measured volume or AGB, develop a project-specific volume and/or AGB allometric equation by applying regression to tree volume and/or AGB as an independent variable to DBH and height. The wood density is also used as an independent variable for the biomass allometric equation.

7.2.4.3 Validating or deriving the branch-trim factor

If a branch-trim factor, f_{branch_trim}, cannot be obtained from the literature, or the branch-trim factor obtained from the literature does not match the forest type and climatic region of the Project Area, it is required to derive or validate, respectively, a project-specific branch-trim factor in the first monitoring event using the following the procedure:

Step 1: Follow Steps 1 to 3 in Section 7.2.4.2 and obtain the biomass of large and small branches and the total AGB.

Step 2: Calculate the branch-trim factor as the ratio of biomass of large branches to the AGB of the tree via the following equation:

Equation 7-4

$$f_{branch\_trim} = \frac{B_{branch\_trim,m_1}}{B_{AGB\_trees,m_1}}$$

Parameter	Description	Unit
f_{branch_trim}	The fraction of branches and trimmings in the aboveground biomass remaining after trimming of the merchantable logs transferred to the DW pool	dimensionless
B_{branch_trim,m_1}	Biomass in large and small branches in year m_1 of first monitoring event	t d.m.
B_{AGB_trees,m_1}	Biomass in the aboveground biomass of sample trees in year m_1 of first monitoring event	t d.m.

Step 3: If a branch-trim factor was employed in ex ante estimations, compare the project-specific branch-trim factor and the estimated branch-trim factor. If the estimated branch-trim factor is within ± 10% of the branch-trim factor value, or the value is lower than the estimated value, it is conservative to use the selected branch-trim factor.

Step 4: If the branch-trim factor value is higher than the estimated value, use the estimated value for the project.

7.2.5 Non-Permanence Risk Assessment

7.2.5.1 Buffer determination

The amount of credits a project must allocate for buffer reserves in the AFOLU Pooled Buffer Account, $CC_{NPbuffer,t}$, is based on the project's potential for future carbon loss. The method to calculate $CC_{NPbuffer,t}$ has been presented in Section 1.2.4, Equation 1-2.

To obtain the project's non-permanence buffer withholding percentage, $NP_{buffer,t}\%$, a risk rating in relation to its potential for reversal of the sequestered/protected carbon will be determined using the most recent version of VCS tool for AFOLU Non-Permanence Risk Analysis and Buffer Determination. The risk assessment must be clearly documented and substantiated in the PD and/or monitoring report.

Once the amount of credits to be deposited in the buffer account is determined, the tradeable carbon credits, VCU_t, can be calculated using Equation 1-3, Section 1.2.4.

7.3 Quality Assurance and Quality Control

Quality assurance (QA) and quality control (QC) are important for verifying and certifying carbon changes throughout the crediting period. The Project Proponent must have QA and QC systems in place at the project development stage in order to provide enough confidence to all the stakeholders on the reliability, accuracy and precision of the measurement. Accurate and precise data collection and analysis requires a trained field team, appropriate equipment, standard data collection procedures and recording, analysis and storage of data.

The PD must describe the QA and QC approach for the IFM-LtPF project and must contain Standard Operating Procedures (SOPs) for:

(i) Conducting field measurement

(ii) Selecting literature values

(iii) Data entry, maintenance and archiving

(iv) Contract procurement.

To ensure good practice in monitoring and inventory a comprehensive QA and QC system will be implemented. The procedures will be based on ISO 9001 and encompass the elements as defined in the relevant sections of the IPCC 2006 Guidelines for National Greenhouse Gas Inventories. Applying the framework proposed by ISO 9001 will ensure that all procedures and systems will be subjected to internal audits as well as being independently verified.

The QA/QC and verification system will adopt a continuous improvement model with a particular emphasis on the key parameters within the Methodology that will be monitored.

7.3.1 QA/QC for Conducting Field Measurements

The capacity and skill set of field teams employed to establish and collect measurement data in PSPs associated with carbon inventory will be assessed by qualified personnel using a combination of theoretical and practical assessment. All field teams will receive extensive training so that they are fully cognisant of all procedures and understand the importance of collecting accurate data. Appropriate training will be developed encompassing a continuous improvement system. The QA/QC system will document and allow traceability of the skill sets, training and continuous improvement of all personnel associated with the project.

If the particular required skill sets are deemed unsatisfactory then the applicable personnel will be required to undergo a formal training program conducted by suitably qualified personnel. This will be recorded in the appropriate QA module.

Standard Operating Procedures (SOPs) will be developed to encompass all the steps required to establish the carbon inventory associated with the major pools, namely AGB, DW and where applicable HWPs. The SOPs will be sufficiently robust to ensure that any new person sent into the field should be able to repeat the previous measurements.

SOPs associated with the number and placement of PSPs will also be developed to ensure their appropriate implementation. SOPs associated with the use and accuracy of all equipment used to take measurements will be developed and implemented.

All PSPs and measurements will in the first instance be established under the guidance of appropriately qualified personnel. The qualifications and expertise of these authorised staff will be identified in the appropriate QA module.

An evaluation of all field teams will be conducted to identify errors in field techniques, verify the measurement process and correct any identified problems before any measurements are undertaken. All PSPs and associated personnel who established and obtained the associated measurements will be subjected to a random audit program to ensure the accuracy and precision of data collected. The audit program will initially consist of 10% of PSPs being re-measured by suitably qualified personnel. The audit program will be fluid in nature so that it targets those plots and personnel that show a significant standard deviation. SOPs will be written to encompass this as well as a system that ensures that all PSPs and or specific measurements are re-taken and re-calculated. SOPs will be written to ensure that any field data collected over time is compared to the original data and discrepancies are verified again.

7.3.2 QA/QC for Selecting Literature Values

The selection of appropriate and current data from the literature is required in order to reduce uncertainty of the net anthropogenic emission reductions of the IFM-LtPF project. Types of data required from literature for the current Methodology are:

 Emission factors

 Rate of oxidation/decay

 Forestry parameters and conversion factors, i.e. biomass expansion factor, biomass conversion and expansion factors, wood density and carbon fraction

 Forestry process factors, i.e. lumber recovery factor, residual stand damage

 Growth models

 Allometric equations.

The Project Proponent is required to choose values/models from the literature from project(s) and area(s) with features and characteristics similar to the IFM-LtPF Project Area, for example a tropical forest with corresponding climate region and ecological zone. In addition when selecting data or parameters from the literature, the Project Proponent must adopt a conservative approach in regards to the net anthropogenic GHG emission reductions. This implies that if two or more values are available for the forest types and condition in the Project Area, the value which does not lead to an over-estimation of the net GHG emission reductions must always be chosen.

Literature values must be obtained from the following sources in the order of the most preferred data source:

(i) Peer-reviewed literature values providing project-specific data

(ii) Country-specific data

(iii) Global IPCC default values.

When recording literature values, the Project Proponent is required to provide the following information in order for the data to be verified:

(1) Source of data, date, table/figure, page number, from which the data is derived
(2) Corresponding features that match with the Project Area, i.e. forest type, climate zone, etc.
(3) Corresponding uncertainty (absolute or relative)
(4) An explanation of the choice of parameter from the range, if a range is provided. The Project Proponent must choose a value that presents the net anthropogenic emission reductions as conservative.

7.3.3 QA/QC for Data Entry and Archiving

According to the guidelines published by the IPCC (2006) it is a prerequisite that all calculations leading to emission or removal estimates should be fully reproducible. As such, QC procedures must be created to address potential errors associated with input data, the conversion of algorithms of a calculation and the output. In addition, because of the relatively long term nature of the IFM-LtPF project activity, data archiving (maintenance and storage), QA procedures and SOPs will be established to ensure the traceability of data analysis and the documentation of calculations over the lifetime of the project. As such the following activities will be developed into formal SOPs.

(i) Numbers entered into spreadsheets will reference the data sources and cells containing derived data as "results" will be clearly marked
(ii) All calculations will be presented in the form of formulas so that auditing tools can be used to track back from a result to the data source, and calculations can be evaluated by analysing the formulae
(iii) All databases, spreadsheets and recording sheets will be clearly referenced by name, version, author, updates, intended use and checking procedures, so that it can be used as a data source of the derived results and referenced further as required in the inventory process
(iv) When using databases, the source of data tables must be referenced to the data source using a referencing column
(v) Wherever possible, queries are to be used when using databases as a means to track back to the data table
(vi) Where queries are not practical and new tables of data need to be generated, scripts or macros wherever used, are to be recorded and referenced in a referencing column
(vii) All data are to be archived electronically so that these can be stored and backed up and kept for at least two years after the end of the crediting period. SOPs will be developed to ensure that this occurs in a timely manner
(viii) Before any calculation is implemented it must be peer reviewed for accuracy and relevance (including unit conversion factors) by two personnel with the relevant skills and authority
(ix) All calculations must be checked by at least one appropriately skilled independent person to ensure they are accurate and consistent with applicable time series

(x) Wherever possible, estimates and calculations are to be compared with literature values. If they are considered significantly different (5%) they are to be checked for accuracy.

7.3.4 QA/QC for Contract Procurement

SOPs will be developed for the procurement of suppliers or contractors. This is to ensure that any analysis undertaken meets internationally recognised standards and that contractors if used, adopt best practice when undertaking specific tasks.

7.4 Ex post Calculation of Net Anthropogenic GHG Emission Reductions

After the completion of the monitoring plan as outlined in the previous sections, the baseline degradation, project activity, and leakage emissions and their uncertainties, must be revised and adjusted at the end of each monitoring period. The net anthropogenic GHG emission reductions on the basis of the ex post measured parameters can be recalculated via the following steps:

Step 1: Calculate annual total carbon emissions due to degradation of the baseline activity, $C'_{degradation,t}$, using procedures outlined in Sections 3.2 and 3.3.

Step 2: Calculate annual total carbon emissions due to implementation of baseline activity, $C'_{emissions,t}$, using procedures outlined in Section 3.4.

Step 3: Calculate annual total carbon emissions associated with the baseline scenario, $C'_{baseline,t}$, using Equation 3-1, Section 3.1.

Step 4: Calculate annual total carbon emissions associated with the project activity, $C'_{actual,t}$, using procedures outlined in Section 4.

Step 5: Calculate the annual total carbon emissions associated with leakage, $C'_{leakage,t}$, using procedures outlined in Section 5.

Step 6: Calculate the net anthropogenic GHG emission reductions, $C'_{IFM-LtPF,t}$, using Equation 1-1, Section 1.2.1.

Step 7: Determine the absolute uncertainties for all parameters employed in the calculation of the net anthropogenic GHG emission reductions using the process outlined in Sections 6.2 to 6.5. Using Equations 6-4 and 6-5, calculate the absolute and relative uncertainty, respectively, associated with the net anthropogenic GHG emission reductions. Follow the procedure (Steps 1 and 2) in Section 6.6 to ascertain if an uncertainty deduction must be applied. Proceed to Section 6.7 to reduce the uncertainty of the net anthropogenic GHG emission reductions. Revise the calculation of the net anthropogenic GHG emission reductions.

Step 8: Determine the non-permanence buffer withholding percentage, $NP_{buffer,t}\%$, from the Non-Permanence Risk Assessment (Section 7.2.4) and calculate the carbon credits to be deposited in the VCS buffer withholding pool, $CC_{NPbuffer,t}$, using Equation 1-2, Section 1.2.4.

Step 9: In the case where $C'_{actual,t}$ < $C'_{baseline,t}$, calculate the carbon credits that can be traded after non-permanence buffer credits have been considered, VCU_t, using Equation 1-3, Section 1.2.4.

Step 10: In the case where $C'_{actual,t}$ > $C'_{baseline,t}$, and carbon is lost from the project, the project will be subjected to procedures for cancellation of buffer credits in accordance with VCS rules.

The ex post calculation of the net GHG anthropogenic emission reductions presented in the monitoring report must be verified.

Appendices

Appendix A: Definitions and Acronyms

Some of the important definitions of terms used throughout the proposed Methodology have been adapted from the GPG LULUCF published by the IPCC (2003). The definition of terms are presented in Appendix A.1.

The acronyms used throughout the Methodology represent internationally defined terms used widely by the Verified Carbon Standard (see VCS), the Intergovernmental Panel on Climate Change (see IPCC), the United Nations Framework Convention on Climate Change (see UNFCCC), and in the disciplines of agriculture, forestry and geography.

A.1 Definition of Terms

Aboveground Biomass, AGB	Living biomass of the trees above the ground that includes stems, stumps, branches, bark, seeds and foliage.
Wood Density, D	Ratio between oven dry biomass and fresh stem-wood volume without bark; units of (tonne of dry matter) m^{-3} ; used as a parameter in equations.
Branches and trimmings	The trimmed components such as large and small branches, whose carbon is transferred into the deadwood pool after harvesting.
Branch-trim factor	Factor accounting only for the carbon in the large and small branches that remain on the forest floor after the trimming process and whose carbon is transferred into the deadwood pool.
Biomass Conversion and Expansion Factor, BCEF	Factor converting growing stock to aboveground biomass, units of (tonne of dry matter) m^{-3} ; used as a parameter in equations.
Biomass Expansion Factor, BEF	Biomass expansion factor for converting volume of extracted roundwood to total AGB (including bark).
Carbon Fraction, CF	Ratio between quantity of carbon and dry biomass, units of (tonnes of carbon) (tonne of dry matter)$^{-1}$; used as a parameter in equations.
Carbon Pool	Reservoir that has the potential to accumulate (or lose) carbon over a period of time. In IFM-LtPF project activity, the pools to be considered are aboveground biomass, deadwood and wood products.

Commercial Log Length	The length of merchantable logs above the stump height to the minimum top diameter.
Crediting Period	Synonymous with project crediting period as defined in VCS rules
Deadwood, DW	Non-living biomass of woody vegetation not contained in the litter, either standing or lying above the soil level, and stumps larger or equal to 10 cm in diameter, or a nationally-specified diameter; used as a subscript in equations.
Dry Matter	Biomass that has been dried to an oven-dry condition, where the temperature of the oven is usually held at 70 °C.
Ex ante	Before an activity; the estimation of the net GHG emission reductions, before the start of the IFM-LtPF project activity, for the project crediting period.
Ex post	After an activity; the calculation of the actual net GHG emission reductions for the years elapsed since the start of the IFM-LtPF project activity.
Forest	Land with biomass that is defined by a minimum area, level of tree crown cover and tree height. Under the Kyoto Protocol, ranges for the three parameters are: 0.05 - 1.0 hectare with crown cover (or equivalent stocking level) of more than 10 - 30% comprising trees, with the potential of the trees to reach a height of 2 - 5 metres at maturity *in situ*.
Forest Degradation	Biomass that is lost through a measurable decrease in canopy cover, but which is not sufficient to reduce canopy cover to below the percent range specified for forest in the relevant country (Penman et al., 2003).
Forest Inventory Report, FIR	A legally approved or sanctioned document by the relevant authority of the host country that includes, but is not limited to, inventory data, forest management plan, and other forest inventory findings obtainable from the host country's forest inventory database.
Forest Product Type	Forest product type includes sawlog, pulplog and commercially harvested fuelwood. The definition of these products are obtained from the relevant authority of the host country.

Fuelwood, FW	Biomass collected for energy production purposes that includes commercial fellings and trees damaged by natural causes, but does not include wood that is produced as a by-product or residual matter from industrial processing of merchantable logs.
Growing Stock	The total volume (over bark) of all living trees with DBH larger than the minimum DBH as specified by the relevant authority in the host country.
Harvested Wood Products, HWPs	Merchantable logs that will be crafted into products, either classed as long-term or short-term products. An example of merchantable logs that will be made into long-term HWPs (ltHWPs) is sawlogs. Examples of merchantable logs that will be made into short-term HWPs (stHWPs) are pulplogs and logs commercially harvested for fuelwood.
Lumber Recovery Factor	Ratio of the volume of sawnwood products (ltHWPs) recovered from harvested sawlog volumes. Lumber recovery factor subtracted from unity results in sawmill residues from the processing of ltHWPs.
Merchantable Logs	Marketable portion of the merchantable trees as defined by the minimum diameter at breast height and tree top, as specified by the relevant authority in the host country.
Merchantable Trees	Trees with a minimum DBH and tree form as defined by the relevant authority in the host country.
Minimum DBH	The diameter at breast height used for defining a merchantable tree as specified by the relevant authority in the host country.
Monitoring event	The implementation of the monitoring activity for measuring the parameters for net GHG emission reductions after the commencement of the IFM-LtPF project.
Monitoring period	The time taken between monitoring events for collecting measurements in the PSPs in the Project Area, and for reviewing non-monitored parameters.
Non-tree	For the purpose of this Methodology, non-tree has been broadly defined as all the vegetation except the trees with the minimum DBH as specified by the relevant authority in the host country (see footnote ## on page 18). It comprises of ground vegetation (seedlings, saplings, herbs and shrubs), hanging veins and lianas and also woody climbers.

Project Area	Geographic area in which the IFM-LtPF project activity will be implemented that reduce emissions from forest degradation.
Project Boundary	Encompasses (i) geographical boundary, (ii) crediting period, (iii) sources and sinks and associated GHGs, and (iv) carbon pools. In this Methodology, on the basis that the overarching component is the geographical boundary, the Project Boundary is therefore referred to as the geographical area in which the project actions and activities will be implemented.
Residual Stand Damage, RSD	Damage to non-harvested trees due to harvesting operations. The residual stand are damaged either by being knocked down, snapped off or due to limb breakage.
Tropical Forests	Forests growing in the tropical region and comprised of the following four broad forest classes: Evergreen Tropical Rainforest, Moist Deciduous Tropical Forest, Dry Tropical Forest and Upland Tropical Forest (FAO, 1998).

A.2 List of Acronyms Used

Abbreviation	Term

A.3 General Notation of Parameters

Parameter symbol type	Description of parameter function and unit type
$\bar{X}$	a per hectare value
X	a value in any particular year
X'	a tCO_2-e value in any particular year
X''	an absolute value

Appendix B: Guidance for Parameter Selection

B.1 Wood Density

Guidance on selecting suitable wood density depends on the type of data available and its application:

Existing Inventory Data Pathway - BCEF Method: Where Less Detailed FIR is Available

Where less detailed FIR information is available and species types are not known, a mean tree density (t d.m.) m^{-3} for the tropical region most appropriate to the Project Area should be employed.

The arithmetic mean and most common wood density values (t d.m.) m^{-3} for tropical tree species in tropical Africa, America and Asia presented in Table B-1, is based on a study by Reyes et al. (1992) using approximately 1280 tree species.

Table B-1 Arithmetic mean for tropical tree species by tropical region (Reyes et al. 1992)

Tropical Region	Arithmetic Mean, (t d.m.) m^{-3}
Africa	0.50
America	0.60
Asia	0.57

Existing Inventory Data Pathway - Allometric Method: Where Detailed FIR is Available

Where species are known, species-specific or group of species-specific wood density should be selected from the following sources:

(i) National species-specific or group of species-specific densities (e.g., from National GHG inventory)

(ii) Species-specific or group of species-specific densities from neighbouring countries of a similar climate region and ecological zone

(iii) Globally species-specific densities (e.g. IPCC, 2006a, Chapter 4, Table 4.13, p. 4.64).

Such data types should be applied at either the species level, for example, in biomass allometric equations that employ species density, along with DBH and H, $f_i(DBH_i, H_i, D_i)$, or applied to determine a weighted average density, based on the dominant species measured in each volume.

A Project Area specific average density can be employed, see Section 7.2.4.1 on how to derive this value.

Measured Data Pathway - Allometric Method: Where FIR Data is not Available

Guidance on density selection is the same as for Existing Inventory Data Pathway - Allometric Method.

B.2 Carbon Fraction

Where species-specific carbon fraction data is not available, the carbon fraction should be obtained from IPCC (2006a), Chapter 4, Table 4.3, p. 4.48, presented here for the tropical and subtropical climate domain in Table B-2:

Table B-2 Carbon fraction for all of tree and wood component for tropical forests (adapted from IPCC, 2006, Chapter 4, Table 4.3, p. 4.49)

Part of Tree	Parameter	Carbon Fraction, tC (t d.m.)$^{-1}$	References
Wood	CF_{wood}	0.49	Feldpausch et al., in IPCC (2006a)
Wood, tree DBH < 10 cm	CF_{wood}	0.46	Hughes et al., in IPCC (2006a)
Wood, tree DBH ≥ 10 cm	CF_{wood}	0.49	
All of tree (AGB)	CF_{AGB}	0.47	Andreae and Merlet, Chambers et al., Lasco and Pulhin in IPCC (2006a)
Default IPCC value, All of tree	CF_{AGB}	0.47	McGroddy et al., in IPCC (2006a)

B.3 Residual Stand Damage

Brown et al. (2005) compiled the factor for residual stand damage (damage over extracted) for various countries and revealed a strong relationship with average commercial log length. The results have been summarised in this Methodology in Table B-3 below.

Table B-3 Factor for residual stand damage (compiled from Brown et. al., 2005, Figure 11, p. 16)

f_{RSD} (tCdamaged tCextracted^{-1})	Commerical Log Length (m)	Country	Reference
1.74	22	Congo	Brown et al. (2005)
2.30	17	Malaysia	Pinard and Putz (1996)
2.78	10.8	Belize	Brown et al. (2005)

f_{RSD} (tCdamaged tCextracted^{-1})	Commerical Log Length (m)	Country	Reference
3.10	9.8	Bolivia	Pearson et al. (2005)

B.4 Lumber Recovery Factor

The lumber recovery factor for sawlog processing is required in order to calculate the volume of the long-term HWP carbon pool.

This factor vary from country to country (see Table B-4), and are dependent on a number of variables that include skilled labour, equipment used, and sawmill facilities (FAO, 2004; Pulkki, 1997).

Table B-4. Country-specific lumber recovery factors

Country (and Sawmill details)	$f_{lumber\_recovery}$, (Range, Where Provided)	Reference
Conventional logging sawmills (*for comparative purposes*)	0.35	FAO (2004)
Cameroon, Malaysia - Sarawak for general use in the absence of country-specific factor	0.36-0.57, dependent on lumber market	FAO (2004)
Ghana	average of 0.40, maximum of 0.50	Loehnertz et al. (1996)
Indonesia (general)	0.45	Silitonga (1987)
Brazil, Old Amazon	0.47	Verissimo et al. (1992)
Indonesia, East Kalimantan	0.50	Muladi (1996)
Malaysia (general)	0.50	Bhargava and Kugan (1988)
Papua New Guinea	average of 0.52 (0.44-0.56)	Kilkki (1992)
Brazil, Maranhao State	0.55	Loehnertz et al. (1996)
Philippines	average value not provided (0.56-0.68)	Niedermaier (1984)

B.5 HWP Rate of Oxidation

The rate of oxidation refers to the proportion of the HWP pool(s) which is oxidized, thereby releasing carbon to the atmosphere. Three approaches can be used to establish the product decay profile for HWP (Ford-Robertson, 2003):

(i) linear decay over the lifetime - so there is nothing left at the end of that period

(ii) exponential decay with a given half-life - in order to generate an equivalent "tonne-year" impact, the half life is equivalent to half of the lifetime used for linear decay

(iii) instant decay of all emissions at the end of the product life - as with the exponential decay, the life used is half of that used for linear decay.

The IPCC default approach (IPCC, 2006b, Chapter 12, Section 12.2.2, p. 12.17) assumes that the carbon in woody material follows a first-order oxidation. It is based on the assumption that HWPs are discarded from use. Table B-5 presents the IPCC default rates of oxidation for HWP categories (ltHWPs and stHWPs).

Table B-5. Rate of oxidation for Harvested Wood Products (adapted from IPCC (2006b), Chapter 12, Table 12.2, p. 12.17)

Harvested Wood Products Category	k_{ltHWP_ox} Rate of oxidation
ltHWPs, e.g. solid wood	0.023
stHWPs, e.g. paper products	0.347

B.6 Harvester Fuel Consumption Factor

Klvac and Skoupy (2009) derived fuel consumption emission factors for equipment required for harvesting operations, as listed in Table B-6.

Table B-6. Equipment types and fuel consumption for harvesting operations (Klvac and Skoupy, 2009)

Operation	Equipment	Factor	Data	Unit
Felling	harvester	Fuel consumption, $FC_{harvest}$	1.28 - 1.73	L m^{-3}

B.7 Electricity Demand of Sawmill Processes

The electricity demand factor can be employed to determine the electricity consumption (kWh) required for a particular volume of merchantable logs. Table B-7 presents data from three international sawmill processes and shows that an approximate range for the electricity demand (e_{demand}) is 20-40 kWh m^{-3}.

Where the country specific value for the electricity demand is available, it should be used. If this is not the case, then a factor from a country that uses similar timber processing technology to that of the project's host country should be used.

Table B-7. Electricity demand for sawmill processing in various countries

Country	Electricity (kWh day $^{-1}$)	Harvest Volume (m^3 day^{-1})	e_{demand} (kWh m^{-3})	Data Source
Indonesia	600	20	30	Budiono (unknown)
Brazil	2756	136	20	Poole and Pinheiro (2003)
New Zealand	-	-	26-41	Li et al. (2006)

B.8 Fuel Consumption Charts

The fuel consumption rate of the generator can be derived from fuel consumption charts for generators. An example is shown in Table B-8 using the generator size (kW) and the anticipated load.

Table B-8 Fuel consumption chart for a diesel generator (Diesel Service and Supply, 2009)

Generator Size (kW)	1/4 Load (kL h^{-1})	Full Load (kL h^{-1})	Generator Size (kW)	1/4 Load (kL h^{-1})	Full Load (kL h^{-1})
20	0.002	0.006	500	0.042	0.135
40	0.006	0.015	750	0.062	0.202
60	0.007	0.018	1000	0.082	0.269
100	0.01	0.028	1250	0.102	0.336
125	0.012	0.034	1500	0.122	0.403
150	0.014	0.041	1750	0.142	0.47
200	0.018	0.055	2000	0.162	0.537
300	0.026	0.081	2250	0.182	0.604

B.9 Forest Product Type

Classification of forest product types into short-term and long-term harvested wood products is presented in Figure B-1 below:

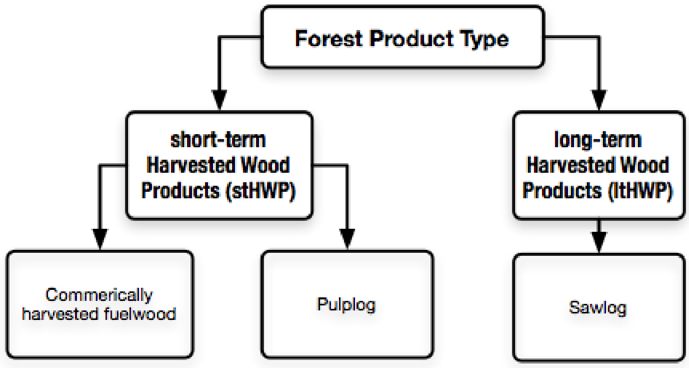

Figure B-1. Classification of forest product types into short-term and long-term harvested wood products

Appendix C: Unit Conversion and GWP Calculations

C.1 Converting Mass of Carbon (tC) to Carbon Dioxide (tCO_2)

Mass of carbon, which is the typical unit expressed in AFOLU projects, is converted to mass of carbon dioxide gas using the following relationship:

Equation C-1

$$m_{CO_2} = m_{carbon} \times \frac{44}{12}$$

Parameter	Description	Unit
m_{CO_2}	Mass of carbon dioxide	tCO_2
m_{carbon}	Mass of carbon	tC
44/12	Molecular ratio of carbon dioxide to carbon	$tCO_2\ tC^{-1}$

C.2 Converting Other GHGs to Carbon Dioxide Equivalents (CO_2-e)

Other GHGs considered in this Methodology subject to significance as determined in Section 1.2.3, are methane (CH_4) and nitrous oxide (N_2O).

Non-CO_2 gas emission factors must be expressed in carbon dioxide equivalents by multiplying their emission factors by their corresponding global warming potentials (GWPs) and summating the results together to obtain an overall emission factor in terms of carbon dioxide equivalents:

Equation C-2

$$EF = \left(EF_{CH_4} \times GWP_{CH_4}\right) + \left(EF_{N_2O} \times GWP_{N_2O}\right)$$

Parameter	Description	Unit
EF_{CH_4}	Emission factor for methane gas, activity data-specific	tCH_4 (activity data unit#)$^{-1}$
EF_{N_2O}	Emission factor for nitrous oxide gas, activity data-specific	tN_2O (activity data unit)$^{-1}$
GWP_{CH_4}	Global warming potential of methane (*see* Table 2-4)	tCO_2-e tCH_4^{-1}
GWP_{N_2O}	Global warming potential of nitrous oxide (*see* Table 2-4)	tCO_2-e tN_2O^{-1}

activity data unit is the unit of the activity data of either the carbon source or sink, e.g. methane emissions, tCH_4 (kL of fuel)$^{-1}$

Where CH_4 and N_2O are determined to be insignificant (determined from Section 1.2.3) to the overall calculations, and HFCs, PFCs and SF_6 are not included, then CO_2 becomes the sole contributor.

Throughout this Methodology, even if CO_2 becomes the sole contributor toward GHG emissions, it is expressed as CO_2-e.

Global Warming Potentials (GWPs) for CH_4 and N_2O must be selected from the most recent UNFCCC publications (e.g. UNFCCC, 2004).

C.3 Converting Units for Fuel Emission Factor

IPCC (2006) emission factors for GHGs (CO_2, CH_4 and N_2O) are recorded in units of kg of GHG (TJ of fuel)$^{-1}$. As such, for each GHG, the emission factor must be multiplied by the fuel's heating value (in TJ kg^{-1}) and density (kg kL^{-1}) to obtain an emission factor in tGHG kL^{-1}. (e.g. tCO_2-e kL^{-1}, tCH_4 kL^{-1} and tN_2O kL^{-1}).

Equation C-3

$$E_{fuel\_GHG} = \frac{EF_{IPCCfuel\_GHG} \times HV_{fuel} \times \rho_{fuel}}{1000}$$

Parameter	Description	Unit
EF_{fuel_GHG}	Fuel emission factor for the greenhouse gas (CO_2, CH_4 or N_2O)	tGHG kL^{-1}
$EF_{IPCCfuel\_GHG}$	IPCC fuel emission factor for greenhouse gas (CO_2, CH_4 or N_2O)	kgGHG TJ^{-1}
HV_{fuel}	Heating value of fuel	TJ kg^{-1}
ρ_{fuel}	Density of fuel	kg kL^{-1}

Heating value and density of fuels can be found from the IPCC Emission Factor Database (2009).

A CO_2 equivalent (CO_2-e) fuel emission factor (EF_{fuel}) can be derived using the global warming potential (GWP) of each gas as outlined in Section C.2.

Appendix D: Example Solution to Equations 3-22a and 3-22b

Equation 3-22a is straight-forward and therefore will not be represented here. However, the mathematical expression of Equation 3-22b is complex and therefore warrants an order of example solution of its application. This example applies also to Equation 3-29b as the procedure to the order of solution is similar. For applying this example to Equation 3-29b, replace the subscript "DW" with "ltHWP" or/and "stHWP" as required.

Equation 3-22b

$$C_{DW_{pool,t}} = \left(F_{DW\_remain,t-(t-1)} \times C_{DW_{in},t}\right) + \left(F_{DW\_remain,t-(t-2)} \times C_{DW_{in},t-1}\right) + \left(F_{DW\_remain,t-(t-3)} \times C_{DW_{in},t-2}\right) + \mathrm{K} + \left(F_{DW\_remain,t-(t-t^*)} \times C_{DW_{in},t-(t^*-1)}\right)$$

Parameter	Description	Unit
$C_{DW_{pool,t}}$	Cumulative carbon remaining in the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC
$F_{DW\_remain_t}$	Annual fraction of carbon in the deadwood pool that would remain in the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity) after applying the rate of decay	dimensionless
$C_{DW_{in,t}}$	Annual total carbon input to the deadwood pool in year *t*, (where *t*=1,2,3 … *t** years elapsed since the start of the IFM-LtPF project activity)	tC

This example assumes that a specific project has a lifetime of 5 years. Hence, the application of Equation 3-22b becomes:

Year 1 $C_{DW_{pool,1}} = \left(F_{DW\_remain,1} \times C_{DW_{in},1}\right)$

Year 2 $C_{DW_{pool,2}} = \left(F_{DW\_remain,1} \times C_{DW_{in},2}\right) + \left(F_{DW\_remain,2} \times C_{DW_{in},1}\right)$

Year 3 $C_{DW_{pool,3}} = \left(F_{DW\_remain,1} \times C_{DW_{in},3}\right) + \left(F_{DW\_remain,2} \times C_{DW_{in},2}\right) + \left(F_{DW\_remain,3} \times C_{DW_{in},1}\right)$

Year 4 $C_{DW_{pool,4}} = \left(F_{DW\_remain,1} \times C_{DW_{in},4}\right) + \left(F_{ltHWP\_remain,2} \times C_{ltHWP_{in},3}\right) + \left(F_{DW\_remain,3} \times C_{DW_{in},2}\right) + \left(F_{DW\_remain,4} \times C_{DW_{in},1}\right)$

Year 5 $C_{DW_{pool,5}} = \left(F_{DW\_remain,1} \times C_{DW_{in},5}\right) + \left(F_{DW\_remain,2} \times C_{DW_{in},4}\right) + \left(F_{DW\_remain,3} \times C_{DW_{in},3}\right) + \left(F_{DW\_remain,4} \times C_{DW_{in},2}\right) + \left(F_{DW\_remain,5} \times C_{DW_{in},1}\right)$

Tables D-1 and D-2 present the application of Equations 3-21 through to 3-23, for a fixed and variable input to the deadwood pool, applying Equations 3-22a and 3-22b, respectively. For parameter descriptions, please refer to the description tables for relevant equations used in Section 3.3.1 (for deadwood pool) and Section 3.3.2 (for long-term HWP pool).

Table D-1. Numerical example for a fixed input into the deadwood pool (applying Equation 3-22a)

Assume that $C_{DW_{in},t}$ has been calculated to have a fixed annual value of 54,000 tC and k_{decay} determined to be 0.03 yr^{-1}				
Project Lifetime	Equation 3-18	Equation 3-21	Equation 3-22a	Equation 3-23
t (yr)	$C_{DW_{in},t}$ (tC)	$F_{DW\_remain,t}$ (tC)	$C_{DWpool,t}$ (dimensionless)	$C_{DW_{out},t}$ (tC)
1	54,000	0.970	52,404	1,596
2	54,000	0.942	103,259	4,741
3	54,000	0.914	152,612	9,388
4	54,000	0.887	200,505	15,495
5	54,000	0.861	246,984	23,016
* Please note that due to numerical rounding, the values presented in this table may not exactly reflect your calculated values.				

Table D-2. Numerical example for a variable input into the deadwood pool (applying Equation 3-22b)

Assume that $C_{DW_{in},t}$ has been calculated to have a variable annual value (see Column 2) and k_{decay} determined to be 0.03 yr^{-1}				
Project Lifetime	Equation 3-18	Equation 3-21	Equation 3-22b	Equation 3-23
t (yr)	$C_{DW_{in},t}$ (tC)	$F_{DW\_remain,t}$ (tC)	$C_{DWpool,t}$ (dimensionless)	$C_{DW_{out},t}$ (tC)

1	54,000	0.970	52,404	1,596
2	26,000	0.942	76,087	3,913
3	30,000	0.914	102,952	7,048
4	12,000	0.887	111,554	10,446
5	13,000	0.861	120,873	14,127
* Please note that due to numerical rounding, the values presented in this table may not exactly reflect your calculated values.

Version 1.2
Sectoral Scope 14

Improved Forest Management in Temperate and Boreal Forests (LtPF)

This methodology is developed by:

3GreenTree Ecosystem Services Ltd.

ERA Ecosystem Restoration Associates Inc.

The previous revision of this methodology to Version 1.2 received support from Camco Group International Inc.

Table of Contents

1 SOURCES

This document reflects an update to VM0012 Improved Forest Management on Privately Owned Properties in Temperate and Boreal Forests (LtPF) v.1.0, which was developed 3GreenTree Ecosystem Services, Ltd. and ERA Ecosystem Restoration Associates, and approved by VCS on April 19, 2011.

This update removes the applicability conditions related to fee simple ownership to become consistent with the VCS Version 3 definitions and requirements related to right of use.

The document has been reorganized to match the VCS Version 3 Project Document Template structure, without materially affecting the original content.

The following documents were used to inform and guide the creation of this methodology:

- VCS Standard 2007.1 (Voluntary Carbon Standard, 2008d)
- VCS Program Guidelines 2007.1 (Voluntary Carbon Standard, 2008e)
- VCS Guidance for AFOLU Projects (Voluntary Carbon Standard, 2008a)
- VCS Tool for AFOLU Methodological Issues (Voluntary Carbon Standard, 2008b)
- Tool for AFOLU Non-Permanence Risk Analysis and Buffer Determination - Proposed (Voluntary Carbon Standard, 2010a)
- CAR Forest Project Protocol Version 3.0 and 3.2 (Climate Action Reserve, 2010)
- VM0003 Methodology for Improved Forest Management through Extension of Rotation Age, v1.0

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology for Improved Forest Management – Logged to Protected Forest quantifies GHG emission reductions/removals from projects on land with forests remaining forests and where carbon sequestration occurs when logging in the baseline scenario is avoided in the project scenario.

2.1 Baseline and Project Scenario Steps:

1. Determine project eligibility and applicability of this methodology.
2. Establish the project area (= private property boundary).
3. Establish a project time horizon.
4. Determine multiple credible and realistic baseline scenarios.
5. Select the baseline scenario
6. Test for additionality using designated tools and requirements.
7. Select the applicable carbon pools and emission sources for the project area.
8. Create detailed baseline scenario and project scenario assumptions:
    a. Spatially stratify the current land cover and land use conditions by area, if necessary:
    b. Determine the timber harvesting land base area(s)
    c. Project the baseline and project scenario forest management schedule, including forest regeneration practices, for a minimum of one rotation. Include spatially located harvestable volume and area by analysis unit and year, identify stand level harvesting methods and assumptions, and identify additional relevant scenario modeling information.
    d. Project the net annual ecosystem carbon stock changes over time under the baseline and project scenarios, including changes due to harvest removals, regeneration, stand growth, mortality, and any additional factors that materially affect carbon balance.
9. Calculate annualized and project total ex-ante carbon pool flows and GHG Emissions for the baseline and project scenarios.

10. Calculate the net change in GHG emissions between the ex-ante ecosystem carbon projections for the baseline and project scenarios, on an annualized basis.
11. Assess leakage risks to determine a leakage factor to be applied to the net annual GHG emission changes.
12. Calculate and estimate the expected net VCU's, including calculating VCS permanence buffer requirements.
13. Calculate and apply an uncertainty factor to net GHG emission reductions.

2.2 Monitoring Steps:

1. Determine the data and assumptions to be monitored to assess ex-post carbon stock changes in the project area.
2. Determine remote sensing activities for monitoring ex-post land use changes on the project area.
3. Develop and implement a systematic field plot network for estimating and monitoring actual stand level biomass within the project boundary.
4. Develop and implement a leakage monitoring plan.
5. Develop a record-keeping procedure to record and archive monitoring activities, results, and related management actions.
6. Design a quality assurance/quality control program related to monitoring.

3 DEFINITIONS

Boreal Forest - as per FAO ecological zone definitions and mapping (FAO, 2001): "The Boreal, or subarctic, domain is found only in the higher latitudes of the Northern Hemisphere between 50-55 to 65-70 degrees. It has at least one and up to 4 month with an average temperature above 10^{o}C. Another feature is the large annual range of temperature. Rainfall is low, generally below 500 mm. The northern boundary, approximately the isotherm of 10^{o}C for the warmest month (usually July), coincides rather well with the poleward limit of tree growth."

Clear cut - Harvest removal of >90% of merchantable trees within a defined area

De minimis – carbon emissions deemed to be insignificant or immaterial to the total GHG calculations. Unless otherwise specified, *de minimis* refers to activities resulting in <5% change in the total project GHG emission reductions. See (CDM, 2007a) for further details.

Logging slash - Dead wood residues (including foliage) left on the forest floor after timber removal

Right of Use – As defined in the most recent version of the VCS Standard.

Temperate Forest – as per FAO ecological zone definitions and mapping (FAO, 2001): "The temperate domain occupies a medial position within the middle latitudes – usually between the subtropical domain equator-wards and the boreal domain pole-wards. The boundaries with the subtropical - and boreal domain are 8 months and 4 months, respectively, with average temperatures of 10°C or above. Its main distribution is in the northern hemisphere".

Timber Harvest Land Base (THLB) – a sub-set of the project area land base subject to timber harvesting, including spatially located areas or reasonable volume-based proxies within the project boundaries which are currently considered biologically and economically feasible for timber harvesting as per typical regional logging practices relevant to the project site. Removals from the THLB may include, but are not limited to: non-forest areas; non-commercial forest types; physically inoperable or inaccessible areas due to terrain, soils, etc.; current and future roads and other non-forest clearings; legally required or voluntary buffers and protected areas (i.e.

riparian zones, wildlife areas, sensitive sites, etc.), long run uneconomical stands, and other areas which are not eligible for harvesting under typical or common practices determined in the baseline and project scenarios. Examples of determining THLB can be found within British Columbia Timber Supply Analysis documentation at http://www.for.gov.bc.ca/hts/tsas.htm in Timber Supply Area (TSA) Analysis Reports (i.e. pg. 10, http://www.for.gov.bc.ca/hts/tsa/tsa13/tsr2/analysis.pdf); however, projects must use methods typical of local forest estate modeling and timber supply analyses. Note that the THLB is a primary stratification which identifies areas eligible for harvesting activities; all project requirements apply to the entire project area.

Tree - A perennial woody plant with a diameter at breast height > 5 cm and a height greater than 1.3 m.

Acronyms:

CAR – Climate Action Reserve

CDM - Clean Development Mechanism

GPG LULUCF - Intergovernmental Panel on Climate Change‘s Good Practice Guidance for Land-Use, Land Use Change and Forestry

IFM - Improved Forest Management (VCS project type)

LtPF – Logged to Protected Forest (VCS IFM project sub-type)

PD - Project Description

VCS - Verified Carbon Standard

VCU - Verified Carbon Units

4 APPLICABILITY CONDITIONS

This methodology is applicable to:

1. Projects which meet the most recent approved criteria for VCS Improved Forest Management – Logged to Protected Forest (IFM-LtPF) eligible projects, and;

2. Projects located in Temperate and Boreal Domain Global Ecological Zones (as defined by FAO (FAO, 2001)) which are forest lands remaining forest lands (as defined by IPCC (IPCC, 2003)), and which can meet IPCC GPG LULUCF Tier III inventory and data requirements (IPCC, 2003); and,

3. Projects that meet the most current approved VCS Standard requirements for ownership; and,

4. Projects on properties where the *starting* average annual illegal, unplanned, and fuelwood removals are less than 5% of total annual harvest levels (in CO_2e) in the baseline scenario[1]; and,

[1] This methodology does not provide specific equations and methods for the treatment of illegal and unplanned harvesting or fuelwood removal. Therefore, projects with non-*de minimis* levels (determined using the Tool for Testing Significance of GHG Emissions in A/R CDM Projects (CDM, 2007a)) of these activities in the starting condition (or as local common practice applicable to the project area) are ineligible. If monitoring reveals conditions change during the project duration, projects will not necessarily be rendered ineligible for this methodology, but rather must demonstrate that new non-*de minimis* illegal or unplanned harvests, and fuelwood removal net emissions reductions are accounted for in the project scenario prior to the next verification, in a manner equivalent to the terms $LB_{FELLINGS,i,t}$ and $LB_{OTHER,i,t}$ (see section 8.2.7). These additional equations and methods will constitute a methodology revision, subject to the latest approved VCS revision -approval process.

5. Projects which do not encompass managed peatland forests (peatland as defined by IPCC GPG LULUCF); and,

6. Projects where the total percentage of wetlands in the project area is not expected to change as part of project activities; and,

7. Projects that can demonstrate there will be no activity shifting to other lands owned or managed by project proponents outside the project boundary at the beginning of the project (within the first year of the project start date)[2]; and,

8. Projects that do not include non-*de minimis* application of organic or inorganic fertilizer in the project scenario.

5 PROJECT BOUNDARY

5.1 Spatial Project Boundaries:

The project boundary is to be defined by the project proponent with maps and legal land descriptions. Such properties may be contiguous or separate properties if they are located within a similar region and forest condition.

Note that all spatially relevant forest land holdings owned or managed by the project proponent will need to be considered in leakage assessments and monitoring, even if they are not included in the defined project area.

5.2 Temporal Project Boundaries

As per VCS requirements for AFOLU projects, project proponents must specify a project-crediting period as set out in the most recent version of the VCS Standard. .

5.3 Leakage Assessment Boundaries

Leakage within this methodology is assessed against a national leakage area.

5.4 Selected Carbon Pools and Emissions Sources:

Table 1 - Selection of Carbon Pools

Carbon Pool	Selected?	Justification/Explanation
Aboveground Tree Biomass	Yes	Required by VCS. Major carbon pool subject to changes from the baseline to the project scenario.
Aboveground Non-tree Biomass	No	Excluded by VCS. Minor carbon pool subject to changes from the baseline to the project scenario
Belowground Biomass Pool	Yes	Required by VCS. Major carbon pool subject to changes from the baseline to the project scenario.

[2] This methodology does not provide specific equations and methods for calculating net emissions related to activity shifting leakage. VCS requires "IFM project developers must demonstrate that there is no leakage within their operations – i.e., on other lands they manage/operate outside the bounds of the VCS carbon project" (Voluntary Carbon Standard, 2008a); and the methodology requires monitoring and reporting on evidence demonstrating no activity shifting is occurring in order to demonstrate compliance with VCS. If, during the project duration, activity shifting is found to be occurring, project should to refer the latest VCS AFOLU requirements.

Dead Wood Pool	Yes	Required by VCS. Minor carbon pool subject to changes from the baseline to the project scenario.
Litter Pool	No	Excluded by VCS for AFOLU projects. Minor carbon pool – generally considered as a transitional pool only.
Soil Carbon Pool	No	Optional in VCS AFOLU IFM projects, but excluded in this methodology. As a conservative approach, changes to soil carbon from harvesting are assumed to be *de minimis*.
Wood Products Pool	Yes	Required by VCS. All baseline scenarios involve logging.

Table 2 - Emissions Sources Included/Excluded from the Project Boundary

Emissions Sources	Gas	Selected?	Justification/Explanation
Use of Fertilizers	CO_2 CH_4 N_2O	No No No	Non-*de minimis* use of fertilizer in the project scenario is excluded. In the baseline scenario, fertilizer emissions are deemed insignificant, as per the VCS May 24th, 2010 AFOLU Program Update (Voluntary Carbon Standard, 2010c). These exclusions are conservative, and do not increase the emission reductions.
Combustion of Fossil Fuels by Vehicles / Equipment	CO_2 CH_4 N_2O	Optional[3] No No	Carbon emissions from harvesting equipment, log transport, and primary forest product manufacturing are included. CH_4 and N_2O emissions from equipment are assumed to be *de minimis*. The exclusion of these combustion gases does not increase the emissions reductions in the project.
Burning of Biomass (on site slash burning)	CO_2 CH_4 N_2O	No No No	However, carbon stock decreases due to biomass burning are accounted as a carbon stock change. These exclusion assumptions do not increase the emission reductions in the project.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO:

This methodology utilizes a project-based baseline scenario approach.

[3] Project developer may choose to exclude this pool is it can be demonstrated that it is conservative with respect to the impact on GHG emission reductions generated.

The flow of GHG emissions over the project duration is based on the creation and projection of a reasonable, credible, and conservative baseline harvesting scenario in the absence of the carbon project. The most plausible baseline scenario is selected from a comparative assessment of the project and the baseline alternatives, including "at a minimum, a comparative assessment of the implementation barriers and net benefits faced by the project and its alternatives" (Voluntary Carbon Standard, 2008d).

This methodology will employ a 3 step process to select a most likely baseline, and is required to be consistent with the assessment and determination of additionality in Section 7[4]:

STEP 1 – Identify Plausible Alternative Baseline Scenarios to the VCS Project Activity

Project proponents must identify and document descriptions, rationale, and information sources for multiple *(at minimum 3)* realistic and credible property forest management scenarios that would have potentially occurred within the proposed project boundary in the absence of the carbon project activity.

The possible baseline scenarios to be evaluated must include, at minimum:

1. Historical Practice Baseline Scenarios: continuation of pre-project historical activity baseline or management plans;
2. Common Practice Baseline Scenarios: activity on the project area which could have been performed without the carbon project, based on evidence of comparable forest management for similar property types and situations in the region[5];

All identified baseline scenarios must, at a minimum:

1. Comply with IFM-LtPF project and eligibility requirements by only including activities and areas where forests remain forests;
2. Comply with legal requirements for forest management and land use in the area, "unless verifiable evidence can be provided demonstrating that common practice in the area does not adhere to such requirements" (Voluntary Carbon Standard, 2008d)[6];
3. Demonstrate that the "projected baseline scenario environmental practices equal or exceed those commonly considered a minimum standard among landowners in the area" (Voluntary Carbon Standard, 2008d).

Realistic and credible baseline scenarios must be based on verifiable information sources such as local or regional land, harvest, or inventory records, observable comparable regional property evidence, formal property appraisals, financial modeling compared against typical published regional industry market return rate targets, regional stakeholder feedback, accredited or certified professionals (i.e. registered professional foresters, etc.) within the regional relevant industry, and other reasonable information sources provided in a manner consistent with typical regional considerations and practices.

---

[4] Although only required as part of the Additionality assessment, project proponents may find utilizing the Tool for the Demonstration and Assessment of Additionality in VCS AFOLU Project Activities (VCS, 2010b) to be useful for additional guidance for identifying and selecting baseline scenarios.

[5] Also considering the financial drivers for management activities based on verifiable market-based financial return expectations of typical market property owners and investors (i.e., IRR, NPV, cost of capital hurdle rates, etc. for data comparisons with available market financial information).

[6] Note that VCS further states: "if it can be shown that these activities result from laws, statutes, regulatory frameworks or policies implemented since 11 November 2001 that give comparative advantage to less emissions-intensive technologies or activities relative to more emissions-intensive technologies or activities they need not be taken into account and the baseline scenario could refer to a hypothetical baseline rate of avoided emissions or sequestration without the national and/or sectoral laws, statutes, regulatory frameworks or policies being in place." (Voluntary Carbon Standard, 2008d).

Project proponents may utilize tools such as the Investment Analysis (Step 2) and Barrier Analysis (Step 3) of the latest approved version of the VCS Tool for Demonstration and Assessment of Additionality as an initial filter to exclude project scenarios which are financially infeasible or face clear barriers to implementation.

The remaining baseline scenarios are then further evaluated to select the most likely baseline scenario, as follows.

STEP 2 – Selection of a Single Baseline Scenario for the Project

Project proponents must select a single baseline scenario for the project using the following steps:

STEP 2a - The Historical Baseline Scenario – based on historical operating practices on the property:

The baseline scenario based on actual property harvest history *must be selected if*:

2a.1 The project proponent has at least 5 years historical harvest level data history[7].

All other cases will utilize the Common Practice Baseline Scenario Selection steps below:

STEP 2b - The Common Practice Baseline Scenario – based on previous owner activities:

2b.1 If the current project proponent has owned the property for less than five years then the project proponent may:

- i. Choose to use the previous managers historical activities or management plan as representative of common practice, in which case the baseline scenario is selected based on the process and criteria in Step 2a; *or*,
- ii. Choose to select the baseline scenario based on common practice and investment analysis of scenarios as outlined in Step 2c below.

STEP 2c - The Common Practice Baseline Scenario – based on common practice activities:

For recent or pending changes in project property management without historical data (> 5 years) (or otherwise not selecting a historical baseline scenario as per Step 2b), the project proponent will select the baseline scenario(s) based on an assessment of regional common practice[8] supported by a financial analysis for achieving typical market returns from forest products.

The project proponent must select the baseline scenario that:

2c.1 Generates the most financial attractive return on investment from forest product returns using the assessment process outlined in Step 2 Option II and/or Option III in the most recent version of the VCS Tool for the Demonstration and Assessment of Additionality in VCS AFOLU Project Activities; and,

2c.2 Can be demonstrated to be regionally common practice and locally operationally implementable, including:

- a. Compliant with the legally required land use and forest management practices in a manner consistent with VCS requirements (see Step 1);

[7] For convenience, projects may utilize a pre-existing forward-looking forest management plan as the historical baseline data, if this management plan can be demonstrated to be consistent with the historical practices and rates, and representative of a forward projection of historical harvest practices.

[8] VCS currently defines common practice as: "Extrapolation of observed similar activities in the geographical area with similar socio-economic and ecological conditions as the project area occurring in the period beginning ten years prior to the project start date" (VCS, 2010b).

b. Consistent with local market capacity for the baseline scenario activities and products (i.e. log markets, contractor capacity, etc.);
c. Consistent with observable and verifiable[9] regional operational practices, including, at minimum:
   i. Harvest types (i.e. clearcut, selective cut, etc.),
   ii. Logging and hauling equipment types and capabilities,
   iii. Annual harvest levels (i.e. m^3/year, ha/year),
   iv. Average minimum harvest age, tree size, and/or stand volume,
   v. Average minimum economic viability (or decision criteria) by stand type,
   vi. Average minimum log utilization specifications (on average based on size and/or species), and waste/breakage assumptions,
   vii. Average tree retention practices, including hydro-riparian buffers, wildlife trees, and other single or grouped merchantable and un-merchantable tree retention,
   viii. Maximum harvest slope or other operability constraints which would limit regional logging equipment,
   ix. Reforestation and stand management practices; and
d. Operationally feasible on the project area using local harvesting and hauling technology, local infrastructure, etc. [10].

Project proponents must provide a description of the selected baseline scenario and related scenario modeling assumptions which justifies and provides supporting evidence that the baseline scenario selected under STEP 2c reflects a credible assessment of typical common practice for similar conditions, as listed above.

STEP 3 – Additionality Test

Project proponents must further ensure the selected most plausible baseline scenario is consistent with the outcome of the additionality assessment of this scenario made under Section 7 in this methodology.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Project proponents must use the newest version of the VCS tool: "Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities". In summary, this tool employs the following steps:

Step 1 - *Identification of alternative land use scenarios to the AFOLU project activity;*

Step 2 - *Investment analysis to determine that the proposed project activity is not the most economically or financially attractive of the identified land use scenarios; or*

Step 3 - *Barriers analysis; and*

Step 4 - *Common practice analysis.*

Project proponents must insure the assessment and outcomes of additionality are consistent with the baseline selection assessment undertaken in Section 6.

[9] Demonstrated by reviewing modeled baseline scenario assumptions in comparison to: directly observable activities on other regional properties, verifiable documentation from previous or current owner/manager operational requirements, property or comparable property appraisals or valuation document assumptions, published documents reviewing regional operational practices, comparable published regional government requirements, testimony of independent local experts and professionals, and/or other verifiable sources.

[10] For example, a baseline scenario could not be selected if it involved using equipment (i.e. helicopter logging) not available regionally. A baseline could not be selected which projected a level of harvest the local mills, road infrastructure, and contractor capacity could clearly not physically handle annually without significant additional capital investment. Relevant independent local expert opinion may be used to further demonstrate the reasonableness of local capacity assumptions.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions:

The baseline emissions are calculated from the baseline scenario selected in Section 6. This baseline scenario does not change during the project duration, however, as outlined in Section 8.2.4, certain data or model parameter changes may require remodeling baseline carbon pools in future verifications.

All calculations in this methodology represent annualized net changes in carbon stocks by polygon. Results from each polygon must therefore be summed across the project activity area to determine the annual total net emissions and reductions.

Valid Starting Inventory Requirements

Project proponents must provide a valid starting forest inventory meeting the following requirements:

1. Pertaining directly to the entire project area; and,
2. Created, updated, or validated <10 years ago; and,
3. Documentation is available describing the methods used to create, update, or otherwise validate the starting inventory, including statistical analysis, field data, and/or other evidence[11,12].

Baseline Scenario Area Stratification

The process of stratifying the area represented in the baseline scenario should include two steps. The first is to divide the area (A_{BSL}) into homogeneous units (polygons) from the perspective of carbon storage and sequestration. The second step is to identify areas within the project area that are eligible for specific forest management activities within the baseline and project scenario.

STEP 1 – Stratify to create homogeneous units

If the project activity area is not homogeneous, stratification should be carried out to improve the accuracy and precision of biomass estimates[13]. Different stratifications may be required for the baseline and project scenarios in order to improve accuracy in the estimates of net GHG removal by sinks. For estimation of the baseline net GHG removals by sinks, or calculation of actual net GHG removals, homogeneous *polygons*[14] *should be defined on the basis of parameters that will be used as key entry variables in the methods used to estimate changes in biomass stocks* (for example, growth models or yield curves/tables). These include:

1. Management regime. For example, types of harvesting (clear cutting, patch retention), and land conversions for roads and landings.
2. Site index / anticipated growth rates
3. Forest species
4. Age class

Useful tools for defining polygons include ground-truthing maps from satellite imagery, aerial photos, and maps of vegetation, soils, and topography.

[11] Note that this methodology evaluates uncertainty using actual results from an ex-post plot network program (see Section 8.5.3) and hence does not mandate a starting inventory accuracy requirement. Project proponents, however, must provide evidence that the starting inventory has been validated to regional common practice minimum standards for use in ex-ante modeling.

[12] Project proponents may provide supporting evidence using local inventory validation results from outside the project area if: they are based on directly comparable inventory methods, overall average forest cover and condition are comparable, and if the data refer to comparable or larger scale properties.

[13] For further details, see http://cdm.unfccc.int/methodologies/DB/YDYGY2G5VNPKVHB7B9SU12RRWRL439/view.html

[14] At minimum, more than one polygon per project is required for the statistical calculations in Section 8.5.3.

In the case where a project area is large and spans a diverse range of forest types and ages, the area may need to be stratified into hundreds or even thousands of polygons. When the number of polygons is ≥ 25, the proponent has the option of aggregating similar polygons into "*analysis units*[15]" to facilitate modeling and monitoring. This practice is common when planning management activities over large forest management areas. The use of *analysis units allows polygons to be grouped based on similarities in the polygon criteria, including removing differences associated with stand age*. Each analysis unit is modeled from the period of stand initiation to a mature end point. The attributes (e.g. biomass and dead organic matter pools) of each analysis unit are recorded for every year of growth and stored in a database that can easily be linked back to a specific stand age.

STEP 2 – Identify areas eligible for specific management activities

To assure the project includes only eligible management activities, proponents must identify areas within the project boundary that would be subject to timber harvesting and other management activities under the baseline scenario. A timber harvesting land base (THLB) should be identified based upon harvesting plans that reflect the historical and future anticipated location and rates of timber extraction. Specific information used to define the THLB should include:

1. The spatial location and extent of forested versus non-forested areas
2. Merchantable and operable forest areas suited to economic timber extraction
3. The spatial location and extent of legal land use restrictions and legally required protected areas.

The THLB is essentially used to refine and focus baseline and project forest management activity projections and modeling, in a manner consistent with the selected scenarios and related common practice.

8.1.1 Model Selection and Use

It will be necessary to employ mathematical models to project annual carbon stock changes over time in the various carbon pools. Although it may be possible to utilize a series of spreadsheet calculations for simple forest situations, in most cases complex forest management models (both at the stand and landscape-level) will need to be employed. Regardless of the type of model used, the same model must be used for both the baseline and project scenarios to ensure consistency in the carbon projections.

A hierarchy of suitability should be applied in selecting an appropriate model, in accordance with the following criteria:

1. Well established (i.e., have been under continuous use and development for 10 years, or longer);
2. Generate values on an annual basis (preferably), or at intervals not exceeding 10 years.
3. Include a reasonable representation of mortality from stand-self thinning and natural disturbance agents that are regionally appropriate. Adjustments may need to be made by project proponents to account for these factors if they are not well represented. Rationale must be provided when making adjustments.
4. Output data are expressed in carbon units (tC/ha) or as biomass (t/ha), and are calculated for each of the required carbon pools (See Table 1). If expansion factors are used in combination with growth and yield model(s), they should be based upon regionally specific studies and applied only for the appropriate region and species.
5. Well documented and expert reviewed. In order of preference, these include (a) ongoing publications in peer-reviewed scientific journals, (b) documented reviews by expert practitioners in forestry/biology/ecology, and/or (c) approved by government for use in forest management activities;
6. Parameterized, calibrated, and tested for the specific conditions of the project.

[15] At minimum, more than one analysis unit is required for the statistical calculations in Section 8.5.3.

The following criteria are preferred but not required:

7. Documented as appropriate for simulating the ecological and management scenarios that define the baseline and project case;
8. Process-based models that simulate carbon dynamics directly (in the case of stand-level models) or in the case of landscape models (i.e. forest estate models), be driven by inputs from these stand level models. Process models that simulate all carbon pools within an ecosystem are preferred because their projections of carbon dynamics in the required and optional pools should be more accurate and easier to monitor and verify. Examples of appropriate stand-level growth models include FORECAST (Seely, Kimmins, Welham, & Scoullar, 1999), and CO2FIX (Masera & et al, 2003)
9. Growth and yield models are commonly used to project productivity in managed and unmanaged forest stands. In most cases their output is in the form of an annual merchantable timber volume increment. Examples include TASS/TIPSY, and VDYP (British Columbia Ministry of Forests and Range[16]), and the US Forest Service's Forest Vegetation Simulator (FVS) model[17]. This approach is less desirable because volume must be converted using a series of expansion factors representing each carbon pool. An example of this approach is the Carbon Budget Model of the Canadian Forest Service (CBM CFS3 (Kurz & et al., 2009), which uses volume curves as input data. For details on the use of expansion factors, see Pearson et al. 2007. This extra step in conversion introduces the potential for additional error into the pool estimates.

In addition, project proponents will make available, at validator/verifier request, documentation of:

1. The appropriateness of the selected model(s) to the particular project application;
2. A listing and explanation of all input data, output data, and model parameters/assumptions.

8.1.2 Calculating the Baseline Carbon Balance

This methodology employs the IPCC gain-loss method (IPCC, 2006a), which requires the biomass carbon loss be subtracted from the biomass carbon increment for the reporting year. This method is particularly appropriate for areas with a mix of stands of different forest types, and/or where biomass change is very small compared to the total amount of biomass. Further details can be found in (IPCC, 2006a) (Ch. 4).

The total annual carbon balance in year, t, for the baseline scenario is calculated as ($\Delta C_{BSL,t}$, in t C yr^{-1}):

$$\Delta \mathbf{C}_{\mathbf{BSL,t}} = \Delta \mathbf{C}_{\mathbf{BSL,P,t}} \qquad \mathbf{(1)}$$

where:

$\Delta C_{BSL,P,t}$ = annual change in carbon stocks in all pools in the baseline across the project activity area; t C yr^{-1} .

$$\Delta \mathbf{C}_{\mathbf{BSL,P,t}} = \Delta \mathbf{C}_{\mathbf{BSL,LB,t}} + \Delta \mathbf{C}_{\mathbf{BSL,DOM,t}} + \Delta \mathbf{C}_{\mathbf{BSl,HWP,t}} \qquad \mathbf{(2)}$$

where:

$\Delta C_{BSL,LB,t}$ = annual change in carbon stocks in living tree biomass (above- and belowground); t C yr^{-1}

$\Delta C_{BSL,DOM,t}$ = annual change in carbon stocks in dead organic matter; t C yr^{-1}

$\Delta C_{BSl,HWP,t}$ = annual change in carbon stocks associated with harvested wood products, t C yr^{-1}.

[16] http://www.for.gov.bc.ca/hre/StandDevMod/index.htm

[17] http://www.fs.fed.us/fmsc/fvs/

$$\Delta C_{BSL,LB,t} = \Delta C_{BSL,G,t} - \Delta C_{BSL,i,t} \quad (3)$$

where:

$\Delta C_{BSL,G,t}$ = annual increase in tree carbon stock from growth; t C yr^{-1}

$\Delta C_{BSL,L,t}$ = annual decrease in tree carbon stock from a reduction in live biomass; t C yr^{-1}.

If the project area has been stratified, carbon pools are calculated for each polygon, i, and then summed during a given year, t.

8.1.3 Live Biomass Gain

Live biomass gain in year, *t*, polygon, *i* ($\Delta C_{BSL,G,i.t}$) is calculated as:

$$\Delta C_{BSL,G,t} = \Sigma(A_{BSL,i} \bullet G_{BSL,i,t}) \bullet CF \quad (4)$$

where:

$A_{BSL,i,}$ = area (ha) of forest land in polygon, *i*;

$G_{BSL,i,t}$ = annual increment rate in tree biomass (t d.m. ha^{-1} yr^{-1}), in polygon, *i*, and;

CF = carbon fraction of dry matter t C t^{-1} d.m. (IPCC default value = 0.5).

$$G_{BSL,i,t} = G_{BSL,AG,i,t} + G_{BSL,BG,i,t} \quad (5a)$$

where:

$G_{BSL,AG,i,t}$ and $G_{BSL,BG,i,t}$ = annual above- and belowground biomass increment rates (t d.m. ha^{-1} yr^{-1});

$$G_{BSL,BG,i,t} = G_{BSL,AG,i,t} \bullet R_i \quad (5b)$$

where R_i is the root:shoot ratio in polygon, *i*. R_i should ideally be estimated for each polygon, but these data are difficult to derive empirically. Hence, general relationships are acceptable as long as they are appropriate for the species and region associated with the project (Cairns, 1997).

Equations 4 and 5 can be used directly to calculate $\Delta C_{BSL,G,t}$ when all tree cover within a polygon is removed by harvesting (i.e., clearfelling) and no residual structure is retained. In cases of partial harvesting and/or multiple entries into a polygon, these equations must be applied separately to each of the resulting sub-polygons (the different age classes that are created). This ensures that growth rates reflect the difference in forest age between the sub-polygons.

The ex ante calculation of $G_{BSL,i,t}$ (either directly, or from its component parts) will be derived from models that require inputs derived, in part, from forest inventory data. Criteria for model suitability are provided in 8.1.1.1. The exact form of the input data depends on the nature of the model but may include site index, species composition, and volume.

Inventory data used for this purpose must:

1. Pertain directly to the project area, and
2. Not be more than 10 years old.

Typically, inventory data provide only a generalized description of stand attributes such that only average values (versus species-specific estimates) can be used in the ex ante modeling exercise.

Some models will require estimates for parameter values not traditionally measured in typical forest inventories activities. Project proponents must make reasonable efforts to acquire sources of such data in accordance with the following priority list (best to least desirable):

1. Project area and forest-type specific
2. Regional estimates, from the same or similar ecosystems or forest types
3. National estimates that represent averages for similar forest types
4. Global estimates for generally similar forest types.

8.1.4 Live Biomass Loss

The annual decrease in live biomass tree carbon from live biomass loss ($\Delta C_{BSL,L,t}$; t C yr^{-1}) is the sum of losses from:

1. Natural mortality (i.e. insects, disease, competition, wind, etc.)
2. Commercial round wood felling
3. Incidental sources.

Losses must be specific to a given polygon; each polygon must be summed in order to calculate total annual loss across the project activity area. The live biomass losses are not emitted directly, but rather are transferred to dead organic matter pools.

$$\Delta C_{BSL,L,t} = \Sigma(LBL_{BSL,NATURALi,t} + LBL_{BSL,FELLINGS,i,t} + LBL_{BSL,OTHER,i,t}) \bullet CF \quad (6)$$

where:

$LBL_{BSL,NATURALi,t}$ = annual loss of live tree biomass due to natural mortality in polygon, *i*; t d.m. yr^{-1}

$LBL_{BSL,FELLINGS,i,t}$ = annual loss of live tree biomass due to commercial felling in polygon, *i*; t d.m. yr^{-1}

$LBL_{BSL,OTHER,i,t}$ = annual loss of live tree biomass from incidental sources in polygon, *i*; t d.m. yr^{-1}

CF = carbon fraction of dry matter; t C t^{-1} d.m. (IPCC default value = 0.5).

$$LBL_{BSL,NATURALi,t} = A_{BSL,i} \bullet LB_{BSL,i,t} \bullet f_{BSL,NATURAL,i,t} \quad (7)$$[18]

where

$A_{BSL,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{BSL,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t*

$LB_{BSL,i,t}$ is calculated for year, *t*, beginning with biomass estimates in year *t*=1 (the project start year) and with annual biomass increments ($G_{BSL,i,t}$) added as per calculations in equation 5a.

$f_{BSL,NATURAL,i,t}$ = the annual proportion of biomass that dies from natural mortality in polygon , *i* (unitless; $0 \leq f_{BSL,NATURALi} \leq 1$), year, *t*. Tree mortality is an ongoing process during stand development. Trees die as a consequence of insect attack, disease, competition, or some combination thereof. Hence, mortality can be highly

[18] Note, for Equation 7, 8, and 9: **$(f_{BSL,NATURAL,i,t} + f_{BSL,HARVEST,i,t} + f_{BSL,DAMAGE,i,t}) \leq 1.0$**

variable between years. This parameter can be applied uniformly across an analysis unit, or individually to a given polygon. Sources for mortality estimates include permanent sample plots in similar stand types, literature reports, and inventory data.

$$\mathbf{LBL_{FELLINGS,i,t} = A_{BSL,i} \bullet LB_{BSL,i,t} \bullet f_{BSL,HARVEST,i,t}} \quad \mathbf{(8)}$$

where:

$A_{BSL,i}$ = area (ha) of forest land in polygon, *i*

$LB_{BSL,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t* (see equation 7 for its calculation).

$f_{BSL,HARVEST,i,t}$ = the proportion of biomass removed by harvesting from polygon, *i,* (unitless; $0 \leq f_{BSL,HARVESTIi} \leq 1$), in year, *t*. Data for this variable should be obtained from harvest schedule information. Values may be constrained by (a) the value of $f_{BSL,NATURAL,i,t}$ (i.e., $f_{BSL,HARVEST,i,t} < 1 - f_{BSL,NATURAL,i,t}$), and/or (b) the area of timber available for commercial harvest.

Incidental loss ($LBL_{BSL,OTHER,i,t}$; t d.m. yr^{-1}) is the additional live tree biomass removed for road and landing construction in the polygon, *i*, and is calculated as a proportion of biomass removed by harvesting:

$$\mathbf{LBL_{BSL,OTHER,i,t} = A_{BSL,i} \bullet LB_{BSL,i,t} \bullet f_{BSL,DAMAGE,i,t}} \quad \mathbf{(9)}$$

where:

$A_{BSL,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{BSL,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t*

$f_{BSL,DAMAGE,i,t}$ = the proportion of additional biomass removed for road and landing construction in polygon, *i,* year, *t* (unitless; $0 \leq f_{BSL,DAMAGE,i,t} \leq 1$)[19]. Data for this variable should be based on regional and local comparative studies and experiential information derived from the local forest industry[20].

8.1.5 Dead Organic Matter Dynamics ($\Delta C_{BSL,DOM}$)

Dead organic matter (DOM) included in this methodology comprises three components: standing dead wood (minimum ≥ 5 cm DBH and 1.3 m height; termed snags), lying dead wood (minimum ≥ 5 cm DBH; LDW), and belowground dead wood (i.e., dead roots). Standing dead wood is < 45º of vertical, while lying dead wood is ≥ 45º of vertical. Carbon stored within dead belowground biomass and lying dead wood pools must not be assumed to be released immediately following disturbance. Rather decay must be modeled using a scientifically credible decay function (such as the exponential model referenced in Equation 13) in which a minimum of 10 years is required for complete loss of stored carbon.

The annual change in carbon stocks in DOM ($\Delta C_{BSL,DOM}$; t C yr^{-1}) is calculated as:

$$\mathbf{\Delta C_{BSL,DOM,t} = \Delta C_{BSL,LDW,t} + \Delta C_{BSL,SNAG,t} + \Delta C_{BSL,DBG,t}} \quad \mathbf{(10)}$$

[19] Projecting ex-ante road and landing removals beyond a few years is difficult and complex. As described, $f_{BSL,DAMAGE,i,t}$ functions as a proxy for estimating biomass impacts of all new roads and landings associated with annual harvesting in polygon, i. Project proponents can simulate $LBL_{BSL,OTHER,i,t}$ directly, if appropriate models are available.

[20] $f_{BSL,DAMAGE,i,t}$ may be zero or de minimis in cases where a polygon is already roaded.

where:

$\Delta C_{BSL,LDW,t}$ = change in lying dead wood (LDW) carbon stocks in year, t; t C yr^{-1}

$\Delta C_{BSL,SNAG,t}$ = change in snag carbon stock in year, t; t C yr^{-1}

$\Delta C_{BSL,DBG,t}$ = change in dead belowground biomass carbon stock in year, t; t C yr^{-1}.

$$\Delta C_{BSL,LDW,t} = \Sigma(LDW_{BSL,IN,i,t} - LDW_{BSL,OUT,i,t}) \bullet CF \quad (11a)$$

$$LDW_{BSL,i,t+1} = LDW_{BSL,i,t} + (LDW_{BSL,IN,i,t} - LDW_{BSL,OUT,i,t}) \quad (11b)$$

where:

$LDW_{BSL,,i,t}$ = The total mass of lying dead wood accumulated in polygon *i* , at time, *t* (t d.m.).

$LDW_{BSL,IN,i,t}$ = annual increase in LDW biomass for polygon *i*, year, *t* (t d.m yr^{-1}). LDW increases occur as a result of natural mortality (typically, blowdown), and as a direct or indirect result of harvesting.

$LDW_{BSL,OUT,i,t}$ = annual loss in LDW biomass through decay, for polygon *i*, year, *t*, (t d.m yr^{-1})

$LDW_{BSL,IN,i,t}$ and $LDW_{BSL,OUT,i,t}$ are summed across polygons.

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$\begin{aligned}LDW_{BSL,IN,i,t} = {} & (LBL_{BSL,NATURALi,t} - LBL_{BSL,NATURALi,t} \bullet R_i) \bullet f_{BSL,BLOWDOWN,i,t} + \\ & ((LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i) + \\ & (LBL_{BSL,OTHER,i,t} - LBL_{BSL,OTHER,i,t} \bullet R_i)) \bullet f_{BSL,BRANCH,i,t} + \\ & ((LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i) + \\ & (LBL_{BSL,OTHER,i,t} - LBL_{BSL,OTHER,i,t} \bullet R_i)) \bullet \\ & (1 - f_{BSL,BRANCH,i,t}) \bullet f_{BSL,BUCKINGLOSS,i,t} + SNAG_{BSL,,i,t} \bullet f_{BSL,SNAGFALLDOWN,i,t} \quad (12)\end{aligned}$$

where:

$LBL_{BSL,NATURALi,t}$, $LBL_{BSL,FELLINGS,i,t,}$ and $LBL_{BSL,OTHER,i,t}$ are as calculated in equations 7, 8, and 9, respectively.

R_i is the root:shoot ratio in polygon, *i* (see equation 5b).

$f_{BSL,BLOWDOWN,i,t}$ = the annual proportion of live aboveground tree biomass subject to blowdown in polygon, *i,* year*, t* (unitless; $0 \leq f_{BSL,BLOWDOWN,i,t} \leq 1$). Ex ante estimates must be derived preferably from regional reports in similar forest types.

$f_{BSL,BRANCH,i,t}$ = the annual proportion of aboveground tree biomass comprised of branches $\geq$ 5 cm diameter in polygon, *i* (unitless; $0 \leq f_{BSL,BRANCH,i,t} \leq 1$). Ex ante data are available from allometric equations and models (for example, (Kurz & Apps, 2006) for Canada; (Smith, Miles, Vissage, & Pugh, 2004) for the U.S.). In the event slash burning was undertaken as part of regular management activities, this parameter should be reduced accordingly to reflect the proportion of biomass remaining. Estimates should be obtained from expert opinion; as a default, assume 100% consumption if slash burning occurs.

$f_{BSL,BUCKINGLOSS,i,t}$ = the annual proportion of the log bole biomass left on site after assessing and/or merchandizing the log bole for quality, in polygon, *i* (unitless; $0 \leq f_{BSL,BUCKINGLOSS,i,t} \leq 1$). Preferably, data for this variable must be based on regional and local comparative studies and experiential information derived from the local forest industry. Otherwise, an average default value of 21% can be used, based on US national summary statistics (Smith, Miles, Vissage, & Pugh, 2004).

$SNAG_{BSL,,i,t}$ = the total mass of the snag pool in polygon, *i*, year, *t* (see equation 14b).

$f_{BSL,SNAGFALLDOWN,i,t}$ = the annual proportion of snag biomass in polygon, *i*, year, *t*, that falls over and thus is transferred to the LDW pool (unitless; $0 \leq f_{SNAGFALLDOWN,i,t} \leq 1$). Ex ante estimates for this parameter can be derived from peer reviewed literature (for example, (Parish, Antos, Ott, & Di Lucca, 2010) and forest carbon accounting models that track the rates of input and losses from dead organic matter pools (for example, (Kurz & et al, 2009).

$$\mathbf{LDW_{BSL,OUT,i,t} = LDW_{BSL,,i,t} \bullet f_{BSL,lwDECAY,i,t}} \quad \textbf{(13)}$$

where:

$LDW_{BSL,,i,t}$ = the total amount of lying deadwood mass in polygon *i,* year*, t (see equation 11b)*. $f_{BSL,lwDECAY,i,t}$ = the annual proportional loss of lying dead biomass due to decay, in polygon *i,* year*, t* (unitless; ; $0 \leq f_{BSL,lwDECAY,i,t} \leq 1$). A common approach to ex ante estimation of $f_{BSL,lwDECAY,i,t}$ is to assume mass loss occurs in proportion to the amount of mass remaining in accordance with a single exponential model, of the general form:

$$Y_t = Y_o e^{-kt}$$

where Y_o is the initial quantity of material, Y_t the amount left at time t, and k is a decay constant (Harmon, et al., 1986). Other types of exponential models are available (reviewed in (Harmon, et al., 1986)) and may be more appropriate to particular forest types (to be described and justified by the project proponent, if used). Ex ante estimates for the decay parameter appropriate for the project should be derived from peer-reviewed literature (for example, (Harmon, et al., 1986); (Laiho & and Prescott, 2004); (Harmon et al, 2008)).

The change in standing dead wood (snag) carbon stock in year, t (t C yr^{-1}) is calculated as:

$$\mathbf{\Delta C_{BSL,SNAG,t} = \Sigma(SNAG_{BSL,IN,i,t} - SNAG_{BSL,OUT,i,t}) \bullet CF} \quad \textbf{(14a)}$$

$$\mathbf{SNAG_{BSL,i,t+1} = SNAG_{BSL,i,t} + (SNAG_{BSL,IN,i,t} - SNAG_{BSL,OUT,i,t})} \quad \textbf{(14b)}$$

where:

$SNAG_{BSL,i,t}$ = The total mass of snags accumulated in polygon *i, at time t (t d.m.).*

$SNAG_{BSL,IN,i,t}$ = annual gain in snag biomass for polygon *i*, year, *t* (t d.m yr^{-1}). Snag biomass develops as a result of natural mortality. In cases where snags are created through management activities, these should be accounted for here.

$SNAG_{BSL,OUT,i,t}$ = annual loss in snag biomass through decay, or falldown (i.e, transfer to the LDW pool)(t d.m yr^{-1})

CF = carbon fraction of dry matter (IPCC default value = 0.5).

Note that $SNAG_{BSL,IN,i,t}$ and $SNAG_{BSL,OUT,i,t}$ are summed across polygons.

$$\mathbf{SNAG_{BSL,IN,i,t} = (LBL_{BSL,NATURALi,t} - LBL_{BSL,NATURALi,t} \bullet R_i) \bullet (1 - f_{BSL,BLOWDOWN,i,t})} \quad \textbf{(15)}$$

where:

$LBL_{BSL,NATURALi,t}$ is as calculated in equation 7, and

1 - $f_{BSL,BLOWDOWN,i,t}$ is the proportion of live tree aboveground biomass that dies in polygon, *i*, year, *t*, but remains as standing dead organic matter (i.e., snags) (unitless; $0 \leq f_{BSL,BLOWDOWN,i,t} \leq 1$). Ex ante default estimates for this calculation can be derived from literature values (for example (Harmon, et al., 1986); (Runkle, 2000); (Harmon et al, 2008)) and should be matched to the ecosystems that most closely characterize the project area.

$$\mathbf{SNAG_{BSL,OUT,i,t} = SNAG_{BSL,i,t} \bullet f_{BSL,SWDECAY,i,t} + SNAG_{BSL,i,t} \bullet f_{BSL,SNAGFALLDOWN,i,t}} \quad \textbf{(16)}$$

where:

$SNAG_{BSL,i,t}$ = the total amount of snag mass in polygon *i,* year*, t* (see equation 14b). $f_{BSL,SWDECAY,i,t}$ = the annual proportional loss of snag biomass due to decay, in polygon, *i*, year, *t* (unitless; $0 \leq f_{BSL,SWDECAY,i,t} \leq 1$). As with lying dead wood, a common approach to estimating $f_{BSL,SWDECAY,i,t}$ is to assume mass loss occurs in proportion to the amount of mass remaining in accordance with a single exponential model (see equation 13). Ex ante estimates for this parameter should be derived from peer reviewed literature appropriate for the project site (for example, Vanderwel et al. 2006a) and forest carbon accounting models that track the rates of input and losses from dead organic matter pools for each forest type, productivity, and age-class (see, for example, Vanderwel et al., 2006b; (Kurz & et al, 2009)).

$f_{BSL,SNAGFALLDOWN,i,t}$ = the annual proportion of snag biomass in polygon, *i*, that falls over and thus is transferred to the LDW pool (unitless; $0 \leq f_{BSL,SNAGFALLDOWN,i,t} \leq 1$). See equation 12 for parameter estimates.

The annual change in DOM derived from dead belowground biomass ($\Delta C_{BSL,DBG,\ ,t}$; t C yr^{-1}) is calculated for each polygon as per equation 17a. Calculation of $\Delta C_{BSL,DBG,t}$ is specific to a given polygon; each polygon must therefore be summed in order to calculate total annual loss across the project activity area.

$$\Delta \mathbf{C_{BSL,DBG,t}} = \mathbf{\Sigma(DBG_{BSL,IN,i,t} - DBG_{BSL,OUT,i,t}) \bullet CF} \quad \textbf{(17a)}$$

$$\mathbf{DBG_{BSL,i,t+1} = DBG_{BSL,i,t} + (DBG_{BSL,IN,i,t} - DBG_{BSL,OUT,i,t})} \quad \textbf{(17b)}$$

where:

$DGB_{BSL,i,t}$ = The total quantity of dead belowground biomass accumulated in polygon *i,* at time*, t* (t d.m.).

$DBG_{BSL,IN,i,t}$ = annual gain in dead belowground biomass for polygon *i*, year, *t* (t d.m yr^{-1}). Dead belowground biomass develops as a result of mortality through natural causes or through harvesting activities.

$DBG_{BSL,OUT,i,t}$ = annual loss in dead belowground biomass through decay, (t d.m yr^{-1})

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$\mathbf{DBG_{BSL,IN,i,t} = [(A_{BSL,i} \bullet LB_{BSL,i,t} \bullet R_i) \bullet (f_{BSL,NATURAL,i,t} + f_{BSL,HARVEST,i,t} + f_{BSL,DAMAGE,i,t})]} \quad \textbf{(17c)}$$

where:

$A_{BSL,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{BSL,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t.* $LB_{BSL,i,t}$ is calculated for year, *t*, beginning with biomass estimates in year *t*=1 (the project start year) and with annual biomass increments ($G_{BSL,i,t}$) added as per calculations in equation 5 a, b. This value is then multiplied by $A_{BSL,i,}$ the area (ha) of forest land in polygon, *i*.

R_i is the root:shoot ratio in polygon, *i* (see equation 5b).

$f_{BSL,NATURAL,i,t}$ = the annual proportion of biomass that dies from natural mortality in polygon, *i* (unitless; $0 \leq f_{NATURALi} \leq 1$), year, *t* (see equation 7),

$f_{BSL,HARVEST,i,t}$ = the proportion of biomass removed by harvesting from polygon, *i,* (unitless; $0 \leq f_{HARVESTIi} \leq 1$), year, *t* (see equation 8),

$f_{BSL,DAMAGE,i,t}$ = the proportion of additional biomass removed or road and landing construction in polygon, *i* (unitless; $0 \leq f_{DAMAGE,i,t} \leq 1$), year, *t* (see equation 9)

$$\mathbf{DBG_{BSL,OUT,i,t} = DBG_{BSL,i,t} \bullet f_{BSL,dgbDECAY,i,t}} \quad \textbf{(17d)}$$

where:

$DBG_{BSL,i,t}$ = the total quantity of dead belowground in polygon *i,* year*, t* (see equation 17b).

$f_{BSL,dgbDECAY,i,t}$ = the annual proportional loss of dead belowground biomass due to decay, in polygon *i,* year*, t* (unitless; ; $0 \leq f_{BSL,lwDECAY,i,t} \leq 1$). The ex ante estimation of the decay of dead belowground biomass should be done using a similar single exponent decay function as that described above for lying deadwood biomass. Estimates for the decay parameter appropriate for specific project should be derived from peer-reviewed literature (see for example: (Moore, Trofymow, Siltanen, Prescott, & CIDET, 2005)); Melin et al. (2009); (Melin, Petersson, & Nordfjell, 2009)).

8.1.6 Harvested Wood Products

This methodology considers the net emissions and carbon storage related to:

a. Wood products created from harvested logs removed from the project site,
b. The fossil fuel emissions from equipment and facilities involved in the harvesting, transportation, and processing of wood products.

The annual change emissions associated with the production of harvested wood products (HWP), $\Delta C_{BSl,HWP,t}$, is calculated as:

$$\mathbf{\Delta C_{BSl,HWP,t} = \Delta C_{BSL,STORHWP,t} - \Delta C_{BSL,EMITFOSSIL,t,}} \quad \textbf{(18)}$$

$\Delta C_{BSL,STORHWP,t}$ = the annual change in harvested carbon that remains in storage after conversion to wood products (t C yr^{-1})

$\Delta C_{BSL,EMITFOSSIL,t}$ = the annual change in fossil fuel emissions from harvesting (logging and log transport) and processing of the various wood products.

8.1.7 Carbon storage in harvested wood products ($\Delta C_{BSL,STORHWP,t}$)

In accordance with the VCS AFOLU requirements (Version 3)[21], emissions of carbon stored within harvested wood products in IFM projects must be modeled based upon the following criteria:

a) For short-term wood products and wood waste that would decay within 3 years, all carbon must be assumed to be lost immediately.

b) For medium-term wood products that are retired between 3 and 100 years, a 20-year linear decay function must be applied.

c) For long-term wood products that are considered permanent (ie, carbon is stored for 100 years or more), it may be assumed no carbon is released.

The annual change in carbon storage in harvested wood products in year *t* ($\Delta C_{BSL,STORHWP,t}$; t C yr^{-1}) is determined based upon the following equation:

$$\Delta C_{BSL,STORHWP,t} = (C_{BSL,STORHWP,t2} - C_{BSL,STORHWP,t1}) / T \qquad (19)$$

where:

$C_{BSL,STORHWP,t2}$ = carbon storage in harvested wood products at t=2; t C

$C_{BSL,STORHWP,t1}$ = carbon storage in harvested wood products at t=1; t C

T = number of years between monitoring t1 and t2

t : 1,2,3…t years elapsed since the project start date

For applications within North America this methodology has adapted data from the Forestry Appendix of the Technical Guidelines of the US Department of Energy's Voluntary Reporting of Greenhouse Gases Program (known as Section 1605(b))[22] to calculate proportions in use for the short-term and long-term wood products, from which a remaining medium-term wood product pool can be calculated and decayed over a 20-year period. In the case where the methodology is applied outside of North America, the project proponent must utilize regionally appropriate data from a peer-reviewed source to complete the steps below. Alternatively, a globally applicable method such as that defined by Winjum et al. (1998)[23] may be utilized to estimate carbon storage in wood products..

Storage in the harvested wood products pool at a given time t ($C_{BSL,STORHWP,t}$; t C) is calculated according to the following steps for each harvest period *h*:

Step 1 (Carbon contained in harvested timber): Determine the carbon contained within harvested timber removed from the project landbase. This can be calculated from measures of total merchantable volume generated during the harvest period *h* using species-specific wood densities and standard carbon conversions or

[21] In previous versions, this methodology used the "100 Year Method" following procedures developed by Miner (Miner, 2006), which have been replaced by the updated methods outlined in this revised version to ensure compliance with version 3.2 of the *AFOLU Requirements*.

[22] http://www.eia.doe.gov/oiaf/1605/Forestryappendix[1].pdf Also available as a US Forest Service General Technical Report at: http://www.fs.fed.us/ne/durham/4104/papers/ne_gtr343.pdf

[23] Winjum, J.K., Brown, S. and Schlamadinger, B. 1998. Forest harvests and wood products: sources and sinks of atmospheric carbon dioxide. Forest Science 44: 272-284

estimated from live biomass removals after accounting for removal of belowground components, branches, and bucking losses (equation 20). In accordance with the 1605(b) approach, the harvested wood carbon ($C_{BSL,TIMBER,h}$) must be divided into the following product type (*k*) categories: 1) softwood saw log, 2) softwood pulpwood, 3) hardwood saw log, 4) hardwood pulpwood. This can be done using local data if available or estimated based upon region and forest type according to Table 1.4 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous US; however, the project proponent must justify the appropriateness of the selected analog . In the case of global project locations outside of North America, the project proponent must identify and justify the use of alternative data from peer-reviewed sources.

$$\mathbf{C_{BSL,TIMBER,h} = \Sigma[(LBL_{BSL,FELLINGS,i,h} - LBL_{BSL,FELLINGS,i,h} \bullet R_i + LBL_{BSL,OTHER,i,h} - LBL_{BSL,OTHER,i,h} \bullet R_i) \bullet (1 - f_{BSL,BRANCH,i,h}) \bullet (1 - f_{BSL,BUCKINGLOSS,i,h})] \bullet \bullet CF} \quad \mathbf{(20)}$$

where:

$C_{BSL,TIMBER,h}$= carbon contained in timber harvested in period *h* (summed for all harvested polygons, *i*); t C

$LBL_{BSL,FELLINGS,i,h}$ = annual removal of live tree biomass due to commercial felling in polygon, *i*; t d.m. (equation 8)

$LBL_{BSL,OTHER,i,h}$ = annual removal of live tree biomass from incidental sources in polygon, *i*; t d.m. (equation 9)

R_i is the root:shoot ratio in polygon, *i* (see equation 5b).

$1 - f_{BSL,BRANCH,i,h}$ the proportion of live tree biomass remaining after netting out branch biomass, in polygon *i* (unitless; $0 \leq f_{BRANCH,i,t} \leq 1$)(see equation 12)

$1 - f_{BSL,BUCKINGLOSS,i,h}$ = the proportion of the log bole remaining after in-woods log processing/bucking for quality, length, etc., in polygon, *i* (unitless; $0 \leq f_{BUCKINGLOSS,i,t} \leq 1$) (equation 12)

h = harvest period ; yr

Step 2: (Carbon contained in harvested timber after milling): Determine the total carbon in harvested timber that will enter the wood products pool by product type accounting for mill efficiencies and estimated product disposition percentages ($C_{BSL,MILL,h}$; t C). The gross quantity of carbon contained in harvested timber for each of the four product types described in Step 1 must be decremented to account for losses during processing (equation 21). These losses including bark and other milling wastes and may be determined using local data or estimated based upon region and product type according to Table 1.5 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous US; however, the project proponent must justify the appropriateness of the selected analog. In the case of global project locations outside of North America, the project proponent must identify and justify the use of alternative data from peer-reviewed sources.).

$$\mathbf{C_{BSL,MILL,h,k} = (C_{BSL,TIMBER,h,k} \bullet f_{RND,k} \bullet r_{RND,k})} \quad \mathbf{(21)}$$

where:

$C_{BSL,MILL,h,k}$ = carbon contained in harvested timber after milling in period h, for product type *k*; t C

$C_{BSL,TIMBER,h,k}$ = carbon contained in timber harvested in period h, for product type *k*; t C

k = wood product type – (softwood saw log, softwood pulpwood, hardwood saw log, or hardwood pulpwood; proportions determined from Table 1.4 of 1605(b) document)

$f_{RND,k}$ = fraction of growing stock volume removed as roundwood for product type *k* (default values by region in Table 1.5 of the 1605(b) document); dimensionless

$r_{RND,k}$ = ratio of industrial roundwood to growing stock volume removed as roundwood for product type *k* (default values by region in Table 1.5 of the 1605(b) document); dimensionless

Step 3: (Carbon storage in medium-term and long-term wood products): Calculate the total carbon lost in short-lived products and stored in medium-term and long-term products. For each harvest period *h*, carbon stored in harvested wood products of a defined type (k) after accounting for milling losses ($\mathbf{C_{BSL,MILL,h,k}}$) must be apportioned into one of the following categories:

a) Short lived wood products: harvested wood products and wood waste that will decay within 3 years.
b) Medium lived wood products: harvested wood products and wood waste that will be retired between 3 and 100 years from the date of harvest.
c) Long lived wood products: harvested wood products and wood waste that may be considered permanent (stored for 100 years or more).

To determine the proportion of harvested wood products (by type) that fall into each category, refer to the "In Use" column for the selected forest region in Table 1.6 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous UShowever,. the project proponent must justify the appropriateness of the selected analog at project validation. In the case of global project locations outside of North America, the project proponent must identify and justify the use of alternative data from peer-reviewed sourcesTable 3

Three values are then calculated from these data selected from Table 1.6 in the 1605(b) document, for each product type, *k* : the short-lived fraction ($P_{BSL,SLF,k}$), medium-lived fraction ($P_{BSL,MLF,k}$), and long-lived fraction ($P_{BSL,LLF,k}$):

$$\mathbf{P_{BSL,SLF,k} = 1 - P_{3\text{-}year}} \quad \textbf{(22a)}$$

$$\mathbf{P_{BSL,LLF,k} = P_{100\text{-}year}} \quad \textbf{(22b)}$$

$$\mathbf{P_{BSL,MLF,k} = P_{3\text{-}year} - P_{100\text{-}year}} \text{,} \quad \textbf{(22c)}$$

Each category of wood products (*k*) stores carbon according to the following rules:

i. Short-lived wood products – immediate emission of all carbon upon harvest
ii. Medium-lived wood products – no emission of carbon upon harvest, but carbon stored will decrease by 1/20th for the next 20 years after harvest, such that after 20 years the term becomes zero
iii. Long-lived wood products – no loss of carbon.

Thus, carbon storage in harvested wood products at time *t* may be calculated using a cohort approach in which medium-term and long-term wood products from each harvest period *h* are tracked independently and then summed over the project time period as indicated in equation 23.

$$C_{BSL,STORHWP,t,} = \Sigma\, \Sigma\, ((C_{BSL,MILL,h,k} \bullet P_{LLF,k}) + [(C_{BSL,MILL,h,k} \bullet P_{MLF,k}) \bullet ((20\text{-}h) / 20)]) \quad \textbf{(23)}$$

where:

$C_{BSL,STORHWP,t,}$ = carbon stored in harvested wood products in year *t* summed for all product types *k* and then over all harvest periods *h*; t C

k = wood product type – (softwood saw log, softwood pulpwood, hardwood saw log, or hardwood pulpwood; proportions determined from Table 1.4 of 1605(b) document)

h = year of harvest (the term (20-h) should not be allowed to drop below 0)

Table 3 – Recommended analogous Regional 1605b Data Substitutions for regions for North America, outside the conterminous U.S.

Region	Regional analog[1]
Coastal British Columbia and Coastal Alaska	Pacific Northwest, West
Columbia (British Columbia)	Pacific Northwest, East
Alpine and Montane (Rocky Mountain region in British Columbia and Alberta)	Rocky Mountain, North
Boreal (across Canada) and Interior Alaska	Northern Lake States
Great Lakes St-Lawrence (central Canada)	Northern Lake States
Carolinian (southwestern Ontario) and Acadian (Maritimes)	Northeast

[1] As per Table 1.6 of the 1605(b) methodology document (see text)

8.1.8 Fossil fuel emissions associated with logging, transport, and manufacture

The annual change in fossil fuel emissions from harvesting and processing of the various wood products ($\Delta C_{BSL,EMITFOSSIL,t}$) are calculated as:

$$C_{BSL,EMITFOSSIL,t} = C_{BSL,EMITHARVEST,t} + C_{BSL,EMITMANUFACTURE,t} + C_{BSL,EMITTRANSPORT,t} \quad \textbf{(24)}$$

where:

$C_{BSL,EMITHARVEST,t}$ is the annual fossil fuel emissions associated with harvesting of raw material (t C yr^{-1})

$C_{BSL,EMITMANUFACTURE,t}$ is the annual fossil fuel emissions associated with the manufacturing of raw material (t C yr^{-1})

$C_{BSL,EMITTRANSPORT,t}$ is the annual fossil fuel emissions associated with the transport of raw material (t C yr^{-1})

The simplest approach to calculating $C_{BSL,EMITFOSSIL,t}$ is to use published or derived carbon emission intensity factors. In the case of harvesting, $_{BSL,}C_{EMITHARVEST,t}$; t C yr^{-1}), can be calculated (summed across harvested polygons)as:

$$\mathbf{C_{BSL,EMITHARVEST,t} = \Sigma[(LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i + LBL_{BSL,OTHER,i,t} - LBL_{BSL,OTHER,i,t} \bullet R_i) \bullet (1 - f_{BSL,BRANCH,i,t}) \bullet (1 - f_{BSL,BUCKINGLOSS,i,t})] \bullet CF \bullet c_{HARVEST}} \quad \mathbf{(25)}$$

where:

$c_{HARVEST}$ is the carbon emission intensity factor (t C emitted/t C raw material) associated with harvesting (see Table 4 for default values); all other terms are as defined in equation 20.

$C_{BSL,EMITTRANSPORT,t}$ must be calculated after consideration of the transport distance from harvest to processing facility, and the means of transportation. This term can be calculated as follows (after (Heath, et al., 2010)):

$$\mathbf{C_{BSL,EMITTRANSPORT,t} = \Sigma[(LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i + LBL_{BSL,OTHER,i,t} - LBL_{BSL,OTHER,i,t} \bullet R_i) \bullet (1 - f_{BSL,BRANCH,i,t}) \bullet (1 - f_{BSL,BUCKINGLOSS,i,t})] \bullet CF \bullet \Sigma(f_{BSL,TRANSPORTk} \bullet d_{TRANSPORTk} \bullet c_{TRANSPORTk})} \quad \mathbf{(26)}$$

where:

$f_{BSL,TRANSPORTk}$ = the fraction of raw material transported by transportation type, *k*. (unitless; $0 \leq f_{BSL,TRANSPORTk} < 1$).

$d_{TRANSPORTk}$ = the distance transported by transportation type, *k*. (km);

$c_{TRANSPORTk}$ is the carbon emission intensity factor (kg C emitted/t C raw material) associated with transportation type, k (see Table 4 for default values); all other terms are as defined in equation 20.

$$\mathbf{C_{BSL,EMITMANUFACTURE,t} = \Sigma[(LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i + LBL_{BSL,OTHER,i,t} - LBL_{BSL,OTHER,i,t} \bullet R_i) \bullet (1 - f_{BSL,BRANCH,i,t}) \bullet (1 - f_{BSL,BUCKINGLOSS,i,t})] \bullet \Sigma(f_{BSL,PRODUCTk} \bullet c_{MANUFACTUREk}) \bullet CF} \quad \mathbf{(27)}$$

$c_{MANUFACTUREk}$ is the carbon emission intensity factor (t C emitted/t C raw material) associated with manufacture of product type, *k*; all other terms are as defined in equation 19.

Default values for $c_{MANUFACTUREk}$ are provided in Table 4. Data are from a comprehensive analysis conducted in Finland (Pingoud, Perälä, Soimakallio, & Pussinen, 2003). Higher comparative values from North America are provided for harvesting and sawnwood manufacturing to illustrate inherent variability. Project proponents may use the default values in Table 4, or substitute regional data, if available.

Table 4 –Carbon emission intensity factors for harvesting, the manufacture of various product categories, k, and for various transportation categories, k.

Activity	Value	Reference	Other (for comparison)
Harvesting ($c_{HARVEST}$) (t C emitted/t C raw material)			
Clearcut harvest	0.016	(Zhang, Cormier, Lyng, Mabee, Ogino, & McLean, 2010)	
Manufacturing ($c_{MANUFACTUREk}$) (t C emitted/t C raw material)			
Sawnwood	0.04	(Pingoud & Lehtila, 2002) – Calculated from Table I & III	0.1 (western US), 0.156 (southern US) (Milota, West, & Hartley, 2005)
Veneer, plywood and structural panels	0.06	(Pingoud & Lehtila, 2002) – Calculated from Table I & III	
Non-structural panels	0.12	(Pingoud & Lehtila, 2002) – Calculated from Table I & III	
Paper		(Pingoud & Lehtila, 2002) – Calculated from Table I & III	
Mechanical pulping	0.48	(Pingoud & Lehtila, 2002) – Calculated from Table I & III	
Chemical pulping	0.13	(Pingoud & Lehtila, 2002) – Calculated from Table I & III	
Transportation ($c_{TRANSPORTk}$) (t C emitted/t C raw material ● km)

Rail	8.2×10^{-6}	(Heath, et al., 2010) - From Supporting Information Table S16	

8.2 Project Emissions

Net project emissions are calculated by repeating the procedures in Section 8.1 (Baseline Emissions), using the project scenario polygons, data, and modeling. Unless otherwise noted and justified by the project proponent, all modeling methods, calculations, assumptions, and data sources should be consistent in both the baseline and project scenarios, with the exception of ex-post monitoring data as outlined below. For purposes of efficacy, it may be advantageous to re-stratify the landbase for the project scenario, as compared to the baseline.

Within this methodology, it is anticipated that project scenarios may undertake ongoing low levels of management activities for forest maintenance, ecological enhancement, and/or risk mitigation (for example, pest management, salvage, etc.). In order to comply with the IFM-LtPF project type and this methodology, these activities must meet the following requirements:

1. All net GHG emissions from project activities must be modeled and accounted for in the project scenario in the same manner as the baseline scenario.
2. Project activities cannot remove > 20% of the harvesting volume projected in the baseline scenario over an equivalent 10-year period.
3. Project proponents must be able to demonstrate that activities:
    a. have a conservation benefit and are consistent with principles of managing for biodiversity, ecosystem function, and carbon retention.
    b. are related to restoration, ecological management, or emissions risk reduction

If a project scenario has no planned timber removals, then all related equations in the project emissions calculations in Section 8.2 can be set to zero.

If the project scenario has planned activities other than those involving the removal of timber that affect non-*de minimis* levels of carbon stock, the project must document these activities, reasonably calculate their carbon impacts, and include these emissions in the total carbon calculations for the project scenario.

All calculations in this methodology represent annualized net changes in carbon stocks by polygon, which must therefore be summed across the project activity area to determine the annual total net emissions and reductions.

Note, additional details for many calculations, including references and background are provided within the equivalent Baseline Emissions section.

8.2.1 Project Scenario Area Stratification

The project scenario will utilize the same methods and steps to create polygons as outlined for the baseline scenario (see Section 8.1) from $A_{PRJ,I}$. However, the project scenario may be stratified differently to accommodate different project management activities and/or changes to inventory data resulting from ex-post monitoring (if new polygons are created as the result of natural disturbance events, for example). There may be differences between the project and baseline scenarios in the areas within the landbase that are eligible for specific forest management activities (i.e., the assumptions used to determine the THLB may differ in the project scenario relative to the baseline). However, the underlying inventory and data assumptions must be the same in the baseline and project scenarios.

8.2.2 Determining Actual Onsite Carbon Stocks

Actual carbon stocks must be calculated prior to each verification, or at a maximum interval of 5 years, by updating the project's forest carbon inventory from the monitoring data.

This is done by:

1. Incorporating any new forest inventory data (including data from new or re-measured sampling plots and other monitored data, as outlined in Section 9.2 and 9.3) obtained during the previous year into the inventory estimate.
2. Updating the forest inventory for spatial monitoring results, including annual project activities and/or disturbances that have occurred during the monitoring period.
3. Using the selected model(s) to project prior-year data from the forest inventory to the current reporting year (as described in Section 8.2.5).
4. Comparing estimates of live biomass and dead organic matter in polygons and calculated from monitoring activities (Section 9.2 and 9.3) against current-year modeled values in the project scenario (see Section 8.2.4).
5. Making calibration adjustments to models and/or parameters such that the fit between the equivalent modeled and measured variables meets targets (as per Section 8.2.4).
6. If any changes are made to the model assumptions or parameters used in Section 8.2, the calculation of baseline emissions (from the current date forward) must be redone using the updated model(s) and parameter sets.
7. Calculate the error terms for use in determining the uncertainty factor (Section 8.5.3).

8.2.3 Ex-Post Calculations of Carbon Stocks

Actual (ex post) annual net carbon stocks are calculated using the equations in this section.

$$\mathbf{C_{ACTUAL,i,t} = C_{LB,i,t} + C_{DOM,i,t}} \qquad \textbf{(28a)}$$

where:

$C_{ACTUAL,i,t}$ = carbon stocks in all selected carbon pools in polygon, *i*, year, *t*; t C

$C_{LB,i,t}$ = carbon stocks in living tree biomass in polygon, *i*, year, *t*; t C

$C_{DOM,i,t}$ = carbon stocks in dead organic matter in year, *t*; t C

Live biomass

Average aboveground biomass for measured polygon, *i,* in year, *t* ($B_{AG,i,t}$) is determined by converting the aboveground, tree-level measurements (kg biomass per tree) described in Section 9.3.2 to area-based, stand-level measurements (t ha^{-1}). This is achieved by summing the aboveground biomass of all the trees within a sample plot, converting kg to t, and then dividing the sum by the plot area in ha. All plots within a particular polygon should be averaged to get an average estimate of stand-level aboveground biomass (t ha^{-1}). Once the average aboveground biomass has been determined for each measured polygon, belowground biomass is estimated by multiplying the aboveground biomass by the root:shoot ratio, R_i (equation 28d) and the two are summed to determine total stand-level live biomass for measured polygon i, time t, ($B_{TOTAL,i,t}$). R_i is described in Section 8.1.3. Finally, the average measured carbon stock in living tree biomass for measured polygon *i*, time *t*, ($C_{LB,i,t}$) is calculated as shown in equation 28c. This value of $C_{LB,i,t}$ must be compared to the equivalent calculation of live biomass ($LB_{PRJ,i,t}$) calculated in the project scenario (Section 8.2.5) (see comparison method and steps below).

$$B_{TOTAL,i,t} = (B_{AG,i,t} + B_{BG,i,t}) \quad (28b)$$

$$C_{LB,i,t} = (B_{TOTAL,i,t}) \bullet CF \quad (28c)$$

where:

$B_{AG,i,t}$ = aboveground tree biomass (t d.m. ha^{-1}) measured in polygon, *i,* year, *t*

$B_{BG,i,t}$ = belowground tree biomass (t d.m. ha^{-1}) measured in polygon, *i,* year, *t*.

$B_{TOTAL,i,t}$ = total tree biomass (t d.m. ha^{-1}) measured in polygon, *i,* year, *t*

$$B_{BG,i,t} = B_{AG,i,t} \bullet R_i \quad (28d)$$

CF = carbon fraction of dry matter (IPCC default value = 0.5)

Dead organic matter

Carbon stored in dead organic matter pools in measured polygon, *i*, year *t*, ($C_{DOM,i,t}$) is calculated as the sum of that stored in lying dead wood and standing snags.

$$C_{DOM,i,t} = (DOM_{LDW,i,t} + DOM_{SNAG,i,t}) \bullet CF \quad (28e)$$

where:

$DOM_{LDW,i,t}$ = average mass of dead organic matter contained in lying dead wood (t d.m. ha^{-1}) in measured in polygon, *i,* year, *t*

$DOM_{SNAG,i,t}$ = average mass of dead organic matter contained in standing snags (t d.m. ha^{-1}) in measured in polygon, *i,* year, *t*

The average quantity of dead organic matter contained in lying dead wood for measured polygon, *i,* in year, *t* ($DOM_{LDW,i,t}$) is calculated according to equations 60a-c in Section 9.3.2. The value of $DOM_{LDW,i,t}$ must be compared to the equivalent calculation of lying dead wood mass ($LDW_{PRJ,i,t}$) in the project scenario (Section 8.2.8) (see comparison method and steps below).

The average quantity of dead organic matter contained in standing snags for measured polygon, *i,* in year, *t* ($DOM_{SNAG,i,t}$ is calculated by summing the mass (aboveground only) of all the measured standing dead trees within a sample plot (converting kg to t) and dividing the sum by the plot area in ha (see Section 9.3.2). The belowground component of snags is treated as dead belowground biomass (see Section 8.2.8) and is not directly measured. All plots within a particular polygon should be averaged to get an average estimate of $DOM_{SNAG,i,t}$. The value of $DOM_{SNAG,i,t}$ must be compared to the equivalent calculation of standing dead tree mass ($SNAG_{PRJ,i,t}$) in the project scenario (Section 8.2.8) (see comparison method and steps below).

8.2.4 Updating the Modeled Project Carbon Balance

In this methodology, the ex ante carbon balances in the project case may be derived from computer model output. In this event, the precision of the modeled carbon stocks should be evaluated for each polygon or analysis unit (depending on the level of stratification used) using the method described for determining mean model error in Section 8.5.3 (equations 60a,b). If the model error term is too high (> 10%), proponents should attempt to improve the model fit by re-evaluating and adjusting model parameters until model error term is < 10%. Model error terms greater than 10% (after model adjustments) will be penalized according the calculation of the uncertainty factor described in Section 8.5.3. If changes in model assumptions or parameters are made, the baseline scenario (from the next year forward) must be recalculated using the revised model.

8.2.5 Calculating the Project Carbon Balance

The total annual carbon balance in year, t, for the project scenario is calculated as ($\Delta C_{PRJ,t}$, in t C yr^{-1}):

$$\Delta C_{PRJ,t} = \Delta C_{PRJ,P,t} \quad (29)$$

where:

$\Delta C_{PRJ,P,t}$ is the annual change in carbon stocks in all pools in the project across the project activity area; t C yr^{-1} .

$$\Delta C_{PRJ,P,t} = \Delta C_{PRJ,LB,t} + \Delta C_{PRJ,DOM,t} + \Delta C_{PRJ,HWP,t} \quad (30)$$

$\Delta C_{PRJ,LB,t}$ = annual change in carbon stocks in living tree biomass (above- and belowground); t C yr^{-1}

$\Delta C_{PRJ,DOM,t}$ = annual change in carbon stocks in dead organic matter; t C yr^{-1}

$\Delta C_{PRJ,HWP,t}$ is the annual change in carbon stocks associated with harvested wood products, t C yr^{-1}.

$$\Delta C_{PRJ,LB,t} = \Delta C_{PRJ,G,t} - \Delta C_{PRJ,L,t} \quad (31)$$

where:

$\Delta C_{PRJ,G,t}$ = annual increase in tree carbon stock from growth; t C yr^{-1}

$\Delta C_{PRJ,L,t}$ = annual decrease in tree carbon stock from a reduction in live biomass; t C yr^{-1}.

If the project area has been stratified, carbon pools are calculated for each polygon, i, and then summed during a given year, t.

8.2.6 Live Biomass Gain

Live biomass gain in year, *t*, polygon, *i* ($\Delta C_{PRJ,G,i.t}$) is calculated as:

$$\Delta \mathbf{C_{PRJ,G,t} = \Sigma(A_{PRJ,i} \bullet G_{PRJ,i,t}) \bullet CF} \quad (32)$$

where:

$A_{PRJ,i,}$ = area (ha) of forest land in polygon, *i*;

$G_{PRJ,i,t}$ = annual increment rate in tree biomass (t d.m. ha^{-1} yr^{-1}), in polygon, *i*, and;

CF = carbon fraction of dry matter t C t^{-1} d.m. (IPCC default value = 0.5).

$$\mathbf{G_{PRJ,i,t} = G_{PRJ,AG,i,t} + G_{PRJ,BG,i,t}} \quad (33a)$$

where $G_{PRJ,AG,i,t}$ and $G_{PRJ,BG,i,t}$ are the annual above- and belowground biomass increment rates (t d.m. ha^{-1} yr^{-1});

$$\mathbf{G_{PRJ,BG,i,t} = G_{PRJ,AG,i,t} \bullet R_i} \quad (33b)$$

where R_i is the root:shoot ratio in polygon, *i*. R_i should ideally be estimated for each polygon, but these data are difficult to derive empirically. Hence, general relationships are acceptable (Cairns, 1997).

Equations 32 and 33 can be used directly to calculate $\Delta C_{PRJ,G,t}$ when all tree cover within a polygon is removed by harvesting (i.e., clearfelling) and no residual structure is retained. In cases of partial harvesting and/or multiple entries into a polygon, these equations must be applied separately to each of the resulting sub-polygons (the different age classes that are created). This ensures that growth rates reflect the difference in forest age between the sub-polygons.

The ex ante and ex post calculation of $G_{PRJ,i,t}$ (either directly, or from its component parts) will be derived from models that require inputs derived, in part, from forest inventory data updated from monitoring sample plots (see Sections 9.3.2 and 8.2.2). Criteria for model suitability are provided in 8.1.1. The exact form of the input data depends on the nature of the model but may include site index, species composition, and volume (see notes in Section 8.1).

8.2.7 Live Biomass Loss

The annual decrease in aboveground tree carbon from live biomass loss (ΔC_{PRJ},L,t; t C yr^{-1}) is the sum of losses from:

1. Natural mortality (i.e. insects, disease, competition, wind, etc.)
2. Commercial round wood felling
3. Incidental sources.

Losses must be specific to a given polygon; each polygon must be summed in order to calculate total annual loss across the project activity area. The live biomass losses are not emitted directly, but rather are transferred to dead organic matter pools.

$$\Delta \mathbf{C_{PRJ,L,t} = \Sigma(LBL_{PRJ,NATURALi,t} + LBL_{PRJ,FELLINGS,i,t} + LBL_{PRJ,OTHERi,t})} \bullet CF \quad (34)$$

where:

$LBL_{PRJ,NATURALi,t}$ = annual loss of live tree biomass due to natural mortality in polygon, *i*; t d.m. yr^{-1}

$LBL_{PRJ,FELLINGS,i,t}$ = annual loss of live tree biomass due to commercial felling in polygon, *i*; t d.m. yr^{-1}

$LBL_{PRJ,OTHER,i,t}$ = annual loss of live tree biomass from incidental sources in polygon, *i*; t d.m. yr^{-1}

CF = carbon fraction of dry matter; t C t^{-1} d.m. (IPCC default value = 0.5).

$$\mathbf{LBL_{PRJ,NATURALi,t} = A_{PRJ,i} \bullet LB_{PRJ,i,t} \bullet f_{PRJ,NATURAL,i,t}} \qquad \textbf{(35)}$$ [24]

where

$A_{PRJ,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{PRJ,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t*

$LB_{PRJ,i,t}$ is calculated for year, *t*, beginning with biomass estimates in year *t*=1 (the project start year) and with annual biomass increments ($G_{PRJ,i,t}$) added as per calculations in equation 33a.

$f_{PRJ,NATURAL,i,t}$ = the annual proportion of biomass that dies from natural mortality in forest type , *i* (unitless; $0 \leq f_{PRJ,NATURALi} \leq 1$), year, *t*. Tree mortality is an ongoing process during stand development. Trees die as a consequence of insect attack, disease, competition, or some combination thereof. Hence, mortality can be highly variable between years. This parameter can be applied uniformly across an analysis unit, or individually to a given polygon. Ex post estimates from regional data sources in corresponding stand types are preferred. Sources for mortality estimates include permanent sample plots in similar stand types, literature reports, and inventory data. Some models (the FORECAST model, for example) simulate annual background mortality rates directly and can accommodate variable age structures following partial harvesting.

$$\mathbf{LBL_{PRJ,FELLINGS,i,t} = A_{PRJ,i} \bullet LB_{PRJ,i,t} \bullet f_{PRJ,HARVEST,i,t}} \qquad \textbf{(36)}$$

where:

$A_{PRJ,i}$ = area (ha) of forest land in polygon, *i*

$LB_{PRJ,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t* (see equation 7 for its calculation).

$f_{PRJ,HARVEST,i,t}$ = the proportion of biomass removed by harvesting from polygon, *i,* (unitless; $0 \leq f_{PRJ,HARVESTIi} \leq 1$), in year, *t*. Data for this variable should be obtained from harvest schedule information. Values may be constrained by (a) the value of $f_{PRJ,NATURAL,i,t}$ (i.e., $f_{PRJ,HARVEST,i,t} < 1 - f_{PRJ,NATURAL,i,t}$), and/or (b) the area of timber available for commercial harvest.

Incidental loss ($LBL_{PRJ,OTHER,i,t}$; t d.m. yr^{-1}) is the additional live tree biomass removed for road and landing construction in the polygon, *i*, and is calculated as a proportion of biomass removed by harvesting:

$$\mathbf{LBL_{PRJ,OTHER,i,t} = A_{PRJ,i} \bullet LB_{PRJ,i,t} \bullet f_{PRJ,HARVEST,i,t} \bullet f_{PRJ,DAMAGE,i,t}} \qquad \textbf{(37)}$$

where:

$A_{PRJ,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{PRJ,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t*

[24] Note, for Equation 35, 36, and 37: $\mathbf{(f_{PRJ,NATURAL,i,t} + f_{PRJ,HARVEST,i,t} + f_{PRJ,DAMAGE,i,t}) \leq 1.0}$

$f_{PRJ,HARVEST,i,t}$ = the proportion of biomass removed by harvesting from polygon, *i,* in year, *t* (unitless; $0 \leq f_{PRJ,HARVEST,i,t} \leq 1$).

$f_{PRJ,DAMAGE,i,t}$ = the proportion of additional biomass removed for road and landing construction in polygon, *i,* year, *t* (unitless; $0 \leq f_{PRJ,DAMAGE,i,t} \leq 1$)[25]. Data for this variable should be based on regional and local comparative studies and experiential information derived from the local forest industry[26].

8.2.8 Dead Organic Matter Dynamics ($\Delta C_{PRJ,DOM}$)

Dead organic matter (DOM) included in this methodology comprises three components: standing dead wood (minimum ≥ 5 cm DBH and 1.3 m height; termed snags), lying dead wood (minimum ≥ 5 cm DBH; LDW), and belowground dead wood (i.e., dead roots). Standing dead wood is < 45º of vertical, while lying dead wood is ≥ 45º of vertical.

The annual change in carbon stocks in DOM ($\Delta C_{PRJ,DOM}$; t C yr^{-1}) is calculated as:

$$\Delta C_{PRJ,DOM,t} = \Delta C_{PRJ,LDW,t} + \Delta C_{PRJ,SNAG,t} + \Delta C_{PRJ,DBG,t} \quad (38)$$

where:

$\Delta C_{PRJ,LDW,t}$ = change in lying dead wood (LDW) carbon stocks in year, *t*; t C yr^{-1}

$\Delta C_{PRJ,SNAG,t}$ = change in snag carbon stock in year, *t*; t C yr^{-1}

$\Delta C_{BSL,DBG,t}$ = change in belowground carbon stock in year, *t*; t C yr^{-1}.

$$\Delta C_{PRJ,LDW,t} = \Sigma(LDW_{PRJ,IN,i,t} - LDW_{PRJ,OUT,i,t}) \bullet CF \quad (39a)$$

$$LDW_{PRJ,i,t+1} = LDW_{PRJ,i,t} + (LDW_{PRJ,IN,i,t} - LDW_{PRJ,OUT,i,t}) \quad (39b)$$

where:

$LDW_{PRJ,i,t}$= The total mass of lying dead wood accumulated in polygon *i* at time t (t d.m.).

$LDW_{PRJ,IN,i,t}$ = annual increase in LDW biomass for polygon *i*, year, *t* (t d.m ha^{-1} yr^{-1}). LDW increases occur as a result of natural mortality (typically, blowdown), and as a direct or indirect result of harvesting.

$LDW_{PRJ,OUT,i,t}$ = annual loss in LDW biomass through decay, for polygon *i*, year, *t*, (t d.m ha^{-1} yr^{-1})

$LDW_{PRJ,IN,i,t}$ and $LDW_{PRJ,OUT,i,t}$ are summed across polygons.

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$LDW_{PRJ,IN,i,t} = (LBL_{PRJ,NATURALi,t} - LBL_{PRJ,NATURALi,t} \bullet R_i) \bullet f_{PRJ,BLOWDOWN,i,t} +$$
$$((LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i) +$$
$$(LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,OTHER,i,t} \bullet R_i)) \bullet f_{PRJ,BRANCH,i,t} +$$

[25] Projecting ex ante road and landing removals beyond a few years is difficult and complex. As described, $f_{PRJ,DAMAGE,i,t}$ functions as a proxy for estimating biomass impacts of all new roads and landings associated with annual harvesting in polygon, *i*. Project proponents can simulate $LBL_{PRJ,OTHER,i,t}$ directly, if appropriate models are available.

[26] $f_{PRJ,DAMAGE,i,t}$ may be zero or de minimis in cases where a polygon is already roaded.

$$\mathbf{((LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i) +}$$

$$\mathbf{(LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,OTHER,i,t} \bullet R_i)) \bullet}$$

$$\mathbf{(1 - f_{PRJ,BRANCH,i,t}) \bullet f_{PRJ,BUCKINGLOSS,i,t} + SNAG_{PRJ,,i,t} \bullet f_{PRJ,SNAGFALLDOWN,i,t} \quad (40)}$$

where:

$LBL_{PRJ,NATURALi,t}$, $LBL_{PRJ,FELLINGS,i,t,}$ and $LBL_{PRJ,OTHER,i,t}$ are as calculated in equations 35, 36, and 37, respectively.

R_i is the root:shoot ratio in polygon, *i* (see equation 33b).

$f_{PRJ,BLOWDOWN,i,t}$ = the annual proportion of live aboveground tree biomass subject to blowdown in polygon, *i,* year*, t* (unitless; $0 \leq f_{PRJ,BLOWDOWN,i,t} \leq 1$). Ex ante estimates must be derived from regional reports in similar forest types.

$f_{PRJ,BRANCH,i,t}$ = the annual proportion of aboveground tree biomass comprised of branches $\geq$ 5 cm diameter in polygon, *i* (unitless; $0 \leq f_{PRJ,BRANCH,i,t} \leq 1$). Ex ante data are available from allometric equations and models (for example, (Kurz & Apps, 2006) for Canada; (Smith, Miles, Vissage, & Pugh, 2004) for the U.S.). In the event slash burning is undertaken, this parameter should be reduced accordingly to reflect the proportion of biomass remaining. Estimates should be obtained from expert opinion; as a default, assume 100% consumption.

$f_{PRJ,BUCKINGLOSS,i,t}$ = the annual proportion of the log bole biomass left on site after assessing and/or merchandizing the log bole for quality, in polygon, *i* (unitless; $0 \leq f_{PRJ,BUCKINGLOSS,i,t} \leq 1$). Preferably, data for this variable must be based on regional and local comparative studies and experiential information derived from the local forest industry. Otherwise, an average default value of 21% can be used, based on US national summary statistics (Smith, Miles, Vissage, & Pugh, 2004).

$SNAG_{PRJ,i,t}$ = the total mass of the snag pool in polygon, *i*, year, *t* (see equation 42b).

$f_{PRJ,SNAGFALLDOWN,i,t}$ = the annual proportion of snag biomass in polygon, *i*, year, *t*, that falls over and thus is transferred to the LDW pool (unitless; $0 \leq f_{PRJ,SNAGFALLDOWN,i,t} \leq 1$). Ex ante estimates for this parameter can be derived from peer reviewed literature (for example, (Parish, Antos, Ott, & Di Lucca, 2010) and forest carbon accounting models that track the rates of input and losses from dead organic matter pools (for example, (Kurz & et al, 2009).

$$\mathbf{LDW_{PRJ,OUT,i,t} = LDW_{PRJ,i,t} \bullet f_{PRJ,lwDECAY,i,t} \quad (41)}$$

where:

$LDW_{PRJ,i,t}$ = the total amount of lying deadwood mass in polygon *i,* year*, t (see equation 39b)*. $f_{PRJ,lwDECAY,i,t}$ = the annual proportional loss of lying dead biomass due to decay, in polygon *i,* year*, t* (unitless; ; $0 \leq f_{PRJ,lwDECAY,i,t} \leq 1$). A common approach to ex ante estimation of $f_{PRJ,lwDECAY,i,t}$ is to assume mass loss occurs in proportion to the amount of mass remaining in accordance with an a single exponential model, of the general form:

$Y_t = Y_o e^{-kt}$

where Y_o is the initial quantity of material, Y_t the amount left at time *t*, and k is a decay constant (Harmon, et al., 1986). Other types of exponential models are available (reviewed in (Harmon, et al., 1986)) and may be more appropriate to particular forest types (to be described and justified by the project proponent, if used). Ex ante estimates for the decay parameter appropriate for the project should be derived from peer-reviewed literature (for example, (Harmon, et al., 1986); (Laiho & and Prescott, 2004); (Harmon et al, 2008)).

The change in standing dead wood (snag) carbon stock in year, *t* (t C yr^{-1}) is calculated as:

$$\Delta C_{PRJ,SNAG,t} = \Sigma(SNAG_{PRJ,IN,i,t} - SNAG_{PRJ,OUT,i,t}) \bullet CF \quad \textbf{(42a)}$$

$$SNAG_{PRJ,i,t+1} = SNAG_{PRJ,i,t} + (SNAG_{PRJ,IN,i,t} - SNAG_{PRJ,OUT,i,t}) \quad \textbf{(42b)}$$

where:

$SNAG_{PRJ,i,t}$ = The total mass of snags accumulated in polygon *i* at time *t* (t d.m.)

$SNAG_{PRJ,IN,i,t}$ = annual gain in snag biomass for polygon *i*, year, *t* (t d.m ha^{-1} yr^{-1}). Snag biomass develops as a result of natural mortality. In cases where snags are created through management activities, these should be accounted for here.

$SNAG_{PRJ,OUT,i,t}$ = annual loss in snag biomass through decay, or falldown (i.e, transfer to the LDW pool)(t d.m ha^{-1} yr^{-1})

CF = carbon fraction of dry matter (IPCC default value = 0.5).

Note that $SNAG_{PRJ,IN,i,t}$ and $SNAG_{PRJ,OUT,i,t}$ are summed across polygons.

$$SNAG_{PRJ,IN,i,t} = (LBL_{PRJ,NATURALi,t} - LBL_{PRJ,NATURALi,t} \bullet R_i) \bullet (1 - f_{PRJ,BLOWDOWN,i,t}) \quad \textbf{(43)}$$

where:

$LBL_{PRJ,NATURALi,t}$ is as calculated in equation 35, and

$1 - f_{PRJ,BLOWDOWN,i,t}$ is the proportion of live tree aboveground biomass that dies in polygon, *i*, year, *t*, but remains as standing dead organic matter (i.e. snags) (unitless; $0 \leq f_{PRJ,BLOWDOWN,i,t} \leq 1$). Ex ante default estimates for this calculation can be derived from literature values (for example (Harmon, et al., 1986); (Runkle, 2000); (Harmon et al, 2008)) and should be matched to the ecosystems that most closely characterize the project area.

$$SNAG_{PRJ,OUT,i,t} = SNAG_{PRJ,i,t} \bullet f_{PRJ,SWDECAY,i,t} + SNAG_{PRJ,i,t} \bullet f_{PRJ,SNAGFALLDOWN,i,t} \quad \textbf{(44)}$$

where:

$SNAG_{PRJ,i,t}$ = the total amount of snag mass in polygon *i,* year*, t (see equation 42b).* $f_{PRJ,SWDECAY,i,t}$ = the annual proportional loss of snag biomass due to decay, in polygon, *i*, year, *t* (unitless; $0 \leq f_{PRJ,SWDECAY,i,t} \leq 1$). As with lying dead wood, a common approach to estimating $f_{PRJ,SWDECAY,i,t}$ is to assume mass loss occurs in proportion to the amount of mass remaining in accordance with an a single exponential model (see equation 41). Ex ante estimates for this parameter can be derived from peer reviewed literature appropriate for the project site (for example, Vanderwel et al. 2006a) and forest carbon accounting models that track the rates of input and losses from dead organic matter pools for each forest type, productivity, and age-class (see, for example, Vanderwel et al., 2006b; (Kurz & et al, 2009)).

$f_{PRJ,SNAGFALLDOWN,i,t}$ = the annual proportion of snag biomass in polygon, *i*, that falls over and thus is transferred to the LDW pool (unitless; $0 \leq f_{PRJ,SNAGFALLDOWN,i,t} \leq 1$). See equation 40 for parameter estimates.

The annual change in DOM derived from dead belowground biomass ($\Delta C_{PRJ,DBG,\ ,t}$; t C yr^{-1}) is calculated for each polygon as per equation 45a. Calculation of $\Delta C_{PRJ,DBG,t}$ is specific to a given polygon; each polygon must therefore be summed in order to calculate total annual loss across the project activity area.

$$\Delta C_{PRJ,DBG,t} = \Sigma(DBG_{PRJ,IN,i,t} - DBG_{PRJ,OUT,i,t}) \bullet CF \quad (45a)$$

$$DBG_{PRJ,i,t+1} = DBG_{PRJ,i,t} + (DBG_{PRJ,IN,i,t} - DBG_{PRJ,OUT,i,t}) \quad (45b)$$

where:

$DGB_{PRJ,i,t}$ = The total quantity of dead belowground biomass accumulated in polygon *i* at time *t* (t d.m.).

$DBG_{PRJ,IN,i,t}$ = annual gain in dead belowground biomass for polygon *i*, year, *t* (t d.m ha^{-1} yr^{-1}). Dead belowground biomass develops as a result of mortality through natural causes or through harvesting activities.

$DBG_{PRJ,OUT,i,t}$ = annual loss in dead belowground biomass through decay, (t d.m ha^{-1} yr^{-1})

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$DBG_{PRJ,IN,i,t} = [(A_{PRJ,i} \bullet LB_{PRJ,i,t} \bullet R_i) \bullet (f_{PRJ,NATURAL,i,t} + f_{PRJ,HARVEST,i,t} + f_{PRJ,DAMAGE,i,t})] \quad (45c)$$

where:

$A_{PRJ,i}$ = area (ha) of forest land in polygon, *i*;

$LB_{PRJ,i,t}$ = average live tree biomass (t d.m. ha^{-1}) in polygon, *i,* for year, *t.* $LB_{PRJ,i,t}$ is calculated for year, *t*, beginning with biomass estimates in year *t*=1 (the project start year) and with annual biomass increments ($G_{PRJ,i,t}$) added as per calculations in equation 33 a, b. This value is then multiplied by $A_{PRJ,i,}$ the area (ha) of forest land in polygon, *i*.

R_i is the root:shoot ratio in polygon, *i* (see equation 33b).

$f_{PRJ,NATURAL,i,t}$ = the annual proportion of biomass that dies from natural mortality in polygon, *i* (unitless; $0 \leq f_{NATURALi} \leq 1$), year, *t* (see equation 35),

$f_{PRJ,HARVEST,i,t}$ = the proportion of biomass removed by harvesting from polygon, *i,* (unitless; $0 \leq f_{PRJ,HARVESTIi} \leq 1$), year, *t* (see equation 36),

$f_{PRJ,DAMAGE,i,t}$ = the proportion of additional biomass removed by for road and landing construction in polygon, *i* (unitless; $0 \leq f_{PRJ,DAMAGE,i,t} \leq 1$), year, *t* (see equation 37),

$$DBG_{PRJ,OUT,i,t} = DBG_{PRJ,i,t} \bullet f_{PRJ,dgbDECAY,i,t} \quad (45d)$$

where:

$DBG_{PRJ,i,t}$ = the total quantity of dead belowground in polygon *i,* year*, t (equation 17b)*. $f_{PRJ,dgbDECAY,i,t}$ = the annual proportional loss of dead belowground biomass due to decay, in polygon *i,* year*, t* (unitless; $0 \leq f_{PRJ,lwDECAY,i,t} \leq 1$). The ex ante estimation of the decay of dead belowground biomass should be done using a similar single exponent decay function as that described above for lying deadwood biomass. Estimates for the decay parameter appropriate for specific project should be derived from peer-reviewed literature (see for example: (Moore, Trofymow, Siltanen, Prescott, & CIDET, 2005); (Melin, Petersson, & Nordfjell, 2009).

8.2.9 Harvested Wood Products

See Section 8.1.6 for various discussion and background on HWP calculations.

The annual change in emissions associated with the production of harvested wood products (HWP), $\Delta C_{BSl,HWP,t}$, is calculated as:

$$\Delta C_{PRJ,HWP,t} = \Delta C_{PRJ,STORHWP,t} - \Delta C_{PRJ,EMITFOSSIL,t,} \quad (46)$$

$\Delta C_{PRJ,STORHWP,t}$ = the annual change in harvested carbon that remains in storage after conversion to wood products (t C yr^{-1})

$\Delta C_{PRJ,EMITFOSSIL,t}$ = the annual change in fossil fuel emissions from harvesting (logging and log transport) and processing of the various wood products.

8.2.10 Carbon storage harvested wood products ($\Delta C_{PRJ,STORHWP,t}$)

If harvesting is occurring in the project case, see Section 8.1.7 for a discussion of key issues.

The annual change in carbon storage in harvested wood products in year *t* ($\Delta C_{PRJ,STORHWP,t}$; t C yr^{-1}) is determined based upon the following equation:

$$\Delta C_{PRJ,STORHWP,t} = (C_{PRJ,STORHWP,t2} - C_{PRJ,STORHWP,t1}) / T \quad (47)$$

where:

$C_{PRJ,STORHWP,t2}$ = carbon storage in harvested wood products at t=2; t C

$C_{PRJ,STORHWP,t1}$ = carbon storage in harvested wood products at t=1; t C

T = number of years between monitoring t1 and t2

t : 1,2,3…t years elapsed since the project start date

Storage in the harvested wood products pool at a given time t ($C_{PRJ,STORHWP,t}$; t C) is calculated according to the following steps for each harvest period *h*:

Step 1 (Carbon contained in harvested timber): Determine the carbon contained within harvested timber removed from the project landbase. This can be calculated from measures of total merchantable volume generated during the harvest period *h* using species-specific wood densities and standard carbon conversions or estimated from live biomass removals after accounting for removal of belowground components, branches, and bucking losses (equation 48). In accordance with the 1605(b) approach, the harvested wood carbon ($C_{PRJ,TIMBER,h}$) must be divided into the following product type (*k*) categories: 1) softwood saw log, 2) softwood pulpwood, 3) hardwood saw log, 4) hardwood pulpwood. This can be done using local data if available or estimated based upon region and forest type according to Table 1.4 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous US; however the project proponent must justify the appropriateness of the selected analog. In the case of global project locations outside of North America, the project proponent must identify and justify the use of alternative data from peer-reviewed sources

$$C_{PRJ,TIMBER,h} = \Sigma[(LBL_{PRJ,FELLINGS,i,h} - LBL_{PRJ,FELLINGS,i,h} \bullet R_i + LBL_{PRJ,OTHER,i,h} - LBL_{PRJ,OTHER,i,h} \bullet R_i) \bullet (1 - f_{PRJ,BRANCH,i,h}) \bullet (1 - f_{PRJ,BUCKINGLOSS,i,h})] \bullet \bullet CF \quad (48)$$

where:

$C_{PRJ,TIMBER,h}$= carbon contained in timber harvested in period *h* (summed for all harvested polygons, *i*); t C

$LBL_{PRJ,FELLINGS,i,h}$ = annual removal of live tree biomass due to commercial felling in polygon, *i*; t d.m. (equation 36)

$LBL_{PRJ,OTHER,i,h}$ = annual removal of live tree biomass from incidental sources in polygon, *i*; t d.m. (equation 37)

R_i is the root:shoot ratio in polygon, *i* (see equation 33b).

1 - $f_{PRJ,BRANCH,i,h}$ the proportion of live tree biomass remaining after netting out branch biomass, in polygon *i* (unitless; $0 \leq f_{BRANCH,i,t} \leq 1$)(see equation 12)

1 - $f_{PRJ,BUCKINGLOSS,i,h}$ = the proportion of the log bole remaining after in-woods log processing/bucking for quality, length, etc., in polygon, *i* (unitless; $0 \leq f_{BUCKINGLOSS,i,t} \leq 1$) (equation 40)

h = harvest period ; yr

Step 2: (Carbon contained in harvested timber after milling): Determine the total carbon in harvested timber that will enter the wood products pool by product type accounting for mill efficiencies and estimated product disposition percentages ($C_{PRJ,MILL,h}$; t C). The gross quantity of carbon contained in harvested timber for each of the four product types described in Step 1 must be decremented to account for losses during processing (equation 49). These losses including bark and other milling wastes and may be determined using local data or estimated based upon region and product type according to Table 1.5 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous US; however, the project proponent must justify the appropriateness of the selected analog.. The 1605(b) document also provides specific examples demonstrating the use of values from Tables 1.4 and 1.5 to determine net carbon storage in wood product types after milling (See examples 1.4 and 1.5 on pages 25-27). In the case of global project locations outside of North America, the project proponent must identify and justify the use of alternative data from peer-reviewed sources

$$\mathbf{C_{PRJ,MILL,h,k} = (C_{PRJ,TIMBER,h,k} \bullet f_{RND,k} \bullet r_{RND,k})} \quad \mathbf{(49)}$$

where:

$C_{PRJ,MILL,h,k}$ = carbon contained in harvested timber after milling in period h, for product type *k*; t C

$C_{PRJ,TIMBER,h,k}$ = carbon contained in timber harvested in period h, for product type *k*; t C

k = wood product type – (softwood saw log, softwood pulpwood, hardwood saw log, or hardwood pulpwood; proportions determined from Table 1.4 of 1605(b) document)

$f_{RND,k}$ = fraction of growing stock volume removed as roundwood for product type *k* (default values by region in Table 1.5 of the 1605(b) document); dimensionless

$r_{RND,k}$ = ratio of industrial roundwood to growing stock volume removed as roundwood for product type *k* (default values by region in Table 1.5 of the 1605(b) document); dimensionless

Step 3: (Carbon storage in medium-term and long-term wood products): Calculate the total carbon lost in short-lived products and stored in medium-term and long-term products. For each harvest period *h*, carbon stored in harvested wood products of a defined type (k) after accounting for milling losses ($\mathbf{C_{PRJ,MILL,h,k}}$) must be apportioned into one of the following categories:

d) Short lived wood products: harvested wood products and wood waste that will decay within 3 years.
e) Medium lived wood products: harvested wood products and wood waste that will be retired between 3 and 100 years from the date of harvest.
f) Long lived wood products: harvested wood products and wood waste that may be considered permanent (stored for 100 years or more).

To determine the proportion of harvested wood products (by type) that fall into each category, refer to the "In Use" column for the selected forest region in Table 1.6 in the 1605(b) document. Table 3 provides recommendations for analogs for areas within North America but outside of the conterminous US; the project proponent must justify the appropriateness of the selected analog .Three values are then calculated from these data selected from Table 1.6 in the 1605(b) document, for each product type, *k* : the short-lived fraction ($P_{PRJ,SLF,k}$), medium-lived fraction ($P_{PRJ,MLF,k}$), and long-lived fraction ($P_{PRJ,LLF,k}$):

$$\mathbf{P_{PRJ,SLF,k} = 1-P_{3\text{-}year}} \qquad \textbf{(50a)}$$

$$\mathbf{P_{PRJ,LLF,k} = P_{100\text{-}year}} \qquad \textbf{(50b)}$$

$$\mathbf{P_{PRJ,MLF,k} = P_{3\text{-}year} - P_{100\text{-}year}}\ , \qquad \textbf{(50c)}$$

Each category of wood products (*k*) stores carbon according to the following rules:

iv. Short-lived wood products – immediate emission of all carbon upon harvest
v. Medium-lived wood products – no emission of carbon upon harvest, but carbon stored will decrease by 1/20th for the next 20 years after harvest, such that after 20 years the term becomes zero
vi. Long-lived wood products – no loss of carbon.

Thus, carbon storage in harvested wood products at time *t* may be calculated using a cohort approach in which medium-term and long-term wood products from each harvest period *h* are tracked independently and then summed over the project time period as indicated in equation 51.

$$\mathbf{C_{PRJ,STORHWP,t,}} = \Sigma\ \Sigma\ \mathbf{((\ C_{PRJ,MILL,h,k} \bullet P_{LLF,k}) + [(C_{PRJ,MILL,h,k} \bullet P_{MLF,k}) \bullet ((20\text{-}h) / 20)])} \qquad \textbf{(51)}$$

where:

$C_{PRJ,STORHWP,t,}$ = carbon stored in harvested wood products in year *t* summed for all product types *k* and then over all harvest periods *h*; t C

k = wood product type – (softwood saw log, softwood pulpwood, hardwood saw log, or hardwood pulpwood; proportions determined from Table 1.4 of 1605(b) document)

h = year of harvest (the term (20-h) should not be allowed to drop below 0)

8.2.11 mustFossil fuel emissions associated with logging, transport, and manufacture

The annual change in fossil fuel emissions from harvesting and processing of the various wood products ($\Delta C_{PRJ,EMITFOSSIL,t}$) are calculated as:

$$\Delta C_{PRJ,EMITFOSSIL,t} = C_{PRJ,EMITHARVEST,t} + C_{PRJ,EMITMANUFACTURE,t} + C_{PRJ,EMITTRANSPORT,t} \quad (52)$$

Where

$C_{PRJ,EMITHARVEST,t}$ = the annual fossil fuel emissions associated with harvesting of raw material (t C yr^{-1})

$C_{PRJ,EMITMANUFACTURE,t}$ = the annual fossil fuel emissions associated with the manufacturing of raw material (t C yr^{-1})

$C_{PRJ,EMITTRANSPORT,t}$ = the annual fossil fuel emissions associated with the transport of raw material (t C yr^{-1})

The simplest approach to calculating $C_{PRJ,EMITFOSSIL,t}$ is to use published or derived carbon emission intensity factors. In the case of harvesting, $_{PRJ,}C_{EMITHARVEST,t}$; t C yr^{-1}), can be calculated as:

$$C_{PRJ,EMITHARVEST,t} = \Sigma[(LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i + LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,OTHER,i,t} \bullet R_i) \bullet (1 - f_{PRJ,BRANCH,i,t}) \bullet (1 - f_{PRJ,BUCKINGLOSS,i,t})] \bullet CF \bullet c_{HARVEST} \quad (53)$$

where:

$c_{HARVEST}$ = carbon emission intensity factor (t C emitted/t C raw material) associated with harvesting (see Table 4 for default values); all other terms are as defined in equation 19.

$C_{PRJ,EMITTRANSPORT,t}$ must be calculated after consideration of the transport distance from harvest to processing facility, and the means of transportation. This term can be calculated as follows (after (Heath, et al., 2010)):

$$C_{PRJ,EMITTRANSPORT,t} = \Sigma[(LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i + LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,OTHER,i,t} \bullet R_i) \bullet (1 - f_{PRJ,BRANCH,i,t}) \bullet (1 - f_{PRJ,BUCKINGLOSS,i,t})] \bullet CF \bullet \Sigma(f_{PRJ,TRANSPORTk} \bullet d_{TRANSPORTk} \bullet c_{TRANSPORTk}) \quad (54)$$

where:

$f_{PRJ,TRANSPORTk}$ = the fraction of raw material transported by transportation type, *k*. (unitless; $0 \leq f_{PRJ,TRANSPORTk} < 1$).

$d_{TRANSPORTk}$ = the distance transported by transportation type, *k*. (km);

$c_{TRANSPORTk}$ = the carbon emission intensity factor (kg C emitted/t C raw material) associated with transportation type, *k* (see Table 4 for default values); all other terms are as defined in equation 48.

$$C_{PRJ,EMITMANUFACTURE,t} = \Sigma[(LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i + LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,OTHER,i,t} \bullet R_i) \bullet (1 - f_{PRJ,BRANCH,i,t}) \bullet (1 - f_{PRJ,BUCKINGLOSS,i,t})] \bullet \Sigma(f_{PRJ,PRODUCTk} \bullet c_{MANUFACTUREk}) \bullet CF \quad (55)$$

$c_{MANUFACTUREk}$ = the carbon emission intensity factor (t C emitted/t C raw material) associated with manufacture of product type, k; all other terms are as defined in equation 48.

Default values for $c_{MANUFACTUREk}$ are provided in Table 4. Data are from a comprehensive analysis conducted in Finland (Pingoud, Perälä, Soimakallio, & Pussinen, 2003). Higher comparative values from North America are provided for harvesting and sawnwood manufacturing to illustrate inherent variability. Project proponents may use the default values in Table 4, or substitute regional data, if available.

8.3 Leakage

Leakage is defined as any increase in GHG emissions that occurs outside the project boundary (but within the same country), and is measurable and attributable to the project activities. All leakage must be assessed and accounted for in GHG calculations. Positive leakage effects must be discounted.

8.3.1 Activity Shifting Leakage:

Activity shifting leakage occurs when the actual agent of harvesting moves to an area outside of the project boundary and initiates compensatory harvesting activities elsewhere. Activity shifting leakage in IFM projects can result from current activities shifting within the project proponent's operations due to the implementation of the carbon project. This effectively offsets a portion of the benefits of the carbon project emissions reductions. The project proponent will demonstrate that, as per VCS requirements for IFM projects and the applicability conditions of this methodology, there is no leakage due to activity shifting within the project proponents' lands upon the start up of the project[27], using the following steps:

STEP 1 - The project proponent must annually provide to the validator and/or verifier the locations and descriptions of all forestlands within the project country over which the project proponent has ownership, management, or legally sanctioned rights of use.

STEP 2 - Project proponents must demonstrate annually that there is no activity shifting leakage to areas that are outside the project area but within the project proponents operating areas, and that the management plans and/or land-use designations of all other lands operated by the project proponent have not materially changed as a result of the project activity (e.g., harvest rates have not been increased). Demonstration methods must include:

1. Historical records showing trends in harvest volumes paired with records from the project time period showing no deviation from historical trends, or
2. Forest management plans prepared ≥ 24 months prior to the start of the project showing harvest plans on all owned/managed lands paired with records from the project time period showing no deviation from management plans; and/or
3. Other evidence and justification to demonstrate activity shifting related to the project is not occurring[28].

8.3.2 Market Leakage:

Market leakage risk occurs when a project significantly reduces the production of a commodity causing a change in the supply and market demand equilibrium that results in a shift of production elsewhere to make up for the lost supply. VCS provides project proponents with two options for quantifying market leakage, which are further defined for this methodology:

[27] See footnote 4 (and applicability criterion 7) for further requirements in the event activity shifting is found to be occurring in later years of the project duration.

[28] The onus is on the project proponent to demonstrate and justify that the source of data and the geographic scale and scope used to assess activity shifting are appropriate for the project to meet the requirements of VCS and the methodology.

1. Apply the most current VCS market leakage tool to determine a discount factor to the net change in carbon stock associated with the activity that reduces timber harvest (see Section 8.3.3); or,

2. Develop a project-specific market leakage factor that accounts for country level leakage within similar forest types[29]. This methodology allows two variations on this option:
   a. Utilize the CAR Forest Protocol 3.2 market leakage equation, if the project is located within countries where CAR applies, or can demonstrate equivalent market conditions (currently CAR applies only in the US but is developing protocol assumptions for Mexico and Canada) (see Section 8.3.4); or
   b. Utilize a detailed leakage risk assessment form provided in this methodology and provide related additional supporting evidence for the assessments made therein (see Section 8.3.5).

8.3.3 Market Leakage Option 1 – VCS Default Market Leakage Discount Factors

In exercising this option, project proponents must utilize the most current approved VCS leakage discount method as outlined in the most recent VCS AFOLU requirements document[30]. Projects will determine the appropriate discount factor in accordance with the most recent requirements for market leakage. Project proponents must provide justification and evidence of how the leakage discount factor is determined.

For project proponents using Market Leakage Option 1:

The outcome of the VCS Leakage Discount Factor determination = the value for MLF_y (56a)

To calculate the project market leakage (LE_Y, t CO2e yr^{-1}):

$$LE_Y = MLF_y \cdot ER_{y,GROSS} \quad \textbf{(56b)}$$

Where,

MLF_y = Market leakage factor, as calculated above.

$ER_{y,GROSS}$ = the gross difference in the overall annual carbon change between the baseline and project scenarios in year 'y' (in tonnes CO_2e yr^{-1}). This term is calculated in equation 57.

8.3.4 Market Leakage Option 2 – CAR Market Leakage Formula

Based on the fact that the CAR forest protocol is widely accepted in North America, thoroughly reviewed, generally mutually recognized by VCS, and developed for a single country leakage condition; it is considered a valid approach to leakage discount factors when applied to projects located in CAR-eligible jurisdictions (currently the United States). Further, project proponents may justify the application of the CAR leakage formula for log market conditions fundamentally similar to the United States and which are currently under development as CAR jurisdictions (i.e. Canada and Mexico pending).

The CAR leakage formula is calculated as per the latest approved CAR Forest Protocol. The currently approved calculation is provided Figure 1, which is to be replaced by the most up to date approved CAR method as required:

---

[29] Specifically: "…market leakage shall be accounted for at the country-scale applied to the same general forest type as the project (i.e., forests containing the same commercial species as the forest in the project area)...." (Voluntary Carbon Standard, 2008b).

[30] Note the VCS May 24th AFOLU Program Update, which specifies using the ratio of merchantable biomass to total biomass in the project versus leakage area.

Figure 1 - CAR Forestry Protocol v.3.2 Market Leakage Process[31][32]

Forest Project Protocol *Version 3.2, August 2010*

6.2.6 Quantifying Secondary Effects

For Improved Forest Management Projects, significant Secondary Effects can occur if a project reduces harvesting in the Project Area, resulting in an increase in harvesting on other properties. Changes in energy-related emissions, which could result from a Forest Project causing consumers of forest products to increase or decrease their use of alternative materials, are not accounted for because it is assumed that energy sector emissions will be capped in the relatively near future under a regulatory cap-and-trade system.

Equation 6.10 must be used to estimate Secondary Effects for Improved Forest Management Projects.

Equation 6.10. Secondary Effects Emissions

$$If \sum_{n=1}^{y-1}(AC_{hv,n} - BC_{hv,n}) > 0, then\ SE_y = 0$$

$$If \sum_{n=1}^{y-1}(AC_{hv,n} - BC_{hv,n}) < 0, then\ SE_y = (AC_{hv,y} - BC_{hv,y}) \times 20\%$$

Where,

SE_y	=	Estimated annual Secondary Effects (used in Equation 6.1)
$AC_{hv,n}$	=	Actual amount of onsite carbon harvested in reporting period n (prior to delivery to a mill), expressed in CO_2-equivalent tonnes
$BC_{hv,n}$	=	Estimated average baseline amount of onsite carbon harvested in reporting period n (prior to delivery to a mill), expressed in CO_2-equivalent tonnes, as determined in Step 1 of Section 6.2.3
y	=	The current year or reporting period

For project proponents using Leakage Option 2:

Utilize the CAR formulas (Equation 6.10 – shown in Figure 1), with variables calculated as follows:

Note: for consistency, y = n = t.

$$BC_{hv,n} = \Sigma[(LBL_{BSL,FELLINGS,i,t} - LBL_{BSL,FELLINGS,i,t} \bullet R_i + LBL_{BSL,OTHER,i,t} - LBL_{BSL,Other,i,t} \bullet R_i) \bullet (1 - f_{BSL,BRANCH,i,t}) \bullet (1 - f_{BSL,BUCKINGLOSS,i,t})] \bullet CF \bullet 44/12 \quad (56c.1)$$

As calculated using the *baseline scenario data*, and where:

$LBL_{BSL,FELLINGS,i,t}$ = annual removal of live tree biomass due to commercial felling in polygon, *i*; t d.m. yr^{-1} (equation 6)

[31] "Secondary Effects" = Market Leakage

[32] Figure 1 is to be replaced with the latest approved CAR Forest Protocol Secondary Effects calculations at the time of PD validation.

$LBL_{BSL,OTHER,i,t}$ = annual removal of live tree biomass from incidental sources in polygon, *i*; t d.m. yr^{-1} (equation 6)

1 - $f_{BSL,BRANCH,i,t}$ = the proportion of aboveground live tree biomass remaining after netting out branch biomass, in polygon *i* (unitless; $0 \leq f_{BRANCH,i,t} \leq 1$)(see equation 12)

1 - $f_{BSL,BUCKINGLOSS,i,t}$ = the proportion of the log bole remaining after processing for quality, in polygon, *i* (unitless; $0 \leq f_{BUCKINGLOSS,i,t} \leq 1$) (equation 12)

R_i = the root:shoot ratio in polygon, *i*

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$\mathbf{AC_{hv,\,n} = \Sigma[(LBL_{PRJ,FELLINGS,i,t} - LBL_{PRJ,FELLINGS,i,t} \bullet R_i + LBL_{PRJ,OTHER,i,t} - LBL_{PRJ,Other,i,t} \bullet R_i) \bullet (1 - f_{PRJ,BRANCH,i,t}) \bullet (1 - f_{PRJ,BUCKINGLOSS,i,t})] \bullet CF \bullet 44/12} \qquad \mathbf{(56c.2)}$$

As calculated using the *project scenario data*, and where:

$LBL_{PRJ,FELLINGS,i,t}$ = annual removal of live tree biomass due to restoration felling in polygon, *i*; t d.m. yr^{-1} (equation 6)

$LBL_{PRJ,OTHER,i,t}$ = annual removal of live tree biomass from incidental sources in polygon, *i*; t d.m. yr^{-1} (equation 6)

1 - $f_{PRJ,BRANCH,i,t}$ = the proportion of aboveground live tree biomass remaining after netting out branch biomass, in polygon *i* (unitless; $0 \leq f_{BRANCH,i,t} \leq 1$)(see equation 12)

1 - $f_{PRJ,BUCKINGLOSS,i,t}$ = the proportion of the log bole remaining after processing for quality, in polygon, *i* (unitless; $0 \leq f_{BUCKINGLOSS,i,t} \leq 1$) (equation 12)

CF = carbon fraction of dry matter (IPCC default value = 0.5).

$$\mathbf{SE_y = LE_y} \qquad \mathbf{(56c.3)}$$

where:

SE_y = Secondary Effects in year 'y' (tCO_2e) calculated using equations in Figure 1 and equations 56c.1, 56c.2 and 56c.3.

LE_Y = Leakage in year y (in tonnes CO_2e yr^{-1}) – used in equation 58.

8.3.5 Market Leakage Option 3 – Leakage Assessment Tool

Currently, the VCS method for assessing leakage used in Option 1 does not provide a mechanism for weighting leakage into different biomass areas, and also does not provide a mechanism to separate domestic versus international leakage proportions. This methodology therefore provides a third option to project proponents who wish to undertake an assessment of market leakage conditions more detailed and specific to their project location and condition.

This tool sets out a procedure to weight the VCS leakage categories according to publically available forest products market data for where the leakage risk is most likely to be leaked to (or replaced from).

Following Table 5, the project proponent must conduct the risk analysis as follows:

1. Determine the proportion of leakage expected to be replaced by international sources (i.e. proportion of international leakage) versus domestic sources, and;
2. For the domestic proportion, determine the proportion of leakage to other national biomass forests, based on the VCS default values and categories, and the ratio of merchantable biomass to total biomass on the project site versus the leakage sites.

Where a project is unable to provide any relevant published justification or supporting evidence for a risk factor selection in Table 5, then the project is not eligible to use this tool and must use one of the other provided options to assess market leakage risk.

Table 5 - Market Leakage Option 3 Assessment Table

1.	**International Leakage Proportion**			
	In order to determine the proportion of potential leakage which will occur within domestic markets versus international markets, the project proponent must calculate the proportion of the project leakage which is expected to be *replaced from* domestic (in-project country) sources versus the proportion that will likely be *replaced from* international source (and hence, be international leakage, which is given a leakage risk of zero in VCS). It is assumed that the forest products market is efficient, and any leakage will be replaced proportionally across the project countries current national forest products market conditions. The following calculation provides a method to estimate the proportion of leakage which is domestic versus international. International Leakage Factor = $(FP_{TO\_DOMESTIC}) * (DOM.DEMAND_{FROM\_INTL}) + (FP_{TO\_EXPORT}) * (EXP.DEMAND_{FROM\_INTL})$ Where, $FP_{TO\_DOMESTIC}$ = Total project country forest products delivered to domestic markets (%) FP_{TO_EXPORT} = Total project country forest products delivered to export (international) markets (%) $DOM.DEMAND_{FROM\_INTL}$ = Proportion of total project country Forest Products to International Markets (%) $EXP.DEMAND_{FROM\_INTL}$ = Weighted sum of the proportions of key markets which are supplied from non-project country sources (%) Definitions: "Domestic" = project country "International" = sum of all non-project countries which individually represent >10% of the total project country's forest products production, and which collectively represent >80% of the total project country's forest products export production. "Forest Products" = the market data utilized must be demonstrated to be representative of >80% of the project harvested wood products product mix. Proponents may use forest products volume or value as long			

as the units are consistent and comparable across markets and used consistently within this entire tool.

"Key market(s)" = collectively must represent >80% of the project country's domestic, import, and export supply, either on a log basis or lumber basis. Individual market countries representing <10% of the total domestic or export market may be excluded.

Example:

Example of *Canadian-based* projects under this tool (Stats Can Data & FAO data) (only the US market meets the key market definition for Canadian forest products production):

$FP_{TO\_DOMESTIC}$ = 20%

FP_{TO_EXPORT} = 80% (>90% to US = single 'Key Market')

$DOM.DEMAND_{FROM\_INTL}$ = 10% (i.e. 10% of the domestic market is supplied by non-Canadian supply)

$EXP.DEMAND_{FROM\_INTL}$ = 65% (i.e. 65% of the US market is supplied by non-Canadian supply)

$LF_{INTL} = (FP_{TO\_DOMESTIC}) * (DOM.DEMAND_{FROM\_INTL}) + (FP_{TO\_EXPORT}) * (EXP.DEMAND_{FROM\_INTL})$

$LF_{INTL} = (0.20 * 0.10) + (0.80 * 0.65) = 54\%$

Therefore, 54% of the market leakage is expected to be replaced by international sources, which is assigned a leakage factor of "0". The remaining domestic/national leakage, 46%, is then further considered in the biomass ratio calculations below.

	International Leakage Factor (LF_{INTL}*)*	$LF_{INTL} = (FP_{TO\_DOMESTIC}) * (DOM.DEMAND_{FROM\_INTL}) + (FP_{TO\_EXPORT}) * (EXP.DEMAND_{FROM\_INTL})$

2.	**Proportional Leakage by Biomass Ratio:**			
	VCS Default Biomass Ratio Categories (see: VCS 2008 May 24, 2010 Program Update) Calculated as: ((Project Biomass Ratio – Leakage Biomass Ratio) / (Project Biomass Ratio)) * 100	> 15%[33] Lower merchantable biomass to total biomass (t/ha)	+/- 15% merchantable biomass to total biomass (t/ha)	>15% Higher merchantable biomass to total biomass (t/ha)
	Starting VCS Default Leakage Factors[34]:	20%	40%	70%

[33] VCS does not specify a quantitative range for determining "higher", "lower" or "similar" biomass ratios, and hence a 15% factor has been selected to represent a reasonable range of biomass ratios. This factor is consistent with other approved VCS and ACR IFM methodology approaches.

[34] These factors are from the 2008 VCS leakage calculation method, and should be retained for use in this leakage tool Option 3 regardless of new VCS market leakage tool calculations.

<table>
<tr><td>1a.</td><td colspan="4">2a Calculating Weighted Average Leakage Biomass Ratio:

This is a typical weighted average calculation, with the objective of creating an average difference in biomass ratio between the project and the national leakage areas, weighted by the proportion of timber supply coming from each leakage forest type:

- Identify national forest type (or ecotype) data where merchantable log volume biomass and total forest biomass estimates are available (i.e. from published national inventory data sources, etc.)
- Determine the biomass ratio in each national forest type (ratio of merchantable volume in biomass (t/ha) to total biomass (t/ha);
- Determine the proportion of the domestic national market that is supplied by each of the national forest types (%);
- Determine the difference between the forest type containing the project and each leakage area biomass ratio (Biomass Ratio Difference (%) = ((Project Biomass Ratio – Leakage Area Biomass Ratio) / Project Biomass Ratio) * 100);
- Select the VCS default leakage factor for each national forest type, based on the difference between the project biomass ratio and each national forest type biomass ratio (see biomass ratio categories above);
- Multiple the proportion (%) of market supplied by each leakage forest type by the VCS Default Leakage Factor from each forest type to determine the weighted average VCS Leakage Factor for biomass ratios.

Example (simplified, using 4 national forest types):

Project is located in national forest type 1 (biomass ratio = 0.65):
Forest Type 1: Biomass Ratio = 0.65; 25% of national timber inventory
Forest Type 2: Biomass Ratio = 0.75; 30% of national timber inventory
Forest Type 3: Biomass Ratio = 0.55; 25% of national timber inventory
Forest Type 4: Biomass Ratio = 0.75; 20% of national timber inventory

Biomass Ratio difference between leakage area and project area:
Forest Type 1 = (0.65 – 0.65)/0.65 = 0 = 40% VCS Leakage Factor
Forest Type 2 = (0.65 – 0.75)/0.65 = -15.4% = 20% VCS Leakage Factor
Forest Type 3 = (0.65 – 0.55)/0.65 = 15.4% = 70% VCS Leakage Factor
Forest Type 4 = (0.65 – 0.75)/0.65 = -15.4% = 20% VCS Leakage Factor

Weighted Average = (25% * 40%) + (30% * 20%) + (25% * 70%) + (20% * 20%) = 37.4%
Example Weighted Biomass Discount Factor = 37.4%</td></tr>
<tr><td></td><td>VCS Default Leakage Discount Factor, by forest type (selected by +-15% criteria)</td><td>20%</td><td>40%</td><td>70%</td></tr>
<tr><td></td><td>Proportional of Market Supplied by National Forest Type in each Leakage Discount Category (note: X + Y + Z = 100%):</td><td>= X</td><td>= Y</td><td>= Z</td></tr>
<tr><td></td><td>Proportional Biomass Leakage Discount Factor ($LF_{BIOMASS}$):</td><td colspan="3">$LF_{BIOMASS} = (20\% * X) + (40\% * Y) + (70\% * Z)$</td></tr>
<tr><td>3.</td><td>MARKET LEAKAGE FACTOR (MLF_y):</td><td colspan="3">$=(1 - LF_{INTL})$[35] $* LF_{BIOMASS}$</td></tr>
</table>

[35] The inverse of the international leakage factor is the portion of the market leakage related to national leakage. International leakage is given a leakage factor discount of "0" in VCS.

For project proponents utilizing Leakage Option 3, project market leakage (LE_Y; t CO_2e yr^{-1}) is calculated as:

$$LE_Y = MLF_y \cdot ER_{y,GROSS} \quad (56d)$$

Where,

MLF_y = the market leakage factor in year, *y* (as calculate per section 8.3.5)

$ER_{y,GROSS}$ = the gross difference in the overall carbon balance between the baseline and project scenarios in year, *y* (t CO_2e yr^{-1}). See equation 57 for its calculation.

8.4 Summary of GHG Emission Reduction and/or Removals

The net GHG emissions and removals are calculated for each scenario following the methods outlined in Section 8.1 and 8.2.

8.5 Summary Gross Emissions Reductions and/or Removals Equation

Gross carbon emissions reductions (ER_y,gross; t CO_2e yr^{-1}) created by the carbon project are calculated annually as the difference between the baseline and project scenario net emission reductions/emissions:

$$ER_{y,GROSS} = (\Delta C_{BSL,t} - \Delta C_{PRJ,t}) \bullet 44/12 \quad (57)$$

Where,

$\Delta C_{BSL,t}$ = total net baseline scenario emissions calculated from equation 1 (t C yr^{-1}).

$\Delta C_{PRJ,t}$ = total net project scenario emissions calculated from equation 29 (t C yr^{-1}).

44/12 = factor to convert C to CO_2e

8.5.1 Summary Net Emissions Reductions and/or Removals Equation

The annual *net* carbon emissions reductions is the actual net GHG removals by sinks from the project scenario minus the net GHG removals by sinks from the baseline scenario, were then calculated by applying the leakage and uncertainty discount factors (but not the VCS permanence buffer), on an annualized basis:

$$ER_y = ER_{y,GROSS} - LE_y \quad (58)$$

where:

ER_y = the net GHG emissions reductions and/or removals in year *y* (the overall annual carbon change between the baseline and project scenarios, net all discount factors except the permanence buffer) (t CO_2e yr^{-1}).

$ER_{y,GROSS}$ = the difference in the overall annual carbon change between the baseline and project scenarios (t CO_2e yr^{-1}).

LE_y = Leakage in year y (t CO_2e yr^{-1}), as calculated in equation 56b.

8.5.2 Calculating Verified Carbon Units (VCU's) for the Project

The number of VCU's the project available for issuance and sale in year, *y* (VCU_y; t CO_2e yr^{-1}), is calculated as:

$$\mathbf{VCU_y = ER_y \cdot (1 - ER_{y,ERR}) - BR_y} \quad \textbf{(59)}$$

where:

ER_y = the net GHG emissions reductions and/or removals in year (t $CO_2e\ yr^{-1}$), as calculated in equation 58.

$ER_{y,ERR}$ = the uncertainty factor for year, y, (calculated in Section 8.5.3), expressed as a proportion.

BR_y = estimated VCU-equivalent tCO_2e issued to the VCS Buffer Pool in year, *y*, calculated using the latest version of the VCS AFOLU Non-Permanence Risk Tool. BRy is calculated by multiplying the most current verified permanence risk Buffer Withholding Percentage for the project by the change in carbon stocks (difference between baseline and project scenario) for the project area as per the latest approved VCS AFOLU Requirements (Voluntary Carbon Standard, 2008a).

8.5.3 Calculation of an Uncertainty Factor

Estimated carbon emissions and removals arising from AFOLU activities have uncertainties associated with forest inventory, carbon stocks, biomass growth rates, modeling error, and their various expansion factors, equations and coefficients. Use of conservative estimates, peer-reviewed scientific data and analysis, and high quality inventory sampling procedures, will mitigate uncertainty, and improve accuracy as new and reliable data are acquired over time.

To be conservative, this methodology employs an over-riding project confidence deduction as a proxy for collective project uncertainty by assessing statistical uncertainty in the forest carbon inventory *and* associated modeling. The approach is based partly on CAR's "Confidence Deduction" module (Climate Action Reserve, 2010). Project proponents are required to apply this uncertainty factor to the net emission reductions claimed by the project each year based on the results of the latest ex-post inventory field data collection and modeling output.

Note that physical field plot measurement error is calculated and compared directly against a set of minimum accuracy threshold requirements, as described in Section 9.

Refer to Section 8.1 for guidance on the process of stratification and how *polygons* and *analysis units* are defined.

The methodology monitoring section specifies that all analysis units or polygons[36] will have representation by one or more field plots. However, due to the difficulty of determining the independence of plot data within individual homogeneous polygons (i.e. a specifically similar forest type, site, and age), it will be necessary to only calculate a single carbon density *observation* for each individual polygon sampled; either through the use of a single plot within that polygon, or calculation of the mean of multiple plots within that polygon. *Throughout these calculations a plot observation, subscript i, is defined to represent the mean of all plots within a given polygon.*

The project-level uncertainty factor is calculated as follows:

Step 1 – Calculate the average percent model error (E_M) for the project based on the average area-weighted difference between measured values in monitored plot observations and model-predicted values using Equations 60a,b. In the case where analysis units have been used for stratification, the difference between the plot observation and model-predicted value (both expressed on a per hectare basis) for a given analysis unit ($y_{d,h,i}$) is weighted by the area of its associated analysis unit ($A_{PRJ,h}$) (Eq. 60a). The use of an area-weighting factor places more emphasis on analysis units that represent a relatively larger proportion of the total project area. In the case

[36] If polygons are the primary stratification unit being used by the project, then each polygon shall have field plot representation. If polygons are grouped into analysis units for the project, then each analysis unit shall have field plot representation (noting that not all polygons will have plot representation within a given analysis unit).

where only polygons are used in the stratification, the area weighting term (see equations 60a-c) would change to the area of the polygon ($A_{PRJ,i}$), and the subscript, *h*, is dropped from the $\mathbf{y_{d,h,i}}$ term in equations 60a-e.

$$E_M = 100 \cdot (\sum y_{d,h,i} / \sum(A_{PRJ,h} \cdot y_{m,h,i})) \quad \textbf{(60a)}$$

where:

The summation is across all plot observations, *i*, and across all analysis units , *h*;

$$y_{d,h,i} = A_{PRJ,h} \cdot (y_{m,h,i} - y_{p,h,i}) \quad \textbf{(60b)}$$

E_M = Mean model error for the project (%)

$y_{d,h,i}$ = the area-weighted difference between measured and predicted carbon storage in analysis unit, *h*, plot observation, *i* (t C)

$y_{m,h,i}$ = carbon storage measured in analysis unit, *h*, plot observation, *i* (t C ha^{-1})

$y_{p,h,i}$ = carbon storage predicted by model for analysis unit , *h*, plot observation, *i* (t C ha^{-1})

$A_{PRJ,h}$ = area of project analysis unit, *h* (ha)

Step 2 – Calculate the inventory error (E_I) at a 90% confidence interval expressed as a percentage of the mean area-weighted inventory estimate from the measured plots.

This methodology was designed to accommodate complex landscapes consisting of hundreds to thousands of polygons, which can be further grouped into analysis units. Inventory error is estimated based upon the difference between modeled and measured values for monitoring plots established in polygons or in polygons grouped within analysis units.

Inventory error, E_I, is estimated by first calculating the standard error of the area-weighted differences between the plot observation measurement and the associated model-predicted carbon storage (both on a per hectare basis) for analysis units or polygons. The standard error is then multiplied by the *t*-value for the 90% confidence interval. Finally E_I is expressed in relative terms (in Equation 60c) by dividing the 90% confidence interval of the area-weighted differences between predicted and measured values in all plots by the area-weighted average of the measured values in all monitoring plots.

$$E_I = 100 \cdot [SE * 1.654 / ((1/N) \cdot \sum(A_{PRJ,h} \cdot y_{m,h,i}))] \quad \textbf{(60c)}$$

Where,

E_I = Inventory error for the project (%)

SE = the project level standard error of the area weighted differences between measured plot observation and predicted values of carbon storage.

N = total number of plot observations in all analysis units or polygons[37]

1.654 = the 90% confidence interval *t*-value

[37] For clarity, the plot observation sample size (N) is equivalent to the number of polygons sampled (for projects using either a polygon or analysis unit stratification method). As noted, a single *plot observation* is created for each polygon using the mean when there are multiple plots within a polygon. Thus, in some situations the number of actual installed plots may be higher than the number of plot observations (N).

All other terms as defined in equation 60a.

$SE = S/\sqrt{N}$ **(60d)**

Where,

N = total number of plot observations in all analysis units or polygons (see Footnote 37)

S = the standard deviation of the area weighted differences between measured and predicted values of carbon storage across all analysis unit or polygons.

$S = \sqrt{[(1/N-1) \cdot \sum(y_{d,h,i} - \bar{y}bar_d)^2]}$ **(60e)**

Where,

$\bar{y}bar_d$ = the project-level mean of the area weighted differences between measured plot observation and predicted values of carbon storage. See equation 60b for the calculation of $\mathbf{y_{d,h,i}}$

All other terms as defined in equation 60b and 60c.

Step 3 - The total error for the project (E_P; %) is calculated by adding the model and inventory error terms, as calculated in Steps 1 and 2.

$E_P = E_M + E_I$ **(60f)**

Step 4 – Compare the result of Step 3 against Table 6 to determine the uncertainty factor:

Table 6 - Uncertainty Factor Calculation

Estimated Project Error, E_P (%)	Uncertainty Factor (=$ER_{Y,ERR}$)
0 – 10%	= 1.5%[38]
>10%	= 1.5% + E_P – 10%

The uncertainty factor is calculated at each verification and applied annually until the next verification.

9 MONITORING

9.1 Data and Parameters Available at Validation

Selection of parameter values and assumptions requires a balance between accuracy and conservativeness. Accuracy should always prevail except when alternative values are of equivalent accuracy, in which case the more conservative value is used, the more conservative being the value that provides the least over-estimation of net anthropogenic GHG removals by sinks.

[38] To be conservative, the minimum uncertainty factor is set to 1.5% to account for possible uncertainty within other unmeasured assumptions used in calculations and modeling.

Data/parameter	$\mathbf{A_{BSL,i}}$
Data unit	Ha
Description:	Area of baseline polygon, *i*
Used in	Various equations from Equation #4-17.
Source of data	GPS coordinates and/or remote sensing and/or inventory records
Measurement procedures	n/a
Comments:	

Data/parameter	$\Delta \mathbf{C_{,t}}$
Data unit	t C yr^{-1}
Description:	The annual carbon balance in the baseline or project scenario for year, *t*
Used in	Equation 57, labeled by baseline (BSL) and project (PRJ).
Source of data	Calculated in equation 1 (Section 8.1); equation 29 (Section 8.2). Labeled with subscript BSL and PRJ, respectively.
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C_{P,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks in all pools in the baseline or project scenario across the project activity area for year, *t*
Used in	Calculation of $\Delta \mathbf{C_{,t}}$
Source of data	Calculated in equation 2 (Section 8.1); equation 30 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C_{LB,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks in living tree biomass (above- and belowground) for year, *t*
Used in	Calculation of $\Delta \mathbf{C_{P,t}}$
Source of data	Calculated in equation 3 (Section 8.1); equation 31 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{DOM,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks in dead organic matter for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{P,t}}$
Source of data	Calculated in equation 10 (Section 8.1); equation 38 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{HWP,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks in harvested wood products for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{P,t}}$
Source of data	Calculated in equation 18 (Section 8.1); equation 46 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{G,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks due to live biomass gain for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{LB,t}}$
Source of data	Calculated in equation 4 (Section 8.1); equation 32 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{L,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in carbon stocks due to live biomass loss for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{LB,t}}$
Source of data	Calculated in equation 6 (Section 8.1); equation 34 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{LDW,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in lying dead wood carbon stocks for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{DOM,t}}$
Source of data	Calculated in equations 11a, 12, 13 (Section 8.1); equations 39a, 40, 41 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{SNAG,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in standing dead wood carbon stocks for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{DOM,t}}$
Source of data	Calculated in equations 14a, 15, 16 (Section 8.1); equations 42a, 43, 44 (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\Delta \mathbf{C}_{\mathbf{DBG,t}}$
Data unit	t C yr^{-1}
Description:	The annual change in dead belowground carbon stocks for year, *t*
Used in	Calculation of $\Delta \mathbf{C}_{\mathbf{DOM,t}}$
Source of data	Calculated in equations 17a, 17c, 17d (Section 8.1); equations 45a, 45c, 45d (Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**CF**
Data unit	t C t^{-1} d.m.
Description:	Carbon fraction of dry matter
Source of data	IPCC default value = 0.5, if more relevant values are not available
Measurement procedures	n/a
Comments:	

Data/parameter	**R_i**
Data unit	unitless
Description:	Root:shoot ratio in polygon , *i*
Source of data	If project-specific values have not been measured, use Cairns 1997).
Measurement procedures	n/a
Comments:	Root allocation can be vary by site productivity; relatively more biomass may be allocated to roots in poor than richer soils

Data/parameter	**BEF**
Data unit	unitless
Description:	Biomass expansion factors for conversion of productivity metrics to biomass
Source of data	The source of data must be chosen with priority from higher to lower preference as follows: (a) Existing local and forest type-specific; (b) National and forest type-specific or eco-region-specific (e.g. from national GHG inventory); (c) Forest type-specific or eco-region-specific from neighboring countries with similar conditions. Sometimes (c) might be preferable to (b); (d) Globally forest type or eco-region-specific (e.g. IPCC literature: Table 3A.1.10 of GPG-LULUCF)
Measurement procedures	n/a
Comments:	BEFs are age dependent, and use of average data may result in significant errors for both young and old stands – as BEFs are usually large for young stands and quite small for old stands.

Data/parameter	**$f_{BRANCH,i,t}$**
Data unit	unitless
Description:	The annual proportion of aboveground tree biomass comprised of branches $\geq$ 5 cm diameter in polygon, i
Source of data	The source of data must be chosen with priority from higher to lower preference as follows: (a) Research publications relevant to the project area; (b) National and species-specific or group of species-specific (e.g. from National GHG inventory); (c) Species-specific or group of species-specific from neighboring countries with similar conditions. Sometimes (b) may be preferable to (a); (d) Globally species-specific or group of species-specific (e.g. IPCC GPG-LULUCF).
Measurement procedures	n/a

Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, same value

Data/parameter	$f_{BUCKINGLOSS,i,t}$
Data unit	unitless
Description:	Annual proportion of the log bole biomass left on site after assessing and/or merchandizing the log bole for quality, in polygon, *i*
Source of data	Preferably, data for this variable must be based on regional and local comparative studies and experiential information derived from the local forest industry. Otherwise, an average default value of 21% can be used, based on US national summary statistics (Smith, Miles, Vissage, & Pugh, 2004).
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**$P_{3\text{-}year}$ and $P_{100\text{-}year}$**
Data unit	unitless
Description:	The proportion of total carbon stored in wood products after 3 years ($P_{3\text{-}year}$); and the proportion of harvested wood stored for 100 years ($P_{100\text{-}year}$), for product type, *k*.
Source of data	Calculated for the baseline and project case
Measurement procedures	n/a
Comments:	

Data/parameter	$P_{BSL,SLF}$, $P_{BSL,MLF}$, $P_{BSL,LLF}$
Data unit	unitless
Description:	The short-lived fraction (P_{SLF}), medium-lived fraction (P_{MLF}), and long-lived fraction (P_{LLF}), respectively, for product type, *k*
Source of data	Calculated as per equations 22a-c (baseline) and equations 50ac (project)
Measurement procedures	n/a
Comments:	

Data/parameter	$f_{TRANSPORTk}$
Data unit	(unitless; $0 \leq f_{BSL,TRANSPORTk} < 1$).
Description:	The fraction of raw material transported by transportation type, *k*.

Source of data	Estimated based on Heath et al. 2006 Supplementary
Measurement procedures	n/a
Comments:	Variables used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$c_{HARVEST}$
Data unit	t C emitted/t C raw material
Description:	The carbon emission intensity factor associated with harvesting
Source of data	See Table 4
Measurement procedures	n/a
Comments:	

Data/parameter	$c_{MANUFACTUREk}$
Data unit	t C emitted/t C raw material
Description:	The carbon emission intensity factor associated with manufacture of product, k
Source of data	See Table 4
Measurement procedures	n/a
Comments:	

Data/parameter	$c_{TRANSPORTk}$
Data unit	t C emitted/t C raw material ● km
Description:	The carbon emission intensity factor associated with the transport of raw material by transportation type of product, k
Source of data	See Table 4
Measurement procedures	n/a
Comments:	

Data/parameter	$d_{TRANSPORTk}$
Data unit	km
Description:	The distance transported by transportation type, *k*.
Source of data	Estimated based on Heath et al. 2006 Supplementary
Measurement procedures	n/a
Comments:	

Data/parameter	**$C_{EMITTRANSPORT,t}$**
Data unit	t C yr^{-1}
Description:	The annual fossil fuel emissions associated with the transport of raw material
Source of data	Heath et al. 2006 Supplementary
Measurement procedures	n/a
Comments:	Variables used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**$G_{AG,i,t}$**
Data unit	t d.m. ha^{-1} yr^{-1}
Description:	Annual increment rate in aboveground biomass (t d.m. ha^{-1} yr^{-1}), in polygon, *i*,
Source of data	Modeled (See Section 8.1 & Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**$G_{BG,i,t}$**
Data unit	t d.m. ha^{-1} yr^{-1}
Description:	Annual increment rate in belowground biomass (t d.m. ha^{-1} yr^{-1}), in polygon, *i*,
Source of data	Calculated from G_{AG} and R_i
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**$LBL_{NATURALi,t}$**
Data unit	t d.m. yr^{-1}
Description:	Annual loss of live tree biomass due to natural mortality in polygon, i; t d.m. yr^{-1}
Source of data	Modeled (See Section 8.1 & Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	**$LBL_{FELLINGSi,t}$**
Data unit	t d.m. yr^{-1}
Description:	Annual loss of live tree biomass due to commercial felling in polygon, i; t d.m. yr^{-1}

Source of data	Modeled (See Section 8.1 & Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{LBL_{OTHERi,t}}$
Data unit	t d.m. yr^{-1}
Description:	Annual loss of live tree biomass from incidental sources in polygon, i; t d.m. yr^{-1}
Source of data	Modeled (See Section 8.1 & Section 8.2)
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{LB_{i,t}}$
Data unit	t d.m. yr^{-1}
Description:	Average live tree biomass in polygon, *i*, for year, *t*
Source of data	Calculated from $G_{i,t}$
Measurement procedures	n/a
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{f_{BSL,NATURAL,i,t}}$
Data unit	unitless; $0 \leq f_{NATURAL,i,t} \leq 1$
Used in:	Equation 7, Section 8
Description:	The annual proportion of biomass that dies from natural mortality in forest type analysis unit or polygon, *i*, year, *t*.
Source of data	Literature reports, and/or inventory data.
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{f_{BSL,HARVEST,i,t}}$
Data unit	unitless; $0 \leq f_{BSL,HARVESTIi} \leq 1$
Used in:	Equation 8, Section 8.1
Description:	The proportion of biomass removed by harvesting from polygon, *i*, in year, *t*.
Source of data	Literature reports, and/or inventory data.
Measurement procedures	

Comments:	

Data/parameter	$\mathbf{f_{BSL,DAMAGE,i,t}}$
Data unit	unitless; $0 \leq f_{BSL,DAMAGE,i,t} \leq 1$
Used in:	Equation 9, Section 8
Description:	The proportion of additional biomass removed for road and landing construction in polygon, *i,* year, *t*
Source of data	Literature reports, and/or inventory data.
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{f_{BSL,BLOWDOWN,i,t}}$
Data unit	unitless; $0 \leq f_{BSL,BLOWDOWN,i,t} \leq 1$
Used in:	Equation 12, Section 8.1
Description:	The annual proportion of live aboveground tree biomass subject to blowdown in polygon, *i*, year, t.
Source of data	Literature reports, and/or inventory data.
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{f_{BSL,SNAGFALLDOWN,i,t}}$
Data unit	unitless; $0 \leq f_{BSL,SNAGFALLDOWN,i,t} \leq 1$
Used in:	Equations 12 & 16, Section 8.1
Description:	The annual proportion of snag biomass in polygon, *i*, year, *t*, that falls over and thus is transferred to the LDW pool.
Source of data	Literature reports, and/or inventory data.
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{f_{BSL,lwDECAY,i,t}}$
Data unit	unitless; ; $0 \leq f_{BSL,lwDECAY,i,t} \leq 1$
Used in:	Equation 13, Section 8.1
Description:	The annual proportional loss of lying dead biomass due to decay, in polygon *i,* year*, t*,
Source of data	Literature reports, and/or inventory data.
Measurement procedures	

Comments:	

Data/parameter	$\mathbf{f_{BSL,SWDECAY,i,t}}$
Data unit	unitless; $0 \leq f_{BSL,SWDECAY,i,t} \leq 1$
Used in:	Equation 16, Section 8.1
Description:	The annual proportional loss of snag biomass due to decay, in polygon, *i*, year, *t*.
Source of data	Literature reports, and/or inventory data.
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{SNAG_{BSL,i,t}}$
Data unit	t d.m. yr^{-1}
Description:	The total amount of snag mass in polygon *i,* year*, t*
Source of data	Calculated in equations 14b, 15,16
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{DBG_{,i,t}}$
Data unit	t d.m. yr^{-1}
Description:	The total quantity of dead belowground biomass accumulated in polygon *i* since the project start; t biomass.
Source of data	Calculated in equations 17b, 17c,17d (Section 8.1); Calculated in equations 45b, 45c,45d (Section 8.2)
Measurement procedures	Modeled.
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{\Delta C_{STORHWP1,t}}$
Data unit	t C yr^{-1}
Used in:	The calculation of the annual change in emissions associated with the production of harvested wood products (HWP), $\Delta C_{BSl,HWP,t}$,
Description:	Annual harvested carbon that remains in permanent storage after conversion to wood products during primary processing
Source of data	Calculated in equation 19 (Section 8.1) and equation 47 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may

	be different

Data/parameter	$\mathbf{C_{MILL,h,k}}$
Data unit	t C
Used in:	The calculation of the annual change in the carbon stored in harvested wood products (HWP), $\Delta C_{BSL,HWP,t}$,
Description:	The carbon contained in harvested timber after milling in period h, for product type *k*
Source of data	Calculated in equation 21 (Section 8.1) and equation 49 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{C_{TIMBER,h}}$
Data unit	t C
Used in:	The calculation of the annual change in the carbon stored in harvested wood products (HWP), $\Delta C_{BSL,HWP,t}$,
Description:	The carbon contained in timber harvested in period *h*
Source of data	Calculated in equation 20 (Section 8.1) and equation 48 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{C_{STORHWP,h,t}}$
Data unit	t C
Used in:	The calculation of the annual change in the carbon stored in harvested wood products (HWP), $\Delta C_{BSL,HWP,t}$,
Description:	The carbon stored in harvested wood products in year *t* summed for all product types *k* and then over all harvest periods *h*; t C
Source of data	Calculated in equation 23 (Section 8.1) and equation 51 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{f_{RND,k}}$
Data unit	dimensionless

Used in:	The calculation of carbon contained in harvested timber after milling in period h, for product type *k* ($C_{MILL,h,k}$).
Description:	The fraction of growing stock volume removed as roundwood for product type *k*
Source of data	(default values by region in Table 1.5 of the 1605(b) document)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario

Data/parameter	$\mathbf{r_{RND,k}}$
Data unit	dimensionless
Used in:	The calculation of carbon contained in harvested timber after milling in period h, for product type *k* ($C_{MILL,h,k}$).
Description:	The ratio of industrial roundwood to growing stock volume removed as roundwood for product type *k.*
Source of data	(default values by region in Table 1.5 of the 1605(b) document)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario

Data/parameter	$\mathbf{\Delta C_{EMITFOSSIL,t}}$
Data unit	t C yr^{-1}
Used in:	The calculation of the annual change in the carbon stored in harvested wood products (HWP), $\Delta C_{HWP,t}$,
Description:	Fossil fuel emissions from harvesting (logging and log transport) and processing of the various wood products.
Source of data	Calculated in equation 24 (Section 8.1) and equation 52 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{C_{EMITHARVEST,t}}$
Data unit	t C yr^{-1}
Used in:	The calculation of $\mathbf{\Delta C_{EMITFOSSIL,t}}$
Description:	Annual fossil fuel emissions associated with harvesting of raw material.
Source of data	Calculated in equation 25 (Section 8.1) and equation 53 (Section 8.2)

Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{C_{EMITMANUFACTURE,t}}$
Data unit	t C yr^{-1}
Used in:	The calculation of $\Delta\mathbf{C_{EMITFOSSIL,t}}$
Description:	Annual fossil fuel emissions associated with the manufacturing of raw material.
Source of data	Calculated in equation 27 (Section 8.1) and equation 55 (Section 8.2)
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{C_{EMITTRANSPORT,t}}$
Data unit	t C yr^{-1}
Used in:	The calculation of $\Delta\mathbf{C_{EMITFOSSIL,t}}$
Description:	Annual fossil fuel emissions associated with the transport of raw material.
Source of data	Must be calculated after consideration of the transport distance from harvest to processing facility, and the means of transportation (after Heath et al. 2006 Supplementary). An example of calculation steps is provided in Section 8.1.
Measurement procedures	
Comments:	Variable used in both baseline (BSL) and project (PRJ) scenario, values may be different

Data/parameter	$\mathbf{LE_y}$
Data unit	t CO2e yr^{-1}
Used in:	The calculation of Market Leakage (Option 1)
Description:	the project market leakage in year, *y*
Source of data	Calculated in Section 8.3.2, Option 1
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{SE_y}$
Data unit	t CO2e yr^{-1}
Used in:	The calculation of Market Leakage (Option 2)
Description:	The project market leakage in year, *y*

Source of data	Calculated in Section 8.3.2, Option 2
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{MLF_y}$
Data unit	Unitless
Used in:	Calculation of $\mathbf{LE_y}$ in year, *y*
Description:	The project market leakage
Source of data	Calculated in Section 8.3.2
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{BC_{hv,\ n}}$
Data unit	t CO2e yr^{-1}
Used in:	Calculation of $\mathbf{SE_y}$
Description:	The estimated average baseline amount of onsite carbon harvested in reporting period, *n* (prior to delivery to a mill).
Source of data	Calculated in Section 8.3.2
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{AC_{hv,\ n}}$
Data unit	t CO2e yr^{-1}
Used in:	Calculation of $\mathbf{SE_y}$
Description:	The actual onsite carbon harvested in reporting period, *n* (prior to delivery to a mill).
Source of data	Calculated in Section 8.3.2
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{ER_{y,GROSS}}$
Data unit	t CO2e yr^{-1}
Used in:	Calculation of $\mathbf{LE_y}$
Description:	The gross difference in the overall annual carbon change between the baseline and project scenarios in year, *y*
Source of data	Calculated in equation 57

Measurement procedures	
Comments:	

Data/parameter	$\mathbf{ER_{y,}}$
Data unit	t CO2e yr^{-1}
Used in:	Calculation of $\mathbf{VCU_y}$
Description:	The net GHG emissions reductions and/or removals in year y (the overall annual carbon change between the baseline and project scenarios, net all discount factors except the permanence buffer)
Source of data	Calculated in equation 58
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{VCU_{y,}}$
Data unit	t CO2e yr^{-1}
Description:	Amount of Verified Carbon Units the project estimates are available for issuance and sale in year 'y'
Source of data	Calculated in equation 59
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{E_M}$
Data unit	%
Used in:	The calculation of uncertainty factor (Section 8.5.3)
Description:	An estimate of model error based on the relative area-weighted difference between of model-predicted values of carbon storage and those values measured in field plots
Source of data	Model output and field data
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{E_I}$
Data unit	%
Used in:	The calculation of uncertainty factor (Section 8.5.3)
Description:	An estimate of Inventory sampling error calculated as the 90% confidence limit of the area-weighted differences between the model-predicted values of carbon storage and those values measured in field plots

Source of data	Model output and field data
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{E_P}$
Data unit	%
Used in:	The calculation of uncertainty factor (Section 8.5.3)
Description:	An estimate of total project error based sum of the model and inventory error terms
Source of data	Model output and field data
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{ER_{y,ERR,}}$
Data unit	Unitless
Used in:	Calculation of $\mathbf{VCU_y}$
Description:	The uncertainty factor calculated for year 'y' in Section 8.5.3
Source of data	Calculated in Section 8.5.3
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{BR_{y,}}$
Data unit	t CO2e yr^{-1}
Used in:	Calculation of $\mathbf{VCU_y}$
Description:	Estimated VCU-equivalent tCO_2e issued to the VCS Buffer Pool in year, *y*.
Source of data	Calculated using the latest version of the VCS AFOLU Non-Permanence Risk Tool
Measurement procedures	
Comments:	

9.2 Data and Parameters Monitored

The following parameters must be monitored during the project activity. When applying all relevant equations provided in this methodology for the ex-ante calculation of net anthropogenic GHG removals by sinks, project proponents must provide transparent estimates for the parameters that are monitored during the crediting period. These estimates must be based on measured or existing published data where possible and project proponents must retain a conservative approach: if different values for a parameter are equally plausible, a value that provides the least over-estimation of net anthropogenic GHG removals by sinks must be selected.

Data/parameter	$\mathbf{A_{PRJ,i,}}$
Data unit	Ha
Used in	Various equations in equation #32-60
Description:	Area of forest land in polygon, *i*
Source of data	Monitoring of polygons and stand boundaries must be done preferably using a Geographic Information System (GIS), which allows for integrating data from different sources (including GPS coordinates and Remote Sensing data).
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{A_{p,i,t}}$
Data unit	m^2
Used in:	Calculation of mean aboveground biomass B_{AG} and DOM_{SNAG} in Section 9.3.2 and 8.2.3.
Description:	Area of sample plot in polygon, *i*, at time, *t*
Source of data	Recording and archiving of size of sample plots
Measurement procedures	
Comments:	

Data/parameter	$\mathbf{DBH_{,t}}$
Data unit	cm
Used in:	Calculation of mean aboveground biomass B_{AG} in Section 9.3.2 and 8.2.3.
Description:	Diameter at breast height measured for each tree in the sample plots at time, *t*
Source of data	Field measurements in sample plots
Measurement procedures	Typically measured at 1.3m height above ground. Measure all trees above minimum DBH (5 cm) in the sample plots that result from the IFM project activity.
Comments:	

Data/parameter	$\mathbf{Height_{,t}}$
Data unit	m
Used in:	Calculation of mean aboveground biomass B_{AG} in Section 9.3.2 and 8.2.3.
Description:	Tree height measured for each tree in the sample plots at time, *t*
Source of data	Field measurements in sample plots

Comments:	

Data/parameter	$L_{,t}$
Data unit	m
Used in:	Calculation of mean mass of DOM_{LDW} in Section 9.3.2 and 8.2.3.
Description:	Length of the transects to used determine volume of lying dead wood in the sample plots at time, *t* (default 100m)
Source of data	Field measurements
Measurement procedures	
Comments:	

Data/parameter	$d_{n,t}$
Data unit	cm
Used in:	Calculation of mean mass of DOM_{LDW} in Section 9.3.2 and 8.2.3.
Description:	Diameter of each piece *n* of dead wood along the transects in the sample plots at time, *t*
Source of data	Field measurements
Measurement procedures	Measured using the line-intersect method (Section 9).
Comments:	

Data/parameter	$D_{LDW,c,i,t}$
Data unit	(t d.m. m^{-3})
Used in:	Calculation of mean mass of DOM_{LDW} in Section 9.3.2 and 8.2.3.
Description:	Density of dead wood in density class, *c* along the transect in polygon, *i*, at time, *t*
Source of data	Field measurements
Measurement procedures	Measured using the line intersect method (Section 9).
Comments:	

Data/parameter	$N_{,t}$
Data unit	unitless
Used in:	Calculation of mean mass of DOM_{LDW} in Section 9.3.2 and 8.2.3.
Description:	Total number of wood pieces intersecting transects in the sample plots at time, *t*
Source of data	Field measurements
Measurement procedures	Measured using the line-intersect method (Section 9).

Comments:	

Data/parameter	$\mathbf{B_{AGi,t}}$
Data unit	t d.m. ha^{-1} (d.m. = dry matter)
Used in:	Calculation of carbon stocks in above- and belowground living tree biomass in equations 28b & 28c, Section 8.2.3.
Description:	Average total aboveground biomass in polygon, *i,* for year, *t*
Source of data	Calculated from $Height_{i,t}$, $DBH_{i,t}$, and $A_{p,i,t}$
Measurement procedures	
Comments:	Calculated

Data/parameter	$\mathbf{B_{BGi,t}}$
Data unit	t d.m. ha^{-1} (d.m. = dry matter)
Used in:	Calculation of carbon stocks in above- and belowground living tree biomass in equations 28b & 28c, Section 8.2.3.
Description:	Average total belowground biomass in polygon, *i,* for year, *t*
Source of data	Estimated from $B_{AGi,t}$
Measurement procedures	
Comments:	Estimated

Data/parameter	$\mathbf{B_{TOTAL,i,t}}$
Data unit	t d.m. ha^{-1} (d.m. = dry matter)
Used in:	Calculation of carbon stocks in above- and belowground living tree biomass in equation 28c, Section 8.2.3.
Description:	Average total live biomass in polygon, *i,* for year, *t*
Source of data	Calculated from $B_{AGi,t}$ and $B_{BGi,t}$
Measurement procedures	
Comments:	Calculated

Data/parameter	$\mathbf{DOM_{LDW,i,t}}$
Data unit	t d.m. ha^{-1} (d.m. = dry matter)
Used in:	Calculation of carbon stocks in dead organic matter (equation 28e, Section 8.2.3)
Description:	Average mass of dead organic matter contained in lying dead wood in polygon, *i,* year, *t*
Source of data	Calculated from $L_{,i,t}$, $d_{n,i,t}$, $D_{LDW,c,i,t}$, and $N_{i,t}$
Measurement procedures	

Comments:	Calculated

Data/parameter	**$DOM_{SNAG,i,t}$**
Data unit	t d.m. ha^{-1} (d.m. = dry matter)
Used in:	Calculation of carbon stocks in dead organic matter (equation 28e, Section 8.2.3)
Description:	Average mass of dead organic matter contained in standing dead wood in polygon, *i,* year, *t*
Source of data	Calculated from $Height_{i,t}$, $DBH_{i,t}$, and $A_{p,i,t}$ of dead trees measured in sample plots described in Section 9
Measurement procedures	
Comments:	Calculated

Data/parameter	**$f_{PRJ,NATURAL,i,t}$**
Data unit	unitless; $0 \leq f_{NATURAL,i,t} \leq 1$
Used in:	Equation 35, Section 8.2
Description:	The annual proportion of biomass that dies from natural mortality in polygon, *i*, year, *t*.
Source of data	Permanent sample plots in similar stand types, literature reports, and inventory data
Measurement procedures	
Comments:	

Data/parameter	**$f_{PRJ,HARVEST,i,t}$**
Data unit	unitless; $0 \leq f_{PRJ,HARVESTIi} \leq 1$
Used in:	Equation 36, Section 8.2
Description:	The proportion of biomass removed by harvesting from polygon, *i*, in year, *t*.
Source of data	Permanent sample plots in similar stand types, literature reports, and inventory data
Measurement procedures	
Comments:	

Data/parameter	**$f_{PRJ,DAMAGE,i,t}$**
Data unit	unitless; $0 \leq f_{PRJ,DAMAGE,i,t} \leq 1$
Used in:	Equation 37, Section 8.2
Description:	The proportion of additional biomass removed for road and landing construction in polygon, *i,* year, *t*

Source of data	Permanent sample plots in similar stand types, literature reports, and inventory data
Measurement procedures	
Comments:	

Data/parameter	$f_{PRJ,BLOWDOWN,i,t}$
Data unit	unitless; $0 \leq f_{PRJ,BLOWDOWN,i,t} \leq 1$
Used in:	Equation 40, Section 8.2
Description:	The annual proportion of live aboveground tree biomass subject to blowdown in polygon, *i*, year, t.
Source of data	Permanent sample plots in similar stand types, literature reports, and inventory data
Measurement procedures	
Comments:	

Data/parameter	$f_{PRJ,SNAGFALLDOWN,i,t}$
Data unit	unitless; $0 \leq f_{PRJ,SNAGFALLDOWN,i,t} \leq 1$
Used in:	Equation 40 & 44, Section 8.2
Description:	The annual proportion of snag biomass in polygon, *i*, year, *t*, that falls over and thus is transferred to the LDW pool.
Source of data	Permanent sample plots in similar stand types, literature reports, and inventory data
Measurement procedures	
Comments:	

Data/parameter	$f_{PRJ,lwDECAY,i,t}$
Data unit	unitless; ; $0 \leq f_{PRJ,lwDECAY,i,t} \leq 1$
Used in:	Equation 41, Section 8.2
Description:	The annual proportional loss of lying dead biomass due to decay, in polygon *i,* year*, t*,
Source of data	Permanent sample plots in similar stand types, literature reports, and/or inventory data
Measurement procedures	
Comments:	

Data/parameter	$f_{PRJ,SWDECAY,i,t}$

Data unit	unitless; $0 \leq f_{PRJ,SWDECAY,i,t} \leq 1$
Used in:	Equation 44, Section 8.2
Description:	The annual proportional loss of snag biomass due to decay, in polygon, *i*, year, *t*.
Source of data	Permanent sample plots in similar stand types, literature reports, and/or inventory data
Measurement procedures

9.3 Description of the Monitoring Plan

The objective of the project monitoring program is to reliably monitor changes in carbon stocks related to the calculation of VCU's prior to each verification. In particular, the program will monitoring changes in spatial forest inventory conditions and collect field data on carbon stocks to compare against modeled carbon stocks and to calculate an uncertainty factor.

9.3.1 Project Monitoring Requirements

The project must develop and maintain an up to date monitoring plan which includes:

1. Spatial inventory change monitoring procedures
2. Carbon stock field plot sampling monitoring procedures
3. Standard Operating Procedures (SOPs) for monitoring activities
4. Quality Control/Quality Assurance and Data Archiving procedures

These elements must meet the requirements described in the sections below.

The results of implementing the monitoring plan must be produced in a project monitoring report for each monitoring period; prior to each verification.

9.3.2 Monitoring Annual Spatial Inventory Changes

Project proponents will undertake and document annual monitoring to identify and update spatial changes in the forest inventory data (i.e. changes in forest polygons due to planned or unplanned project activities and natural disturbances which change the classification of spatial areas within the project boundary).

Projects will undertake remote and ground-based monitoring (for example: satellite and aerial photography, aerial observation, ground observation, aerial and ground-based GPS mapping, etc.) to identify and update inventory data for:

a. Natural disturbance events > 4ha (i.e. fires, pest & disease outbreaks, slides and other disturbances;
b. Planned project activities (i.e. harvests, road construction, reforestation, etc.); and
c. Unplanned man-made disturbances (for example, non-*de minimis* illegal or unplanned harvests).

Annual spatial monitoring activities will be documented and dated, and inventory data updates identified by date or other notations.

9.3.3 Carbon Stock Monitoring Field Plot Sampling Design and Stratification

9.3.4 Stratification for Field Plot Sampling:

When an area is not homogeneous, stratification generally reduces monitoring costs by grouping areas with low variation in carbon stocks (Pearson et al. 2007).

Stratification for monitoring sample design should be consistent with that employed for the calculation of carbon stocks in the baseline (Section 8.1) and project (Section 8.2) scenarios.

The project proponent has the option to further stratify modeled polygons or analysis units to facilitate efficient field carbon stock monitoring. In particular, projects may need to further stratify modeled polygons or analysis units to gain sampling representation within analysis unit age classes. For example, an analysis unit might include similar forest type polygons that range from 40-200 years. For monitoring plot sampling, the analysis unit would likely need to be stratified into age classes with similar stand carbon content.

Any stratification undertaken for monitoring purposes must be documented and justified, including documenting any variation from stratification made for modeling in Section 8.1 and 8.2. Monitoring stratification may be updated based on monitoring results (see Section 9.3.10).

9.3.5 Field Plot Sampling Framework

The objective of the field plot network is to determine the statistical accuracy of the modeled carbon stocks by polygon or analysis unit. The field-measured values of the tree biomass and dead organic matter pools described below will be compared against the associated modeled values described in Section 8.2 to determine error in the modeled value for a particular polygon or analysis unit (see Section 8.2.2). Some deviation of the field-measured values from the modeled values can be expected, which is then accounted for in the uncertainty factor calculation (Section 8.5.3).

The "Sourcebook for Land Use, Land-Use Change and Forestry Projects" (Pearson, Walker, & Brown, 2005) provides methods and procedures to generate accurate and precise estimates of changes in carbon stocks. (Pearson, Brown, & Birdsey, 2007). Project proponents can substitute other comparable published and peer-reviewed forest carbon sampling and measurement manuals and techniques if they are demonstrated to be applicable and consistent with the data collection requirements of this methodology.

Type and Number of Sampling Plots

Plot Type

For forestry activities, both permanent and temporary sampling plots have been used to estimate changes in carbon pools (Pearson, Brown, & Birdsey, 2007). Permanent sample plots are regarded as statistically more efficient for estimating changes in forest-carbon stocks over time than temporary plots because there is high covariance between observations in successive sampling events (Pearson, Brown, & Birdsey, 2007). Moreover, the use of permanent plots allow for efficient verification. Hence, the majority of plots used in the monitoring program should be geo-referenced, permanently re-measurable plots with all trees marked. Geo-referenced temporary plots may also be used for efficient supplemental data collection.

Number of Plots, Precision, and Sample Size

The proponent will develop a plot network with representation in every polygon or analysis unit[39] (based on the primary stratification method identified in Section 8.1 and used throughout the project calculations) and a design

[39] See Section 8.5.3 for additional clarification on plot requirements. If using a polygon stratification, representation of each polygon is required; if using an analysis unit stratification, representation of each analysis unit is required (and not each polygon within the analysis unit).

target of establishing enough plots such that the estimate of carbon stocks across all polygon or analysis units will lie within 10 percent of the true value of the mean at the 90-percent confidence level[40].

Project proponents may develop initial estimates of the number of plots needed for monitoring using variance estimates from existing or comparable forest inventory data and following procedures outlined in (Pearson et al. 2007), or other peer reviewed published methods.

For practical purposes it is recognized that on large or complex project areas the plot network may need to be developed across several years (no longer than 5 years) to approach the target level of precision. Samples sizes should be evaluated for suitability following the initial monitoring period and then adjusted as appropriate to achieve the desired level of precision.

Plot Sampling Design

Plot Layout

Permanent sample plots can be located at random or systematically using a plot grid. The latter approach results in greater precision if some areas within polygons have higher carbon content than others (Pearson, Brown, & Birdsey, 2007).

Size and Shape of Sample Plots

Plot shape and size can be determined by the project proponent based on local common practice and the most suitable methods for the project conditions, so long as the procedures are fully documented in project SOP's and the results provide verifiable statistical sampling as required by this methodology. Projects may consider consistent fixed area square or circular plots, or consider a variable nested plot area design which may be better suited to highly variable stand diameter conditions ((see (Pearson, Brown, & Birdsey, 2007)).

Measurement and Data Analysis Techniques

Trees

Although the tree carbon stock is estimated most accurately and precisely by direct methods (whereby all the trees in a sample plot above a minimum diameter are harvested, dried and weighed), it is expected this approach will be impractical for most projects. Therefore, tree biomass should be estimated from allometric biomass equations that predict aboveground biomass from mathematical relationships between DBH and/or height and species. Allometric biomass equations have been published for many species and regions. The project proponent should select the most appropriate equations by determining which published equations are most representative of the species and conditions on the project site. Other factors that should be taken into account include the relative statistical accuracy of the equations, and the number and size range of the samples used to generate the equation parameters.

All living trees within a sample plot with DBH ≥ 5cm must be measured for height (m) and diameter (cm) at breast height (1.3m).

Tree-level measurements (kg biomass per tree) must be converted to area-based stand-level measurements (t ha^{-1}). A description of the steps and equations employed in the process are provided in Section 8.2.3.

Dead Organic Matter

An efficient method for sampling lying dead wood is the line-intersect (Pearson, Brown, & Birdsey, 2007). For example, (Harmon & Sexton, 1996) use a minimum 100m line length[41]. Placing two 50-m sections of line at right

[40] The uncertainty factor calculation in Section 8.5.3 accounts for, and penalizes the project credits for higher uncertainty error, and hence this target is provided as guidance for plot network design to achieve the lowest uncertainty factor.

angles across the plot center also is an efficient and valid approach. To allow re-measurement of the same "dead wood plot", it is important to accurately record where the line was placed. The diameters of all pieces of wood that intersect the line are measured and the density class noted. A minimum diameter for measurement is defined in this methodology as 5 cm (Harmon & Sexton, 1996).

Each piece of dead wood will be assigned to one of three density classes, sound (1), intermediate (2), and rotten (3) (details below). The volume per unit area is calculated for each density class, *c*, as:

$$V_{LDW,c} = \pi^2 * [(d_1^2 + d_2^2 \ldots d_n^2)/8L] \quad \textbf{(60a)}$$

where:

d_1, d_2, d_n = diameter (cm) of each of *n* pieces intersecting the line, and

L = the length of the line (100 m default (Harmon, et al., 1986).

The mass of LDW in density class, *c* (t ha^{-1}), is:

$$M_{LDW,c} = V_{LDW,c} * D_{LDW,c} \quad \textbf{(60b)}$$

where:

$V_{LDW,c}$ = the volume per unit area calculated for each density class, *c*, as calculated in 60a.

$D_{LDW,c}$ = the density of LDW in density class, *c* (t d.m. m^{-3})

The total mass of LDW in each plot summed over all density classes (t ha^{-1}) is:

$$DOM_{LDW} = \sum M_{LDW,c} \quad \textbf{(60c)}$$

where:

$M_{LDW,c}$ = the mass of LDW in density class, *c* (t ha^{-1}), is as calculated in 60b.

A key step in this method is classifying the dead wood into its correct density class and then sampling a sufficient number of logs in each class to derive a reasonable estimate of wood density. Ideally at least 10 logs should be sampled for each density class (Pearson, Brown, & Birdsey, 2007). For a given piece of dead wood, a field characterization of its density class can be made by striking it with a strong sharp blade. If the blade bounces off it is classed as sound, if it enters slightly it is of intermediate density, and if the wood falls apart it is rotten. Samples of dead wood in each class will then be collected to determine their density in the laboratory, after drying for 48 hours. Mass of dead wood is calculated as the product of volume per density class and the wood density for that class (as per equations 60 a-c)[42].

The total mass of lying dead wood for a given polygon should be calculated as the average of all transects measured for that polygon. This value is then used for calculations of carbon storage in dead organic matter (**$DOM_{LDW,i,t}$**), as described in Section 8.2.3.

[41] Other sample line lengths may be used if referenced from other published sources (i.e. see (Harmon et al, 2008)).

[42] Alternatively, projects may use other published decay sampling classifications and methods, and in particular may find useful additional methods outlined in Harmon et al. 2008. Woody Detritus Density and Density Reduction Factors for Tree Species in the United States: A Synthesis. USDA Forest Service GTR NRS-29.

Standing dead wood should be measured in the same plots as used for measuring live trees. Snags suitability is defined using the same criteria for live trees. However, measurement records will differ slightly from those for live trees, depending on the degree to which branches and twigs are present. If the snag possesses branches and twigs and its structure resembles a live tree (but without leaves), this should be indicated in the field data records. From the measurement of DBH, the amount of biomass can then be estimated using the appropriate allometric biomass equation and subtracting the biomass of leaves. Snags may possess only a fraction of their full complement of small and large branches, only large branches, or no branches at all. These conditions will be recorded in the field measurements. Branches will then be classified in proportion to the size of the standing dead tree so that the total biomass can be reduced accordingly to account for less of the dead tree remaining. When a tree has no branches and is only the bole, biomass can be estimated from measurements of its basal diameter and height and an estimate of top diameter.

Once the biomass of standing dead trees within a plot has been calculated, the tree-level measurements (kg biomass per tree) must be converted to area-based stand-level measurements (t ha^{-1}) by summing the total mass (aboveground + belowground) of all the standing dead trees within a sample plot (converting kg to t) and dividing the sum by the plot area in ha. All plots within a particular polygon should be averaged to get an average estimate of stand-level live biomass (t ha^{-1}). This value is an estimate of the average snag biomass variable ($\mathbf{DOM_{SNAG,i,t}}$) used in Section 8.2.3.

9.3.6 Quality Assurance/Quality Control (QA/QC) Methods

The monitoring plan or associated SOPs should include QA/QC procedures for: (1) collecting reliable field measurements; (2) verifying laboratory procedures; (3) verifying data entry; and (4) data archiving.

QA/QC for Field Measurements

A set of Standard Operating Procedures (SOP) must be developed for field carbon measurements. The SOPs will detail all phases of the field measurements so that the measurements can be repeated reliably. A document will be produced and filed with the project documents verifying that all QA/QC steps have been taken.

Field crews must be trained in all field data collection SOPs and records of training kept by the project proponent.

An audit program for field measurements and sampling must be established. A typical audit program should consist of three types of checks. During a hot check, auditors observe members of the field crew during actual data collection (this is primarily for training purposes). Cold checks occur when field crews are not present for the audit. Blind checks represent the complete re-measurement of a plot by the auditors. Hot checks allow the correction of errors in technique. Measurement variance can be calculated through blind checks.

At a minimum, 10% of the measured field plots will be check-cruised using blind checks with 100% re-measurement of all variables. Minimum thresholds in measurement error are as follows:

1. DBH (standing live and dead): +/- 10% standard error at 90% confidence interval

2. Height (standing live and dead): +/- 10% standard error at 90% confidence interval

3. Tree Count: +/- 10% standard error at 90% confidence interval

These are minimum thresholds for monitoring plot field accuracy, and will require re-measurement or re-establishment of plots as necessary to meet these requirements.

QA/QC for Laboratory Measurements

SOPs will be prepared and followed for each laboratory analyses. Typical steps in the SOP for laboratory measurements will include calibrating standards for instruments used. Where practical, 10 percent of the samples will be re-analyzed/re-weighed following the check cruise thresholds outlined above.

QA/QC for Data Entry

Projects must develop procedures to ensure proper entry of data and conversion between paper and electronic formats. Data anomalies will be resolved using the original field data, or re-measurement of data if feasible. If there are anomalies that cannot be resolved, the plot will be omitted from the analysis.

Data Archiving

The project will provide data archiving SOPs which provide procedures for securely retaining and maintaining the following records for each monitoring period for 2 years past the duration of the project:

1. Original copies of the field measurement, check plots, laboratory data, and related data summaries will be maintained in their original and electronic form
2. Copies of all monitoring data analyses, models, model input and output files, carbon calculations required for this methodology, GIS inventory dated by year, and copies of the monitoring reports.
3. Records of the version and relevant change history of software or data storage media changed between monitoring periods.

9.3.7 Leakage Monitoring

Activity shifting leakage monitoring requires reporting the ‘demonstration of activity shifting’ annually, as required by VCS, and as per the methods outlined in section 8.3.1.

Market leakage monitoring requirements depend on the selected option:

1. Market Leakage Option 1 – VCS Default Market Leakage Discount Factors:
   a. No further leakage monitoring required
2. Market Leakage Option 2 – CAR Market Leakage Factor
   a. The project proponent will annually update the leakage calculation using the most current project plan harvest levels.
3. Market Leakage Option 3 – Leakage Assessment Tool
   a. Project proponents must re-evaluate the data and calculations at each verification.

9.3.8 Frequency of monitoring

Permanent sample plots must be re-measured at intervals of ≤ 5 years.

Spatial monitoring and leakage monitoring, are to be monitored annually.

9.3.9 Use of Monitoring Data to Update Carbon Stock Calculations

Data gathered through the monitoring process must be used to:

1. Update the project inventory data and related modeling and monitoring stratification as per Section 8.2.2 and 9.3.10;
2. Update leakage calculations in Section 8.3;
3. Update the inventory error estimates used in the calculation of the uncertainty factor described in Section 8.5.3; and,

4. Update and improve calculations of carbon stocks in Section 8.2 and possibly Section 8.1 as described in Section 8.2.2.

9.3.10 Updating of Monitoring Polygons

The ex-post stratification and polygon assignment to specific analysis units (see Section 9.3.2) must be updated on an annual basis and, at minimum prior to each verification, for any of the following reasons:

1. Errors in the inventory from field sampling or other monitoring. If the criteria used to allocate a polygon are not in accordance with field evidence, that polygon should be updated and re-assigned accordingly if necessary. Any non-*de minimis* updates due to errors in the inventory will require recalculation of both the annual project emissions (Section 8.2.5) and the annual baseline emissions (Section 8.1.2) prior to the next verification;
2. Changes to spatial inventory from monitoring for natural disturbance and planned/unplanned project activities. Updates will be made for any monitored event that affects the criteria used to define a given polygon or analysis unit in the project inventory. Note that disturbance or activity events may result in creation of a new polygon, or an age reclassification for the stand, and/or a re-assignment of the polygon. These updates only affect the calculation of carbon emissions from the project scenario (Section 8.2.5).
3. Established polygons may be merged if the original justification for their separate creation no longer applies. These updates only affect the calculation of carbon emissions from the project scenario (Section 8.2.5).

DOCUMENT HISTORY

Version	Date	Comment
v1.0	19 Apr 2011	Initial version released
v1.1	4 May 2012	Updates: 1) Removed applicability condition that projects must be developed on fee simple or freehold private ownership properties.
v1.2	23 July 2013	Updates: 1) Emissions from harvesting equipment, log transport, and primary forest product manufacturing were made optional. 2) Procedures for calculating storage in harvested wood products have been updated from 100-year method to a method that accounts for decay of carbon in short-term, medium term and long-term wood products in accordance with the VCS rules. 3) Minor edits to language were made (eg, the term 'must' has been used where a procedure is required by the methodology).

Approved VCS Methodology

Version 1.0
Sectoral Scope 3

Calculating Emission Reductions from Jet Engine Washing

Scope

This methodology provides a procedure to determine the net CO_2 emissions reductions associated with the on-wing washing of jet turbine engine washing.

Methodology Developer

The methodology was developed by Pratt & Whitney, in collaboration with United Technologies Corporation and Det Norske Veritas Certification, Ltd.

Authors

William Welch, Chris Garrity, Colin Karsten, Rick Love

1 SUMMARY

This methodology was developed to calculate the emission reductions generated by washing jet engines. All engines become contaminated through normal operation leading to restricted airflow, higher exhaust gas temperature, and increased fuel consumption. By eliminating engine contamination, engine washings improve propulsive efficiency measured as a decrease in thrust specific fuel consumption or TSFC, resulting in decreased emissions of carbon dioxide (CO_2).

It is anticipated that the methodology will be used by airline owners of jet engines who wish to utilize on-wing jet engine washing as a means of increasing engine thrust efficiency and reducing CO_2 emissions. Jet engine washing technology service providers might also use the methodology to assist airline customers in overall engine emissions reduction measurement.

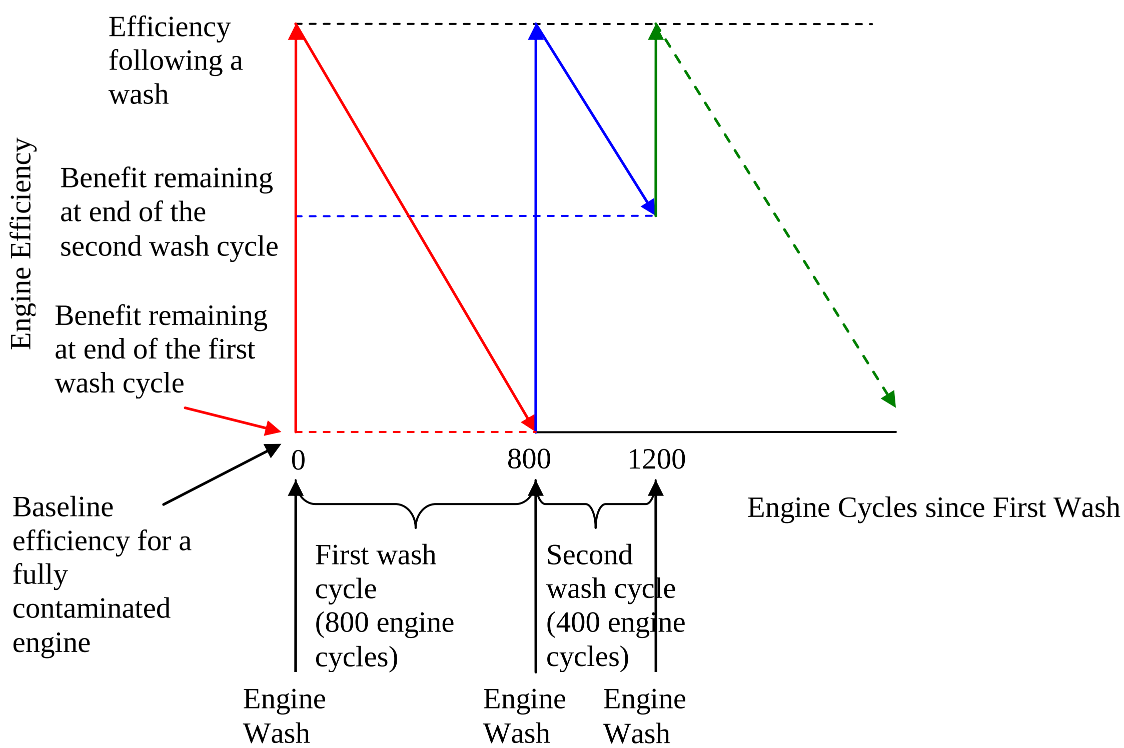
Figure 1 illustrates the general process of washing a jet engine. Once an engine is washed, it starts a wash cycle defined as the interval between two consecutive washes. As a result of the washing, engines will experience improved propulsive efficiency while in operation; the operation of an engine between one takeoff and one subsequent landing is called an engine cycle. As the number of engine cycles increase, the engine will become re-contaminated and the efficiency improvement realized by the washing will decline until the engine is washed again. The change in the efficiency improvement during the first washing cycle is tracked in red in Figure 1. This second washing terminates the first cycle and begins the subsequent cycle. The change in efficiency during the second wash cycle is tracked in blue in Figure 1. As demonstrated in Figure 1, washing cycles may not contain the same number of engine cycles for a variety of reasons, including:

Safety procedures – Some maintenance procedures prevent all engines on an aircraft from being washed at the same time. This reduces the risk that the same mistake made on one engine will be repeated on all engines of an aircraft, thus reducing the chance that all engines will fail at the same time.

Scheduling – Due to time constraints, it may not be feasible to wash all engines on an aircraft at once. Also, as engines are routinely switched between airplanes, the optimal wash interval for one engine may be different from that of the other engine on the same plane.

Since the number of engine cycles is directly correlated to the change in efficiency following a washing, the average efficiency improvement realized during the washing cycle will differ. Taking into account the average efficiency benefit realized during the wash cycle and the amount of fuel consumed by each engine cycle in a wash cycle, the fuel savings can be calculated and converted to emission reductions. As an additional environmental benefit, the methodology uses a closed-loop system for the collection, filtration and reuse of water used to wash the engine. This both saves water (of particular importance in water constrained areas of the world where engines may be washed) and eliminates the potential contamination of soil and groundwater associated with non closed-loop engine washing.

Figure 1 – Illustration of Engine Washing Process



2 SOURCE, DEFINITIONS AND APPLICABILITY

2.1 Source

- The approach for this baseline and monitoring methodology is based on elements from AMS II.J., the approved CDM (Clean Development Mechanism) small-scale baseline and monitoring methodology for demand-side activities for efficient lighting technologies. Jet engine washing technology is similar to lighting technology under AMS II.J. since both technologies provide benefits that may increase their market penetration in the baseline scenario. However, the market penetration of both technologies will increase far more rapidly under the project case. In the two methodologies, it is the additional market penetration growth achieved due to the project activities that are counted as emission reductions.

For more information regarding the methodology, please refer to http://cdm.unfccc.int/goto/MPappmeth.

2.2 Defintions

For the purpose of this methodology, the following definitions apply:

- **Engine cycle** The operation of an engine between one takeoff and one subsequent landing
- **Fleet** refers to a group of identical engines that use the same type of jet fuel and are attached to the same type of aircraft frame
- **Cruise EGT** refers to exhaust gas temperature (degrees Celsius) recorded during flight
- **Cruise Fuel Flow** refers to the rate (kg per hour or m^3 per hour) at which fuel is consumed by the engines during flight
- **Exhaust Gas Temp (EGT)** refers to temperature of the engine exhaust gases resulting from combustion of the fuel mixture, expressed in degree Celsius
- **Participant** refers to an individual airline that has agreed to wash all or a part of their fleet
- **Project Proponent** refers to the entity that is organizing airlines to wash all or part of their fleet
- **Project's engine washing technology** refers to any engine washing technology that decreases TSFC through the removal of engine contamination
- **Take off EGT** refers to engine exhaust gas temperature (degrees Celsius) recorded during takeoff
- **Thrust Specific Fuel Consumption (TSFC)** is an engineering term referring to fuel efficiency of an engine. TSFC represents the amount of fuel an engine burns to produce thrust, as measured in (Kg/hr)/Newton of thrust.
- **Wash** refers to the cleaning of an individual jet engine
- **Washing cycle** refers to the interval between consecutive washes for a particular engine

2.3 Applicability Conditions

The methodology is applicable to engine washing technology that meets the following conditions:

- The engine washing technology cleans any or all three of the compressive components of an engine: fan, low pressure compressor, and high pressure compressor.

- The engine washing was performed and completed in compliance with the wash requirements as provided in the engine's maintenance manual, or an alternative specification document as approved by a governing aviation regulatory body, such as the United States Federal Aviation Administration. Compliance with this condition will be indicated by the completion and maintenance supervisor signature on a 'released to service' form. Released to service forms are globally required for all aircraft undergoing any maintenance prior to their being put back into service.

- The only emission reductions claimed under this methodology are those related to increased propulsive efficiency due to engine washing. The project will not claim any emissions reductions as a result of other measures that result in changes in fuel consumption, e.g., changes in routes, operators' behaviour, etc, or fuel chemical property changes which increase fuel combustion efficiency.

- The engine is left on-wing during the washing and the engine washing technology is transported to the engine as opposed to removing the engine from the wing and transporting it to another location for the engine wash.

- The engine washing project will include a minimum of 100 engine washes per fleet to assure the methodology adequately compensates for single-engine model data variability.

- Applicable engines will be only those which during the period for which engine washing benefit is measured have not undergone an on-wing modification that could improve efficiency as measured by TSFC.

3 BASELINE METHODOLOGY PROCEDURE

3.1 Project Boundary

The project boundary is the physical, geographical location of each engine washed by the project technology, and the flight routes on which the emissions reductions occur. The project boundary includes emissions from generators and equipment used to transport engine wash equipment to the wash location.

The greenhouse gases included in or excluded from the project boundary are shown in Table 1.

Table 1: Emissions sources included in or excluded from the project boundary

<table>
<tr><th colspan="2">Source</th><th>Gas</th><th>Included?</th><th>Justification / Explanation</th></tr>
<tr><td rowspan="3">Baseline</td><td rowspan="3">Jet engines that are washed in the project case</td><td>CO_2</td><td>Yes</td><td>Emissions from fuel combustion represent the major emission source in the baseline</td></tr>

3.2 Identification of the baseline scenario

The project baseline activity will be demonstrated using the latest version of the *"Combined tool to identify the baseline scenario and demonstrate additionality"* that is available on the UNFCCC website.

3.3 Procedure for demonstrating additionality

Additionality shall be demonstrated using the latest version of the *"Combined tool to identify the baseline scenario and demonstrate additionality"* that is available on the UNFCCC website.

3.4 Baseline emissions

The following equations are used to estimate the baseline emissions for jet engines:

$$BE_y = \sum_{m}^{z} \left(BFC_y * EF_{CO2,ACFuel,y} \right) \quad \textbf{(1)}$$

Where:

BE_y	=	Baseline emissions in year *y* (t CO_2/yr)
M	=	An individual fleet
Z	=	Total number of fleets
BFC_y	=	Baseline fuel consumption by all engines in fleet m in year y (mass or volume unit)
$EF_{CO2,ACFuel,y}$	=	CO_2 emission factor for fuel used in fleet *m* engines (ton CO_2/mass or volume unit)

Procedure for estimating the CO_2 emission factor for fuel used in jet engines, $EF_{CO2,ACFuel,y}$

$$EF_{CO2,ACFuel,y} = EF_{C,ACFuel,y} * 44/12 * OXID_{ACFuel} * NCV_{ACFuel} \quad \textbf{(1.1)}$$

Where:

$EF_{CO2,ACFuel,y}$	=	CO_2 emission factor for fuel used in aircraft engines in fleet *m* (tonne of CO_2/mass or volume unit)
$EF_{C,ACFuel,y}$	=	Carbon content of fuel used in aircraft engines in fleet *m* (tonne/Tera Joule)
$OXID_{ACFuel}$	=	Oxidation factor of fuel used in aircraft engines in fleet *m*
NCV_{ACFuel}	=	Net caloric value of fuel used in aircraft engines in fleet *m* (Tera Joule/mass or volume units)

Procedure for estimating the baseline fuel consumption, BFC_y

$$BFC_y = \sum_{j=1}^{n} \left[\sum_{wc=1}^{x} \left[\sum_{ec=1}^{NECj,wc} MFC_r \right] \right] \quad \textbf{(1.2)}$$

Where:

BFC_y	=	Baseline fuel consumption by all engines in fleet *m* in year *y* (mass or volume units)
J	=	An individual engine in fleet *m*
N	=	Total number of engines in fleet *m* in year *y*
Wc	=	A wash cycle, or the interval between two consecutive washes
X	=	Total number of wash cycles for engine *j* in year *y*
$NEC_{j,wc}$	=	Number of engine cycles for engine *j* during wash cycle, *wc*, not to exceed $ACFC_m$

(number of cycles leading to full engine contamonation without a wash)

Ec = An engine cycle

MFC_r = Modelled fuel consumption in the baseline case, based on engine utilization (*r*) during the engine cycle (mass or volume units)

- Note: If the fuel used in an engine is changed during the project crediting period, the engine will be assigned to a different fleet corresponding to the appropriate combination of aircraft frame, engine type and fuel type for the wash cycle when the fuel switch occurs and all subsequent wash cycles where the new fuel is used.

- The methodology uses a Business Penetration (BP) factor, by which emissions reductions compared to baseline are reduced to reflect the current market penetration of jet engine washing technology. The BP factor is applied to the total modelled fuel consumption units to develop MFC_r as used above.

3.5 Project emissions

The following equation estimates the project emissions:

$$PE_y = \sum_m^z \left(PE_{EA,y} + PE_{WE,y}\right) \quad \textbf{(2)}$$

Where:

PE_y = Project emissions in year *y* (t CO_2)

m = An individual fleet

Z = Total number of fleets

$PE_{EA,y}$ = Emissions from fuel combustion by fleet *m* in year y (t CO_2)

$PE_{WE,y}$ = Emissions generated in the process of washing fleet *m* engines in year y (t CO_2)

Procedure for estimating the project emissions associated with fuel combustion by fleet *m* engines in year *y*, $PE_{EA,y}$

$$PE_{EA,y} = FC_{.y} * EF_{CO2,ACFuel,y} \quad \textbf{(2.1)}$$

Where:

$PE_{EA,y}$ = Emissions from jet engine fuel combustion in year *y* (tonne of CO_2)

FC_y = Fuel consumption by fleet *m* in year *y* (mass or volume unit)

$EF_{CO2,ACFuel,m,y}$ = Carbon dioxide emission factor of fuel used in fleet *m* engines (tonne of CO_2/ mass or volume unit)

Procedure for estimating the CO_2 emission factor for the fuel used in engines in year *y*, $EF_{CO2,ACFuel,y}$

$$EF_{CO2,ACFuel,y} = EF_{C,ACFuel,y} * 44/12 * OXID_{ACFuel} * NCV_{ACFuel} \quad \textbf{(2.1.1)}$$

Where:

$EF_{CO2,ACFuel,y}$	=	Carbon dioxide emission factor of fuel used in fleet *m* engines (tonne of CO_2/ mass or volume unit)
$EF_{C,ACFuel,y}$	=	Carbon content of fuel used in aircraft engines (tonne/Tera Joule)
$OXID_{ACFuel}$	=	Oxidation factor of fuel used in aircraft engines
NCV_{ACFuel}	=	Net caloric value of fuel used in aircraft engines (Tera Joule/mass or volume units)

Procedure for estimating the fuel consumption by fleet *m* in year *y*, *$FC_{m,y}$*

$$FC_y = \sum_{j=1}^{n}\left[\sum_{wc=1}^{x}\left[\left(\sum_{ec=1}^{NECj,wc} MFC_r\right) * \left(1 - \overline{TSFC_{j,wc}}\right)\right]\right] \quad \textbf{(2.1.2)}$$

Where:

FC_y	=	Fuel consumption by all engines in fleet *m* in year *y* (mass or volume units)
J	=	An individual engine in fleet *m*
N	=	Total number of engines in fleet *m* in year *y*
Wc	=	A wash cycle, or the interval between two consecutive washes
X	=	Total number of wash cycles for engine *j* in year *y*
$NEC_{j,wc}$	=	Number of engine cycles for engine *j* during wash cycle, *wc*, not to exceed $ACFC_m$
Ec	=	An engine cycle
MFC_r	=	Modelled fuel consumption in the baseline case, based on engine utilization (*r*) during the engine cycle (mass or volume units)
$\overline{TSFC_{j,wc}}$	=	Average TSFC improvement for engine *j* throughout the wash cycle, *wc,* due to wash *w* (%)

- As described above, the benefit of a wash will vary for each washing cycle depending on the number of engine cycles. However, airlines do not track fuel consumption at the level of detail that would be required to determine fuel consumption per wash cycle (fuel consumption is tracked at the fleet level, not by aircraft, engine or cycle). Since data limitations prevent accurate reporting of fuel consumption by wash cycle in the project case, the baseline fuel consumption for each engine cycle is determined using industry standard models (as described in section 4) and aggregated for each washing cycle. Wash cycle fuel consumption is then adjusted based on the average TSFC benefit realized during the wash cycle, to determine the wash cycle fuel consumption in the project case. This is aggregated across all wash cycles to determine annual fuel consumption for an engine, and then engine fuel consumption is aggregated across the fleet.

- Note 1: If the fuel used in an engine is changed during the project crediting period, the engine will be assigned to a different fleet (corresponding to the appropriate combination of aircraft frame, engine type and fuel type) for the wash cycle when the fuel switch occurs and all subsequent wash cycles where the new fuel is used.

- Note 2: Fuel consumption associated with engine cycles that are in excess of $ACFC_m$ during a particular wash cycle will not be included in this calculation. This is described further under equation 2.1.2.1.2

Procedure for estimating the average TSFC improvement per wash cycle, $\overline{TSFC}_{j,wc}$

$$\overline{TSFC}_{j,wc} = \left(\frac{\Delta TSFC_{j,w} + \Delta TSFC_{j,NECj,wc}}{2} \right) \quad \textbf{(2.1.2.1)}$$

Where:

$\overline{TSFC}_{j,wc}$	=	Average TSFC improvement for engine *j* throughout the washing cycle, *wc*, due to wash *w* (%)
$\Delta TSFC_{j,w}$	=	TSFC improvement for engine *j* following wash *w* (%)
$\Delta TSFC_{j,NECj,wc}$	=	TSFC improvement remaining for engine *j* after $NEC_{j,wc}$ cycles following a wash
W	=	An individual engine washing

Immediately following a wash, aircraft engines will realize the greatest increase in TSFC (represented by $\Delta TSFC_{j,w}$) and this declines in a linear fashion as the engine becomes more contaminated with each engine cycle (as shown in Figure 1 above) until the end of the wash cycle (the TSFC improvement remaining at the end of the wash cycle is represented by $\Delta TSFC_{j,NECj,wc}$). Since this decline is linear, the net effect of the wash throughout the wash cycle can be expressed as the average TSFC benefit.

Procedure for estimating the TSFC improvement for engine *j* following wash *w*, $\Delta TSFC_{j,w}$

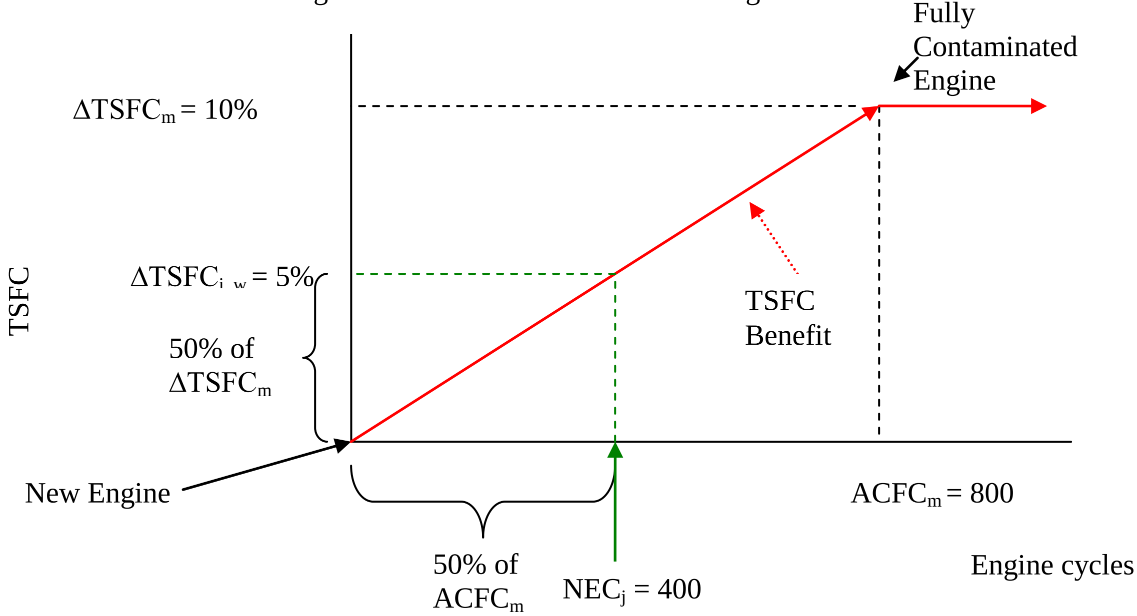
$$\Delta TSFC_{j,w} = \Delta TSFC_m * \left(\frac{NEC_j}{ACFC_m} \right) \quad \textbf{(2.1.2.1.1)}$$

Where:

$\Delta TSFC_{j,w}$	=	TSFC improvement for engine *j* following wash *w* (%)
$\Delta TSFC_m$	=	TSFC improvement for an engine in fleet *m* following a wash (%)
NEC_j	=	Number of engine cycles for engine j since it was put into service, not to exceed $ACFC_m$
$ACFC_m$	=	Number of engine cycles that, in the absence of any engine washings, will lead a clean engine in fleet *m* to become fully contaminated.

The TSFC improvement following washing in the project case ($\Delta TSFC_{j,w}$) can, in most cases, be compared to a fully contaminated engine, as defined by $\Delta TSFC_{m}$. The exception is an engine that has not yet travelled the number of cycles that causes full contamination as defined by $ACFC_m$, such as a new engine that has just been put into service. If an engine is washed before it reaches $ACFC_m$ cycles, it would be inappropriate to compare the wash benefit to the fully contaminated case. As engine contamination increases in a linear fashion relative to engine cycles until $ACFC_m$ is reached, and because engine contamination and TSFC benefit are directly correlated, the TSFC benefit for a wash that occurs before $ACFC_m$ cycles can be found by discounting the maximum TSFC benefit by the proportion of $ACFC_m$ cycles that has been reached before the wash takes place (see Figure 2).

Figure 2 – TSFC Benefit for a New Engine



Procedure for estimating the TSFC improvement remaining at the end of the wash cycle, $\Delta TSFC_{j,NECj,wc}$

$$\Delta TSFC_{j,NECj,wc} = \left(\Delta TSFC_m * \left(1 - \frac{NEC_{j,wc}}{ACFC_m} \right) \right) \qquad \textbf{(2.1.2.1.2)}$$

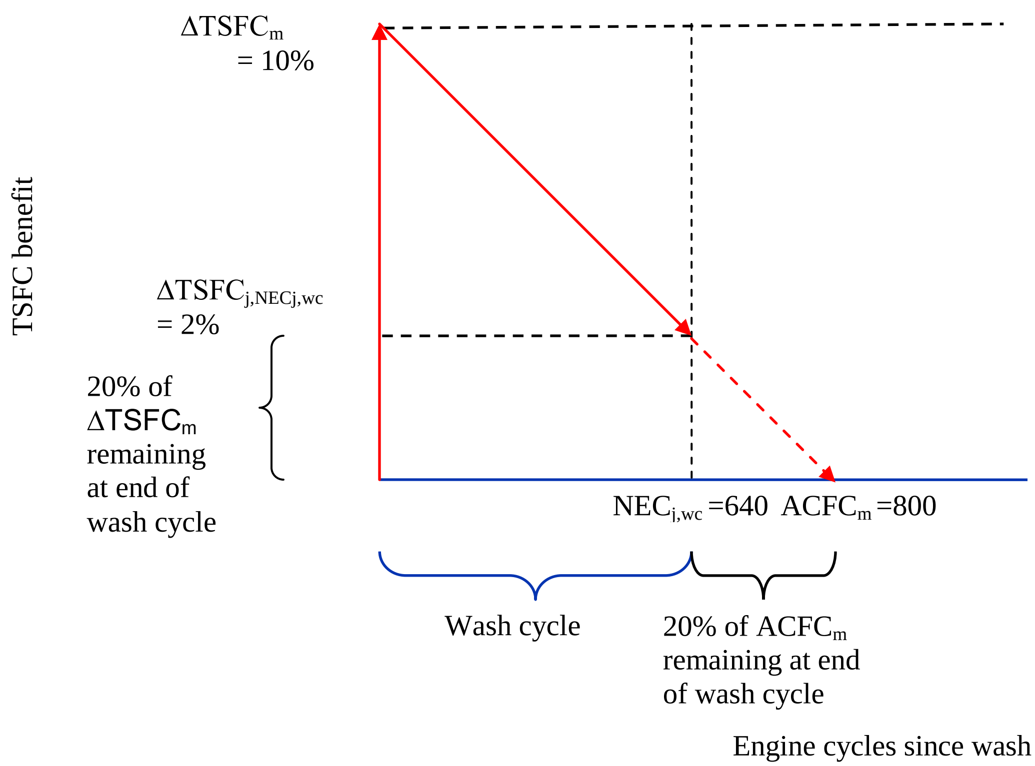
Where:

$\Delta TSFC_{j,NECj,wc}$	=	TSFC improvement for engine *j* after $NEC_{j,wc}$ cycles following a wash
$\Delta TSFC_m$	=	TSFC improvement for engine *j* following a wash (%)
$NEC_{j,wc}$	=	Number of engine cycles for engine ***j*** during wash cycle, *wc*, not to exceed $ACFC_m$
$ACFC_m$	=	Number of engine cycles that, in the absence of any engine washings, will lead a clean engine in fleet *m* to become fully contaminated.
W	=	An individual wash

If it were certain that the wash cycle would contain $ACFC_m$ engine cycles, equation 2.1.2.1 would simply take the average between $\Delta TSFC_{j,w}$ (the benefit immediately following wash *w*) and 0 (since $ACFC_m$ represents the point where the TSFC benefit is entirely lost). However, project participants may elect to shorten the wash cycle (note that cycles in excess of $ACFC_m$ are eliminated from consideration – see below), as demonstrated in figure 3. As a result, the TSFC benefit remaining at the end of this shortened wash cycle, $\Delta TSFC_{j,NECj,wc}$, is calculated in equation 2.1.2.1.2 Since the decline in TSFC is linear as the number of engine cycles increases, this equation calculates $\Delta TSFC_{j,NECj,wc}$ by multiplying the initial TSFC benefit by one minus the proportion of the maximum engine cycles realized during the wash cycle. For instance, if $ACFC_m$ is 800 and $NEC_{j,wc}$ is 640, then 1-(640/800) = 0.2. If the $\Delta TSFC_m$ is 10%, then the remaining TSFC benefit is 10% * 0.2 =2%.

As mentioned above, cycles in excess of $ACFC_m$ following a wash are eliminated from consideration. Once an engine reaches $ACFC_m$ cycles following a wash, it is by definition fully contaminated. The fuel efficiency is therefore no better than it would have been in the baseline and so the project does not provide any additional benefit.

Figure 3 – TSFC Benefit Remaining at End of Wash Cycle



Procedure for estimating the emissions generated during the engine washing process per year, $PE_{WE,y}$

$$PE_{WE,m,y} = GE_{m,y} + TE_{m,y} \qquad \textbf{(2.2)}$$

Where:

$PE_{WE,y}$	=	Emissions generated during the washing process in year *y* (t CO_2)
$GE_{m,,y}$	=	Emissions from energy usage to run generators during the washing of engines in fleet *m* in year *y* (t CO_2)
$TE_{m,y}$	=	Emissions from the transport of washing technology to the wash engines in fleet *m* in year *y* (t CO_2)

Procedure for estimating the emissions from energy usage to run the generator during the washing of engines in fleet *m*, $GE_{m,y}$

$$GE_{m,y} = \sum_{g}^{q} \left(FC_{gen,y} * EF_{CO2,GenFuel,y} \right) \quad \textbf{(2.2.1)}$$

Where:

$GE_{m,y}$	=	Emissions from energy usage to run generators during the washing of engines in fleet *m* in year *y* (t CO_2)
G	=	A particular fuel used by generators during the washing of fleet *m* engines
Q	=	Total number of different fuels used by all generators to wash engines in year *y*
$FC_{gen,y}$	=	Fuel consumption by generators used to wash the engines of fleet m in year *y* (mass or volume of fuel)
$EF_{CO2,GenFuel,y}$	=	CO_2 emission factor for the fuel consumed by generator *g* in year *y* (t CO_2/ mass or volume unit)

Procedure for estimating the fuel consumption by generators used to wash the engines of fleet *m* in year *y*, $FC_{gen,y}$

$$FC_{gen,y} = \sum_{j}^{n} \left[\sum_{w}^{x} \left(CR_{fuel} * D_{w} \right) \right] \quad \textbf{(2.2.1.1)}$$

Where:

$FC_{gen,y}$	=	Fuel consumption by generators used to wash the engines of fleet *m* in year *y* (mass or volume of fuel)
J	=	An individual engine in fleet *m*
N	=	Total number of engines in fleet *m* in year *y*
W	=	An engine wash
X	=	Total number of engine washes for engine *j* in year *y* (note that the number of wash cycles is equal to the number of washes, and so the same variable *x* is used)
CR_{fuel}	=	Fuel consumption rate of the generator in year *y* (mass or volume of fuel per hour)
D_w	=	Length of time that the generator is in use during a wash (hours)

Procedure for estimating the CO_2 emission factor for the fuel consumed by the generator in year *y*, $EF_{CO2,GenFuel,y}$

$$EF_{CO2,GenFuel,y} = EF_{C,GenFuel,y} * 44/12 * OXID_{GenFuel} * NCV_{GenFuel} \quad \textbf{(2.2.1.2)}$$

Where:

$EF_{CO2,GenFuel,y}$	=	CO_2 emission factor for the fuel consumed by the generator in year *y* (tonne of CO_2/ mass or volume unit)
$EF_{C,GenFuel,y}$	=	Carbon content of the fuel consumed by the generator (ton/Tera Joule)
$OXID_{GenFuel}$	=	Oxidation factor of the fuel consumed by the generator (%)
$NCV_{GenFuel}$	=	Net caloric value of the fuel consumed by the generator (Tera Joule/mass or volume units)

Procedure for estimating the emissions from the transport of washing technology to the wash location in year *y*, TE_y

$$TE_{m,y} = \sum_{f=1}^{l} \left(FC_{TV,fuel} * EF_{CO2,TVFuel,y} \right) \quad \textbf{(2.2.2)}$$

Where:

$TE_{m,y}$	=	Emissions from the combustion of fuel in vehicles used to transport washing equipment to the wash location in year *y* (mass or volume unit)
F	=	A particular fuel used by vehicles to transport wash equipment to wash engines in fleet *m*
L	=	Total number of different fuels that are used by vehicles to transport wash equipment (i.e., propane and electricity)
FC_{TVF}	=	Fuel consumption by vehicles during the transport of washing equipment in year *y* (volume units)
$EF_{CO2,TVFuel,y}$	=	CO2 emission factor for a fuel consumed by transport vehicles in year *y* (tonnetonneof CO_2/mass or volume unit)

Procedure for estimating the quantity of a particular fuel consumed in the transport of washing equipment, FC_{ETF}

$$FC_{TV,fuel} = \sum_{j=1}^{n}\left[\sum_{w=1}^{x}\left[\sum_{v=1}^{p}(TD/FE)\right]\right] \quad \textbf{(2.2.2.1)}$$

Where:

$FC_{TV,fuel}$	=	Fuel consumption by vehicles during the transport of engine washing equipment in year *y* (volume units)
J	=	An individual engine in fleet m
N	=	Total number of engines in fleet m in year y
W	=	A wash
X	=	Total number of washings for engine *j*
V	=	A vehicle used to transport engine washing equipment for a wash
P	=	Total number of vehicles used to transport engine washing equipment for a wash
TD	=	Total distance travelled by a vehicle to transport washing equipment for a wash (distance units)
FE	=	Fuel efficiency of a vehicle used to transport washing equipment (volume units per distance units)

Procedure for estimating the CO_2 emission factor for fuel consumed by transport vehicles in year *y*, $EF_{CO2,TVF,y}$

$$EF_{CO2,TVFuel,y} = EF_{C,TVFuel,y} * 44/12 * OXID_{TVFuel} * NCV_{TVFuel} \quad \textbf{(2.2.2.2)}$$

Where:

$EF_{CO2,TVFuel,y}$	=	CO_2 emission factor for fuel consumed by transport vehicles in year *y* (tonne of CO_2/mass or volume unit)
$EF_{C,TVFuel,y}$	=	Carbon content of the fuel consumed by transport vehicles (tonne/Tera Joule)
$OXID_{TVFuel}$	=	Oxidation factor of the fuel consumed by transport vehicles (%)
NCV_{TVFuel}	=	Net caloric value of the fuel consumed by transport vehicles (Tera Joule/mass or volume units)

3.6 Leakage

There are no identified sources of leakage for this project activity

3.7 Emission reductions

Since the impact of an engine wash will vary by fleet, the calculation of emission reductions is done for each fleet and then aggregated across all fleets. Emission reductions are calculated as follows:

$$ER_y = (BE_y - PE_y) \quad \textbf{(3)}$$

Where:

ER_y = Emission reductions in year *y* (tonne of CO_2e/yr)
BE_y = Baseline emissions in year *y* (tonne of CO_2e/yr)
PE_y = Project emissions in year *y* (tonne of CO_2/yr)

4 MONITORING METHODOLOGY

All data collected as part of monitoring will be archived electronically and will be kept at least for 2 years after the end of the last crediting period. The data to be monitored is listed in the tables below. All measurements will be conducted with calibrated measurement equipment according to relevant industry standards.

In addition, the monitoring provisions in the tools referred to in this methodology apply.

4.1 Data and parameters not monitored

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

Data / parameter:	BP
Data unit:	%
Description:	Business penetration factor
Source of data:	Fleet-specific wash penetration data.
Measurement procedures (if any):	Option 1: Project proponents must use fleet-specific wash penetration data to establish this parameter. The parameter is expressed as the percentage of engines washed in a given fleet (i.e., Number of engine washes / total potential engine washes). Option 2: Where fleet-specific data is not available, a default BP factor of 5% shall be used. The default BP factor was developed to discount total project emissions reductions by an amount comparable to the small market adoption of the project technology by potential project participants prior to commencement of the project. The factor was developed using aviation industry estimates indicating that in 2009 approximately 3,000 engines were washed on wing. The commercial aviation market eligible for the project has 40,000 jet engines and to improve performance and reduce emissions, each of these engines should be washed approximately twice per year, for a total of 80,000 potential washes. Using these figures, the project technology market penetration in 2009 was estimated at 3.75%. To provide a more conservative analysis of the market penetration data, the 3.75% has been rounded up to 5%.
Any comment:	The BP factor shall be determined at validation and at the renewal of each crediting period.

Data / parameter:	$ACFC_m$
Data unit:	Cycles
Description:	Number of engine cycles that, in the absence of any engine washings will lead a clean engine in fleet *m* to be fully contaminated.
Source of data:	Previous data analysis indicates that aircraft engines become fully contaminated between 800-1200 engine cycles, depending on the fleet and route. To assure the conservativeness of the emission reduction calculations, the default value has been set at 800 cycles. As an option, projects may use a fleet-specific $ACFC_m$ calculated as follows. The optional $ACFC_m$ value will apply for the complete duration of the crediting period and will reflect the composition of the fleet included in the project.
Measurement procedures (if any):	To calculate $\Delta TSFC_m$, data must be collected for a period of time before and after the wash such that accurate levels can be obtained for each period of time. This data is then analyzed to determine the TSFC benefit of each wash. The TSFC benefit corresponding to the wash cycle length (which corresponds to the number of engine cycles in the wash cycle or the number of cycles required for the engine to become fully contaminated) can then be determined through interpretation of the individual wash TSFC benefits plotted vs. NEC on a scatter plot. The point at which the TSFC benefit plateaus is the benefit that can be expected by a wash of a fully contaminated engine, or $\Delta TSFC_m$. The number of engine cycles that corresponds to $\Delta TSFC_m$ is $ACFC_m$.
Any comment:	Default value = 800

4.2 Data and parameters monitored

Data / parameter:	R
Data unit:	Hours
Description:	Engine utilization for each cycle or hours of operation
Source of data:	Engine operator records
Measurement procedures (if any):	Record hours per cycle, as well as date and time of cycle and the engine serial number, so that utilization can be allocated to a particular engine and wash cycle
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	

Data / parameter:	w
Data unit:	Wash
Description:	A wash for engine j
Source of data:	Engine operator records
Measurement procedures (if any):	Record date and time of the aircraft engine wash as well as the engine serial number, so that fuel consumption can be assigned to a particular engine and wash cycle.
Monitoring frequency:	Continuously
QA/QC procedures:	A signed 'Release to Service' form following completion of engine washing
Any comment:	

Data / parameter:	Ec / NECj,wc
Data unit:	Engine Cycle
Description:	Engine cycle for engine *j*, where an engine cycle includes one takeoff and one landing.
Source of data:	Aircraft engine operator records
Measurement procedures (if any):	Record data and time of cycle, as well as engine serial number so that engine cycle can be assigned to a wash cycle
Monitoring frequency:	Continuously, aggregated per wash cycle to determine $NEC_{j,wc}$. Cycles in excess of $ACFC_m$ during a wash cycle are eliminated from consideration, as described in equation 2.1.2.1.2
QA/QC procedures:	
Any comment:	

Data / parameter:	g
Data unit:	Fuel type
Description:	Fuel type consumed by each generator that is used to wash engines in year *y*
Source of data:	Operator records
Measurement procedures (if any):	
Monitoring frequency:	Recorded one time per year
QA/QC procedures:	
Any comment:	

Data / parameter:	CR_{fuel}
Data unit:	Mass or volume of fuel per hour
Description:	Fuel consumption rate for each generator used to wash engines in year *y*
Source of data:	Vehicle manufacturers specification sheet
Measurement procedures (if any):	
Monitoring frequency:	Recorded one time per year
QA/QC procedures:	
Any comment:	

Data / parameter:	D_w
Data unit:	Hours
Description:	Length of time that a generator is in use during a wash
Source of data:	Measurements by project proponent
Measurement procedures (if any):	In addition to duration of generator use, record date and time of wash, as well as engine serial number(s). In lieu of continuously recording wash duration, average duration of 15 washes for engines with at least $ACFC_m$ cycles may be used as default value for all washes in the fleet. Fully contaminated engines can take longer to clean, resulting in a more conservative estimation of project emissions.
Monitoring frequency:	Continuously If default value is used, record during first engine wash.
QA/QC procedures:	Data taken from written wash log data sheets
Any comment:	The use of default values is acceptable because the emissions associated with energy use during the washing process are likely to be de-minimus.

Data / parameter:	f
Data unit:	Fuel type
Description:	Fuel type consumed by a transport vehicle to transport wash equipment in year *y*
Source of data:	Vehicle operator records
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	

Data / parameter:	TD_{TV}
Data unit:	Distance units
Description:	Total distance travelled by vehicles transporting engine washing equipment per engine wash
Source of data:	Vehicle odometer
Measurement procedures (if any):	Vehicle operator must record the roundtrip distance travelled for each engine wash, as well as the engine serial number that was washed and the time and date that the wash occurs. Alternatively, the vehicle operator can record the greatest roundtrip distance travelled to perform an engine wash for each location (i.e., airport), and this distance can be used as a default value for all other washings.
Monitoring frequency:	Roundtrip distance recorded for every washing. Alternatively, the distance is recorded once based on the greatest possible distance.
QA/QC procedures:	
Any comment:	

Data / parameter:	FE_{TV}
Data unit:	Mass or volume units per distance units
Description:	Fuel efficiency of a vehicle used to transport engine washing equipment to the wash location
Source of data:	Vehicle manufacturers specification sheet
Measurement procedures (if any):	
Monitoring frequency:	Recorded one time per year
QA/QC procedures:	
Any comment:	

Data / parameter:	$\Delta TSFC_m$
Data unit:	%
Description:	TSFC improvement for an engine in fleet *m* following a wash (%)
Source of data:	Engine trend data obtained from aircraft operator, including Takeoff EG Margin, Cruise EGT and Cruise Fuel Flow

Measurement procedures (if any):	To calculate $\Delta TSFC_m$, data must be collected for a period of time before and after the wash such that accurate levels can be obtained for each period of time. This data is then analyzed to determine the TSFC benefit of each wash. The TSFC benefit corresponding to the wash cycle length (which corresponds to the number of engine cycles in the wash cycle or the number of cycles required for the engine to become fully contaminated) can then be determined through interpretation of the individual wash TSFC benefits plotted vs. NEC on a scatter plot. The point at which the TSFC benefit plateaus is the benefit that can be expected by a wash of a fully contaminated engine, or $\Delta TSFC_m$. The number of engine cycles that corresponds to $\Delta TSFC_m$ is $ACFC_m$. This is shown in Figure 1. Step 1 - To calculate the TSFC improvement for varying wash cycle lengths, the following procedure is used: For each of the following variables - Takeoff EGT Margin, Cruise EGT and Cruise Fuel Flow data – obtain 20 data points before the wash and 20 data points after the wash from engine trend data. These data should be available from the aircraft on board flight performance tracking system, and should be collected immediately preceding and immediately following the wash for washed engines of the fleet in question. Make sure that all data acquired is normalized to account for differences in ambient conditions and power setting. Most industry-standard engine monitoring software programs provide fully normalized data that can be evaluated directly. If this is not available, raw data can be acquired and normalized manually. Detect and correct any biases that may be present in the data. Identify any trends in the data or performance shifts occurring before or after the wash that are not related to the wash. Omit data before the wash or after the wash that show the trend or performance shift. Omit outlier data that is greater than the appropriate variation threshold (typically 2 standard deviations) from the data population average. A minimum of 10 data points before the wash and 10 data points following the wash must remain following step 2 for accurate analysis. If fewer than 10 data points are available, a new dataset must be collected. For each variable, calculate the difference between the average of the remaining points following the wash and the remaining points prior to the wash. This difference will be defined as the "delta_delta". Input the measured "delta_delta" parameters into a thermodynamic engine model or use an applicable correlation coefficient to calculate the TSFC improvement for that wash. If correlations are used, compare the TSFC calculated based on WF and EGT to ensure accurate results. If the TSFC benefits calculated based on various parameters agree within an acceptable threshold, the data are considered valid and the wash benefit for that wash ($\Delta TSFC$)

	Step 2 – Once sufficient data points have been collected under Step 1 for the fleet (approximately 30), they are analyzed to determine $\Delta TSFC_m$. This is accomplished through a linear regression of wash TSFC benefits vs. engine contamination cycles, where the regression is forced through the origin. For the purposes of this regression, all washes taking place after more than $ACFC_m$ cycles will be re-defined as taking place at $ACFC_m$ cycles. The $\Delta TSFC_m$ benefit for each fleet will then be equivalent to the $ACFC_m$ contamination cycle intercept of the TSFC benefit regression line. Figure 1 Monitoring frequency:	Analysis is conducted when data from a minimum of 100 engine washes has been collected from each fleet. Analysis is performed once and the resulting $\Delta TSFC_m$ value is applicable for the entire crediting period.
QA/QC procedures:	
Any comment:	- Project proponents must demonstrate to the VCS project validator applicability of the models used in Steps 1 and 2. - No performance shifting activities (i.e., as instrumentation changes, software upgrades, engine maintenance or upgrades) should be conducted between the measurement of pre and post-wash data.

Data / parameter:	MFC_r
Data unit:	Mass or volume units
Description:	Modelled fuel consumption in the baseline case, based on engine utilization (*r*) during the engine cycle
Source of data:	Data is modelled based on: utilization rates (average cycles per year and hours/cycle) as reported from aircraft operators, and fleet performance specifications obtained from airplane performance documents.
Measurement procedures (if any):	Aircraft operators report total engine cycles and total hours per year for the fleet. The average cycles per year and average hours per cycle for the fleet are calculated and these averages are used as inputs to the model.
Monitoring frequency:	Annual ex-post analysis
QA/QC procedures:	
Any comment:	At validation, project proponents must demonstrate the applicability of the model used to estimate fuel consumption. Acceptable models must have been approved by an aircraft engine manufacturer, and include those used in the certification of aircraft engine performance standards. Calculation of MFC_r must include application of the Business Penetration factor to eliminate potential non-additional emissions reductions associated with engines washed prior to methodology approval. When applied in calculation of project modelled fuel consumption, MFCr, the Business Penetration factor is expressed as 1 – BP.

Data / parameter:	NCV_{ACFuel}
Data unit:	Mega Joule / mass or volume units
Description:	Net caloric value of fuel used in aircraft engines
Source of data:	Actual measured or local data are to be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$EF_{C,ACFuel,y}$
Data unit:	tonnes of carbon / mass or volume units
Description:	Carbon content of the fuel combusted in aircraft engines
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$OXID_{ACFuel}$
Data unit:	Fraction
Description:	Oxidation factor for the fuel used in aircraft engines
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data is local or regional

Data / parameter:	$OXID_{GenFuel}$
Data unit:	Fraction
Description:	Oxidation factor for the fuel consumed by the generator
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$NCV_{GenFuel}$
Data unit:	Mega Joule / mass or volume units
Description:	Net caloric value of the fuel consumed by the generator
Source of data:	Actual measured or local data are to be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$EF_{C,GenFuel, y}$
Data unit:	tonnes of carbon / mass or volume units
Description:	Carbon content of the fuel consumed by the generator
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$OXID_{TVFuel}$
Data unit:	Fraction
Description:	Oxidation factor for the fuel consumed by transport vehicles
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	NCV_{TVFuel}
Data unit:	Mega Joule / mass or volume units
Description:	Net caloric value of the fuel consumed by transport vehicles
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	$EF_{C,TVFuel, y}$
Data unit:	tonne of carbon / mass or volume units
Description:	Carbon content of the fuel consumed by transport vehicles
Source of data:	Actual measured or local data should be used. If not available, regional data should be used, and in its absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories
Measurement procedures (if any):	Measurements taken according to best international practices
Monitoring frequency:	Yearly
QA/QC procedures:	
Any comment:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements. Values must be compared to IPCC defaults if data are local or regional

Data / parameter:	Δ Takeoff EGT Margin
Data unit:	°C
Description:	Change in Takeoff Exhaust Gas Temperature Margin resulting from the engine wash
Source of data:	Aircraft on-board flight performance tracking system
Measurement procedures (if any):	
Any comment:	Comparison to other measured parameters should be made to ensure validity. Values are to be used in conjunction with engineering judgment by a professional with experience in engine performance analysis.

Data / parameter:	Δ Cruise EGT
Data unit:	°C
Description:	Change in Cruise Exhaust Gas Temperature resulting from the engine wash
Source of data:	Aircraft on-board flight performance tracking system
Measurement procedures (if any):	
Any comment:	Comparison to other measured parameters should be made to ensure validity. Values are to be used in conjunction with engineering judgment by a professional with experience in engine performance analysis.

Data / parameter:	Δ Cruise fuel flow
Data unit:	%
Description:	Change in Cruise fuel flow resulting from the engine wash
Source of data:	Aircraft on-board flight performance tracking system
Measurement procedures (if any):	
Any comment:	Comparison to other measured parameters should be made to ensure validity. Values are to be used in conjunction with engineering judgment by a professional with experience in engine performance analysis.

Version 1.0
Sectoral Scopes 1, 10

Interception and Destruction of Fugitive Methane from Coal Bed Methane (CBM) Seeps

Scope
This methodology applies to projects that capture and destroy fugitive methane emissions occurring at coal bed outcroppings near active coal bed methane production operations.

Methodology Developers
The methodology element was developed by the Southern Ute Indian Tribe - Growth Fund and WSP Environment & Energy. Det Norske Veritas and Bureau Veritas provided methodology validation support through the VCS Double Approval Process.

Authors
Mike Huisenga (WSP) and Kyle Siesser (SUIT)

TABLE OF CONTENTS

I. SOURCE, DEFINITIONS AND APPLICABILITY

Sources

This baseline and monitoring methodology is based on the following approved baseline and monitoring methodologies:

ACM0008 V7*"Consolidated methodology for coal bed methane, coal mine methane and ventilation air methane capture and use for power (electrical or motive) and heat and/or destruction through flaring or flameless oxidation"*

- This consolidated methodology applies to active coal mines where methane mitigation projects are implemented to reduce emissions of methane during pre-mine drainage, post mine drainage and from ventilation air methane. Captured methane can be flared, used to generate heat and / or power and delivered to gas grids for heat and / or power use or in vehicles. ACM0008 has been approved as a baseline and monitoring methodology by the CDM Executive Board for use in registered Clean Development Mechanism (CDM) projects and which is recognized by the VCS.

- This baseline and monitoring methodology is similar to AMC0008 in that the sources of project emissions are nearly identical, because the potential uses for recovered methane are the same. However, the baseline emissions of methane from a CBM gas seep result from different physical causes than CMM emissions. ACM0008 applies to projects located at coal mines where the emissions are a result of mining operations while this methodology applies to projects located at CBM gas extraction operations where coal mining is not occurring. Furthermore, ACM0008 defines CBM as gas drainage which precedes the mining of a coal seam. This can be done to sell gas, but is mainly done to degasify the seam and make it safe for mining. The type of CBM production covered in this methodology strictly pertains to gas extraction from coal seams which aren't being mined. Fugitive methane emissions mitigated by projects covered by this methodology are a result of disturbing the equilibrium in the seam during gas extraction.

AM0009 V4*"Recovery and utilization of gas from oil wells that would otherwise be flared or vented"*

- This methodology applies to the capture and destruction of associated gas recovered during oil production. This gas is typically vented rather than put to beneficial use. Under the methodology proponents can generate power, compress and transport gas to processing facilities for upgrading.

- AM0009 is similar to this methodology in that it applies to the capture and destruction of methane which is produced as an undesirable by-product of the primary production of oil (or gas). A key difference between these methodologies and project types is that oil production operations utilizing AM0009 typically have the opportunity to recover methane at the well head; where methane recovered from CBM seeps require the use of additional capital equipment to intercept and aggregate methane from coal seam outcroppings.

This methodology also refers to the latest versions of the following CDM Executive Board approved tools:

- "Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion";
- "Tool to calculate project emissions from electricity consumption";
- "Combined tool to identify the baseline scenario and demonstrate additionality";
- "Tool to determine project emissions from flaring gases containing methane";
- "Tool to determine the emission factor for an electricity system".

Definitions

For the purpose of this methodology, the following definitions apply:

- **Coal Bed Methane (CBM).** Coal bed methane is the methane gas that resides inside underground coal seams, under pressure, and thus adsorbed to the coal.
- **Coal Bed Methane Production (CBM Production).** Coal bed methane production refers to the extraction of methane from underground coal seams, the subsequent treatment and injection of the gas into natural gas grids for utilization by end users. CBM extraction involves the removal of water or gas from the coal seam decreasing the hydrostatic pressure in order to cause methane to desorb from coal allowing for its removal. For the purposes of this methodology, the act of removing water from coal seams to produce methane constitutes a coal bed methane project.
- **"Up-dip".** The up-dip areas of the coal seam refer to the ground level elevations where coal outcroppings and methane gas seeps exist. Coal bed methane flows from down-dip to up-dip within the coal seam until it reaches the outcropping where it is released to the atmosphere as fugitive emissions.
- **"Down-dip".** The down-dip areas of the coal seam refer to the location where coal bed methane extraction typically takes place. Down-dip can be considered to be in the coal seam at 1000 to 4000 feet below the surface where high pressures readily allow for the removal of methane.
- **Produced water.** Water which is pumped and removed from a coal seam in order to liberate methane from the coal.
- **Coal bed methane seep**. Ground level fugitive methane emissions from coal seam outcroppings which originate from coal beds deep underground.
- **Gas interception system**. A system consisting of vertical or horizontal gas wells or gas collection membranes, vacuum compressors and gas transmission pipelines designed to intercept and recover gas in coal seams or at the ground surface prior to its release at coal outcroppings.
- **Fugitive methane**. Methane which is emitted to the atmosphere from underground coal seams and results partly from down dip coal bed methane production operations.

- **Monitoring Wells**. Wells which have been drilled into a coal seam to monitor water levels or other environmental conditions in the context of coal, oil or gas resource assessments. These wells may be repurposed and used as gas interception wells

Applicability conditions

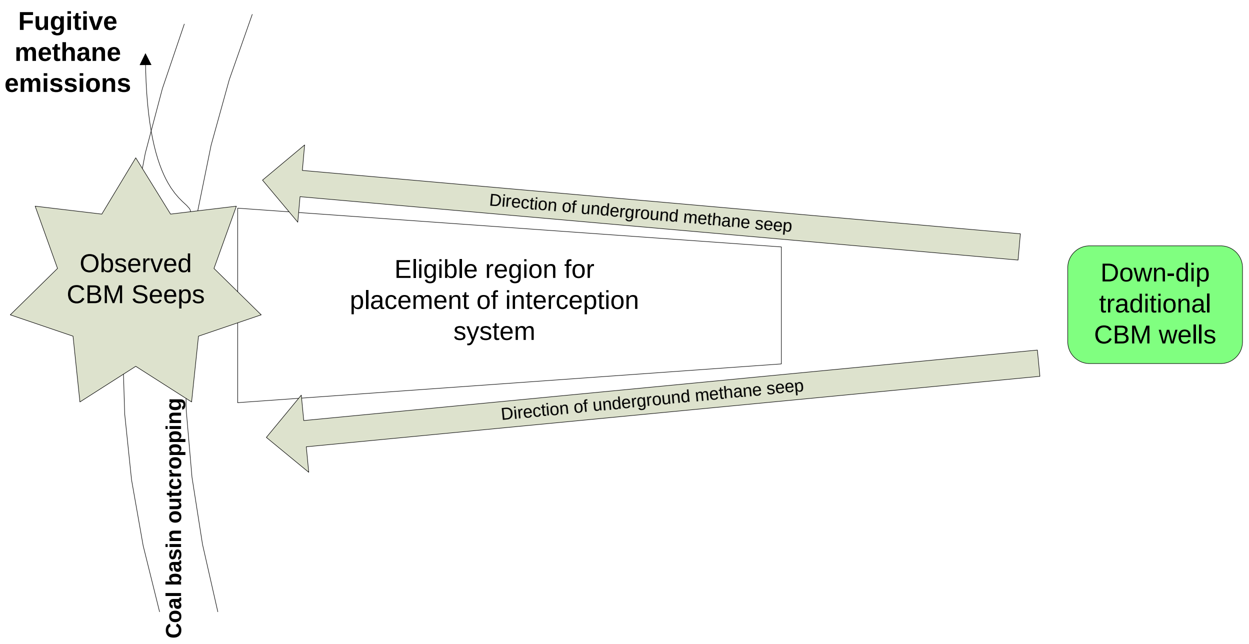
This methodology applies to project activities that capture and destroy methane which would otherwise be released to the atmosphere from coal bed outcroppings. Projects using this methodology will be implemented on coal seams or where exposed coal bed outcroppings exist having documented coal bed methane seeps. The methodology does not apply to methane captured at CBM extraction operations, but will apply to mitigation projects located between coal seam outcroppings and CBM operations.

The methodology applies to project activities that involve the use of any of the following extraction techniques:

- The use of gas drainage wells and monitoring wells, serving as gas interception wells, drilled near locations where methane gas seeps are present. Gas interception wells must be located between documented methane gas seeps at coal seam outcroppings and down dip traditional CBM wells. In other words, traditional CBM wells themselves cannot qualify as interception wells.

- The use of a gas membranes, surface covers or underground horizontal well fields to capture fugitive methane emissions at or just below the ground surface level.

Figure 1: Illustration showing that eligible interception system must be placed between CBM operations and or at locations of observed CBM gas seeps.



This methodology applies to fugitive methane capture project activities at or near known locations of methane gas seeps as well as the on-site or off-site utilization and destruction of captured methane. The baseline is the partial or total atmospheric release of the methane and the project activities include the following gas destruction scenarios:

- Captured methane is destroyed through flaring; and/or
- Captured methane is destroyed through utilization on-site to produce electricity, and/or thermal energy; and/or
- Captured methane is destroyed off-site through utilization by end users following injection into natural gas distribution grids.

This methodology **does not apply** to the following project activities:

- Methane captured at active traditional CBM extraction wells;
- Methane captured at active or abandoned coal mines;
- Degasification of methane from coal seams prior to coal mining activities.
- Injection of any fluid/gas "down-dip" of the location of methane interception in order to enhance methane capture;
- Removal of water from coal seams where gas interception systems are constructed in order to enhance gas recovery. If suitable and eligible wells which lie on the path from down-dip traditional CBM wells to up-dip exposed outcroppings and having documented methane gas seeps are flooded, they may be dewatered in order to be operated as interception wells.

II. BASELINE METHODOLOGY PROCEDURE

Project boundary

For the purpose of determining **project activity emissions**, project participants shall include:

- CO2 emissions from the combustion of methane in a flare, engine, power plant, or heat generation plant;
- CO2 emissions from the combustion of non-methane hydrocarbons (NMHCs), if they represent more than 1% by volume of the extracted coal mine gas:
- CO2 emissions from on-site fuel consumption due to the project activity, including transport of the fuel
- Fugitive methane emissions from on-site gas processing equipment
- Fugitive emissions from unburned methane and from gas treatment equipment

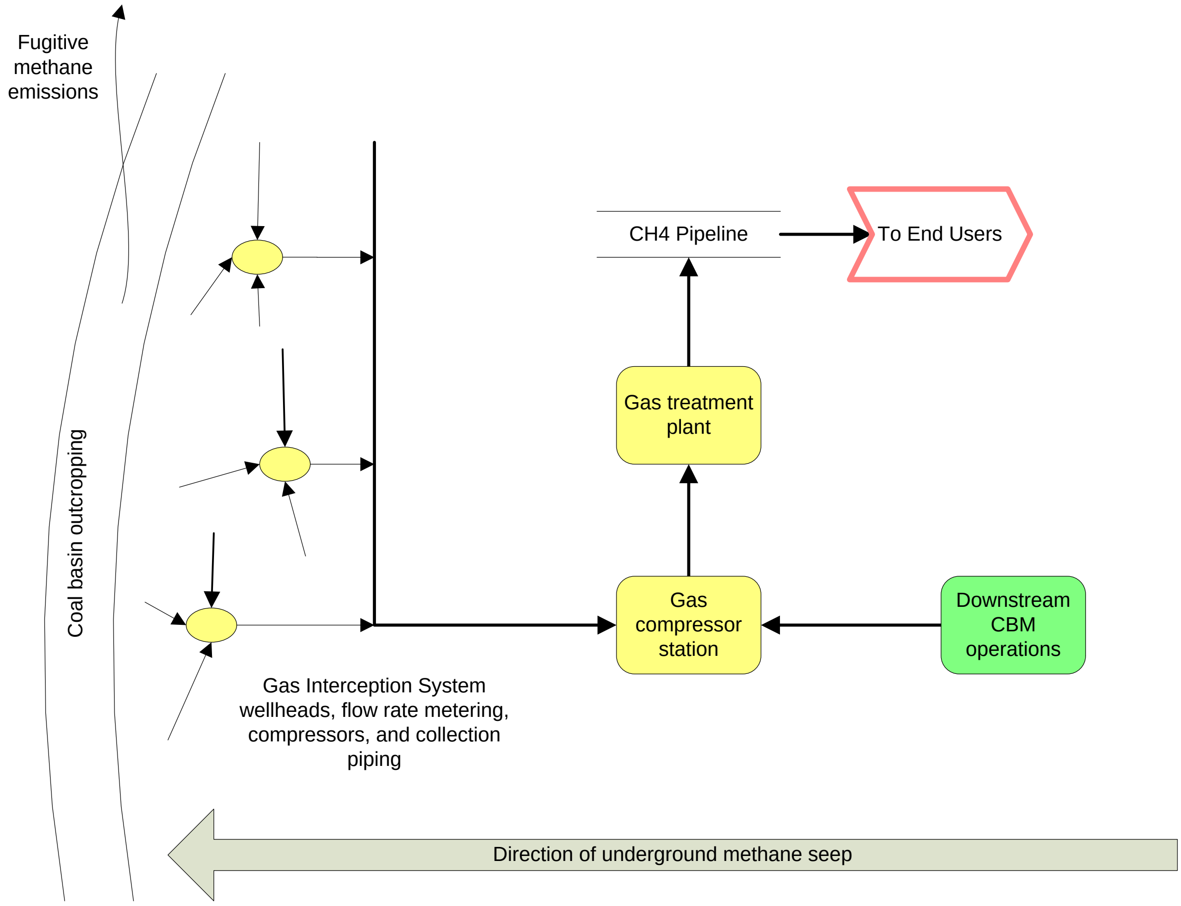
For the purpose of determining **baseline emissions**, project participants shall include the following emission sources:

- Fugitive CH_4 emissions from coal bed methane seeps;
- CO_2 emissions from the destruction of methane in the baseline scenario;
- CO_2 emissions from the production of heat and power (motive and electrical) that is replaced by the project activity.

The **spatial extent** of the project boundary encompasses:

- All equipment installed and used as part of the project activity for the extraction, compression, storage, and treatment of intercepted fugitive methane at the project site, and transport to an off-site user, including transport through natural gas distribution grids. Certain project equipment may be common between methane emissions mitigation projects and co-located CBM operations such as gas compression and treatment systems and in which case fugitive emission should be allocated appropriately
- Flaring, captive power and/or heat generation facilities installed and used as part of the project activity.
- Power plants connected to the electricity grid, where the project activity exports power to the grid, as per the definition of the project electricity system and connected electricity system given in "Tool to calculate the emission factor for an electricity system."
- Combustion of methane by end users connected to natural gas grids into which gas has been injected.

Figure 2: Hypothetical project schematic showing a gas interception system consisting of 9 vertical wellheads connected to three compression and metering systems to deliver raw gas to a common pipeline booster compressor station and gas treatment plant shared by an existing CBM operation



The greenhouse gases included in or excluded from the project boundary are shown in

Table 1.

Table 1: Emissions sources included in or excluded from the project boundary

Source		Gas	Included?	Justification / Explanation
Baseline	Emissions of methane from surface gas seeps at coal outcroppings	CO_2	No	Excluded for simplification. This is conservative.
		CH_4	Yes	This is the main source of emissions. The amount included in the baseline is the volume of methane captured by gas interception systems. This is not a total inventory of all methane seepage in the project's spatial boundary.
		N_2O	No	Excluded for simplification. This is conservative.

Source		Gas	Included?	Justification / Explanation
	Grid electricity generation (electricity provided to the grid)	CO_2	Yes	Only CO_2 emissions associated with the quantity of electricity exported to the grid which replaces marginal sources of electricity generation in the baseline will be counted; use of combined margin method as described in “Tool to calculate the emission factor for an electricity system” should be made.
		CH_4	No	Excluded for simplification. This is conservative.
		N_2O	No	Excluded for simplification. This is conservative.
	Captive power and/or heat and injection into gas grids	CO_2	Yes	Only when the baseline scenario involves such usage.
		CH_4	No	Excluded for simplification. This is conservative.
		N_2O	No	Excluded for simplification. This is conservative.
Project	On-site fuel and electricity consumption due to the project activity required to transport, compress, clean and upgrade the gas	CO_2	Yes	Energy consumption from equipment required for compressing, cleaning, upgrading and transporting gas will be accounted for. Energy use allocations will be made in cases where production facilities are shared between multiple operations.
		CH_4	No	Excluded for simplification. This emission source is assumed to be very small.
		N_2O	No	Excluded for simplification. This emission source is assumed to be very small.
	Emissions from methane destruction	CO_2	Yes	From the combustion of methane in a flare, flameless oxidation, or heat/power generation.
	Emissions from NMHC destruction	CO_2	Yes	From the combustion of NMHC in a flare of flameless oxidizer or heat/power generation, if NMHC accounts for more than 1% by volume of extracted gas.
	Fugitive emissions of un-combusted methane	CH_4	Yes	Small amounts of methane will remain unburned in flares.
	Fugitive methane emissions from on-site gas processing equipment	CH_4	Yes	If gas sales are metered upstream of a processing facility, then fugitive emissions are to be accounted for. If gas sales are metered downstream of a processing facility, then this source is not included.
	Fugitive methane emissions from gas supply pipeline	CH_4	No	Excluded for simplification. This emission source is assumed to be very small.
	Accidental methane release	CH_4	No	Excluded for simplification. This emission source is assumed to be very small.

Identification of the baseline scenario

Project participants should refer to the latest version of the "Combined tool to identify the baseline scenario and demonstrate additionality", and follow the specific guidance outlined below for step 1.

Step 1: Identify technically feasible options for capturing and/or utilizing fugitive CBM

Step 1: Options for gathering fugitive CBM

The baseline scenario alternatives should include all possible options that are technically feasible to collect CBM gas that would be emitted as fugitive methane and which comply with safety regulations. These options should include:

A. The use of vertical gas wells and collection systems drilled into the coal seam down dip of the location of known CBM gas seeps;

B. The use of surface membranes or covers or subsurface horizontal gas wells and collection systems;

C. Possible combinations of options A and B with relative shares of gas specified.

These options should include the VCS project activity not implemented as a VCS project.

Step 1b: Options for captured CBM gas treatment

A. Venting

B. Flaring of CBM

C. Use for grid power generation

D. Use for captive power generation

E. Use for heat generation

F. Feed into gas pipeline to be used as fuel for vehicles or heat/power generation

G. Possible combinations of options A to F with the relative shares of gas treated under each option specified

Step 1c: Options for energy production

The baseline scenario alternatives should include all possible options to generate electricity (grid, captive power generation using CBM or other fuels) and/or heat (using CBM or other fuels) and/or to fuel vehicles.

These options should include the proposed project activity that has however not been implemented as a VCS project activity.

Refer to "Combined tool to identify the baseline scenario and demonstrate additionality" v2.2 and complete step 2 to step 5.

Additionality

The additionality of the project activity shall be demonstrated and assessed using the latest version of the Clean Development Mechanism tool called “Combined tool to identify the baseline scenario and demonstrate additionality”.

Baseline emissions

Baseline emissions included in this methodology are:

- CO2 emissions resulting from the destruction of methane by flares and combustion in heat and / or power generation equipment
- CH_4 from free flowing gas seeps at locations where exposed coal outcroppings exist
- CO2 emissions from the generation of heat and / or power replaced by the project activity using recovered methane

Baseline emissions are calculated as follows:

$$\mathbf{BE_y = BE_{MD,y} + BE_{MR,y} + BE_{USE,y}} \quad \textbf{(1)}$$

Where:

BE_y	=	Baseline emissions in year *y* (t CO_2e/yr)
$BE_{MD,y}$	=	Baseline emissions from destruction of methane in the baseline scenario in year *y* (t CO_2e/yr)
$BE_{MR,y}$	=	Baseline emissions from release of methane into the atmosphere in year *y* that is avoided by the project activity (t CO_2e/yr)
$BE_{USE,y}$	=	Baseline emissions from the production of power, heat or supply to the gas grid replaced by the project activity in year *y* (t CO2e/yr)

Methane destruction in the baseline

Depending on the project type, methane destruction may already be occurring in the baseline in flares, flameless oxidation units or for the production or heat and/or power.

$$BE_{MD} = (CEF_{CH4} + r \times CEF_{NMHC}) \times \sum_i CM_{BL,i} \quad \textbf{(2)}$$

With:

$$r = PC_{NMHC}/PC_{CH4} \quad \textbf{(3)}$$

Where:

$BE_{MD,y}$	=	Baseline emissions from destruction of methane in the baseline scenario in year *y* (t CO_2e/yr)
CEF_{CH4}	=	Carbon emission factor for combusted methane (2.75 t CO_2/ t CH_4)
CEF_{NMHC}	=	Carbon emission factor for combusted non-methane hydrocarbons. This parameter should be obtained through periodical analysis of captured methane (t CO_2/ t NMHC)
$CM_{BL,i}$	=	Captured methane that is destroyed by use *i* in the baseline (t CH_4)
r	=	Relative proportion of NMHC compared to methane

PC_{CH4} = Concentration (in mass) of methane in extracted gas (%), measured on wet basis
PC_{NMHC} = NMHC concentration (in mass) in extracted gas (%) measured on wet basis

Methane released into the atmosphere

Fugitive methane emissions generated at down-dip traditional coal bed methane operations are freely flowing gases which migrate up-dip and are emitted at coal seam outcroppings at the ground surface. Intercepted fugitive coal bed methane is not gas that is stored in an underground reservoir or adsorbed in the coal seam below the wells. Because the gas captured by these interception systems is freely flowing up the coal seam, the effect of applying vacuum pressure to the wellhead will increase the volume of free flowing gas that can be evacuated by each well, thus increasing the methane interception rate and decreasing fugitive emissions at the outcropping. Since vacuum pumps do not act to liberate adsorbed methane or drain underground gas reservoirs, but rather act to increase the area of drainage for each interception well, all of the methane captured during a given monitoring period can be said to have been emitted at the outcropping in the absence of the project activity during the same monitoring period. Furthermore, it is true that because these wellheads do not desorb methane from coal or drain gas from reservoirs, they are only capturing up-dip migrating methane that would very soon be released to the atmosphere. In the absence of a methane interception system, this gas would be emitted to the atmosphere at coal seam outcroppings at the ground surface level.

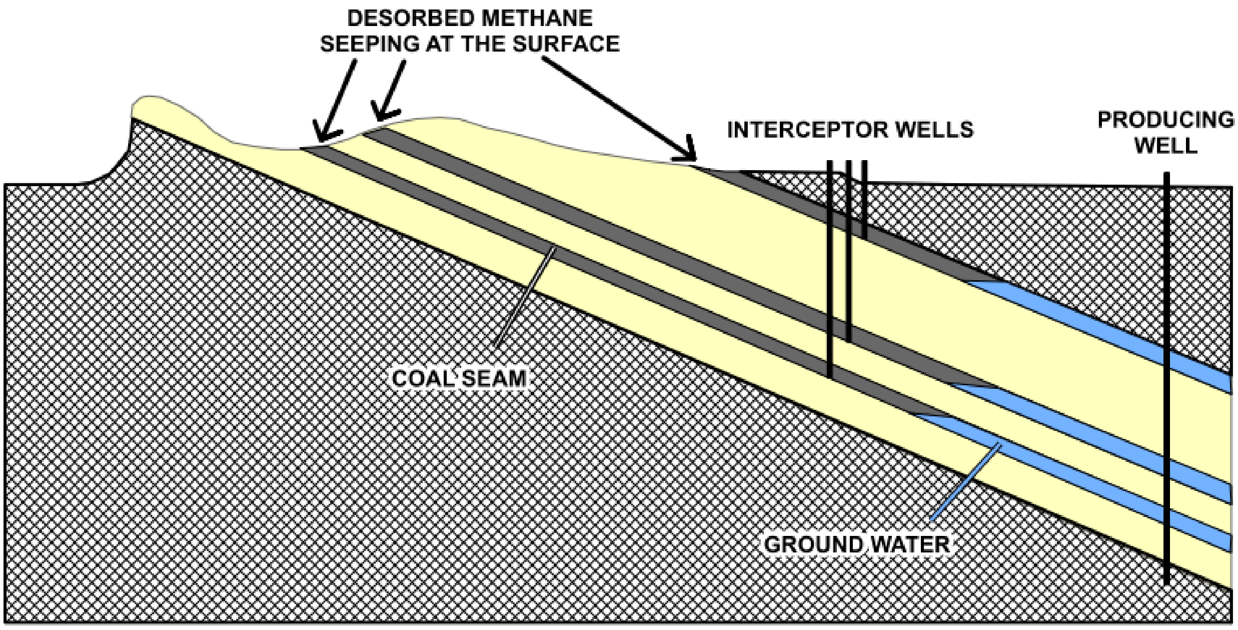
For the reasons discussed above, baseline emissions of methane for each monitoring period are determined using the volume of captured methane from the interception well system. Project proponents are required to submit documented evidence that coal bed methane gas seeps are present up-dip of where gas interception systems are placed.

This evidence may take either of the following forms:

- Arial LIDAR mappings showing the coal outcropping, the location of the proposed gas interception system and ground level methane concentration at the outcropping

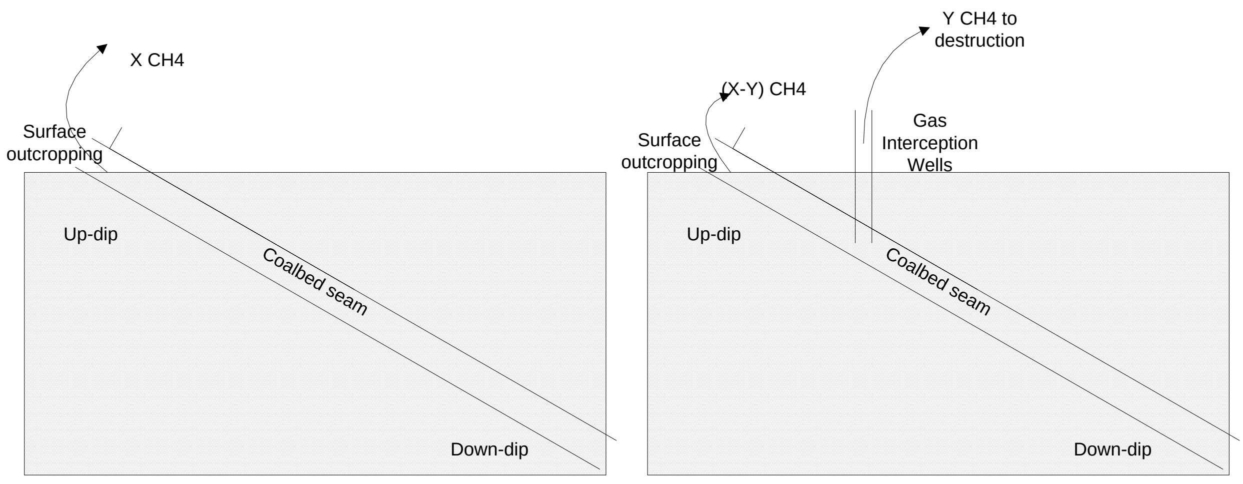
- Field surveys of the coal seam outcropping located up-dip of the interception systems using a methane flux chamber to establish ground level methane flux in mol/m^2-day

Figure 3: Cross section showing how gas interception system wells can be placed between CBM operations and the coal outcroppings where fugitive emissions occur in order to capture methane before it reaches the surface. Fugitive methane emitted at the surface can originate both from within the seam above the ground water level as well as from the main part of the CBM field below the ground water level



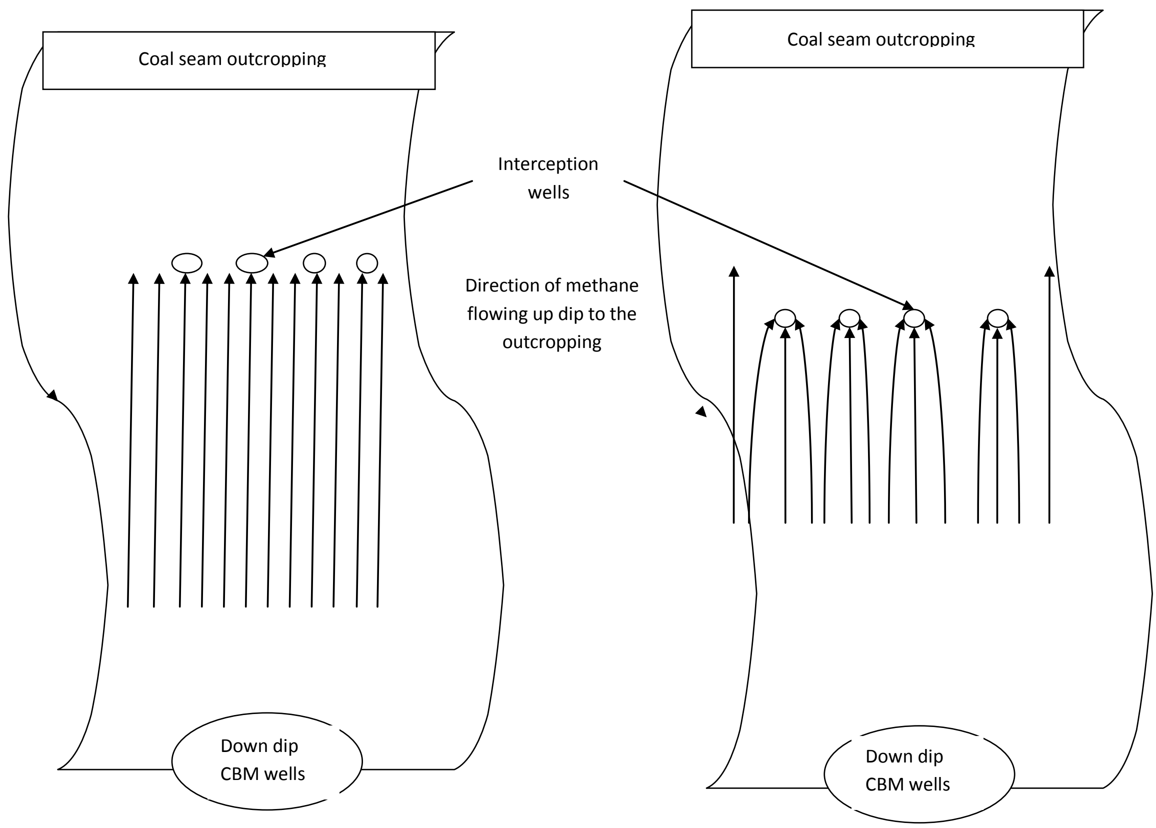
The interception system will only capture a portion of the fugitive methane emitted at the outcroppings (X CH4), as illustrated by Figure 4. The volume of gas captured by the system will be considered the baseline emissions (Y CH4) and fugitive methane eluding capture (X-Y CH4) is excluded from the project boundary, since this would be emitted in both the baseline and project cases. The figure also shows how methane flows from down-dip to up-dip before being emitted at the outcroppings. The down-dip traditional CBM extraction wells are excluded from the project boundary. Traditional CBM extraction wells and systems are ineligible as these systems act to free adsorbed methane from the coal seam and do not prevent fugitive methane emissions.

Figure 4: Schematic illustrating the change in fugitive emissions at the coal seam outcropping resulting from methane capture by the gas interception systems, in this case, vertical wells.



CBM interception wells or surface membranes will intercept and capture methane flowing up the coal seam to the outcropping or capture membrane at the outcropping in the absence of an imparted vacuum. However, the use of vacuum pumps will aid these wells by increasing their drainage area in the seam. Interception wells spaced laterally across the upward slowing coal seam will ideally capture methane flowing across the lateral line. This is illustrated in Figure 5.

Figure 5: Schematic, on the left, showing vertical gas interception wells placed in the flow of fugitive migrating CBM gas intercepting some of the gas. On the right, vacuum pressure is applied to the wells and increases each well's ability to drain gas horizontally across the seam, effectively allowing it to capture a larger share of the fugitive methane.



Baseline emissions from methane release to the atmosphere are calculated by subtracting methane which is captured and used in the baseline scenario from the methane which is captured and used by the project activity for each use.

$$BE_{MR} = GWP_{CH4} * \sum_i \left(CM_{PJ,i,y} - CM_{BL,i,y} \right) \quad \textbf{(4)}$$

Where:

BE_{MR}	=	Baseline emissions from release of methane into the atmosphere that is avoided by the project activity (t CO_2e)
$CM_{PJ,i,y}$	=	Captured methane that is destroyed by use *i* of the project activity in year *y* (tCH4)
$CM_{BL,i}$	=	Captured methane that would have been destroyed by use *i* in the baseline scenario in year *y* (t CH_4)

Emissions from power/heat generation replaced by project

$$BE_{USE} = GEN \times EF_{ELEC} + HEAT \times EF_{HEAT} + GAS \times EF_{GAS} \quad \textbf{(5)}$$

Where:

BE_{USE}	=	Baseline emissions from the production of power and / or heat or from destruction following injection into gas grids replaced by the project activity (t CO_2e/yr)
GEN	=	Electricity generated by project activity (MWh)
EF_{ELEC}	=	Emission factor of electricity (grid, captive or a combination) replaced by project (t CO_2/MWh)
HEAT	=	Heat generated by project activity (GJ)
EF_{HEAT}	=	Emission factor of heat production replaced by project activity (t CO_2/GJ)
GAS	=	Gas delivered to the gas grid (GJ)
EF_{GAS}	=	Emission factor for gas grid fuel replaced by the project activity (t CO_2/GJ)

Grid power emission factor

If the baseline scenario includes grid power supply that would be replaced by the project activity, the combined margin emission factor for replaced electricity shall be calculated using the "Tool to calculate the emission factor for an electricity system". However, projects based in the United States can choose to use emission factors corresponding to the applicable grid sub-region in the most recent version of the EPA's eGRID database.

Captive power emissions factor

If the baseline scenario includes captive power generation (either existing or new) that would be replaced by the project activity, the Emissions Factor for replaced electricity is calculated as follows:

$$EF_{captive} = \frac{EF_{CO2,i}}{Eff_{captive}} \times \frac{44}{12} \times \frac{3.6TJ}{1000MWh} \quad \textbf{(6)}$$

Where:

$EF_{captive}$	=	Emission factor for captive power generation (t CO_2e/MWh)
$EF_{CO2,i}$	=	CO2 emission factor of fuel used in captive power generation (tC/TJ)
$Eff_{captive}$	=	Efficiency of the captive power generation (%)
44/12	=	Carbon to Carbon Dioxide conversion factor
3.6/1000	=	TJ to MWh conversion factor

Combination of grid power and captive power emissions factor

If the baseline scenario selection determines that both captive and grid power would be used, then the emission factor for the baseline is the weighted average of the emissions factor for grid power and captive power.

$$EF_{ELEC} = s_{grid} \times EF_{grid} + s_{captive} \times EF_{captive} \quad \textbf{(7)}$$

Where:

EF_{ELEC}	=	CO_2 baseline emission factor for the electricity replaced due to the project activity (t CO_2/MWh)
EF_{grid}	=	CO_2 baseline emission factor for the grid electricity replaced due to the project activity (t CO_2/MWh)
$EF_{captive}$	=	CO_2 baseline emission factor for the captive electricity replaced due to the project activity (t CO_2/MWh)
s_{grid}	=	Share of facility electricity demand supplied by grid imports over the last 3 years (%)[1]
$s_{captive}$	=	Share of facility electricity demand supplied by captive power over the last 3 years (%)1

Heat generation emissions factor

If the baseline scenario includes heat generation (either existing or new) that is replaced by the project activity, the Emissions Factor for replaced heat generation is calculated as follows:

$$EF_{HEAT} = \frac{EF_{CO2,i}}{Eff_{heat}} \times \frac{44}{12} \times \frac{1TJ}{1000GJ} \quad \textbf{(8)}$$

Where:

EF_{HEAT}	=	Emission factor for heat generation (t CO_2/GJ)
$EF_{CO2,i}$	=	CO_2 emission factor of fuel used in heat generation (t C/TJ)
Eff_{heat}	=	Boiler efficiency of the heat generation (%)
44/12	=	Carbon to Carbon Dioxide conversion factor
1/1000	=	TJ to GJ conversion factor

To estimate the boiler efficiency, project propoents may choose between the following two options:

Option A:

Use the highest value among the following three values as a conservative approach:

(a) Measured efficiency prior to project implementation

(b) Measured efficiency during monitoring

(c) Manufacturer nameplate data for efficiency of the existing boilers

[1] If the facility is a new facility, then the share of grid versus import power determined to be the most likely baseline scenario should be used.

Option B:

Assume a boiler efficiency of 100% based on the net calorific values as a conservative approach.

Gas grid emission factor

The emission factor occuring in the baseline from the use of gas grid fuel replaced by the project activity is calculated as follows:

$$EF_{GAS} = EF_{CO2,i} \times \frac{1}{Eff_{processing}} \times \frac{44}{12} \times \frac{1TJ}{1000GJ} \quad \textbf{(9)}$$

Where:

EF_{GAS}	=	Emission factor for gas grid fuel replaced by the project activity (t CO_2/GJ)
$EF_{CO2,i}$	=	CO_2 emission factor for displaced gas grid fuel (t C/TJ)
$Eff_{processing}$	=	The efficiency of gas processing facilities used to treat captured methane onsite prior to injection into gas grids (%)[2]
44/12	=	Carbon to Carbon Dioxide conversion factor
1/1000	=	TJ to GJ conversion factor

Project emissions

Project emissions included in this methodology are:

- CO_2 emissions due to consumption of fossil fuels and electricity for the recovery, compression, and transportation of the raw gas stream;
- CO_2 emissions from the destruction of methane and non-methane hydrocarbons by flares, by heat and / or power generation equipment ;
- CH_4 emissions from incomplete combustion of raw gas by flares

Project emissions are calculated as follows:

$$PE_y = PE_{ME,y} + PE_{MD,y} + PE_{UM,y} \quad \textbf{(10)}$$

Where:

PE_y	=	Project emissions in year *y* (t CO_2e/yr)
$PE_{ME,y}$	=	Project emissions from energy use to capture and use methane in year *y* (t CO_2e/yr)
$PE_{MD,y}$	=	Project emissions from methane destroyed in year *y* (t CO_2e/yr)
$PE_{UM,y}$	=	Project emissions from un-combusted methane in year *y* (t CO_2e/yr)

[2] This efficiency refers to the combined efficiency of upgrading and injection into gas grids where resulting losses are fugitive emissions, gas flared and / or used for heat and power onsite. If gas delivered to gas grids is metered after the processing facility, then $Eff_{processing}$ is equal to 1. When gas sales to grid are metered before processing, $Eff_{processing}$ should reflect the fugitive emissions by the processing facility used.

Combustion emissions from additional energy required for methane capture and use

Additional energy may be used for the capture, compression, clean-up, and use or destruction of methane. Emissions from this energy use should be included as project emissions.

$$PE_{ME} = CONS_{ELEC,PJ} \times CEF_{ELEC} + CONS_{HEAT,PJ} \times CEF_{HEAT} + CONS_{FossFuelPJ} \times CEF_{FossFuel} \quad \textbf{(11)}$$

Where:

PE_{ME}	=	Project emissions from energy use to capture and use or destroy methane (t CO_2/yr)
$CONS_{ELEC,PJ}$	=	Additional electricity consumption for capture and use or destruction of methane, if any (MWh)[3]
CEF_{ELEC}	=	Carbon emissions factor of electricity used by the process equipment (t CO_2/MWh)
$CONS_{HEAT,PJ}$	=	Additional heat consumption for capture and use or destruction of methane, if any (GJ)
CEF_{HEAT}	=	Carbon emissions factor of heat used by the process equipment (t CO_2/GJ)
$CONS_{FossFuel,PJ}$	=	Additional fossil fuel consumption for capture and use or destruction of methane, if any (GJ)
$CEF_{FossFuel}$	=	Carbon emissions factor of fossil fuel used by the process equipment (t CO_2/GJ)

For electricity emissions factor, the same formulae are used as in the calculations of baseline emissions. In other words, if the source of power for the process equipment is the grid, then the formulae from "Tool to calculate the emission factor for an electricity system" for calculating the combined margin emissions factor are used. If the source of power for the process equipment is captive power generation, then the emissions factor is calculated based on the emission factor for the fuel used and efficiency of the captive power plant.

For the heat generation emission factor, the same formulae are used as in the calculations of baseline emissions. In other words, the boiler efficiency and the emission factor for the fuel used are the basis of the emissions factor.

Combustion emissions from use of captured methane

When the captured methane is burned in a flare, heat or power plant, mechanical power generation equipment, or oxidized in a flameless oxidation unit, combustion emissions are released. In addition, if NMHC account for more than 1% by volume of the extracted raw gas, combustion emissions from these gases should also be included. Captured methane delivered to heat and / or power generation is equal to the methane destroyed by these end uses since IPCC 2006 assumes complete combustion in these end uses.

$$PE_{MD} = (MD_{FL} + CM_{ELEC} + CM_{MECH} + CM_{HEAT} + CM_{GAS}) \times (CEF_{CH4} + r \times CEF_{NMHC}) \quad \textbf{(12)}$$

With:

$$r = PC_{NMHC}/PC_{CH4} \quad \textbf{(13)}$$

Where:[4]

PE_{MD}	=	Project emissions from destruction of captured methane (t CO_2/yr)
MD_{FL}	=	Methane destroyed through flaring (t CH_4)

[3] For example, electricity may be required to run pumps, motors, compressors, and gas clean-up equipment
[4] Note that throughout this baseline methodology, it is assumed that measured quantities of raw gas are converted to tones of methane using the measured concentration of the extracted raw gas and the density of methane.

CM_{ELEC} = Captured methane destroyed through electrical power generation (t CH_4)
CM_{MECH} = Captured methane destroyed through mechanical power generation (tCH4)
CM_{HEAT} = Captured methane destroyed through heat generation (t CH_4)
CM_{GAS} = Captured methane destroyed after being supplied to natural gas grid (t CH_4)
CEF_{CH4} = Carbon emissions factor for combusted methane (2.75 t CO_2/ t CH_4)
CEF_{NMHC} = Carbon emissions factor for combusted non-methane hydrocarbons (the concentration varies and, therefore, to be obtained through periodical analysis of captured methane) (t CO_2/ t NMHC)
r = Relative proportion of NMHC compared to methane
PC_{CH4} = Concentration (in mass) of methane in extracted gas (%), measured on wet basis
PC_{NMHC} = NMHC concentration (in mass) in extracted gas (%) measured on wet basis

In each end-use, the amount of gas destroyed depends on the efficiency of combustion of each end use.

$$MD_{FL} = CM_{FL} - \left(PE_{flare} / GWP_{CH4}\right) \quad \textbf{(14)}$$

Where:
MD_{FL} = Methane destroyed through flaring (t CH_4)
CM_{FL} = Captured methane delivered to flare (t CH_4)
PE_{flare} = Project emissions of non-combusted CH_4, expressed in terms of CO_2e, from flaring of the raw gas stream (t CO_2e)
GWP_{CH4} = Global warming potential of methane (21 t CO_2e/tCH_4)

The project emissions of non-combusted CH_4 expressed in terms of CO_2e from flaring of the raw gas stream (PE_{flare}) shall be calculated following the procedures described in the "Tool to determine project emissions from flaring gases containing methane". PE_{flare} can be calculated on an annual basis or for the required period of time using this tool.

Un-combusted methane from project activity

Not all of the methane sent to the flare will be combusted, so a small amount will escape to the atmosphere. These emissions are calculated using the following:

$$PE_{UM} = PE_{flare} \quad \textbf{(15)}$$

Where:
PE_{UM} = Project emissions from un-combusted methane (t CO_2e)
PE_{flare} = Project emissions of non-combusted CH4 expressed in terms of CO2e from flaring of the raw gas stream (t CO_2e)

The project emissions from flaring of the raw gas stream (PE_{flare}) shall be calculated following the procedures described in the "Tool to determine project emissions from flaring gases containing methane". PE_{flare} can be calculated on an annual basis or for the required period of time using this tool.

Leakage

There are no known sources of emissions leakage caused by the project type.

Emission Reductions

Emission reductions are calculated as follows:

$$ER_y = BE_y - PE_y - LE_y \quad \textbf{(16)}$$

Where:

ER_y = Emission reductions in year *y* (t CO_2e/yr)
BE_y = Baseline emissions in year *y* (t CO_2e/yr)
PE_y = Project emissions in year *y* (t CO_2/yr)
LE_y = Leakage emissions in year *y* (t CO_2/yr)

III. MONITORING METHODOLOGY

All data collected as part of monitoring should be archived electronically and be kept at least for 2 years after the end of the last crediting period. 100% of the data should be monitored if not indicated otherwise in the tables below. All measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

In addition, the monitoring provisions in the tools referred to in this methodology apply.

Data and parameters not monitored

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

Data / parameter:	$CM_{BL,i}$
Data unit:	tCH4
Description:	Captured methane that would have been destroyed by use *i* in the baseline
Source of data:	
Measurement procedures (if any):	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	$CM_{PJ,i}$
Data unit:	tCH4
Description:	Captured methane destroyed by use *i* in the project activity
Source of data:	
Measurement procedures (if any):	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	EF_{HEAT}
Data unit:	t CO_2/GJ
Description:	The emission factor of heat replaced by the project
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data / parameter:	EF_{GAS}
Data unit:	t CO_2/GJ
Description:	The emission factor of gas grid fuel replaced by the project
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data / parameter:	$EF_{CO2,i}$
Data unit:	t C/TJ
Description:	The emission factor of fuel used in captive power generation
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data / parameter:	CEF_{ELEC}
Data unit:	t CO_2/MWh
Description:	Carbon emission factor for electricity used by the project activity
Source of data:	Calculated using the combined margin method in the "Tool to calculate the emission factor for an electricity system". US based projects can use the EPA's eGRID database for the grid sub-region in which the project is located.
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data / parameter:	$CEF_{FossFuel}$
Data unit:	t CO_2/GJ
Description:	Carbon emission factor for fossil fuel used by the project activity to capture and use or destroy methane
Source of Data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data / parameter:	CEF_{CH4}
Data unit:	t CO_2/ t CH_4
Description:	Carbon emission factor for combusted methane captured by the project activity
Source of Data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	Set at 2.75 t CO_2/ t CH_4

Data / parameter:	CEF_{HEAT}
Data unit:	t CO_2/GJ
Description:	Carbon emission factor of heat used by the project activity
Source of Data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	*Ex ante*
QA/QC procedures:	
Any comment:	

Data and parameters monitored

Data / parameter:	GEN
Data unit:	MWh
Description:	Electricity generated by the project activity
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuous
QA/QC procedures:	
Any comment:	

Data / parameter:	HEAT
Data unit:	GJ
Description:	Heat generated by the project activity
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuous
QA/QC procedures:	
Any comment:	

Data / parameter:	GAS
Data unit:	GJ
Description:	Gas delivered to natural gas distribution grids and supplied to end users by the project activity.
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuous
QA/QC procedures:	
Any comment:	Gas flow meters will measure methane injected into pipelines. The energy content of methane is determined by converting this volumetric measurement to energy. Utility sales invoices should be used where available.

Data / parameter:	EF_{ELEC}
Data unit:	t CO_2/MWh
Description:	The emission factor of electricity replaced by the project
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Annually or *Ex ante*
QA/QC procedures:	
Any comment:	If grid electricity is replaced by the project, the combined margin emission factor should be calculated annually using “Tool to calculate the emission factor for an electricity system” For projects based in the United States, emission factors from the US EPA’s eGRID database corresponding to the gird sub-region in which the project is located can be used.

Data / parameter:	$Eff_{captive}$
Data unit:	%
Description:	The efficiency of captive power generation
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Annually
QA/QC procedures:	
Any comment:	Annual average electrical efficiency based on the lower heating value of the fuel

Data / parameter:	Eff_{heat}
Data unit:	%
Description:	Boiler efficiency of the heat generation
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Annually
QA/QC procedures:	
Any comment:	Annual average thermal efficiency based on the lower heating value of the fuel

Data / parameter:	$Eff_{processing}$
Data unit:	%
Description:	The efficiency of gas processing including cleanup, compression, and upgrading prior to injection into gas grids. Combined efficiency including losses for use as fuel, flaring, venting and fugitive emissions. Only to be used if gas sales metered before processing facility.
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously or Annually
QA/QC procedures:	
Any comment:	

Data / parameter:	$CONS_{ELEC,PJ}$
Data unit:	MWh
Description:	Additional electricity consumption for capture and use or destruction of methane
Source of data:	Project site
Measurement procedures (if any):	Taken from machinery data acquisition systems or utility bills
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	

Data / parameter:	$CONS_{HEAT,PJ}$
Data unit:	GJ
Description:	Additional heat consumption for capture and use or destruction of methane
Source of data:	Project site
Measurement procedures (if any):	Taken from machinery data acquisition systems or utility bills
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	

Data / parameter:	$CONS_{FossFuel,PJ}$
Data unit:	GJ
Description:	Additional fossil fuel consumption for capture and use or destruction of methane
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	

Data / parameter:	CEF_{NMHC}
Data unit:	t CO_2/ t NMHC
Description:	Carbon emission factor for combusted non methane hydrocarbons captured by the project activity
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Annually
QA/QC procedures:	
Any comment:	To be obtained through annual analysis of the fractional composition of captured gas delivered to end users

Data / parameter:	CM_{FL}
Data unit:	t CH_4
Description:	Captured methane delivered to a flare and combusted
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	CM_{ELEC}
Data unit:	t CH_4
Description:	Captured methane delivered to a power plant
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	CM_{MECH}
Data unit:	t CH_4
Description:	Captured methane destroyed through mechanical energy generation
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	CM_{HEAT}
Data unit:	t CH_4
Description:	Captured methane delivered to a heat plant
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	CM_{GAS}
Data unit:	t CH_4
Description:	Captured methane delivered to a natural gas grid
Source of data:	Project site
Measurement procedures (if any):	
Monitoring frequency:	Continuously
QA/QC procedures:	
Any comment:	Flow meters will record gas volumes, pressure and temperature. Metered gas volumes are converted to mass using a density of 0.67 kg/m^3 under normal conditions of temperature and pressure.

Data / parameter:	PC_{CH4}
Data unit:	%
Description:	Concentration (in mass) of methane in captured gas (%), measured on wet basis
Source of data:	Concentration meters, optical and calorific
Measurement procedures (if any):	
Monitoring frequency:	Hourly/Daily
QA/QC procedures:	
Any comment:	To be measured on wet basis

Data / parameter:	PC_{NMHC}
Data unit:	%
Description:	Concentration (in mass) of non-methane hydrocarbons in extracted gas (%), measured on wet basis
Source of data:	Concentration meters, optical and calorific
Measurement procedures (if any):	
Monitoring frequency:	Annually
QA/QC procedures:	
Any comment:	To be measured on wet basis

VERIFIED CARBON STANDARD

TABLE OF CONTENTS

SOURCES

This methodology is based on the draft REDD project description for the "Reserva do Juma Conservation Project" in Amazonas (Brazil), whose *baseline* study, monitoring and project design documents were prepared by IDESAM, the Amazonas Sustainable Foundation (FAS) and the Government of Amazonas (SDS/SEPLAN-AM), with inputs and review from a selected group of experts and scientists in Brazil.

The methodology is an adaptation to all kinds of "*Unplanned Deforestation*" of the draft methodology for "*Mosaic Deforestation*" developed by the BioCarbon Fund for the REDD project activity "Ankeniheny - Zahamena Biological Corridor" in Madagascar, whose baseline study, monitoring and project design documents are being prepared by the Ministry of the Environment, Water, Forests and Tourism of Madagascar with assistance of Conservation International and the International Bank for Reconstruction and Development as Trustee of the BioCarbon Fund.

SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology is for estimating and monitoring greenhouse gas (GHG) emissions of project activities that avoid unplanned deforestation (AUD). It also gives the option to account for carbon stock enhancements in forests that would be deforested in the baseline case, when these are measurable and significant. Credits for reducing GHG emissions from avoided degradation are excluded in this methodology.

The methodology has no geographic restrictions and is applicable globally under the following conditions:

a) Baseline activities may include planned or unplanned logging for timber, fuel-wood collection, charcoal production, agricultural and grazing activities as long as the category is unplanned deforestation according to the most recent VCS AFOLU guidelines.

b) Project activities may include one or a combination of the eligible categories defined in the description of the scope of the methodology (see table 1 and figure 2).

c) The project area can include different types of forest, such as, but not limited to, old-growth forest, degraded forest, secondary forests, planted forests and agro-forestry systems meeting the definition of "forest".

d) At project commencement, the project area shall include only land qualifying as "forest" for a minimum of 10 years prior to the project start date.

e) The project area can include forested wetlands (such as bottomland forests, floodplain forests, mangrove forests) as long as they do not grow on peat. Peat shall be defined as organic soils with at least 65% organic matter and a minimum thickness of 50 cm. If the project area includes a forested wetlands growing on peat (e.g. peat swamp forests), this methodology is not applicable.

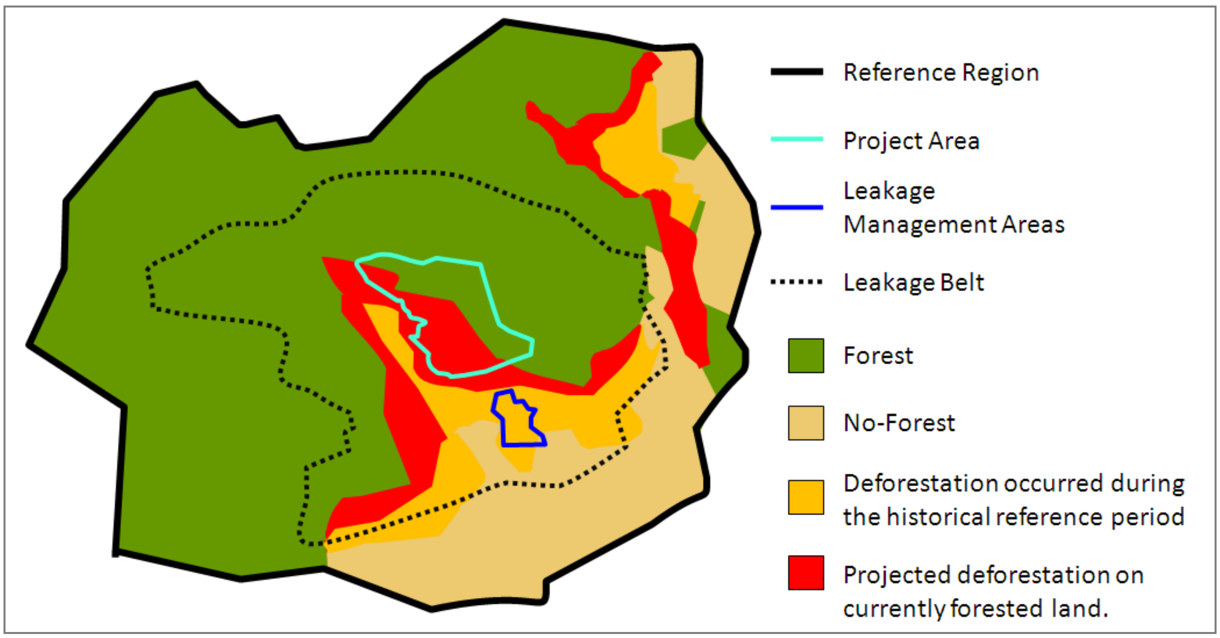
The methodology requires the use of existing deforestation baselines if these meet the applicability criteria of the methodology.

Leakage in this methodology is subject to monitoring, reporting, verification and accounting (MRV-A). However, if the project area is located within a broader sub-national or national region that is subject to MRV-A of GHG emissions from deforestation under a VCS or UNFCCC registered (and VCS endorsed) program (= "jurisdictional program"), leakage may be subject to special provisions because any change in carbon stocks or increase in GHG emissions outside the project area would be subject to MRV-A under the broader jurisdictional program. In such cases, the most recent VCS *Jurisdictional and Nested REDD+ (JNR) Requirements* shall be applied.

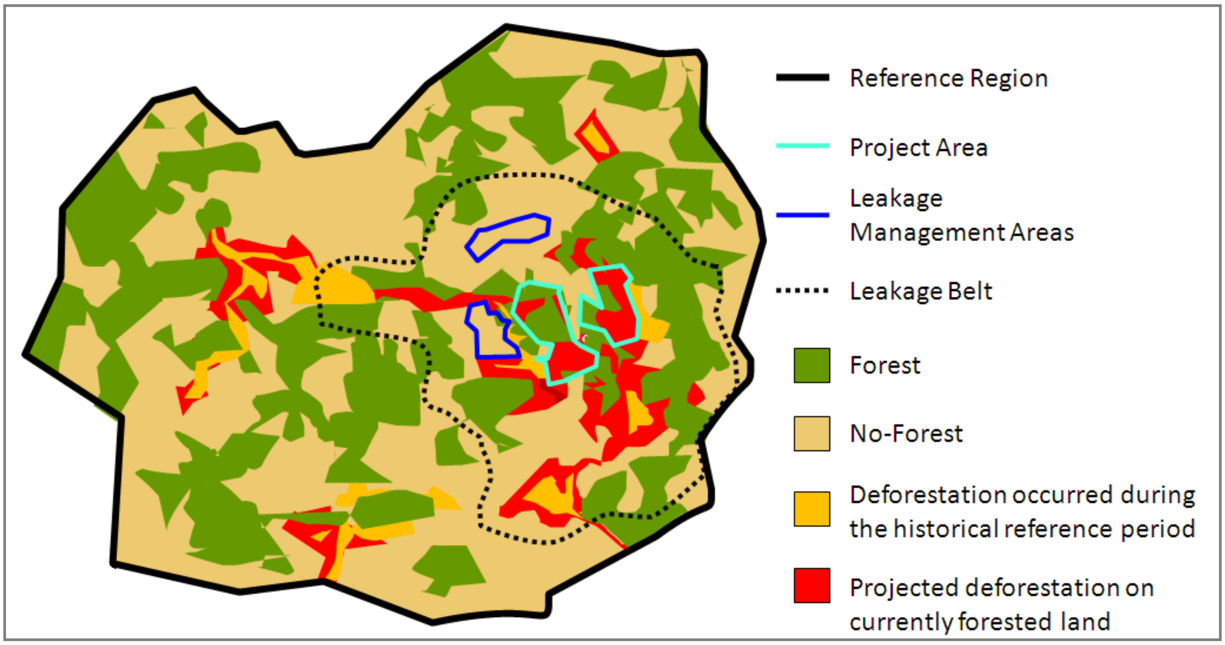
The methodology defines four spatial domains: a broad "reference region", the "project area", a "leakage belt", and a "leakage management area". The project area, leakage belt and leakage management areas are subsets of the reference region and are always spatially distinct (not overlapping) areas (see figure 1).

Figure 1. Spatial domains considered in this methodology

a) Frontier configuration



b) Mosaic configuration



- The "reference region" is the analytical domain from which information on historical deforestation is extracted and projected into the future to spatially locate the area that will be deforested in the baseline case.
- The "project area" is the area (or areas) under the control of the project participants in which the AUD project activity will be implemented and GHG emission reductions accounted.
- The "leakage belt" is the area where any deforestation above the baseline projection will be considered leakage. It must be defined only if MRV-A for leakage is required.
- The "leakage management area" is the area (or areas) specifically designed to implement activities that reduce the risk of activity displacement leakage. These are areas dedicated to enhanced crop-land and grazing land management, agro-forestry, silvo-pastoral activities and reforestation activities. At the project start date, leakage management areas shall be non-forest land.

The baseline projections must be revisited every 10 years and adjusted, as necessary, based on land-use and land-cover changes observed during the past period and changes at the level of agents, driver and underlying causes of deforestation, which are subject to monitoring. The period of time during which a validated baseline must not be reassessed is called "fixed baseline period" in this methodology. The baseline may be reassessed before the fixed 10 year baseline expires only if an applicable jurisdictional baseline becomes available.

The boundary of the leakage belt must be revisited at the end of each fixed baseline period and any time when an AFOLU project located in the project´s leakage belt area is registered under the VCS. In such case, the project area of the new AFOLU project must be excluded from the leakage belt area from the date of its registration[1]. Changes in the leakage belt boundary shall be monitored and are subject to VCS verification.

Emissions of non-CO_2 gases in the baseline are conservatively omitted, except CH_4 emissions from biomass burning, which can be counted when fire is the main technology used to deforest and when the project proponent considers that ignoring this source of emissions would substantially underestimate the baseline emissions. However, CH_4 emissions from forest fires in the project case must be accounted when they are significant.

If leakage must be estimated and accounted, then the methodology considers two potential sources of leakage:

(i) If more deforestation in the leakage belt area is observed during project implementation, this will be considered as activity displacement leakage, and the decrease in carbon stocks and increase of GHG emissions (if emissions from forest burning are included in the baseline) must be subtracted in the calculation of the project's net anthropogenic GHG emissions reductions.

(ii) If leakage prevention measures include tree planting, agricultural intensification, fertilization, fodder production and/or other measures to enhance cropland and grazing land areas in leakage management areas, then any decrease in carbon stocks and increase in GHG emissions associated with these activities is estimated and subtracted in the calculation of the project's net anthropogenic emissions reductions.

Any decrease in carbon stock or increase in GHG emissions attributed to the project activity must be accounted when it is significant, otherwise it can be neglected. Significance in this methodology is assessed using the most recent CDM-approved and VCS-endorsed version of the "Tool for testing significance of GHG emissions in A/R CDM project activities"[2].

PART 1 – SCOPE, APPLICABILITY CONDITIONS AND ADDITIONALITY

1 SCOPE OF THE METHODOLOGY

This methodology is for estimating and monitoring GHG emissions of project activities that avoid unplanned deforestation (AUD). The forest landscape configuration can be mosaic, frontier or a transition between the two. Carbon stock enhancements in forests that would be deforested in the baseline case can also be accounted under this methodology. However, credits for reducing GHG emissions from avoided degradation are excluded.

Baseline activities and project activities may include harvesting of timber, fuel-wood collection and charcoal production[3]. Project activities may include some level of planned deforestation, but planned deforestation is excluded from the baseline.

---

1 This is to avoid double counting of emissions when a new VCS AFOLU registered project and/or its leakage belt are located (partially or totally) in the leakage belt of the proposed AUD project.

2 Available at: http://cdm.unfccc.int/EB/031/eb31_repan16.pdf

3 Accounting for carbon stock decrease due to timber harvesting, fuel-wood collection and charcoal production is mandatory in both the baseline and project scenarios if the decrease is significant. The increase of carbon stocks in forests that would be deforested in absence of the project activity is optional in this methodology and can conservatively be omitted.

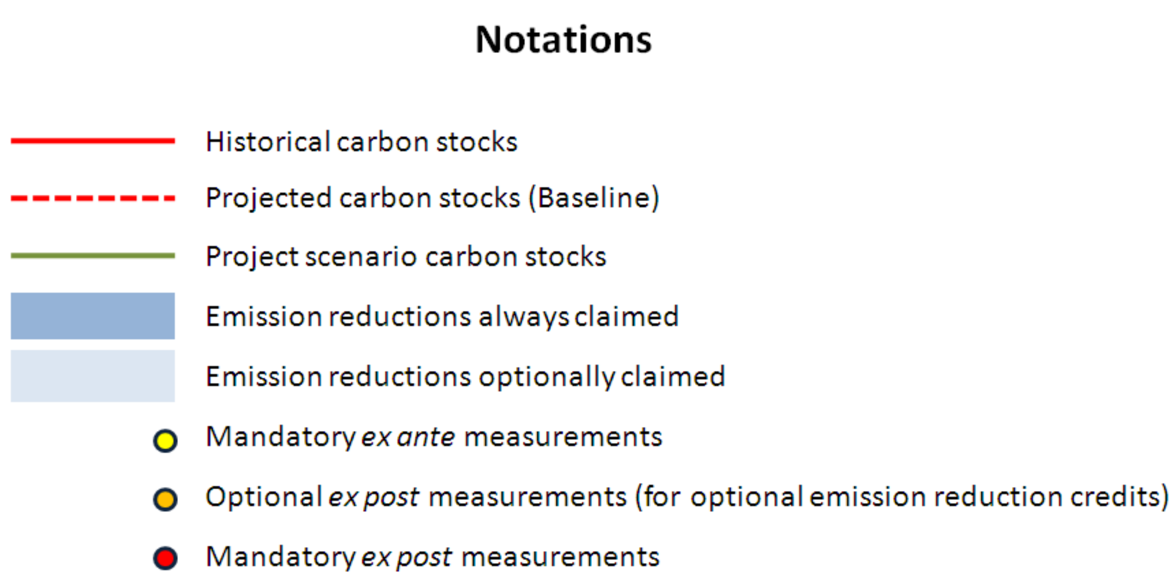
The eligible categories of project activity covered by this methodology are represented with the letters **A** to **H** in table 1 and figure 2.

Table 1. Scope of the methodology

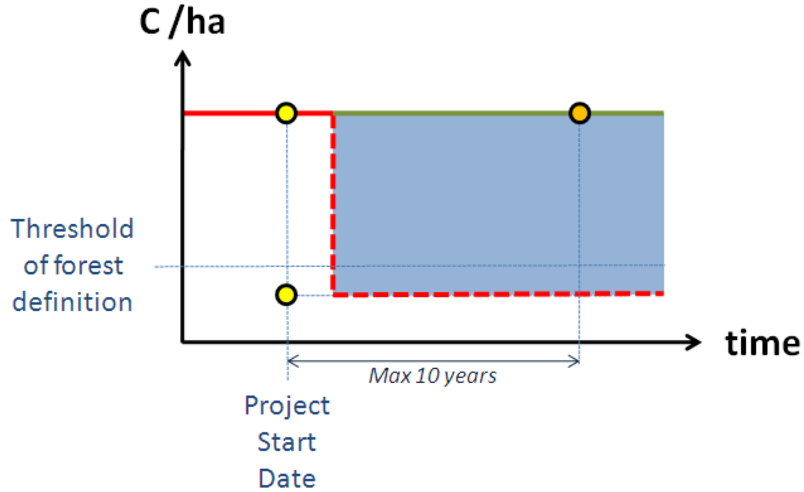
			PROJECT ACTIVITY	
			Protection without logging, fuel wood collection or charcoal production	Protection with controlled logging, fuel wood collection or charcoal production
BASELINE	Deforestation	Old-growth without logging	**A**	**B**
		Old-growth with logging	**C**[1]	**D**[1]
		Degraded and still degrading	**E**[1]	**F**[1]
		Secondary growing	**G**[1]	**H**[1]
	No-deforestation[2]	Old-growth without logging	No change	Degradation
		Old-growth with logging	IFM	IFM-RIL
		Degraded and still degrading	IFM	IFM
		Secondary growing	No change	Degradation

1. Accounting for carbon stock increase in the project scenario is optional and can conservatively be omitted.
2. If the baseline is not deforestation, the change in carbon stocks is not covered in this methodology.

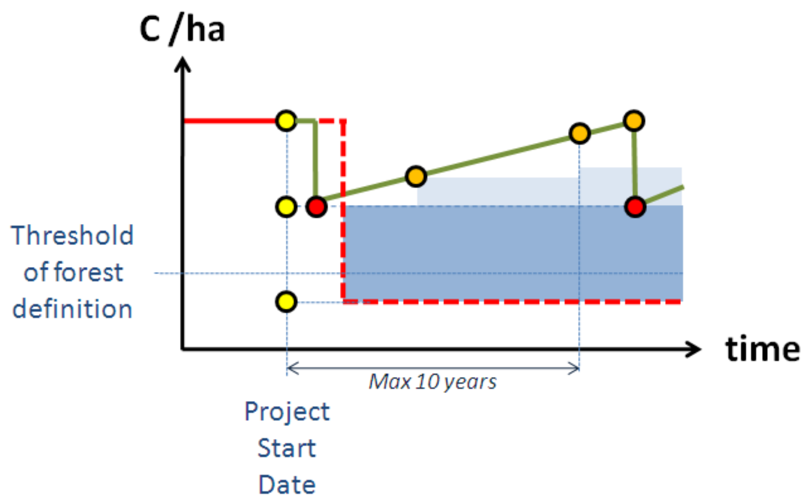
Figure 2. Categories included in the scope of this methodology



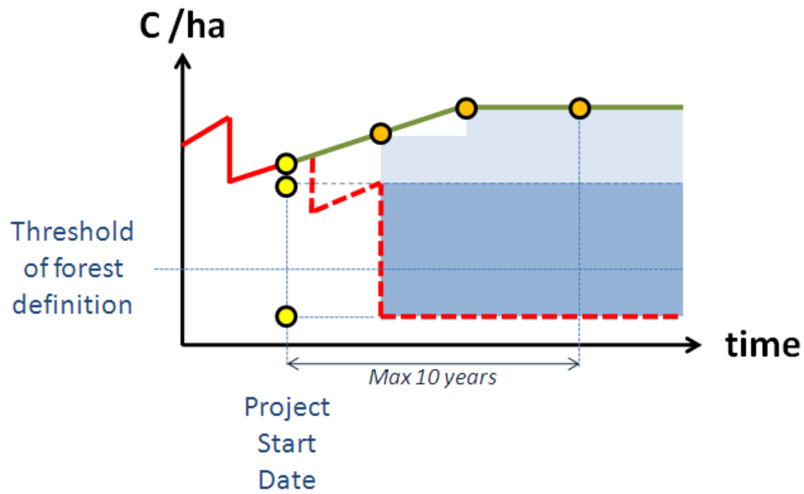
A - Avoided Deforestation without Logging



B – Avoided Deforestation with Logging in the Project Case
+ Carbon Stock Increase (optional)

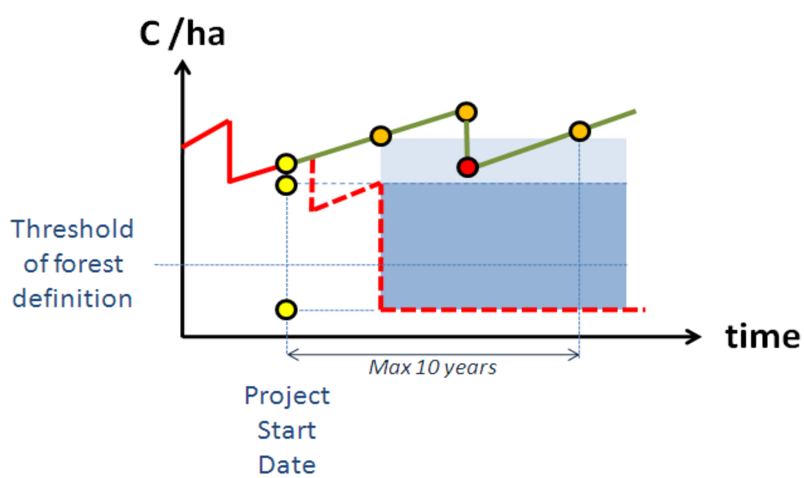


C – Avoided Deforestation with Logging Suppression
+ Carbon Stock Increase (optional)



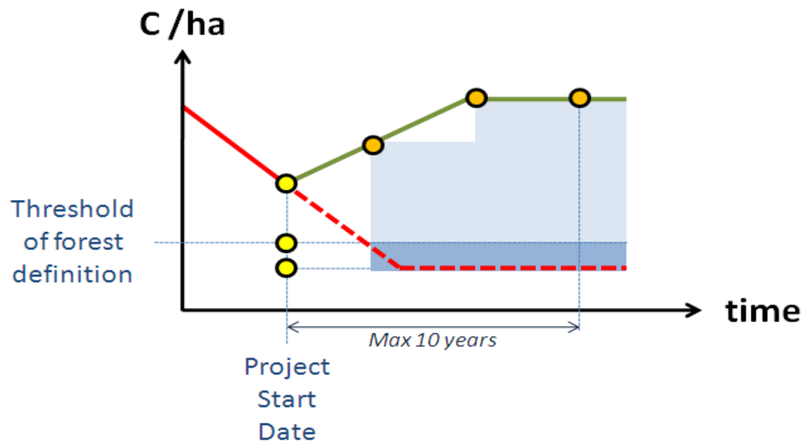
Note: Avoided degradation occurring prior to deforestation is conservatively not claimed.

D – Avoided Deforestation with Logging in the Baseline and Project Cases
+ Carbon Stock Increase (optional)



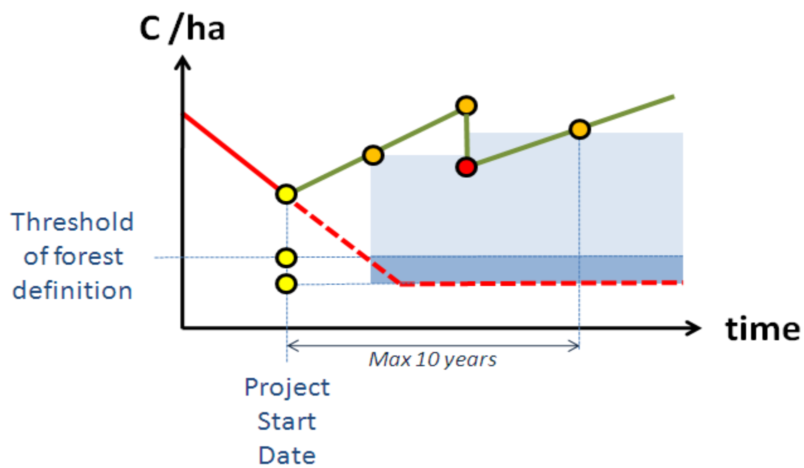
Note: Avoided degradation occurring prior to deforestation is conservatively not claimed.

E - Avoided Deforestation of Degrading Forest
+ Carbon Stock Increase (optional)



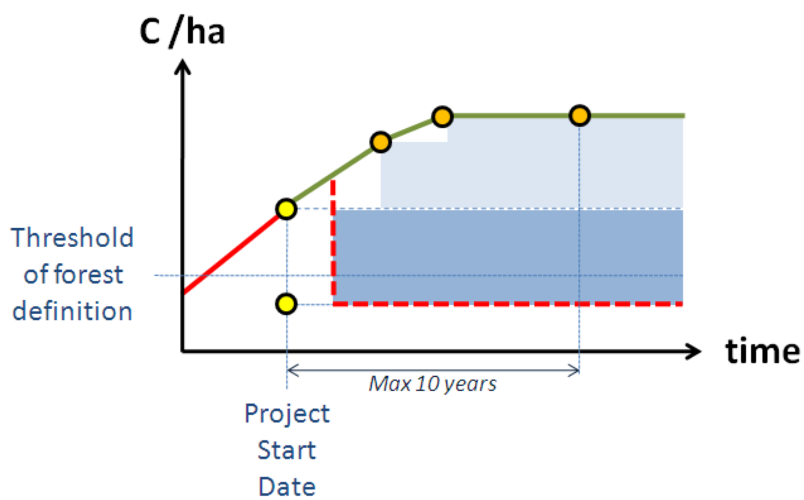
<u>Note:</u> Avoided degradation occurring prior to deforestation is conservatively not claimed.

F - Avoided Deforestation of Degrading Forest with Logging in the Project Case
+ Carbon Stock Increase (optional)

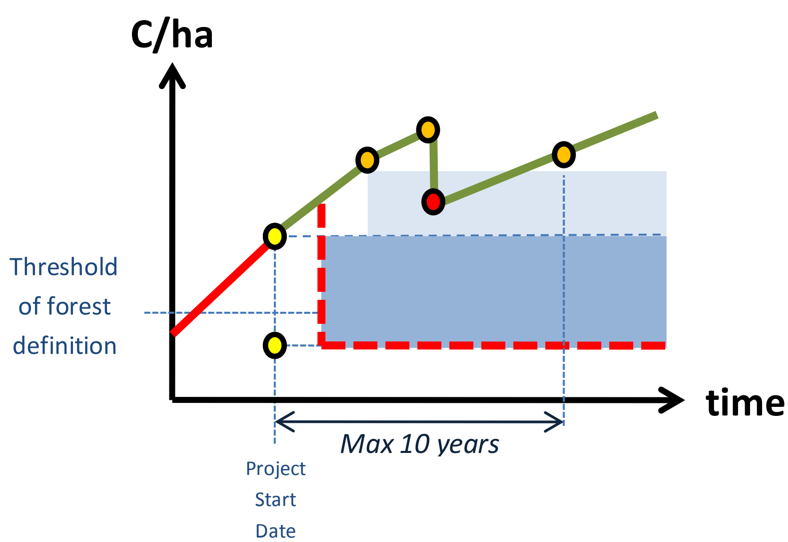


<u>Note:</u> Avoided degradation occurring prior to deforestation is conservatively not claimed.

G – Avoided Deforestation of Secondary Forest
+ Carbon Stock Increase (optional)



H – Avoided Deforestation of Secondary Forest
with Logging in the Project Case
+ Carbon Stock Increase (optional)



2 APPLICABILITY CONDITIONS

The methodology has no geographic restrictions and is applicable globally under the following conditions:

a) Baseline activities may include planned or unplanned logging for timber, fuel-wood collection, charcoal production, agricultural and grazing activities as long as the category is unplanned deforestation according to the most recent VCS AFOLU requirements.

b) Project activities may include one or a combination of the eligible categories defined in the description of the scope of the methodology (table 1 and figure 2).

c) The project area can include different types of forest, such as, but not limited to, old-growth forest, degraded forest, secondary forests, planted forests and agro-forestry systems meeting the definition of "forest".

d) At project commencement, the project area shall include only land qualifying as "forest" for a minimum of 10 years prior to the project start date.

e) The project area can include forested wetlands (such as bottomland forests, floodplain forests, mangrove forests) as long as they do not grow on peat. Peat shall be defined as organic soils with at least 65% organic matter and a minimum thickness of 50 cm. If the project area includes a forested wetlands growing on peat (e.g. peat swamp forests), this methodology is not applicable.

Demonstrate that the methodology is applicable to the proposed AUD project activity.

3 ADDITIONALITY

Additionality of the proposed AUD project activity must be demonstrated using either the most recent VCS-approved *VT0001Tool for the Demonstration and Assessment of Additionality in VCS AFOLU Project Activities*[4] noting the following:

The earliest start date of the proposed AUD project activity is January 1st, 2002. However, the start date can be earlier than January 1st, 2002, provided the requirements for projects with a start date prior to 2002, as set out in the most recent version of the VCS Standard, are met.

PART 2 - METHODOLOGY STEPS FOR EX-ANTE ESTIMATION OF GHG EMISSION REDUCTIONS

The nine methodology steps that will lead to the calculation of *ex ante* net anthropogenic GHG emission reductions are summarized in Figure 3. In the PD refer to each of these steps and sub-steps using the same titles and numbers so that the application of the methodology can transparently be validated.

---

[4] Available at www.v-c-s.org

Figure 3. *Ex ante* methodology steps

Step 1. Definition of the boundaries of the proposed AUD project activity: spatial boundaries, temporal boundaries, carbon pools and sources of greenhouse gas

↓

Step 2. Analysis of historical land-use and land-cover change in the reference region going back about 10-15 years from present.

↓

Step 3. Analysis of agents, drivers and underlying causes of deforestation, and sequencing of the typical chain of events leading to land-use and land-cover change.

↓

Step 4. Projection of the annual areas and location of deforestation in the reference region in the without project case.

↓

Step 5. Identification of forest classes in the areas that will be deforested under the baseline scenario and of post-deforestation land-use classes in the project area.

↓

Step 6. Estimation of baseline carbon stock changes and, where forest fires are included in the baseline assessment, of non-CO_2 emissions from biomass burning.

↓

Step 7. *Ex ante* estimation of actual carbon stock changes and non-CO_2 emissions under the project scenario.

↓

Step 8. *Ex ante* estimation of leakage associated to leakage prevention measures and activity displacement.

↓

Step 9. *Ex ante* calculation of net anthropogenic GHG emission reductions.

1 STEP 1: DEFINITION OF BOUNDARIES

The purpose of this step is to define the following categories of project boundaries:

1.1 Spatial boundaries;

1.2 Temporal boundaries;

1.3 Carbon pools; and

1.4 Sources of emissions of greenhouse gases (other than carbon stock changes).

1.1 Spatial boundaries

Define the boundaries of the following spatial features:

1.1.1 Reference region;

1.1.2 Project area;

1.1.3 Leakage belt;

1.1.4 Leakage management areas; and

1.1.5 Forest.

The reference region is the largest unit of land and the project area, leakage belt and leakage management areas are subsets of the reference region. For each spatial feature, the criteria used to define their boundaries must be described and justified in the PD. Vector or raster files in a common projection and GIS software formats shall be provided in order to allow the identification of the boundaries unambiguously.

1.1.1 Reference region

The boundary of the reference region is the spatial delimitation of the analytic domain from which information about rates, agents, drivers, and patterns of land-use and land-cover change (LU/LC-change) will be obtained, projected into the future and monitored.

The reference region should contain strata with agents, drivers and patterns of deforestation that in the 10-15 year period prior to the start date of the proposed AUD project activity are similar to those expected to exist within the project area.

The boundary of the reference region shall be defined as follows:

1. If sub-national or national baselines exist, that meet VCS specific guidance on applicability of existing baselines, such baselines must be used. Any pre-existing baseline should be analyzed and if it meets the criteria listed in table 2, it should be used. In both cases, the existing baseline will determine the boundary of the reference region.
2. If no such applicable sub-national or national baseline is available, the national and, where applicable, sub-national government shall be consulted to determine whether the country or sub-national region has been divided in spatial units for which deforestation baselines will be developed. If such divisions exist and are endorsed by the national or sub-national government, they must be used to determine the boundary of the reference region.
3. If such divisions do not exist, a baseline must be developed for a reference region encompassing the project area, the leakage belt and any other geographic area (stratum *i*) that is relevant to determine the baseline of the project area.
4. A geographic area is relevant for determining the baseline of the project area when agents, drivers and overall deforestation patterns observed in it during the 10-15 year period preceding the start date of the proposed AUD project activity represent a credible proxy for possible future deforestation patterns in the project area.

Table 2. Criteria determining the applicability of existing baselines

Applicability criteria	
1	The existing baseline must cover a broader geographical region than the project area. If a leakage belt must be defined[1], the broader region must include the leakage belt area.
2	The existing baseline must cover at least the duration of the first fixed baseline period and is not outdated[2].
3	The existing baseline must depict the location of future deforestation on a yearly base.
4	The spatial resolution of the existing baseline must be equal or finer than the minimum mapping unit of "forest land" that will be used for monitoring deforestation during the fixed baseline period.
5	Methods used to develop the existing baseline must be transparently documented and be consistent with a VCS approved and applicable baseline methodology.

1. If the project area is located within a jurisdictional program the most recent VCS *JNR Requirements* must be applied to determine whether a leakage belt is required. In all other cases, a leakage belt is required.
2. A baseline is considered outdated 10 years after its establishment.

The reference region may include one or several discrete areas. It must be larger[5] than the project area and include the project area.

Where the current situation within the project area is expected to change (e.g. because of population growth, infrastructure development or any other plausible reason), the reference region should be divided in *i* strata, each representing proxies for the chrono-sequence of current and future conditions within the project area. The boundary of such strata may be static (fixed during a fixed baseline period) or dynamic[6] (changing every year), depending on the modeling approaches used.

Three main criteria are relevant to demonstrate that the conditions determining the likelihood of deforestation within the project area are similar or expected to become similar to those found within the reference region

- **Agents and drivers of deforestation** expected to cause deforestation within the project area in absence of the proposed AUD project activity must exist or have existed elsewhere in the reference region. The following requirements are to be met:

---

[5] Brown *et al*. (2007) suggest the following rule of thumb:

- For projects above 100,000 ha, the reference region should be about 5-7 times larger than the project area.
- For projects below 100,000 ha, the reference region should be 20-40 times the size of the project area.

These figures are indicatives; the exact ratio between the two areas depends on the particular regional and project circumstances. Where a project activity deals with an entire island, the reference region must include other islands or forested landscapes with similar conditions.

[6] Dynamic = with shifting boundaries, according to modeled changes at the level of driver variables such as population, infrastructure and other to be determined by the project proponent.

- **Agent groups**: Deforestation agent´s groups (as identified in step 3) expected to encroach into the project area must exist or have existed and caused deforestation elsewhere in the reference region during the historical reference period.
- **Infrastructure drivers.** If new or improved infrastructure (such as roads, railroads, bridges, hydroelectric reservoirs, etc.) is expected to develop near or inside the project area[7], the reference region must include a stratum where such infrastructure was built in the past and where the impact on forest cover was similar to the one expected from the new or improved infrastructure in the project area.
- **Other spatial drivers expected to influence the project area**. Any spatial deforestation driver considered relevant according to the analysis of step 3 (e.g. resettlement programs, mining and oil concessions, etc.) must exist or have existed elsewhere in the reference region. The historical impact of such drivers must have been similar to the one expected in the project area.

- **Landscape configuration and ecological conditions:** At least three of the following four conditions must be satisfied:
  - **Forest/vegetation classes:** At least 90% of the project area must have forest classes or vegetation types that exist in at least 90% of the rest of the reference region.
  - **Elevation:** At least 90% of the project area must be within the elevation range of at least 90% of the rest of the reference region.
  - **Slope:** The average slope of at least 90% of the project area shall be within ± 10% of the average slope of at least 90% of the rest of the reference region.
  - **Rainfall:** The average annual rainfall in at least 90% of the project area shall be within ± 10% of the average annual rainfall of at least 90% of the rest of the reference region.
- **Socio-economic and cultural conditions:** The following conditions must be met:
  - **Legal status of the land**: The legal status of the land (private, forest concession, conservation concession, etc.) in the baseline case within the project area must exist elsewhere in the reference region. If the legal status of the project area is a unique case, demonstrate that legal status is not biasing the baseline of the project area (e.g. by demonstrating that access to the land by deforestation agents is similar to other areas with a different legal status).
  - **Land tenure**: The land-tenure system prevalent in the project area in the baseline case is found elsewhere in the reference region.
  - **Land use:** Current and projected classes of land-use in the project area are found elsewhere in the reference region.
  - **Enforced policies and regulations**: The project area shall be governed by the same policies, legislation and regulations that apply elsewhere in the reference region.

[7] Areas of planned deforestation in the baseline case must be excluded from the project area.

1.1.2 Project area

The project area is the area or areas of land under the control of the project proponent on which the project proponent will undertake the project activities. At the project start date, the project area must include only forest land.

Any area affected by planned deforestation due to the construction of planned infrastructure (except if such planned infrastructure is a project activity) must be excluded from the project area.

The project area must include areas projected to be deforested in the baseline case and may include some other areas that are not threatened according to the first baseline assessment (see figure 1). Such areas will not generate carbon credits, but they may be included if the project proponent considers that future baseline assessments, which have to be carried out at least every 10 years, are likely to indicate that a future deforestation threat will exist, also the demonstration is not possible at the time of validation.

Where less than 80 percent of the total proposed area of the project is under control at validation, new discrete units of land may be integrated into an existing project area if included in the monitoring report at the time of the first verification. For the full rules and requirements regarding control over the entire project area at validation, please see the most recent version of the VCS AFOLU requirements.

The boundary of the project area shall be defined unambiguously as follows:

- Name (or names, as appropriate) of the project area.
- Physical boundary of each discrete area of land included in the project area (using appropriate GIS software formats).
- Description of current land-tenure and ownership, including any legal arrangement related to land ownership and the AUD project activity.
- List of the project participants and brief description of their roles in the proposed AUD project activity.

1.1.3 Leakage belt

If the project area is located within a jurisdictional program, leakage may not have be assessed and a leakage belt may not be required because any decrease in carbon stocks or increase in GHG emissions outside the project area would be measured, reported, verified and accounted under the jurisdictional program[8]. In such cases, the most recent VCS *JNR Requirements* shall be applied. In all other cases, leakage is subject to MRV-A in an area called "leakage belt" in this methodology.

The leakage belt is the land area or land areas surrounding or adjacent to the project area in which baseline activities could be displaced due to the project activities implemented in the project area.

To define the boundary of the leakage belt, two methodological options can be used:

- Opportunity cost analysis (Option I); and
- Mobility analysis (Option II).

Under both options, the boundary of the leakage belt must be revisited at the end of each fixed baseline period, as opportunity costs and mobility parameters are likely to change over time. In addition, the

8 In such cases, the sub-national or national government may define specific sub-national or national policies and regulations to deal with the issue of leakage.

boundary of the leakage belt may have to be revisited when other VCS-AFOLU projects are registered nearby the project area, as further explained below.

If mobility parameters or opportunity costs are projected for each future year, the boundary of the leakage belt that will remain static for the whole duration of the fixed baseline period shall be the one determined for the last year of the fixed baseline period.

Option I: Opportunity cost analysis

This option is applicable where economic profit is an important driver of deforestation. To demonstrate that Option I is applicable, use historical records, i.e. demonstrate that at least 80% of the area deforested in the reference region (or some of its strata) during the historical reference period[9] has occurred at locations where deforesting was profitable (i.e. for at least one product, $PPx_l \geq 1$). Alternatively, use literature studies, surveys and other credible and verifiable sources of information. If Option I is not applicable, use Option 2.

If the main motivation is economic profit, agents not allowed to deforest within the project area will only displace deforestation outside the project area if doing so brings economic benefits to them. Based on this rationale leakage can only occur on land outside the project area where the total cost of establishing and growing crops or cattle and transporting the products to the market is less than the price of the products (i.e. opportunity costs are > 0).To identify this land area do the following:

a) List the main land-uses that deforestation agents are likely to implement within the project area in the baseline case, such as cattle ranching and/or different types of crops.

b) Find credible and verifiable sources of information on the following variables:

- *S$x* = Average selling price per ton of the main product *Px* (or product mixture in case of agro-forestry or mixed production systems) that would be established in the project area in the baseline case (meat, crop type A, crop type B, etc.);
- SPx_l = Most important selling points (spatial locations) for each main product *Px* in the reference region.
- PCx_i = Average *in situ* production costs per ton of product. Stratify the reference region as necessary in *i* strata, as production costs may vary depending on local conditions (soil, technology available to the producer, etc.).
- TC_v = Average transport cost per kilometer for one ton of product *Px* transported on different types of land-uses (e.g. pasture, cropland, forest), roads, railroads, navigable rivers, etc. using the most typical transport technology available to the producer.

Note: For simplicity, current prices and costs can be used to project opportunity costs. Price and cost projections shall only be used if reliable and verifiable sources of information are available.

c) Using a GIS, generate for each main product a surface representing the least transport cost of one ton of product to the most important selling points within the reference region. Do this by considering the most typical transport technology available to deforestation agents.

---

9 See section 1.2.1 for the definition of "historical reference period."

d) For each main product, add to the surface created in the previous step the average *in situ* cost for producing one ton of product. The result is a surface representing the total cost of producing and bringing to the market one ton of product.

e) For each main product, subtract from the average price of one ton of product the total cost surface created in the previous step. The result is a surface representing potential profitability of each product.

<u>Note:</u> If several products exist and can be produced on the same site, the maximum value of all potential profitability surfaces will represent the opportunity cost of conserving the forest.

f) The leakage belt is the area where the surface created in the previous step (potential profitability) has a positive value at the last year of the fixed baseline period.

The above methodology procedure can be summarized as follows:

A land unit (pixel or polygon *l*) is inside the leakage belt if the potential profitability of at least one product (PPx_l) is positive, where PPx_l is calculated as follows:

$$PPx_l = S\$x - PCx_i - \sum_{v=1}^{V}(TDv * TCv) \qquad (1)$$

Where:

PPx_l	Potential profitability of product *Px* at location *l* (pixel or polygon); $/t
S$x	Selling price of product *Px*; $/t
PCx_i	Average *in situ* production costs for one ton of product *Px* in stratum *i*; $/t
TCv	Average transport cost per kilometer for one ton of product *Px* on land, river or road of type *v*; $/t/km
TDv	Transport distance on land, river or road of type *v*; km
v	1, 2, 3 *…V,* type of surface to on which transport occurs; dimensionless

<u>Note:</u> Option I is based on the assumption that deforestation agents in the project area will not displace their activities beyond the reference region, where other forested areas with potentially positive opportunity costs may exist. Demonstrate that this assumption is credible using expert opinion, participative rural appraisal (PRA), literature and/or other verifiable sources of information. If the evidence collected is not convincing, use Option II (mobility analysis).

Option II: Mobility analysis

Mobility analysis can always be used but must be used where Option I is not applicable, i.e. when less than 80% of the area deforested in the reference region (or some of its strata) during the historical reference period has occurred at locations where deforesting was profitable. With this option, the potential mobility of deforestation agents is assessed using multi-criteria analysis. The following methodology steps shall be applied:

a) Using historical data, expert opinion, participative rural appraisal (PRA), literature and/or other verifiable sources of information list all relevant criteria that facilitate (at least one criterion) and constrain (at least one criterion) the mobility of the main deforestation agents identified in step 3. The overall suitability of the land for the activities of deforestation agents shall be considered.

b) For each criterion, generate a map using a GIS.

c) Using multi-criteria analysis, determine the boundary of the leakage belt. Justify any assumption and weight assigned to the individual criteria.

d) Methods used to perform the analysis shall be transparently documented and presented to VCS verifiers at the validation.

Consideration of other VCS AFOLU projects

If the leakage belt area of the proposed AUD project includes the area or part of the areas of other VCS AFOLU projects, do the following to avoid double counting of emissions:

- Exclude from the leakage belt area of the proposed AUD project the project area of the other VCS AFOLU project(s).
  a) The exclusion shall enter into force at the registration date of the other project
  b) Carbon accounting shall consider the exclusion of the project area of the other project beginning with the start date of the other projects
  c) An excluded area shall again be included in the leakage belt area of the proposed AUD project at the time the other project has not verified its emission reductions for more than five consecutive years, or when it ends its project crediting period under the VCS.
- If the leakage belt overlaps with the leakage belt of other VCS AFOLU projects, do the following:
  a) Identify the carbon pools and sources of GHG emissions that are monitored by the other projects. Only for common carbon pools and sources of GHG emissions the boundary of the leakage belt area can be modified as further explained below.
  b) Analyze the overlapping area(s) with the proponents of each of the other VCS AFOLU projects and come to an agreement with them on the location of the boundaries of the different leakage belts, so that there will be no overlaps and gaps between the different leakage belt areas as well as carbon pools and GHG sources.
  c) As an indicative rule, the percentage of forest land area within the leakage belt of a project relative to the total forest area of all leakage belts shall be similar to the percentage of baseline deforestation of the project relative to the total baseline deforestation of all projects:

$$\%LKBA = BLDA / (BLDA + BLDB + \ldots + BLDN) \quad (2.a)$$

$$\%LKBB = BLDB / (BLDA + BLDB + \ldots + BLDN) \quad (2.b)$$

…

$$\%LKBN = BLDN / (BLDA + BLDB + \ldots + BLDN) \quad (2.n)$$

Where:

%LKBA Percentage of the overlapping leakage belts area to be assigned to Project A; %

%LKBB Percentage of the overlapping leakage belts area to be assigned to Project B; %

%LKBN Percentage of the overlapping leakage belts area to be assigned to Project N; %

BLDA Total area of projected baseline deforestation during the fixed baseline period of Project A (see PD of project A); ha

BLDB Total area of projected baseline deforestation during the fixed baseline period of Project B (see PD of project B); ha

BLDN Total area of projected baseline deforestation during the fixed baseline period of Project N (see PD of Project N); ha

Note: The proponents of the different projects shall agree on the criteria used to define the boundaries of their leakage belts in the overlapping areas and are not required to use the above rule. However, if they decide to use this rule, the area of the overlapping leakage belts assigned to Project A shall be the closest to the boundary of Project A; the area of the overlapping leakage belts assigned to Project B shall be the closest to the boundary of Project B and so on (the area of the overlapping leakage belts assigned to Project N shall be the closest to the boundary of Project N).

d) The final boundary of the leakage belt of each project is subject to validation and periodical verification. A project may report a smaller leakage belt only if another VCS registered project has included in its leakage belt the portion left out.

e) If the proponents of the different projects do not agree on how to split the overlapping leakage belt area, each project will have to include in its leakage belt the overlapping areas.

f) A "Leakage Belt Agreement" between the proponents of the different projects must be signed and presented to VCS verifiers at the time of validation/verification. The agreement shall contain the maps of the agreed leakage belts and each project shall have a digital copy of these maps in the projection and GIS software formats used in each project.

g) If a project ends or has not presented a verification to the VCS for more than five consecutive years, the other projects participating in the "leakage belt agreement" shall amend the agreement in order to ensure that the whole area of the originally overlapping leakage belts is always subject to MRV-A. The amendment is subject to VCS verification. If no amendment is made, the proposed project will have to include in its leakage belt the land area that is no longer be subject to MRV-A by a another VCS project.

1.1.4 Leakage management areas

These are non-forest areas located outside the project boundary in which the project proponent intends to implement activities that will reduce the risk of activity displacement leakage, such as afforestation, reforestation or enhanced crop and grazing land management. The boundary of such areas must be defined according to existing management plans or other plans related to the proposed AUD project activity. Such plans shall be made available to the VCS Validation/Verification Body (VVB) at the time of validation. The boundary of leakage management areas must be clearly defined using the common projection and GIS software formats used in the project and shall be reassessed and validated at each fixed baseline period

1.1.5 Forest

The boundary of the forest is dynamic and will change over time. It must be defined using an explicit and consistent forest definition over different time periods.

In the baseline case, changes in the boundary of forest land will be projected, and the baseline projections must be reassessed at least every 10 years. In the project area and leakage belt, the *ex post* boundary of forest land will be subject to periodical monitoring, verification and reporting (MRV).

To define the boundary of the forest, specify:

- The definition of forest that will be used for measuring deforestation during the project crediting period (see appendix 1 for criteria to define "forest").
- The Minimum Mapping Unit (MMU). The MMU size of the LULC maps created using RS impagery shall not be more than one hectare irrespective of forest definition.

An initial Forest Cover Benchmark Map is required to report only gross deforestation going forward. It should depict the locations where forest land exists at the project start date. The baseline projections in step 4.2 will generate one such map for each future year of the fixed baseline period and, optionally, project crediting period.

Areas covered by clouds or shadows should be analyzed by complementing the analysis of optical sensor data with non-optical sensor data. However, if some obscured areas remain for which no spatially explicit and verifiable information on forest cover can be found or collected (using ground-based or other methods), such areas shall be excluded (masked out). This exclusion would be:

- **Permanent**, unless it can reasonably be assumed that these areas are covered by forests (e.g. due to their location).
- **Temporal** in case information was available for the historical reference period, but not for a specific monitoring period. In this case, the area with no information must be excluded from the calculation of net anthropogenic GHG emission reductions of the current monitoring period, but not for subsequent periods, when information may become available again. When information becomes available again, and the land appears with vegetation parameters below the thresholds for defining "forest", the land should be considered as "deforested".

1.2 Temporal boundaries

Define the temporal boundaries listed below.

1.2.1 Starting date and end date of the historical reference period

The starting date should not be more than 10-15 years in the past and the end date as close as possible to the project start date. The project start date is the date at which the additional AUD project activities have or are to be started.

1.2.2 Starting date of the project crediting period of the AUD project activity

The length of the project crediting period shall be established as set out on the most recent version of the VCS Standard.

1.2.3 Starting date and end date of the first fixed baseline period

The fixed baseline period shall be 10 years. The starting and end dates must be defined.

1.2.4 Monitoring period

The minimum duration of a monitoring period is one year and the maximum duration is one fixed baseline period.

1.3 Carbon pools

The six carbon pools listed in table 3 are considered in this methodology.

Table 3. Carbon pools included or excluded within the boundary of the proposed AUD project activity

Carbon pools	Included / TBD[1]/ Excluded	Justification / Explanation of choice
Above-ground	Tree: Included	Carbon stock change in this pool is always significant
	Non-tree: TBD	Must be included in categories with final land cover of perennial crop
Below-ground+	TBD	Optional and recommended but not mandatory
Dead wood+	TBD	Recommended only when significant
Harvested wood products+	Included	To be included when significant
Litter	TBD	Recommended only when significant.
Soil organic carbon+	TBD	Recommended when forests are converted to cropland. Not to be measured in conversions to pasture grasses and perennial crop according to VCS Program Update of May 24th, 2010.

1. TBD = To Be Decided by the project proponent. The pool can be excluded only when its exclusion does not lead to a significant over-estimation of the net anthropogenic GHG emission reductions of the AUD project activity.
2. The VCS defines as "significant" those carbon pools and sources that account more than 5% of the total GHG benefits generated (VCS 2007.1, 2008 p.17). To determine significance, the most recent version of the "Tool for testing significance of GHG emissions in A/R CDM project activities" shall be used[10].
3. + = The VCS *AFOLU Requirements* require methodologies to consider the decay of carbon in soil carbon, belowground biomass, dead wood and harvested wood products. Note that the immediate release of carbon from these pools in the baseline case must not be assumed.

- Carbon pools that are expected to decrease their carbon stocks in the project scenario compared to the baseline case must be included if the exclusion would lead to a significant overestimation of the net anthropogenic GHG emission reductions generated during the fixed baseline period.

---

[10] Available at: http://cdm.unfccc.int/EB/031/eb31_repan16.pdf

- Carbon pools considered insignificant according to the latest VCS AFOLU requirements can always be neglected.
- Above-ground biomass of trees must always be selected because it is in this pool that the greatest carbon stock change will occur.
- Non-tree biomass must be included if the carbon stock in this pool is likely to be relatively large in the baseline compared to the project scenario such as when short-rotation woody corps are commonly planted in the region where the project area is located. The significance criterion shall apply.
- Below-ground biomass of trees is recommended, as it usually represents between 15% and 30% of the above-ground biomass.
- Harvested wood products must be included if removal of timber is associated with significantly more carbon stored in long-term wood products in the baseline case compared to the project scenario. The significance criterion shall apply. When included, short-lived fraction (decaying in less than 3 years) is assumed to decay inmidiatly at the year of deforestation ($t = t^*$), the medium-lived fraction (decaying in 3-100 years) is assumed to decay in a 20-year period and the long-term fraction is assumed to never decay (*i.e.* it never results in an emission). Thus, it is conservative to assume that 100% of the carbon stock in wood products is long-lived.
- In most cases the exclusion of a carbon pool will be conservative, except when the carbon stock in the pool is higher in the baseline compared to the project scenario.
- The inclusion of a carbon pool is recommended (but not mandatory) where the pool is likely to represent an important proportion (> 10%) of the total carbon stock change attributable to the project activity (“expected magnitude of change”).
- For excluded pools, briefly explain why the exclusion is conservative.
- When the exclusion of a carbon pool is not conservative, demonstrate that the exclusion will not lead to a significant overestimation of the net anthropogenic GHG emission reduction. If the exclusion is significant, the pool must be included.
- Carbon pools that are excluded or not significant according to the *ex ante* assessment do not need to be monitored *ex post*.
- In most cases the same carbon pools shall be considered for all categories of LU/LC change. However, including different carbon pools for different categories of LU/LC change is allowed depending on “significance”, “conservativeness” and “expected magnitude of change”. For instance, harvested wood products may only be considered in the categories where this pool exists.
- The final selection of carbon pools per category is done in step 2.3. Within a category of LU/LC-change, the same carbon pools must be selected for the two classes involved. Table 1 in appendix 2 provides an indication of the level of priority for including different carbon pools depending on the category of LU/LC change.
- If a pool is conservatively excluded at validation, project proponent cannot in subsequent monitoring and verification periods decide to measure, report and verify the excluded carbon pool. However, the reverse is possible i.e., if a pool is included at validation, it may be conservatively excluded in subsequent monitoring and verification periods provided all methodology requirements are applied to carry out the estimations and these are independently verified. Further guidance on the selection of

carbon pools can be found in the most recent version of the GOFC-GOLD sourcebook for REDD[11] and further details are given in appendix 3.

1.4 Sources of GHG emissions

The two sources of GHG emissions listed in table 4 are considered in this methodology.

Table 4. Sources and GHG included or excluded within the boundary of the proposed AUD project activity

Sources	Gas	Included/TBD[1]/ excluded	Justification / Explanation of choice
Biomass burning	CO_2	Excluded	Counted as carbon stock change
	CH_4	TBD	See guidance below
	N_2O	Excluded	Considered insignificant according to VCS Program Update of May 24th, 2010
Livestock emissions	CO_2	Excluded	Not a significant source
	CH_4	TBD	See guidance below
	N_2O	TBD	See guidance below

1. TBD = To Be Decided by the project proponent. The source can be excluded only when its exclusion does not lead to a significant over-estimation of the net anthropogenic GHE emission reductions of the AUD project activity.
2. The VCS defines as "significant" those carbon pools and sources that account more than 5% of the total GHG benefits generated (VCS 2007.1, 2008 p.17). To determine significance, the most recent version of the "Tool for testing significance of GHG emissions in A/R CDM project activities" shall be used[12].

- Sources of emissions that are expected to increase in the project scenario compared to the baseline case must be included if the exclusion would lead to a significant overestimation of the total net anthropogenic GHG emission reductions generated during the fixed baseline period.
- Sources considered insignificant according to the latest VCS AFOLU requirements can always be neglected.
- The inclusion of a source is recommended (but not mandatory) where the source is likely to represent an important proportion (> 10%) of the total emissions reductions attributable to the project activity ("expected magnitude of change").
- The exclusion of a source is allowed only if the omission is conservative or the source is insignificant.
- Sources of GHG emissions that are not significant according to the *ex ante* assessment do not need not to be monitored *ex post*.

---

[11] GOFC-GOLD, 2012. A sourcebook of methods and procedures for monitoring and reporting anthropogenic greenhouse gas emissions and removals caused by deforestation, gains and losses of carbon stocks in forests remaining forests and forestation. Available at: http://www.gofc-gold.uni-jena.de/redd/

[12] Available at: http://cdm.unfccc.int

- For excluded sources, briefly explain why the exclusion is conservative.
- In the baseline scenario: Non-CO_2 emissions from fires used to clear forests can be counted when sufficient data are available to estimate them. However, accounting for these emissions can conservatively be omitted. GHG emissions from land-uses implemented on deforested lands (including from biomass burning) are conservatively omitted in this methodology.
- In the project scenario: It is reasonable to assume that the project activity, including when harvest activities are planned (such as logging for timber, fuel-wood collection and charcoal production), produces less emissions of GHG than the baseline activities implemented prior and after deforestation on the deforested lands. Therefore, the omission of certain sources of GHG emissions, such as the consumption of fossil fuels, will not cause an overestimation of the net anthropogenic GHG emission reductions. However, non-CO_2 emissions from forest fires must be counted in the project scenario when they are significant.
- In the estimation of leakage: GHG emissions by sources that are attributable to leakage prevention measures (e.g. those implemented in leakage management areas) and that are increased compared to pre-existing GHG emissions count as leakage and should be estimated and counted if they are significant. Non-CO_2 emissions from displaced baseline activities, which are conservatively omitted in the baseline, can be ignored, as in the worst case scenario they would be similar to baseline emissions. However, if non-CO_2 emissions from forest fires used to clear forests are counted in the baseline, they must also be counted in the estimation of activity displacement leakage.

2 STEP 2: ANALYSIS OF HISTORICAL LAND-USE AND LAND-COVER CHANGE

The goal of this step is to collect and analyze spatial data in order to identify current land-use and land-cover conditions and to analyze LU/LC change during the historical reference period within the reference region and project area. The tasks to be accomplished are the following:

2.1 Collection of appropriate data sources;

2.2 Definition of classes of land-use and land-cover;

2.3 Definition of categories of land-use and land-cover change;

2.4 Analysis of historical land-use and land-cover change;

2.5 Map accuracy assessment; and

2.6 Preparation of a methodology annex to the PD.

2.1 Collection of appropriate data sources

Collect the data that will be used to analyze land-use and land-cover change during the historical reference period within the reference region and project area. It is good practice to do this for at least three time points, about 3-5 years apart. For areas covered by intact forests, it is sufficient to collect data for one single date, which must be as closest as possible to the project start date ($\leq$ 2 years).

As a minimum requirement:

- Collect medium resolution spatial data[13] (from 10m x 10m up to a maximum of 100m x 100m resolution) from optical and non-optical sensor systems, such as (but not limited to) Landsat[14], SPOT, ALOS, AVNIR2, ASTER, IRS sensor data) covering the past 10-15 years.
- Collect high resolution data from remote sensors (< 5 x 5 m pixels) and/or from direct field observations for ground-truth validation of the posterior analysis. Describe the type of data, coordinates and the sampling design used to collect them.
- In tabular format (table 5), provide the following information about the data collected:

Table 5. Data used for historical LU/LC change analysis

Vector (Satellite or airplane)	Sensor	Resolution		Coverage	Acquisition date	Scene or point identifier	
		Spatial	Spectral	(km^2)	(DD/MM/YY)	Path / Latitude	Row / Longitude

Where already interpreted data of adequate spatial and temporal resolution are available, with some caution[15] these can also be considered for posterior analysis.

2.2 Definition of classes of land-use and land-cover

Identify and describe the land-use and land-cover (LU/LC) classes present in the reference region at the project start date. A LU/LC class is a unique combination of land-use and land-cover for which:

a) The boundary can be defined at hand of remotely sensed data and/or other sources of information, such as maps of vegetation, soil, elevation, management category, etc., as defined by the project proponent to unambiguously define a LU/LC class; and

---

13 Guidance on the selection of data sources (such as remotely sensed data) can be found in chapter 3A.2.4 of the IPCC 2006 GL AFOLU and in the latest version of the GOFC-GOLD sourcebook on REDD.

14 On May 31, 2003, the scan-line-corrector (SLC) aboard Landsat 7 failed, producing horizontal zero-filled wedges in 22% of scenes from that point on. The nadir portion of full scene images is usually intact, though both east and west of nadir gaps extend to the scene edges. Gap-filling functions have been created, but algorithmic mechanisms that blur, average, or otherwise change spatial relationships between pixels spanning these gaps to existing pixels in the scene being filled are unsatisfactory from the perspective of the spatial modeling needs of REDD. Instead, users should fill in these gaps post-processing with spatially and spectrally satisfactory classifications from other sources (such as other complimentary optical and radar platforms).

15 Existing maps should be used with caution because they often do not report documentation, error estimates, whether they were of the site or region in question or extracted from a national map, or whether they were obtained by change detection techniques rather than by static map comparison, etc. If data about historical LU/LC and/or LU/LC-change is already available, information about the minimum mapping unit, the methods used to produce these data, and descriptions of the LU/LC classes and/or LU/LC-change categories must be compiled, including on how these classes may match with IPCC classes and categories.

b) Carbon stocks per hectare (tCO_2-e ha^{-1})[16] within each class are about homogeneous across the landscape. Carbon stocks must only be estimated for classes inside the project area, leakage belt and leakage management areas, which will be done in step 6.

The following criteria shall be used to define the LU/LC classes:

- The minimum classes shall be "Forest Land" and "Non-Forest Land".
- "Forest-land" will in most cases include strata with different carbon stocks. Forest-land must therefore be further stratified in forest classes having different average carbon densities within each class.
- "Non-Forest Land" may be further stratified in strata representing different non-forest classes. IPCC classes used for national GHG inventories may be used to define such classes (Crop Land, Grass Land, Wetlands, Settlements, and Other Land). See IPCC 2006 GL AFOLU Chapter 3, Section 3.2, p. 3.5 for a description of these classes. However, where appropriate to increase the accuracy of carbon stock estimates, additional or different sub-classes may be defined.
- The description of a LU/LC class must include criteria and thresholds that are relevant for the discrimination of that class from all other classes. Select criteria and thresholds allowing a transparent definition of the boundaries of the LU/LC polygons of each class. Such criteria may include spectral definitions as well as other criteria used in post-processing of image data, such as elevation above sea level, aspect, soil type, distance to roads[17] and existing vegetation maps. Where needed, in the column "description" of table 6 refer to more detailed descriptions in the methodological annex to be prepared in step 2.6.
- For all forest classes present in the project area, specify whether logging for timber, fuel wood collection or charcoal production are happening in the baseline case. If different combinations of classes and baseline activities are present in the project area, define different classes for each combination, even if carbon stocks are similar at the project start date.
- If a forest class has predictably growing carbon stocks (i.e. the class is a secondary forest) and the class is located both in the project area and leakage belt, two different classes must be defined (see step 6.1 for explanations).
- In most cases one single Land-Use and Land-Cover Map representing the spatial distribution of forest classes at the project start date will be sufficient. However, where certain areas of land are expected to undergo significant changes in carbon stock due to growth or degradation in the baseline case, a sequence of Land-Use and Land-Cover Maps representing the mosaic of forest-classes of each future year may be generated.

---

16 The carbon stock per hectare is sometimes referred to as "carbon density" in the literature.

17 Some classes may be defined using indirect criteria (e.g. "Intact old-growth forest" = Forest at more than 500 m from the nearest road; "Degraded forest" = Forest within 500 m from the nearest road. In this example, the assumption is made that logging activities usually do not occur, or are of very low intensity, when the trees are at more than 500 m from the nearest road). The use of indirect criteria shall be briefly justified in the PD at hand of verifiable information, such as independent studies, literature, etc. Using a definition of "degraded forest" as in this example, the boundary of the polygon class "degraded forest" would be a function of how the road network develops over time, which implies that such development will have to be monitored.

- The generation of such a sequence of maps is mandatory only for areas within the project boundary that are undergoing degradation in the baseline case, i.e. categories C, D, E and/or F are present in the project area (see table 1 and figure 2).
- Any assumption on changing carbon stocks in the baseline case must be documented at hand of credible and verifiable sources of information, such as measurements in plots representing a chrono-sequence, published literature, and other sources, as appropriate.
- List the resulting final LU/LC-classes in table 6.

Table 6. List of all land use and land cover classes existing at the project start date within the reference region

Class Identifier		Trend in Carbon stock[1]	Presence in[2]	Baseline activity[3]			Description (including criteria for unambiguous boundary definition)
ID_{cl}	Name			LG	FW	CP	
1							
2							
…							
Cl							

1. Note if “decreasing”, “constant”, “increasing”
2. RR = Reference region, LK = Leakage belt, LM = Leakage management Areas, PA = Project area
3. LG = Logging, FW = Fuel-wood collection; CP = Charcoal Production (yes/no)
4. Each class shall have a unique identifier (ID_{cl}). The methodology sometimes uses the notation *icl* (= 1, 2, 3, … *Icl*) to indicate “initial” (pre-deforestation) classes, which are all forest classes; and *fcl* (= 1, 2, 3, … *Fcl*) to indicate final” (post-deforestation) classes. In this table all classes (“initial” and “final”) shall be listed.

2.3 Definition of categories of land-use and land-cover change

Identify all LU/LC-change categories that could occur within the project area and leakage belt during the project crediting period in both, the baseline and project case. This can be done by analyzing a land-use change matrix that combines all LU/LC-classes previously defined.

List the resulting LU/LC-change categories in table 7.a and 7.b:

Table 7.a. Potential land-use and land-cover change matrix

		Initial LU/LC class			
	ID_{cl}	*I1*	*I2*	*I…*	*In*
Final LU/LC class	*F1*	I1/F1	I2/F1	I…/F1	In/F1
	F2	I1/F2	I2/F2	I…/F2	In/F2
	F…	I1/F…	I2/F…	I…/F3	In/F…
	Fn	I1/Fn	I2/Fn	I…/Fn	In/Fn

Table 7.b. List of land-use and land-cover change categories

ID_{ct}	Name	Trend in Carbon stock	Presence in	Activity in the baseline case			Name	Trend in Carbon stock	Presence in	Activity in the project case		
				LG	FW	CP				LG	FW	CP
I1/F1												
I1/F2												
I1/F…												
I2/F1												
I2/F2												
I2/F…												
I…/F1												
I…/F2												
I…/F…												

2.4 Analysis of historical land-use and land-cover change

Using the data collected in step 2.1, divide the reference region in polygons[18] representing the LU/LC-classes and LU/LC-change categories defined in steps 2.2 and 2.3. In the case of the project area, LU/LC-change analysis is required to exclude any area with forests that are less than 10 years old at the project start date.

Use existing LU/LC or LU/LC-change maps if the classes and categories are well described in these maps, so that they can be used for completing steps 2.2 and 2.3.

Where processed data of good quality are not available, unprocessed remotely sensed data must be analyzed to produce LU/LC maps and LU/LC-change maps. Given the heterogeneity of methods, data sources and image processing software, LU/LC-change detection should be performed by trained interpreters.

Typically, the analysis of LU/LC-change involves performing the following three tasks:

2.4.1 Pre-processing;

2.4.2 Interpretation and classification; and

2.4.3 Post-processing.

2.4.1 Pre-processing

Pre-processing typically includes:

a) Geometric corrections to ensure that images in a time series overlay properly to each other and to other GIS maps used in the analysis (i.e. for post-classification stratification). The average location error between two images should be < 1 pixel.

---

18 Raster or grid data formats are allowed.

b) Cloud and shadow removal using additional sources of data (e.g. radar, aerial photographs, field-surveys).

c) Radiometric corrections may be necessary (depending on the change-detection technique used) to ensure that similar objects have the same spectral response in multi-temporal datasets.

d) Reduction of haze, as needed.

See the most recent version of the GOFC-GOLD sourcebook for REDD or consult experts and literature for further guidance on pre-processing techniques.

Duly record all pre-processing steps for later reporting.

2.4.2 Interpretation and classification

Two main categories of change detection exist and can be used (see IPCC 2006 GL AFOLU, Chapter 3A.2.4):

(1) Post-classification change detection: Two LU/LC maps are generated for two different time points and then compared to detect LU/LC changes. The techniques are straightforward but are also sensitive to inconsistencies in interpretation and classification of the LU/LC classes.

(2) Pre-classification change detection: These are more sophisticated approaches to LU/LC-change detection. They also require more pre-processing of the data (i.e. radiometric corrections). The basic approach is to compare by statistical methods the spectral response of the ground using two data sets acquired at different dates to detect the locations where a change has occurred and then to allocate different patterns of spectral change to specific LU/LC-change categories. This approach is less sensitive to interpretation inconsistencies but the methods involved are less straightforward and require access to the original unclassified remotely sensed data.

As several methods are available to derive LU/LC and LU/LC-change maps from multi-temporal data sets, the methodology does not prescribe any specific method. As a general guidance:

- Automated classification methods should be preferred because the interpretation is more efficient and repeatable than a visual interpretation.
- Independent interpretation of multi-temporal images should be avoided (but is not forbidden).
- Interpretation is usually more accurate when it focuses on change detection with interdependent assessment of two multi-temporal images together. A technique that may be effective is image segmentation followed by supervised object classification.
- Minimum mapping unit size shall not be more than one hectare irrespective of forest definition.
- See the most recent version of the GOFC-GOLD sourcebook on REDD or consult experts and literature for further guidance on methods to analyze LU/LC-change using remotely sensed data.

Duly record all interpretation and classification steps for later reporting.

2.4.3 Post-processing

Post-processing includes the use of non-spectral data to further stratify LU/LC-classes with heterogeneous carbon density in LU/LC classes with homogenous carbon density. Post-classification stratification can be performed efficiently using a Geographical Information System (GIS).

Current remote sensing technology is unable to discriminate carbon density classes, although some progress is being made using lidar and other technologies that combined with field-surveys can be used under this methodology. Some forest types (e.g. broadleaved forest, coniferous forests, mangroves) can be discriminated with high accuracy using remotely-sensed data only.

LU/LC-classes that cannot be stratified further using remote sensing techniques but that are likely to contain a broad range of carbon density classes should be stratified using:

- Biophysical criteria (e.g. climate or ecological zone, soil and vegetation type, elevation, rainfall, aspect, etc.)[19];
- Disturbance indicators (e.g. vicinity to roads; forestry concession areas; etc.); age (in cases of plantations and secondary forests);
- Land management categories (e.g. protected forest, indigenous reserve, etc.); and/or
- Other criteria relevant to distinguish carbon density classes.

See the most recent version of the GOFC-GOLD sourcebook for REDD and IPCC 2006 GL AFOLU for further guidance on stratification. The criteria finally used should be reported transparently in the PD and referenced to in table 6. Some iteration between steps 2.2, 2.3, and 2.4.3 may be necessary.

Duly record all post-processing steps for later reporting.

At the end of step 2, the following products should be prepared for the reference region and project area:

a) A <u>Forest Cover Benchmark Map</u> for at least the most recent date (±2 years from the project start date) and 10 (± 2) years[20] prior to the project start date, showing only “forest” and “non-forest”.

b) A <u>Land-Use and Land-Cover Map</u> for at least the most recent date (±2 years from the project start date) depicting the LU/LC-classes defined in step 2.2. If such a map cannot be generated at the levels of accuracy required by this methodology (see step 2.5), areas of the different LU/LC-classes may be estimated by sampling techniques (e.g. by overlaying a grid of dots on the satellite image and then counting the points falling in each LU/LC-class, or by sampling the landscape with higher resolution images and then classifying the sampled images), or by using other sources of data, such as official statistical data on land-use (e.g. agricultural census data):

c) A <u>Deforestation Map</u> for each sub-period analyzed, depicting at least the category “deforestation”. Many projects will have some level of no-data areas because of cloud-cover. In this case change rates should be calculated for each time step based only on areas that were not cloud-obscured in either date in question. Then, a maximum possible forest cover map should be made for the most recent year (±2 years from the project start date). The historical rate in % should be

[19] IPCC 2006 Guidelines for National GHG Inventories provide default climate and soil classification schemes in Annex 3A.5 and guidance on stratifying LU/LC areas in Section 3.3.2.

[20] This is to exclude from the project area forests that are less than 10 years old at the project start date.

multiplied by the maximum forest cover area at the start of the period for estimating the total area of deforestation during the period.

d) A Land-Use and Land-Cover Change Map for at least the most recent period analyzed (3-5 years) depicting the LU/LC-change categories defined in step 2.3. In most cases, this map will be prepared by combining the Deforestation Map of the most recent period (3-5 years) with the most recent Land-Use and Land-Cover Map. If the area of the LU/LC-classes was estimated using sampling techniques or other sources of information, a LU/LC-Change Map is not required.

e) A Land-Use and Land-Cover Change Matrix for at least the most recent period analyzed, derived from the LU/LC-change map or the Deforestation Map and the post-deforestation land-use data mentioned above, showing activity data for each LU/LC-change category. See appendix 2, table 4 for an example of a LU/LC change matrix.

2.5 Map accuracy assessment

A verifiable accuracy assessment of the maps produced in the previous step is necessary to produce a credible baseline[21].

The accuracy must be estimated on a class-by-class (LU/LC map) and, where applicable, category-by-category (LU/LC-change map) basis, respectively. A number of sample points on the map and their corresponding correct classification (as determined by ground-surveys or interpretation of higher resolution data as collected in step 2.1) can be used to create an error matrix with the diagonal showing the proportion of correct classification and the off-diagonal cells showing the relative proportion of misclassification of each class or category into the other class or, respectively, categories. Based on the error matrix (also called confusion matrix), a number of accuracy indices can be derived (see e.g. Congalton, 1991 and Pontius, 2000).

The minimum overall accuracy of the Forest Cover Benchmark Map should be 90%.

The minimum classification accuracy of each class or category in the Land-Use and Land-Cover Map and Land-Use and Land-Cover Change Map, respectively, should be 80%. If the classification of a class or category is lower than 80%:

- Consider merging the class/category with other classes/categories[22]; or
- Exclude from the Forest Cover Benchmark Map the forest-classes that are causing the greatest confusion with non-forest classes according to the error matrix (e.g. initial secondary succession and heavily degraded forest may be difficult to distinguish from certain types of grassland or cropland, such as agro-forestry and silvo-pastoral systems not meeting the definition of "forest"). This implies conservatively reducing the area of the Forest Cover Benchmark Map.
- Both commission errors (false detection of a class/category, such as "deforestation") and omission errors (non-detection of actual class/category, such as "deforestation") should be estimated and reported.

[21] See Chapter 5 of IPCC 2003 GPG, Chapter 3A.2.4 of IPPC 2006 Guidelines for AFOLU, and the most recent version of the GOFC-GOLD Sourcebook on REDD for guidance on map accuracy assessment.

[22] The tradeoff of merging classes or categories is that carbon estimates will be subject to a higher degree of variability.

- If ground-truthing data are not available for time periods in the past, the accuracy can be assessed only at the most recent date, for which ground-truthing data can be collected.

Where the assessment of map accuracy requires merging or eliminating classes or categories to achieve the required map accuracy, the definitions in the previous sub-steps must be adjusted accordingly. The final maps and the class/category definitions must be consistent.

2.6 Preparation of a methodology annex to the PD

LU/LC-change analysis is an evolving field and will be performed several times during the project crediting period. A consistent time-series of LU/LC-change data must emerge from this process.

In general, the same source of remotely sensed data and data analysis techniques must be used within a period for which the baseline is fixed (fixed baseline period). However, if remotely sensed data have become available from new and higher resolution sources (e.g. from a different sensor system) during this period, these can only be used if the images based on interpretation of the new data overlap the images based on interpretation of the old data by at least 1 year and they cross calibrate to acceptable levels based on commonly used methods in the remote sensing community.

To achieve a consistent time-series, the risk of introducing artifacts from method change must be minimized. For this reason, the detailed methodological procedures used in pre-processing, classification, post classification processing, and accuracy assessment of the remotely sensed data, must be carefully documented in an Annex to the PD. In particular, the following information must be documented:

a) Data sources and pre-processing: Type, resolution, source and acquisition date of the remotely sensed data (and other data) used; geometric, radiometric and other corrections performed, if any; spectral bands and indexes used (such as NDVI); projection and parameters used to geo-reference the images; error estimate of the geometric correction; software and software version used to perform pre-processing tasks; etc.

b) Data classification and post-processing: Definition of the LU/LC classes and LU/LC-change categories; classification approach and classification algorithms; coordinates and description of the ground-truthing data collected for training purposes; ancillary data used in the classification, if any; software and software version used to perform the classification; additional spatial data and analysis used for post-classification analysis, including class subdivisions using non-spectral criteria, if any; etc.

c) Classification accuracy assessment: Accuracy assessment technique used; coordinates and description of the ground-truth data collected for classification accuracy assessment; post-processing decisions made based on the preliminary classification accuracy assessment, if any; and final classification accuracy assessment.

3 STEP 3: ANALYSIS OF AGENTS, DRIVERS AND UNDERLYING CAUSES OF DEFORESTATION AND THEIR LIKELY FUTURE DEVELOPMENT

Understanding “who” is deforesting the forest (the “agent”) and what drives land-use decisions (“drivers” and “underlying causes”) is necessary for two mains reasons: (i) Estimating the quantity and location of future deforestation; and (ii) Designing effective measures to address deforestation, including leakage prevention measures.

This analysis is performed through the following five sub-steps[23]:

3.1 Identification of agents of deforestation;

3.2 Identification of deforestation drivers;

3.3 Identification of underlying causes;

3.4 Analysis of chain of events leading to deforestation; and

3.5 Conclusion

3.1 Identification of agents of deforestation

Identify the main agent groups of deforestation (farmers, ranchers, loggers, etc.) and their relative importance (i.e. the amount of historical LU/LC-change that can be attributed to each of them). To do this identification, use existing studies, the maps prepared in step 2, expert-consultations, field-surveys and other verifiable sources of information, as needed.

Sometimes, the relative importance of each agent can be determined from the LU/LC-change matrix developed in step 2.4, since each agent usually converts forests for a specific purpose (cattle ranching, cash-crop production, subsistence farming, etc.).

If the relative importance of different agents is spatially correlated (e.g. small farmers are concentrated in the hills, while ranchers on the planes) it may be useful to stratify the reference region, the project area and the leakage belt accordingly (in I_{RR} strata), and to continue the baseline assessment for each stratum *i* separately in order to increase the accuracy of the projections.

For each identified agent group, provide the following information:

a) Name of the main agent group or agent;

b) Brief description of the main social, economic, cultural and other relevant features of each main agent group. Limit the description to aspects that are relevant to understand why the agent group is deforesting;

c) Brief assessment of the most likely development of the population size of the identified main agent groups in the reference region, project area and leakage belt;

d) Statistics on historical deforestation attributable to each main agent group in the reference region, project area and leakage belt.

3.2 Identification of deforestation drivers

For each identified agent group, analyze factors that drive their land-use decisions. The goal is to identify the immediate causes of deforestation.

Two sets of driver variables have to be distinguished:

a) Driver variables explaining the quantity (hectares) of deforestation (to be used in step 4.1 and 4.3, as appropriate), such as:
   - Prices of agricultural products;

[23] See Angelsen and Kaimowitz (1999) and Chomiz *et al*. (2006) for comprehensive analysis of deforestation agents and drivers.

- Costs of agricultural inputs;
- Population density;
- Rural wages;
- Etc.

b) Driver variables explaining the location of deforestation, also called “predisposing factors” (de Jong, 2007) (to be used in step 4.2), such as:
   - Access to forests (such as vicinity to existing roads, railroads, navigable rivers and coastal lines);
   - Slope;
   - Proximity to markets;
   - Proximity to existing or industrial facilities (e.g. sawmills, pulp and paper mills, agricultural products processing facilities, etc.);
   - Proximity to forest edges;
   - Proximity to existing settlements;
   - Spatial variables indicating availability within the forest of land with good ecological conditions to expand agricultural activities, such as soil fertility and rainfall;
   - Management category of the land (e.g. national park, indigenous reserve, etc.);
   - Etc.

For each of these two sets of variables:

1) List the 1 to 5 key driver variables and provide any relevant source of information that provides evidence that the identified variables have been a driver for deforestation during the historical reference period.

2) Briefly describe for each main agent group identified in step 3.1 how the key driver variables have and will most likely impact on each agent group’s decision to deforest.

3) For each identified key driver variable provide information about its likely future development[24], by providing any relevant source of information.

4) For each identified driver variable briefly describe the project measures that will be implemented to address them[33], if applicable.

3.3 Identification of underlying causes of deforestation

The agents’ characteristics and decisions are themselves determined by broader forces, the underlying causes of deforestation, such as:

- Land-use policies and their enforcement;
- Population pressure;
- Poverty and wealth;
- War and other types of conflicts;
- Property regime;
- Etc.

[24] This does not apply to spatial variables, such slope, elevation etc.

1) List the 1 to 5 key underlying causes and cite any relevant source of information that provides evidence that the identified variables have been an underlying cause for deforestation during the historical reference period.

2) Briefly describe how each key underlying cause has determined and will most likely determine the key drivers identified in step 3.2 and the decisions of the main agent groups identified in step 3.1.

3) For each identified key underlying cause provide information about its likely future development, by citing any relevant source of information.

4) For each identified underlying cause describe the project measures that will be implemented to address them, if applicable.

3.4 Analysis of chain of events leading to deforestation

Based on the historical evidence collected, analyze the relations between main agent groups, key drivers and underlying causes and explain the sequence of events that typically has lead and most likely will lead to deforestation. Consult local experts, literature and other sources of information, as necessary. Briefly summarize the results of this analysis in the PD.

3.5 Conclusion

The analysis of step 3 must conclude with a statement about whether the available evidence about the most likely future deforestation trend within the reference region and project area is:

- Inconclusive or
- Conclusive.

"Conclusive" evidence in this methodology means that the hypothesized relationships between agent groups, driver variables, underlying causes and historical levels of deforestation can be verified at hand of statistical tests, literature studies, or other verifiable sources of information, such as documented information provided by local experts, communities, deforestation agents and other groups with good knowledge about the project area and the reference region.

To arrive at an overall "conclusive" conclusion when multiple agents and drivers are present, the evidence obtained for each of them must lead to a "conclusive" decision for all.

When the evidence is conclusive, state whether the weight of the available evidence suggests that the overall trend in future baseline deforestation rates will be:

- Decreasing;
- About constant;
- Increasing.

Then proceed to step 4.

When the evidence is inconclusive and the historical deforestation trend has been decreasing or about constant, additional analysis must be carried out under step 3, such as more literature reviews, expert consultations, and, as the case may be, additional field surveys, until conclusive evidence on the most likely future deforestation trend is found, otherwise it will not be possible to continue with the next steps of the methodology. If the historical deforestation trend has been increasing and the evidence is inconclusive, the deforestation rate to be used in the projections will be the average historical rate (see step 4.1.1). Alternatively, additional analysis could be carried out under step 3 until finding conclusive evidence.

Where different strata have been considered in the analysis, a conclusion and statement of trend is needed for each stratum. For a conservative baseline projection, the project proponent shall consider that in all the scenarios the agents and drivers of the deforestation activities are realistic and conservative, based on published and reliable data, and consistent with existing concrete actions and enforced laws avoiding deforestation, such as effective surveillance and law enforcement.

4 STEP 4: PROJECTION OF FUTURE DEFORESTATION

This step is the core of the baseline methodology. Its objective is to locate in space and time the baseline deforestation expected to occur within the reference region during the first fixed baseline period and, optionally, the project crediting period.

Where a baseline has already been defined for a geographic area that includes the project area and its leakage belt and this baseline is applicable according to the most recent VCS requirements on regional baselines or the criteria specified in table 2, the existing baseline must be used and the methodology continues with step 5.

4.1 Projection of the quantity of future deforestation

This sub-step is to determine the quantity of baseline deforestation (in hectares) for each future year within the reference region.

Where appropriate, the reference region can be stratified according to the findings of step 3 and different deforestation rates be estimated for each stratum[25]. If the reference region is stratified, the rationale for the stratification must be explained and a map of the strata provided. Briefly summarize the stratification criteria, and the strata using table 8:

Table 8. Stratification of the reference region

Stratum ID		Description	Area at year[1]			
			1	2	…	*T*
ID_i	Name		ha	ha	ha	ha
1						
2						
..						
n						
I_{RR}						

1. If the boundary of the strata is dynamic, explain the rationale and provide the estimated annual area of each stratum in the table.

If a jurisdiction (national or sub-national government) has adopted a VCS or UNFCCC registered (and VCS endorsed) baseline deforestation rate that is applicable to the reference region, project area and

25 Strata may be static (with fixed boundaries) or dynamic (with boundaries shifting over time).

leakage belt according to the most recent VCS *JNR Requirements*, the adopted rate must be used and no further analysis is required under this sub-step (continue with step 4.2).

Where the above condition does not exist, a projected deforestation rate must be determined by the project proponent taking into account possible future changes at the level of agents, drivers and underlying causes of deforestation, as well as the remaining forest area that is potentially available for conversion to non-forest uses. This task is performed through the following three analytical sub-steps:

4.1.1 Selection of the baseline approach;

4.1.2 Quantitative projection of future deforestation.

4.1.1 Selection of the baseline approach

To project future deforestation three baseline approaches are available:

a) Historical average approach: Under this approach, the rate of baseline deforestation is assumed to be a continuation of the average annual rate measured during the historical reference period within the reference region or, where appropriate, within different strata of the reference region.

b) Time function approach: With this approach, the rate of baseline deforestation is estimated by extrapolating the historical trend observed within the reference region (or its strata) as a function of time using either linear regression, logistic regression or any other statistically sound regression technique (see step 4.1.3). This approach requires multiple deforestation measurements during the past 10-15 years.

c) Modeling approach: With this approach, the rate of baseline deforestation will be estimated using a model that expresses deforestation as a function of driver variables selected by the project proponents. Such driver variables may be spatial and consistency with the analysis of step 3 must exist.

Select and justify the most appropriate baseline approach following the decision criteria described below. Different approaches can be used in different strata of the reference region, where appropriate.

1. The deforestation rates measured in different historical sub-periods in the reference region (or a stratum of it) do not reveal any trend (decreasing, constant or increasing deforestation) and:

   1.1 No conclusive evidence emerges from the analysis of agents and drivers explaining the different historical deforestation rates: do additional assessments under step 3, such as more literature reviews, expert consultations, and, as the case may be, additional field surveys, until finding conclusive evidence.

   1.2 Conclusive evidence emerges from the analysis of agents and drivers explaining the different historical deforestation rates: use approach "c" if there is at least one variable that can be used to project the deforestation rate, otherwise use approach "a".

2. The deforestation rates measured in different historical sub-periods in the reference region (or a stratum of it) reveal a clear trend and this trend is:

   2.1 A decrease of the deforestation rate and:

   - Conclusive evidence emerges from the analysis of agents and drivers explaining the decreasing trend and making it likely that this trend will continue in the future: use approach "b".

- Conclusive evidence emerges from the analysis of agents and drivers explaining the decreasing trend and this evidence also suggest that the decreasing trend will change in the future due to predictable changes at the level of agents and drivers: use approach "c".

- No conclusive evidence emerges from the analysis of agents and drivers explaining the decreasing trend: do additional assessments under step 3, such as more literature reviews, expert consultations, and, as the case may be, additional field surveys, until finding conclusive evidence, then use approach "b".

2.2 A constant deforestation rate and:

- Conclusive evidence emerges from the analysis of agents and drivers explaining the historical trend and making it likely that this trend will continue in the future: use approach "a".

- Conclusive evidence emerges from the analysis of agents and drivers explaining the historical trend and this evidence also suggests that the historical trend will change in the future due to predictable changes at the level of agents and drivers: use approach "c".

- No conclusive evidence emerges from the analysis of agents and drivers explaining the historical trend: do additional assessments under step 3, such as more literature reviews, expert consultations, and, as the case may be, additional field surveys, until finding conclusive evidence, then use approach "a".

2.3 An increase of the deforestation rate and:

- Conclusive evidence emerges from the analysis of agents and drivers explaining the increased trend and making it likely that this trend will continue in the future: use approach "b". If the future deforestation trend is likely to be higher than predicted with approach "b", use approach "c".

- Conclusive evidence emerges from the analysis of agents and drivers explaining the increased trend but this evidence also suggests that the future trend will change: use approach "a" or develop a model (approach "c").

- No conclusive evidence emerges from the analysis of agents and drivers explaining the increasing trend: use approach "a".

4.1.2 Quantitative projection of future deforestation

The methodology procedure is to first project the annual areas or rates of baseline deforestation within the reference region (or – where appropriate – within different strata of the reference region), then to analyze the spatial location of these annual areas in the reference region (step 4.2), and finally, to determine the annual areas and location of deforestation in the project area and leakage belt.

4.1.2.1 Projection of the annual areas of baseline deforestation in the reference region

The method to be used depends on the baseline approach selected.

Approach "a": Historical average

The annual baseline deforestation area that applies at year *t* to stratum *i* within the reference region is calculated as follows:

$$ABSLRR_{i,t} = ARR_{i,t-1} * RBSLRR_{i,t} \quad (3)$$

Where:

$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at year *t*; ha yr^{-1}
$ARR_{i,t-1}$	Area with forest cover in stratum *i* within the reference region at year *t-1*: ha
$RBSLRR_{i,t}$	Deforestation rate[26] applicable to stratum *i* within the reference region at year *t*; %
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless

Approach "b": Time function

The annual area of baseline deforestation that applies at a year *t* to stratum *i* within the reference region during the first $Toptimal_i$ years is calculated using one of the following equations:

- Linear regression: $ABSLRR_{i,t} = a + b*t$ (4.a)
- Logistic regression: $ABSLRR_{i,t} = ARR_i / (1+e^{-k*t})$ (4.b)
- Other types of regression: $ABSLRR_{i,t} = f(t)$ (4.c)

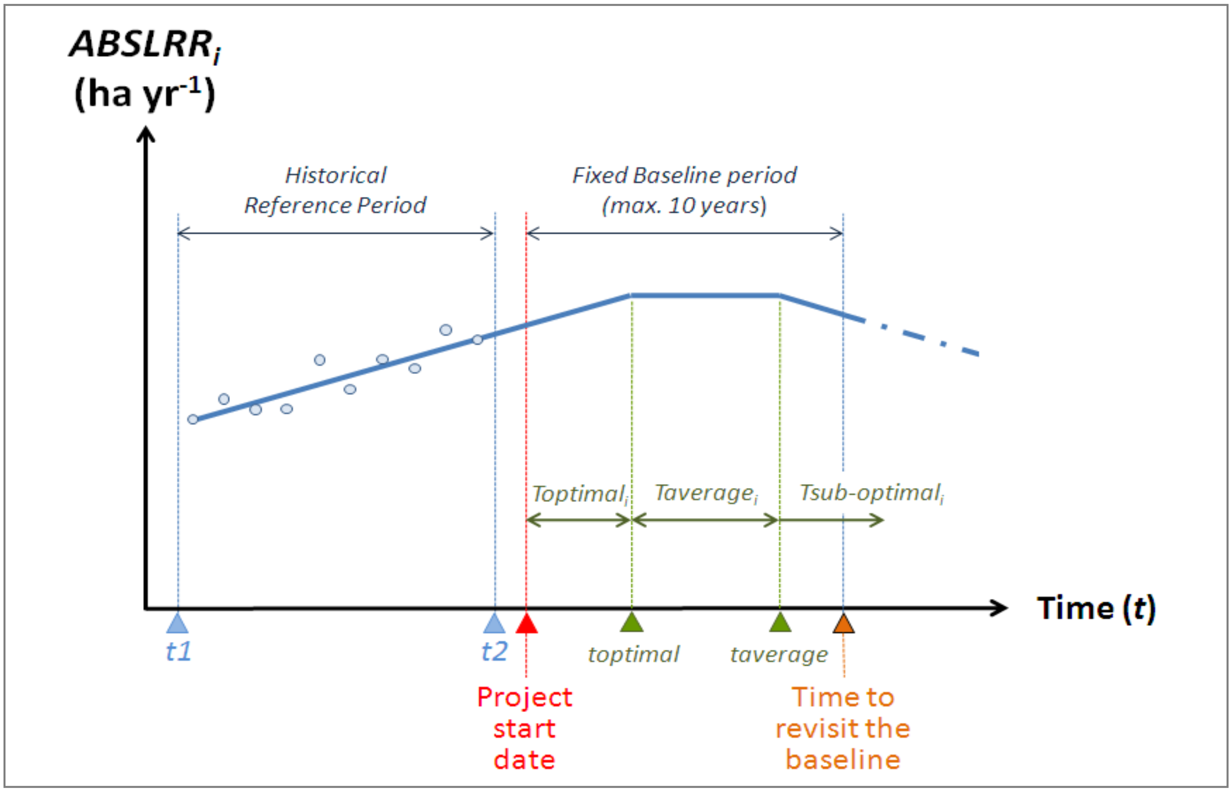
Where:

$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year *t*; ha yr^{-1}
a	Estimated intercept of the regression line; ha yr^{-1}
b	Estimated coefficient of the time variable (or slope of the linear regression); ha yr^{-1}
e	Euler number (2,71828); dimensionless
k	Estimated parameter of the logistic regression; dimensionless
ARR_i	Total forest area in stratum *i* within the reference region at the project start date; ha
$f(t)$	A function of time
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless

The model and its parameters are derived from data obtained from the historical reference period and are used to project future deforestation trends as shown in the figure 4 below.

26 See Puyravaud, J.-P., 2003. Standardizing the calculation of the annual rate of deforestation. Forest Ecology and Management, 177: 593-596

Figure 4. Approach "b" for modeling *ABSLRR*$_i$



The model must demonstrably comply with statistical good practice, and evidence that such requirement has been met shall be provided to VCS verifiers at the time of validation.

If $ABSLRR_{i,t}$ decreases as a function of time, $Toptimal_i$ is the period of time during which $ABSLRR_{i,t}$ yields a positive value. After that period of time, $ABSLRR_{i,t} = 0$.

If $ABSLRR_{i,t}$ increases as a function of time, $Toptimal_i$ is the period of time between $t = 1$ and $t = toptimal_i$, the latter being the year at which the following condition is satisfied:

$$Aoptimal_i = \sum_{t=1}^{toptimal_i} ABSLRR_{i,t} \qquad (5)$$

Where:

$Aoptimal_i$	Area of "optimal" forest land suitable for conversion to non-forest land within stratum *i* (see below); ha
$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year *t*; ha yr^{-1}
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless
$toptimal_i$	Year at which $Toptimal_i$ ends; yr

If: $Toptimal_i \geq$ Project crediting period: $ABSLRR_{i,t}$ calculated with equations 4 is applicable during the entire project crediting period.

If: $Toptimal_i <$ Project crediting period: $ABSLRR_{i,t}$ calculated with equations 4 is applicable only to the first $Toptimal_i$ years. For the following $Taverage_i$ years use value of $ABSLRR_{i,t}$ calculated for the year $t = Toptimal_i$: $Taverage_i$ is the period of time between $t = toptimal_i$ and $t = taverage_i$, the latter being the year at which the following condition is satisfied:

$$Aaverage_i = \sum_{t=toptimal_i}^{taverage_i} ABSLRR_{i,t} \qquad (6)$$

Where:

$Aaverage_i$	Area of "average" forest land suitable for conversion to non-forest land within stratum *i* (see below); ha
$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year *t*; ha yr^{-1}
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless
$toptimal_i$	Year at which $Toptimal_i$ ends; yr
$taverage_i$	Year at which $Taverage_i$ ends; yr

If: $Toptimal_i + Taverage_i \geq$ Project crediting period: $ABSLRR_{i,t}$ calculated for the year $t = toptimal_i$ is applicable during the period of time between $t = toptimal_i$ and $t = taverage_i$.

If: $Toptimal_i + Taverage_i <$ Project crediting period: $ABSLRR_{i,t}$ calculated for the year $t = toptimal_i$ is applicable only to the first $Taverage_i$ years following after year $toptimal_i$. For the following 20 years assume a linear decrease of $ABSLRR_{i,t}$ down to zero hectares per year in t=*faverage*+20.

$$ABSLRR_{i,t} = ABSLRR_{taverage,i}\ (1 - 1/20\ * (t - taverage_i)) \qquad (7)$$

Where:

$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year *t*; ha yr^{-1}
$ABSLRR_{taverage,i}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year $taverage_i$; ha yr^{-1}
$taverage_i$	Year at which $Taverage_i$ ends; yr
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless

Note: After $taverage_i$ + 20 years $ABSLRR_{i,t}$ will be zero hectares per year in all cases..

Calculation of $Aoptimal_i$ and $Aaverage_i$ under Approach "b"

$Aoptimal_i$ (area of "optimal" forest land suitable for conversion to non-forest land within stratum *i*) and $Aaverage_i$ (area of "average" forest land suitable for conversion to non-forest land within stratum *i*) must be determined to avoid non-conservative projections of baseline deforestation when "increasing deforestation" is projected under Approach "b". Deforestation can increase in the future only if there are no constraints to the conversion of forest land to non-forest land. This is typically the case when the project area is located in a country or region still with significant forest cover (Olander *et al*., 2006).

To assess whether there is scarcity of forest land that is accessible to deforestation agents and potentially exposed to the risk of deforestation do the following:

1) Identify land-use constraints: Identify the appropriate biophysical constraints (e.g. soil, climate, elevation and/or slope) and appropriate socio-economic constraints (e.g, mobility, land-use rights and/or areas with presence of conflicts and crime) that limit the geographical area where deforestation agents could expand their land-use activities in currently forested areas. Consider the constraints as they are perceived by the main groups of deforestation agents, taking into consideration their socio-economic conditions. To determine how constraints are perceived by the main groups of deforestation agents, determine the threshold conditions under which they have deforested historically (for example, range of slopes, types of soil, minimum/maximum rainfall, and/or elevation range, are relevant to determine the range where main types of crops and animals could survive). Use spatial data, literature, surveys, and/or participative rural appraisal (PRA) as appropriate.
2) Estimate the remaining forest area that could be converted to non-forest land: Using the constraints identified above, develop a Maximum Potential Deforestation Map, which maps the area currently covered by forests that is potentially available for the further expansion of non-forest uses in the reference region.
3) Stratify the Maximum Potential Deforestation Map in broad suitability classes: Considering the constraints identified above, define criteria and thresholds that delineate "optimal", "average" and "sub-optimal" conditions for each of the main land uses implemented by the main agent groups (e.g. by defining ranges of slope, rainfall or types of soils, or ranges of deforestation risks according to the deforestation risk map created for the spatial model (See step 4.2)). Select thresholds that are relevant from the point of view of the deforestation agents. Using the selected criteria and thresholds stratify the Maximum Potential Deforestation Map in three broad suitability classes representing "optimal", "average" and "sub-optimal" areas for non-forest uses. When available from other sources, use existing maps.
4) $Aoptimal_i$ will be the area of the "optimal" suitability class within stratum *i;* and $Aaverage_i$ will be the area of the "average" suitability class within stratum *i.*

Approach "c": Modeling

The annual area of baseline deforestation that applies at year *t* in stratum *i* within the reference region is estimated using a statistical model, such as simple regression, multiple regressions, logistic regression, or any other possible model to be proposed and justified by the project proponent. The proposed model must demonstrably comply with statistical good practice, and evidence that such requirement has been met shall be provided to VCS verifiers at the time of validation.

The following equations are given for illustration purposes only:

$$ABSLRR_{i,t} = a + b1_i * V1_{i,t} \quad (8.a)$$

$$ABSLRR_{i,t} = a + b1_i * V1_{i,t} + b2_i * V2_{i,t} \quad (8.b)$$

$$ABSLRR_{i,t} = ARR_i / (1 + e^{-k * V1_{i,t}}) \quad (8.c)$$

Where:

$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at a year *t*; ha yr^{-1}
$a; b1_i; b2_i; \ldots; bn_i; k$	Estimated coefficients of the model
e	Euler number (2,71828); dimensionless
$V1_{i,t}; V2_{i,t}; \ldots; Vn_{i,t}$	Variables included in the model
ARR_i	Total forest area in stratum *i* within the reference region at the project start date; ha
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless
i	1, 2, 3 … I_{RR}, a stratum within the reference region; dimensionless

The model may also be constructed with the annual area deforested ($ABSLRR_{i,t}$), or the deforestation rate ($RBSLRR_{i,t}$ = percentage of remaining forest area at year *t-1* in stratum *i* to be deforested at year *t*) as the dependent variable, and independent variable(s) (e.g. population density in stratum *i* at time *t*, average opportunity costs in stratum *i* at time *t*, etc.) from which the annual areas of deforestation ($ABSLRR_{i,t}$) or the deforestation rates ($RBSLRR_{i,t}$) are inferred from changes in the independent variables.

For each of the selected independent variables, there must be a description of the historical data (including source), an explanation of the rationale for using the variable(s), and a credible future projection based on documented and verifiable sources. To determine the future values of the variables included in the model, official projections, expert opinion, other models, and any other relevant and verifiable source of information must be used. Justify with logical and credible explanations any assumption about future trends of the driver variables and use values that yield conservative estimates of the projected deforestation ($ABSLRR_{i,t}$ or $RBSLRR_{i,t}$).

The model and its rationale must be explained by the project proponent using logical arguments and verifiable sources of information and must be consistent with the analysis of step 3.The model must demonstrably comply with statistical good practice, and evidence that such requirement has been met shall be provided to VCS verifiers at the time of validation.

4.1.2.2 Projection of the annual areas of baseline deforestation in the project area and leakage belt

Location analysis of future deforestation within reference region is required to determine the annual areas of deforestation within the project area and leakage belt (step 4.2). Once location analysis is completed, the portion of annual areas of baseline deforestation of each stratum *i* within the project area and leakage belt must be determined using a GIS.

To do this step, step 4.2.4 must be completed first.

4.1.2.3 Summary of step 4.1.2

Present the results of the previous assessments in Tables 9.a and 9.b. Do this at least for the fixed baseline period and, optionally, for the entire project crediting period.

Table 9.a. Annual areas of baseline deforestation in the reference region

Project year *t*	Stratum *i* in the reference region				Total	
	1	2	…	i_{RR}	annual	cumulative

4.2 Projection of the location of future deforestation

Step 4.1 was to estimate the annual areas of baseline deforestation in the reference region. Step 4.2 is to analyze where future deforestation is most likely to happen in the baseline case in order to match the location of the projected deforestation with carbon stocks and determine the annual areas of baseline deforestation in the project area and leakage belt.

Step 4.2 is based on the assumption that deforestation is not a random event but a phenomenon that occurs at locations that have a combination of bio-geophysical and economic attributes that is particularly attractive to the agents of deforestation. For example, a forest located on fertile soil, flat land, and near to roads and markets for agricultural commodities is likely to be at greater risk of deforestation than a forest located on poor soil, steep slope, and far from roads and markets. Locations at higher risk are assumed to be deforested first. This hypothesis can be tested empirically by analyzing the spatial correlation between historical deforestation and geo-referenced bio-geophysical and economic variables. In the previous example, soil fertility, slope, distance to roads and distance to markets are the hypothesized spatial driver variables (SDV_i) or “predisposing factors” (De Jong, 2007). These variables can be represented in a map (or “Factor Map”) and overlaid to a map showing historical deforestation using a Geographical Information System (GIS). From the combined spatial dataset information is extracted and analyzed statistically in order to produce a map that shows the level of deforestation risk at each spatial location (“pixel” or “grid cell”). The deforestation risk (or probability of deforestation) at a given spatial location changes at the time when one or more of the spatial driver variables change their values due to projected changes, e.g. when population density increases within a certain area, when a road is build nearby, or when areas recently deforested are coming closer, etc.

The basic tasks to perform the analysis described above are:

4.2.1 Preparation of factor maps;

4.2.2 Preparation of risk maps for deforestation;

4.2.3 Selection of the most accurate deforestation risk map; and

4.2.4 Mapping of the locations of future deforestation.

Several model/software are available and can be used to perform these tasks in slightly different ways, such as Geomod, Idrisi Taiga, Dinamica Ego, Clue, and Land-Use Change Modeler. The model/software used must be peer-reviewed and must be consistent with the methodology (to be proven at validation).

4.2.1 Preparation of factor maps

Based on the analysis of step 3 and step 4.1, identify the spatial variables that most likely explain the patterns of baseline deforestation in the reference region. Obtain spatial data for each variable and create digital maps representing the Spatial Features of each variable (i.e. the shape files representing the point, lines or polygon features or the raster files representing surface features). Some models will require producing Distance Maps from the mapped features (e.g. distance to roads or distance to already deforested lands) or maps representing continuous variables (e.g. slope classes) and categorical variables (e.g. soil quality classes). If the model/software allows working with dynamic Distance Maps (i.e. the software can calculate a new Distance Maps at each time step), these should be used. For simplicity, these maps are called "Factor Maps". Other models do not require Factor Maps for each variable, and instead analyze all the variables and deforestation patterns together to produce a risk map.

Where some of the spatial variables are expected to change, collect information on the expected changes from credible and verifiable sources of information. Then prepare Factor Maps that represent the changes that will occur in different future periods. Sometimes, projected changes can be represented by a dynamic spatial model that may change in response to deforestation.

In case of planned infrastructure (e.g. roads, industrial facilities, settlements) provide documented evidence that the planned infrastructure will actually be constructed and the time table of the construction. In case of planned new roads, road improvements, or railroads provide credible and verifiable information on the planned construction of different segments (e.g. how many kilometers will be constructed, where and when). Evidence includes: approved plans and budgets for the construction, signed construction contracts or at least an open bidding process with approved budgets and finance. If such evidence is not available exclude the planned infrastructure from the factors considered in the analysis.

Any area affected by planned deforestation due to the construction of planned infrastructure must be excluded from the project area.

In case of unplanned infrastructure (e.g. secondary roads), provide evidence that the unplanned infrastructure will actually develop, e.g. from historical developments. Specifically, from a wall-to-wall assessment (or at least five randomly sampled observations in the reference region) or from literature sources appropriate to the reference region, estimate the average annual length[27] of new unplanned infrastructure per square kilometer[28] that was constructed during the historical reference period. Alternatively, determine the historical rate of change as related to variables for which there are good projections (e.g. km of new unplanned infrastructure as related to population). To avoid projecting unplanned infrastructure in areas where geographic and socio-economic conditions are unfavorable for infrastructure developments (e.g. areas with steep slopes, swampy soils, low opportunity costs, etc.), develop a map representing a proxy of the suitability for future infrastructure development. For each

---

27 Other parameters relevant for modeling the construction of secondary roads may also be measured in this analysis, such as distance between roads, number of destinations per year, etc. Parameters to be assessed are dependent on the modeling approach used to project the development of the road network and are therefore not further specified here.

28 Or per km of official new road constructed, or per other landscape features that can be mapped (such as new industrial facilities, settlements, mining concessions etc.), as appropriate.

"suitability" class or gradient (using a minimum of two classes, e.g. suitable, not suitable), determine the most plausible rate of unplanned infrastructure development. To do this, apply the following steps:

a) Using historical data, expert opinion, participative rural appraisal (PRA), literature and/or other verifiable sources of information list all relevant criteria that facilitate (at least one criterion) and constrain (at least one criterion) the development of new unplanned infrastructure.

b) For each criterion, generate a map using a GIS.

c) Using multi-criteria analysis, determine the most likely rate of unplanned infrastructure development (e.g. km km^{-2} yr^{-1} or a similar indicator) per different sectors (suitability classes or gradients) within the reference region.

Projections of unplanned infrastructure development shall be conservative, in particular projections in forested areas shall meet this requirement.

To create the Factor Maps use one of the following two approaches:

- **Empirical approach:** Categorize each Distance Map in a number of predefined distance classes (e.g. class 1 = distance between 0 and 50 m; class 2 = distance between 50 and 100 m, etc.). In a table describe the rule used to build classes and the deforestation likelihood assigned to each distance class[29]. The deforestation likelihood is estimated as the percentage of pixels that were deforested during the period of analysis (i.e. the historical reference period).

- **Heuristic approach**: Define "value functions" representing the likelihood of deforestation as a function of distance from point features (e.g., saw mills) or linear features (e.g., roads), or as a function of polygon features representing classes (e.g. of soil type, population density) based on expert opinion or other sources of information. Specify and briefly explain each value function in the PD.

  For Distance Maps, a useful approach to estimate value functions is to sample spatially uncorrelated points and their corresponding location in the maps representing historical deforestation (Land-Use and Land-Cover Change Maps produced with step 2) and to use regression techniques[30] to define the probability of deforestation as a function of "distance".

The empirical approach should be preferred over the heuristic approach. Use the heuristic approach only where there is insufficient information about the spatial location of historical deforestation or where the empirical approach does not produce accurate results when validated against a historical period.

4.2.2 Preparation of deforestation risk maps

A Risk Map shows at each pixel location l the risk (or "probability") of deforestation in a numerical scale (e.g., 0 = minimum risk; 255 = maximum risk).

---

[29] When building classes of continuous variables it is important to build classes that are meaningful in terms of deforestation risk. This implies the parameterization of a "value function" based on specific measurements. For instance, the criterion "distance to roads" might not have a linear response to assess the deforestation risk: a forest located at 50 km from the nearest road may be subject to the same deforestation risk of a forest located at 100 km, while at 0.5 km the risk may be twice as much as at 1.0 km. Data to model the value function and build meaningful classes can be obtained by analyzing the distribution of sample points taken from historically deforested areas.

[30] e.g. logistic regression.

Models use different techniques to produce Risk Maps and algorithms may vary among the different modeling tools. Algorithms of internationally peer-reviewed modeling tools are eligible to prepare deforestation risk maps, provided they are shown to conform to the methodology at time of validation.

Several Risk Maps should be produced using different combinations of Factor Maps and modeling assumptions in order to allow comparison and select the most accurate map.

A list of Factor Maps, including the maps used to produce them and the corresponding sources shall be presented in the PD (table 10) together with a flow-chart diagram illustrating how the Risk Map is generated.

Table 10. List of variables, maps and factor maps

Factor Map		Source	Variable represented		Meaning of the categories or pixel value		Other Maps and Variables used to create the Factor Map		Algorithm or Equation used	Comments
ID	File Name		Unit	Description	Range	Meaning	ID	File Name		

4.2.3 Selection of the most accurate deforestation risk map

Confirming the quality of the model output (generally referred to as model validation in the modeling community) is needed to determine which of the deforestation risk maps is the most accurate. A good practice to confirm a model output (such as a risk map) is "calibration and validation", referred to here as "calibration and confirmation" (so as not to be confused with validation as required by the VCS).

Two options are available to perform this task: (a) calibration and confirmation using two historical sub-periods; and (b) calibration and confirmation using tiles. Option (b) should be preferred where recent deforestation trends have been different from those in the more distant past.

a) Where two or more historical sub-periods have shown a similar deforestation trend, data from the most recent period can be used as the "confirmation" data set, and those from the previous period as the "calibration" data set.

   Using only the data from the calibration period, prepare for each Risk Map a Prediction Map of the deforestation for the confirmation period. Overlay the predicted deforestation with locations that were actually deforested during the confirmation period. Select the Prediction Map with the best fit and identify the Risk Map that was used to produce it. Prepare the final Risk Map using the data from the calibration and the confirmation period.

b) Where only one historical sub-period is representative of what is likely to happen in the future, divide the reference region in tiles and randomly select half of the tiles for the calibration data set and the other half for the confirmation set. Do the analysis explained above (see Castillo-Santiago *et al.,* 2007).

The Prediction Map with the best fit is the map that best reproduced actual deforestation in the confirmation period. The best fit must be assessed using appropriate statistical techniques. Most peer-reviewed modeling tools, such as Geomod, Idrisi Taiga, Land Use Change Modeler, and Dinamica Ego, include in the software package appropriate assessment techniques, which can be used under this methodology. Preference should be given to techniques that assess the accuracy of the prediction at the polygon level, such as the predicted quantity of total deforestation within the project area as compared to the observed one.

One of the assessment techniques that can be used is the "Figure of Merit" (*FOM*) that confirms the model prediction in statistical manner (Pontius *et al*. 2008; Pontius *et al*. 2007)[31].

The *FOM* is a ratio of the intersection of the observed change (change between the reference maps in time 1 and time 2) and the predicted change (change between the reference map in time 1 and simulated map in time 2) to the union of the observed change and the predicted change (equation 9). The FOM ranges from 0.0, where there is no overlap between observed and predicted change, to 1.0 where there is a perfect overlap between observed and predicted change. The highest percent FOM must be used as the criterion for selecting the most accurate Deforestation Risk Map to be used for predicting future deforestation.

$$FOM = B / (A+B+C) \quad (9)$$

Where:

FOM	"Figure of Merit"; dimensionless
A	Area of error due to observed change predicted as persistence; ha
B	Area correct due to observed change predicted as change; ha
C	Area of error due to observed persistence predicted as change; ha

The minimum threshold for the best fit as measured by the Figure of Merit (FOM) shall be defined by the net observed change in the reference region for the calibration period of the model. Net observed change shall be calculated as the total area of change being modeled in reference region during the calibration period as percentage of the total area of the reference region. The FOM value shall be at least equivalent to this value. If the FOM value is below this threshold, the project proponent must demonstrate that at least three models have been tested, and that the one with the best FOM is used.

4.2.4 Mapping of the locations of future deforestation

Future deforestation is assumed to happen first at the pixel locations with the highest deforestation risk value. To determine the locations of future deforestation do the following:

---

31 Pontius, R. G., Jr, W Boersma, J-C Castella, K Clarke, T de Nijs, C Dietzel, Z Duan, E Fotsing, N Goldstein, K Kok, E Koomen, C D Lippitt, W McConnell, A Mohd Sood, B Pijanowski, S Pithadia, S Sweeney, T N Trung, A T Veldkamp, and P H Verburg. 2008. Comparing input, output, and validation maps for several models of land change. Annals of Regional Science, 42(1): 11-47. Pontius, R G, Jr, R Walker, R Yao-Kumah, E Arima, S Aldrich, M Caldas and D Vergara. 2007. Accuracy assessment for a simulation model of Amazonian deforestation. Annals of Association of American Geographers, 97(4): 677-695

- In the most accurate Deforestation Risk Map select the pixels with the highest value of deforestation probability. Add the area of these pixels until their total area is equal to the area expected to be deforested in the reference region in project year one according to table 9.a. The result is the Map of Baseline Deforestation for Year 1.
- Repeat the above pixel selection procedure for each successive project year *t* to produce a series of Maps of Baseline Deforestation for each future project year. Do this at least for the upcoming fixed baseline period and, optionally, for the entire project crediting period.
- Add all yearly (baseline deforestation maps in one single map showing the expected Baseline Deforestation for the fixed baseline period and, optionally, for the entire project crediting period. Present this map in the PD.

The described pixel selection procedure and production of annual maps of baseline deforestation can be programmed in most state of the art modeling tools/software.

To obtain the annual areas of baseline deforestation within the project area, combine the annual maps of baseline deforestation for the reference region with a map depicting only the polygon corresponding to the project area. After this step, table 9.b can be filled-out. The same must be done for the leakage belt area to fill-out table 9.c.

5 STEP 5: DEFINITION OF THE LAND-USE AND LAND-COVER CHANGE COMPONENT OF THE BASELINE

The goal of this step is to calculate activity data[32] of the initial forest classes (*icl*) that will be deforested and activity data of the post-deforestation classes (*fcl*) that will replace them in the baseline case.

After step 4, the area and location of future deforestation are both known and pre-deforestation carbon stocks can be determined by matching the predicted location of deforestation with the location of forest classes with known carbon stocks.

Pre-deforestation carbon stocks shall be those existing or projected to exist at the year of the projected deforestation. This implies that forest classes in areas undergoing degradation in the baseline case will not be the ones existing at the project start date, but the ones projected to exist at the year of deforestation.

Post-deforestation carbon stocks can either be determined as the historical area-weighted average carbon stock, or using location analysis (modeling).

Apply the following sub-steps:

5.1 Calculation of baseline activity data per forest class;

5.2 Calculation of baseline activity data per post-deforestation class; and

5.3 Calculation of baseline activity data per LU/LC change category.

Sub-step 5.3 applies only if the location of post-deforestation classes is known (i.e. the location of post-deforestation classes has been modeled).

[32] Activity data = hectares per year

5.1 Calculation of baseline activity data per forest class

Combine the Maps of Annual Baseline Deforestation of each future year produced in the previous step with the Land-Use and Land-Cover Map produced for the current situation in step 2 to produce a set of maps showing for each forest class the polygons that that would be deforested each year in absence of the AUD project activity. Extract from these maps the number of hectares of each forest class that would be deforested and present the results in table 11 (11.a for the reference region[33], 11.b for the project area and 11.c for the leakage belt area). Do this at least for the fixed baseline period and, optionally, for the project crediting period.

In most cases one single Land-Use and Land-Cover Map representing the spatial distribution of forest classes at the project start date will have been produced in step 2. However, where certain areas of land are expected to undergo significant changes in carbon stocks due to growth or degradation in the baseline case, a sequence of Land-Use and Land-Cover Maps representing the mosaic of forest-classes of each future year may have been generated in step 2, in which case it must be used this step.

5.2 Calculation of baseline activity data per post-deforestation forest class

Two methods are available to project the LU/LC classes that will replace forests in the baseline case; (1) "Historical LU/LC-change" and (2) "Modeling".

Method 1: Historical LU/LC-change

Historical LU/LC-changes are assumed to be representative for future trends. Hence, post-deforestation land-uses are allocated to the projected areas of annual deforestation in same proportions as those observed on lands deforested during the historical reference period in the reference region.

Divide the reference region (or at least the area encompassing the project area, leakage belt and leakage management areas) in *Z* zones (at least one zone), each representing different combinations of possible post-deforestation land uses (zone 1, zone 2, etc.) taking into account the historical location of post-deforestation LU/LC-classes and the requirements (climate, soil, economic factors) that different classes have to be established within a given zone in the baseline case.

If more than one zone exists, include in the PD a map showing the location of these zones (Map of Zones of Post-Deforestation Land Uses) and provide a brief explanation of the rationale of the zoning. In Table 12, report the area of each zone and the areas of each post-deforestation LU/LC class present in each zone (based in the maps and data produced in step 2).

Table 12. Zones of the reference region* encompassing different combinations of potential post-deforestation LU/LC classes

Zone		Name:		Name:		Name:		Total of all other LU/LC classes present in the Zone		Total area of each Zone	
		ID_{fcl}	1	*ID_{fcl}*	2	*ID_{fcl}*	*Fcl*				
		Area	% of Zone	Area	% of Zone	Area	% of Zone	Are a	%of Zone	Are a	% of Zone
IDz	*Name*	ha	%	ha	%	ha	%	ha	%	ha	%
1	Zone 1										
2	Zone 2										
…	Zone …										
Z	Zone Z										
Total area of each class *fcl*		-									

* A smaller area than the reference region can be considered, but this smaller area must at least contain the project area, the leakage belt and the leakage management areas.

Calculate the area projected to be deforested in each zone and report the result in table 13.b (for the project area) and 13.c (for the leakage belt). Do this at least for the fixed baseline period and, optionally, for the entire project crediting period. Doing the same for the reference region (table 13.a) is optional.

3						
T						

Method 2: Modeling

The future spatial distribution of post-deforestation LU/LC classes is determined using a spatial model. Two modeling techniques can be used:

a) Projection of LU/LC-change categories: Some deforestation modeling tools can be used to project several LU/LC-change categories at the same time, instead of just the broad category "deforestation". In such cases, the non-forest classes are determined by each projected category of change. Methods discussed in section 4.2.3 shall be used to select the most accurate prediction map.

b) Suitability modeling:

- Criteria must be identified determining the suitability of each main post-deforestation LU/LC class, such as soil type, elevation, slope, etc. (as selected and justified by the project proponent).
- Using multi-criteria analysis the suitability of each post-deforestation LU/LC class is determined for each spatial location. At each spatial location the class with the highest suitability value is assumed to be the one that deforestation agents will implement in absence of the AUD project activity.

- Show the results obtained in maps and summarize the results in tables 13.b and 13.c above (13.a is optional). Note that by using Method 2, each post-deforestation LU/LC class *fcl* will represent one and only one "zone" *z* (i.e. "*fcl*" = "*z*")
- The model must demonstrably comply with statistical good practice, and evidence that such requirement has been met shall be provided to VCS verifiers at the time of validation.

5.3 Calculation of baseline activity data per LU/LC change category

This sub-step is only applicable in conjunction with the Method 2 described above. The goal of this sub-step is to identify the categories of LU/LC-change (*ct*) and the level of activity data of each of these categories. This is performed as follows:

- Combine the maps showing the polygons of forest classes (*icl*) that would be deforested during each future year produced in step 4.2.4 with the map showing the post-deforestation LU/LC classes (*fcl*) prepared in step 5.2.
- From the combined datasets produce a new set of maps showing the polygons of the categories of LU/LC change (*ct*) for each future year. Some spatial modeling tools can produce these maps directly.
- Extract from the maps produced above the number of hectares (i.e., activity data) corresponding to each future year.
- Summarize the results in table 14.a (optional), 14.b and 14.c for the fixed baseline period and, optionally, for the project crediting period.

Table 14.a. Baseline activity data for LU/LC change categories (*ct*) in the reference region

6 STEP 6: ESTIMATION OF BASELINE CARBON STOCK CHANGES AND NON-CO_2 EMISSIONS

The goal of this step is to finalize the baseline assessment by calculating:

6.1 Baseline carbon stock changes; and (optionally)

6.2 Baseline non-CO_2 emissions from forest fires used to clear forests.

6.1 Estimation of baseline carbon stock changes

Before calculating the baseline carbon stock changes it is necessary to estimate the average carbon stock (tCO_2-e ha^{-1}) of each LU/LC class.

6.1.1 Estimation of the average carbon stocks of each LU/LC class

Average carbon stocks must be estimated only for:

- the forest classes existing within the project area[34];

[34] In most cases the forest classes existing within the project area at the project start date will remain the same in the baseline case. However, where certain areas within the project boundary are subject to baseline degradation

- the forest classes existing within the leakage belt[35];
- the post-deforestation classes projected to exist in the project area in the baseline case;
- the post-deforestation classes projected to exist in the leakage belt in the project case; and
- the non-forest classes existing in leakage management areas.

Collect existing carbon-stock data for these classes from local published studies and existing forest and carbon inventories. Do additional field measurements for the classes for which there is insufficient information. Follow the guidance below:

a) Assess the existing data collected and, where appropriate, use them. It is likely that some existing data could be used to quantify the carbon stocks of one or more classes. These data could be derived from a forest inventory or perhaps from scientific studies. Analyze these data and use them if the following criteria are fulfilled:

   - The data are less than 10 years old;
   - The data are derived from multiple measurement plots;
   - All species above a minimum diameter are included in the inventories;
   - The minimum diameter for trees included is 30 cm or less at breast height (DBH);
   - Data are sampled from good coverage of the classes over which they will be extrapolated.

   Existing data that meet the above criteria shall only be applied across the classes from which they were representatively sampled and not beyond that. See the latest version of the GOFC-GOLD sourcebook on REDD and Gillespie, *et al.* (1992) for methods to analyze these data.

b) Collect missing data. For the classes for which no existing data are available it will be necessary to either obtain the data from field measurement or to use conservative estimates from the literature.

   Field measurements:

   - Locate the sampling sites. If the locations of future deforestation are known at the time of field measurements, the sample sites should be located at the locations expected to be deforested to achieve maximum accuracy of the carbon stock estimates.
   - Design the sampling framework and conduct the field measurements following the guidance of appendix 3 (see also chapter 4.3 of GPG LULUCF and in the sourcebook for LULUCF by Pearson *et al*., 2005). Summarize the sampling design in the PD and provide a map and the coordinates of all sampled locations.

   Literature estimates:

   - The use of carbon stock estimates in similar ecosystems derived from local studies, literature and IPCC defaults is permitted[36], provided the accuracy and conservativeness of the estimates are demonstrated.

---

due to unsustainable logging, fuel wood collection, charcoal production and other reasons, the decrease in carbon stocks must be projected. If carbon stocks are subject to enhancement, the projection is optional and can conservatively be omitted.

[35] In most cases the forest classes existing at the project start date within the leakage belt will remain the same in the baseline case. However, where certain areas within the leakage belt are subject to enhancement in the baseline case, carbon stocks must be projected for each year. If carbon stocks are subject to baseline degradation, projecting the changes in carbon stocks is optional and can conservatively be omitted.

- When defaults are used, the lowest value of the range given in the literature source (or the value reduced by 30%) must be used for the forest classes, and the highest value (or the value augmented by 30%) for non-forest classes.

c) Calculate the carbon stocks existing in each forest class in the project area prior to the year of baseline deforestation. For all years preceding the year in which the projected baseline deforestation will occur (*t* <= *t**) carbon stocks and boundaries of the forest-classes are assumed to remain the same, except in the following cases:

- If in the baseline case the forest within certain polygons of the project area is degrading and loosing carbon stocks, a map sequence showing the spatial and temporal sequence of forest classes with successively lower carbon stocks must be prepared to account for the degradation occurring prior to deforestation. If the boundary of the forest classes undergoing degradation is fixed (i.e. does not change over time) it is sufficient to show the estimated changes in carbon stocks in a table (Table 15a and Table 15b). To do the projection, use credible and verifiable sources of data from existing studies, or measure field plots in degraded forests of different known age.
- If in the baseline case the forest within certain polygons of the project area has increasing carbon stocks, changes in carbon stocks can conservatively be omitted. If a projection is done, use credible and verifiable sources of data from existing studies, or measure field plots in secondary forests of different known age.
- If carbon stocks in the project area are decreasing more in the project case than in the baseline case (e.g. when the project activity involves logging for timber, fuel-wood collection or charcoal production in areas not subject to such activities in the baseline case), this will have to be accounted in the project case.
- If logging activities are present in the baseline, the harvested wood product carbon pool must be estimated and, if significantly higher in the baseline compared to the project scenario, it will have to be accounted.
- Report the results of the estimations in Table 15.a (estimated values) and Table 15.b (values used in calculations after considering discounts for uncertainties according to "f" below).
- Carbon stocks in the harvested wood products carbon pool must be estimated as the sum of planned and unplanned harvesting activities in the baseline case and the additional volume harvested prior to the deforestation event in year *t** (if applicable).

d) Calculate the carbon stocks existing in each forest class in the leakage belt prior to the year of baseline deforestation (*t* = *t**): For all years preceding the year in which the projected baseline deforestation will occur (*t* > *t**) carbon stocks and boundaries of the forest-classes are assumed to remain the same, except in the following cases:

- If in the baseline case the forest within certain polygons of the leakage belt is growing and carbon stocks are increasing, a map sequence showing the spatial and temporal sequence of forest classes with successively higher carbon stocks must be prepared to account for the

---

[36] Attention must be paid on data units. In this methodology calculations are done in tCO_2-e while IPCC tables often provide data in tC (1 tC = 44/12 t CO_2-e)

carbon stock enhancement. To do the projection, use credible and verifiable sources of data from existing studies, or measure field plots in secondary forests of different known age.

- If in the baseline case the forest within certain polygons of the leakage belt is degrading and loosing carbon stocks, changes in carbon stocks can conservatively be omitted and preparing a map sequence is optional for these polygons.
- Report the results of the estimations in Table 15.a (estimated values) and Table 15.b (values used in calculations after considering discounts for uncertainties according to "f" below).

The space "Notes" in table 15.1.2 is intended to insert explanations (or references to explanations) about how uncertainties have been considered.

Where:

Cab_{icl}	Average carbon stock per hectare in the above-ground biomass carbon pool of class *icl*; tCO_2-e ha^{-1}
Cbb_{icl}	Average carbon stock per hectare in the below-ground biomass carbon pool of class *icl*; tCO_2-e ha^{-1}
Cdw_{icl}	Average carbon stock per hectare in the dead wood biomass carbon pool of class *icl*; tCO_2-e ha^{-1}
Cl_{icl}	Average carbon stock per hectare in the litter carbon pool of LU/LC class *icl*; tCO_2-e ha^{-1}
$Csoc_{icl}$	Average carbon stock per hectare in the soil organic carbon pool of LU/LC class *icl*; tCO_2-e ha^{-1}
Cwp_{icl}	Average carbon stock per hectare accumulated in the harvested wood products carbon pool between project start and the year of deforestation of class *icl*; tCO_2-e ha^{-1}

Note: In the baseline case, Cwp_{cl} must be subtracted from the sum of the other pools in the calculation of $Ctot_{cl}$

$Ctot_{icl}$	Average carbon stock per hectare in all accounted carbon pools of LU/LC *icl*; tCO_2-e ha^{-1}

e) Calculate the long-term (20-years) average carbon stocks of post-deforestation classes: These classes often do not have a stable carbon stock because different land uses may be implemented in a time sequence or because the land use after deforestation implies carbon stocks changes over time (e.g. in case of tree plantations). The carbon stock of post-deforestation classes must be estimated as the long-term (20 years) average carbon stock and can be determined from measurements in plots of known age, long-term studies and other verifiable sources.

For each post-deforestation LU/LC class, report the calculation of the long-term (20-year) average carbon stock using Table 16.

f) Do an uncertainty assessment of all carbon stock estimates following the methods described in appendix 2, Box 2. If the uncertainty of the total average carbon stock ($Ctot_{cl}$) of a class *cl* is less than 10% of the average value, the average carbon stock value can be used. If the uncertainty is higher than 10%, the lower boundary of the 90% confidence interval must be considered in the calculations if the class is an initial forest class in the project area or a final non-forest class in the leakage belt, and the higher boundary of the 90% confidence interval if the class is an initial forest class in the leakage belt or a final non-forest class in the project area.

g) Calculate the area-weighted average carbon stocks of the post-deforestation LU/LC classes existing within each zone using Table 17.

Table 16. Long-term (20-years) average carbon stocks per hectare of post-deforestation LU/LC classes present in the reference region (the selection of carbon pools is subject to the latest VCS requirements on this matter, see table 3)

6.1.2 Calculation of carbon stock change factors

The *AFOLU Requirements* requires methodologies to consider the decay of carbon stock in soil carbon, below-ground biomass, dead wood and harvested wood products in the baseline case.

In this methodology default linear functions are applied to account for the decay of carbon stock in initial forest classes (*icl*) and increase in carbon stock in post-deforestation classes. This is done as follows:

a) Above-ground biomass:

- Initial forest classes (*icl*): immediate release of 100% of the carbon stock (as estimated in Table 15.b) is assumed to happen at the end of year $t = t^*$ (= year in which deforestation occurs).
- Post-deforestation classes (*fcl*) (or their area weighted average per zone *z*): linear increase from 0 tCO_2-e/ha in year $t = t^*$ to 100% of the long-term (20-years) average carbon stock (as estimated in Table 17) in year $t = t^*+9$ is assumed to happen in the 10-years period following deforestation (i.e. $1/10^{th}$ of the final carbon stock is accumulated each year).

b) Below-ground biomass:

- Initial forest classes (*icl*): an annual release of $1/10^{th}$ of the initial carbon stock (as estimated in Table 15.b) is assumed to happen each year between $t = t^*$ and $t = t^*+9$.
- Post-deforestation classes (*fcl*) (or their area weighted average per zone *z*): linear increase from 0 tCO_2-e/ha in year $t = t^*$ to 100% of the long-term (20-years) average carbon stock (as estimated in Table 17) in year $t = t^*+9$ is assumed to happen in the 10 years period following deforestation (i.e. $1/10^{th}$ of the final carbon stock is accumulated each year).

c) Litter:

- Initial forest classes (*icl*): immediate release of 100% of the carbon stock (as estimated in Table 15.b) is assumed to happen at the end of year $t = t^*$.
- Post-deforestation classes (*fcl*) (or their area weighted average per zone *z*): a linear increase from 0 tCO_2-e/ha in year $t = t^*$ to 100% of the long-term (20-years) average carbon stock (as estimated in Table 17) in year $t = t^*+9$ is assumed to happen in the 10-years period following deforestation (i.e. $1/10^{th}$ of the final carbon stock is accumulated each year).

d) Dead wood:

- Initial forest classes (*icl*): an annual release of $1/10^{th}$ of the initial carbon stock (as estimated in Table 15.b) is assumed to happen each year between $t = t^*$ and $t = t^*+9$.
- Post-deforestation classes (*fcl*) (or their area weighted average per zone *z*): a linear increase from 0 tCO_2-e/ha in year $t = t^*$ to 100% of the long-term (20-years) average carbon stock (as estimated in Table 17) in year $t = t^*+9$ is assumed to happen in the 10-years period following deforestation (i.e. $1/10^{th}$ of the final carbon stock is accumulated each year).

e) Wood products:

- Initial forest classes (*icl*): Three fractions are considered:

  1) Fraction decaying in less than three years: This short-lived fraction is assumed to be released 100% at the end of year t^* (i.e. 100% of the stock estimated in Table 15.b).

2) Fraction decaying between 3 and 100 years: This medium-lived fraction is assumed to linearly decay in 20 years (i.e. each year 1/20 of the stock estimated in Table 15.b).

3) Fraction decaying in more than 100 years: This long-lived fraction is assumed to never decay (i.e. never be released into the atmosphere).

- Post-deforestation classes (*fcl*) (or their area weighted average per zone *z*): it is assumed that carbon stocks in wood products are always insignificant (i.e. carbon stock in all wood products is zero).

f) Soil organic carbon:

- It is assumed that in a 20-years period the carbon stock changes from the level estimated for the initial forest classes (*icl*) (in Table 15.b) to the level estimated for the post-deforestation class *fcl* (or their area weighted average per zone *z*). The change occurs linearly and can be either a decrease or an increase, depending on the carbon stock estimated for the initial forest class and for the final post-deforestation class *fcl* or zone *z*.

- If carbon stocks in the soil organic carbon pool are included in the baseline, it will be necessary to calculate activity data per category (*ct*). This is because the linear decay (or increase) function is category-dependent. If method 2 was used in Step 5.3, Table 14 will provide the information on activity data per category *ct*. If method 1 was used, it will be necessary to define categories (from initial forest classes *icl* to zones *z*). Use Table 18.a and 18.b to describe these categories and combine the Map of Zones of Post-Deforestation Land Uses with the map of initial forest classes and the annual maps of projected deforestation to calculate activity data of these categories (*ctz*). Report the results in Tables 19.a, 19.b and 19.c. Do this at least for the fixed baseline period and the project area and leakage belt and, optionally, for the entire project crediting period and for the reference region.

Tables 20.a, 20.b and 20.c summarize how carbon stock change factors are calculated.

6.1.3 Calculation of baseline carbon stock changes

The choice of the method to calculate carbon stock changes depends on whether activity data are available for classes or for categories. If soil organic carbon is included in the baseline only Method 2 can be used (i.e. activity data must be defined for categories).

If activity data are available for classes (Method 1), the total baseline carbon stock change in the project area at year *t* is calculated as follows:

$$\Delta CBSLPA_t = \sum_{p=1}^{P}\Bigg(\sum_{icl=1}^{Icl} ABSLPA_{icl,t} * \Delta Cp_{icl,t=t*} - \sum_{z=1}^{Z} ABSLPA_{z,t} * \Delta Cp_{z,t=t*}$$
$$+ \sum_{icl=1}^{Icl} ABSLPA_{icl,t-1} * \Delta Cp_{icl,t=t*+1} - \sum_{z=1}^{Z} ABSLPA_{z,t-1} * \Delta Cp_{z,t=t*+1}$$
$$+ \sum_{icl=1}^{Icl} ABSLPA_{icl,t-2} * \Delta Cp_{icl,t=t*+2} - \sum_{z=1}^{Z} ABSLPA_{z,t-2} * \Delta Cp_{z,t=t*+2} \quad + \cdots$$
$$+ \sum_{icl=1}^{Icl} ABSLPA_{icl,t-19} * \Delta Cp_{icl,t=t*+19} - \sum_{z=1}^{Z} ABSLPA_{z,t-19} * \Delta Cp_{z,t=t*+19}\Bigg) \tag{10}$$

Where:

$\Delta CBSLPA_t$	Total baseline carbon stock change within the project area at year *t*; tCO_2-e
$ABSLPA_{icl,t}$	Area of initial forest class *icl* deforested at time *t* within the project area in the baseline case; ha

Note: Prepare a similar table for all selected carbon pools (Table 21.c.2 for below-ground biomass; Table 21.c.3 for dead wood; Table 21.c.4 for litter; and Table 21.c.6 for wood products– Use Method 2 if soil organic carbon is included).

<u>If activity data are available for categories (Method 2),</u> first calculate the carbon stock change factors of each category as shown in table 20.c and then calculate the baseline carbon stock changes for the reference region (optional), project area and leakage belt area by multiplying activity data with their corresponding emission factors. Do this at least for the fixed baseline period and, optionally, for the entire project crediting period.

Report the result of the calculations in Tables 22.a 1-6 (for the reference region); Tables 22.b.1-6 (for the project area); and Tables 22.c1-6 (for the leakage belt area).

Note: It is possible (and simpler) to calculate baseline carbon stock changes using Method 1 for all carbon pools (except soil organic carbon) and, if soil organic carbon is included, using Method 2 just for this pool.

6.2 Baseline non-CO_2 emissions from forest fires

Emissions from fires used to clear forests in the baseline can always be omitted.

Conversion of forest to non-forest involving fires is a source of emissions of non-CO_2 gases (CH_4 and N_2O). When sufficient data on such forest fires are available from the historical reference period and the project proponent considers that these emissions are an important component of the baseline, CH_4 emissions from biomass burning can be estimated. Where such data are unavailable, or of insufficient accuracy, emissions from biomass burning should not be considered (which is conservative).

The effect of fire on carbon emissions is counted in the estimation of carbon stock changes; therefore CO_2 emissions from forest fires should be ignored to avoid double counting.

To estimate non-CO_2 emissions from forest fires, it is necessary to estimate the average percentage of the deforested area in which fire was used, the average proportion of mass burnt in each carbon pool ($Pburnt_{,p}$), and the average combustion efficiency of each pool (CE_p). These average percentage values are estimated for each forest class (*icl*) and are assumed to remain the same in the future.

Based on revised IPCC 1996 GL LULUCF, GHG emissions from biomass burning can be estimated as follows.

$$EBBtot_{icl,t} = EBBN2O_{icl,t} + EBBCH4_{icl,t} \quad (11)$$

Where:

$EBBtot_{icl,t}$ Total GHG emission from biomass burning in forest class *icl* at year *t*; tCO_2-e ha^{-1}

$EBBN2O_{icl,t}$	N_2O emission from biomass burning in forest class *icl* at year *t*; tCO_2-e ha^{-1}
$EBBCH4_{icl,t}$	CH_4 emission from biomass burning in forest class *icl* at year *t*; tCO_2-e ha^{-1}

$$EBBN2O_{icl,t} = EBBCO2_{icl,t} * 12/44 * NCR*ER_{N2O}*44/28*GWP_{N2O} \quad (12)$$

$$EBBCH4_{icl,t} = EBBCO2_{icl,t} * 12/44 * ER_{CH4}*16/12*GWP_{CH4} \quad (13)$$

Where:[41]

$EBBCO2_{icl,t}$	Per hectare CO_2 emission from biomass burning in slash and burn in forest class *icl* at year *t*; tCO_2-e ha^{-1}
$EBBN2O_{icl,t}$	Per hectare N_2O emission from biomass burning in slash and burn in forest class *icl* at year *t*; tCO_2-e ha^{-1}
$EBBCH4_{icl,t}$	Per hectare CH_4 emission from biomass burning in slash and burn in forest class *icl* at year *t*; tCO_2-e ha^{-1}
NCR	Nitrogen to Carbon Ratio (IPCC default value = 0.01); dimensionless
ER_{N2O}	Emission ratio for N_2O (IPCC default value = 0.007)
ER_{CH4}	Emission ratio for CH_4 (IPCC default value = 0.012)
GWP_{N2O}	Global Warming Potential for N_2O (IPCC default value = 310 for the first commitment period)
GWP_{CH4}	Global Warming Potential for CH_4 (IPCC default value = 21 for the first commitment period)

$$EBBCO2_{icl,t} = Fburnt_{icl} * \sum_{p=1}^{P} (C_{p,icl,t} * Pburnt_{p.icl} * CE_{p,icl}) \quad (14)$$

Where:

$EBBCO2_{icl,t}$	Per hectare CO_2 emission from biomass burning in the forest class *icl* at year *t*; tCO_2-e ha^{-1}
$Fburnt_{icl}$	Proportion of forest area burned during the historical reference period in the forest class *icl*; %
$C_{p,icl,t}$	Average *carbon stock* per hectare in the carbon pool *p* burnt in the forest class *icl* at year *t*; tCO_2-e ha^{-1}
$Pburnt_{p,icl}$	Average proportion of mass burnt in the carbon pool *p* in the forest class *icl*; %
$CE_{p,icl}$	Average combustion efficiency of the carbon pool *p* in the forest class *icl*; dimensionless
p	Carbon pool that could burn (above-ground biomass, dead wood, litter)

[41] Refers to table 5.7 in 1996 Revised IPCC Guideline for LULUCF and equation 3.2.19 in IPCC GPG-LULUCF

icl	1, 2, 3, …*Icl* (pre-deforestation) forest classes
t	1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless

The combustion efficiencies may be chosen from table 3.A.14 of IPCC GPG LULUCF. If no appropriate combustion efficiency can be used, the IPCC default of 0.5 should be used. The Nitrogen to Carbon Ratio (*NCR*) is approximated to be about 0.01. This is a general default value that applies to leaf litter, but lower values would be appropriate for fuels with greater woody content, if data are available. Emission factors for use with above equations are provided in Tables 3.A 15 and 3.A.16 of IPCC GPG LULUCF.

Report the values of all estimated parameters in the following table.

7 STEP 7: *EX ANTE* ESTIMATION OF ACTUAL CARBON STOCK CHANGES AND NON-CO_2 EMISSIONS IN THE PROJECT AREA

The goal of this step is to provide an *ex ante* estimate of future carbon stock changes and non-CO_2 emissions from forest fires under the project scenario (“actual”). Since actual carbon stock changes and GHG emissions will be subject to MRV-A, the rationale of estimating them at the beginning of a fixed baseline period is to assist in guiding optimal implementation of emission reduction measures, and to allow reasonable projections of revenue to be made.

7.1 *Ex ante* estimation of actual carbon stock changes

These are due to the following:

7.1.1 Planned activities within the project area.

7.1.2 Unplanned deforestation that cannot be avoided.

Carbon stock changes due to possible future catastrophic events cannot be predicted and are therefore excluded from the *ex ante* assessment.

7.1.1 *Ex ante* estimation of actual carbon stock changes due to planned activities

It is possible that certain discrete areas of forest within the project area will be subject to project activities that will change the carbon stocks of these areas compared to the baseline. Such activities are:

a) Planned deforestation (e.g. to build project infrastructure);

b) Planned degradation (e.g. timber logging, fuel-wood collection or charcoal production);

c) Protection without harvesting leading to carbon sequestration in forest classes that at project start are below their carbon stock potential at maturity *in situ*.

If the project activity generates a significant decrease in carbon stocks during the fixed baseline period, the carbon stock change must be estimated *ex ante* and measured *ex post*. If the decrease is not significant, it must not be accounted, and *ex post* monitoring will not be required.

If the project activity generates an increase in carbon stocks, ignoring the carbon stock change is conservative. However, if the project proponent wishes to be credited for carbon stock increases on areas projected to be deforested in the baseline case, *ex post* monitoring of the carbon stock increase is mandatory[42].

Changes in carbon stocks that are not attributable to the project activity cannot be accounted.

Mandatory accounting of significant carbon stock decreases:

Where the AUD project activity includes planned deforestation, harvesting of timber[43], fuel-wood collection or charcoal production above the baseline case do the following:

a) Identify the forest areas (polygons) within the project area that will be subject to planned deforestation and planned degradation activities (logging, fuel-wood collection or charcoal production) during the project crediting period.

b) Prepare maps showing the annual locations of the planned activities.

c) Identify the forest classes that are located within these polygons.

d) Define activity data (annual areas) for each forest class, according to the planned interventions and types of intervention.

e) Estimate the impact of the planned activities on carbon stocks as follows:

- Planned deforestation: Conservatively assume that 100% of the carbon stocks will be lost at the year of the planned deforestation.
- Areas subject to planned logging, fuel-wood collection or charcoal production above the baseline case: Conservatively assume that the carbon stock of these areas will be the lowest of the production cycle according to the planned levels of extraction.

f) Summarize the result of the previous assessments and calculations in Tables 25.a – 25.d. Tables 25.b and 25.c can only be filled out *ex post* and do not need to be filled out *ex ante* (i.e. their *ex ante* values are 0). These tables are for unpredictable carbon stock decreases that may have to be measured and reported *ex post* due to uncontrolled forest fires and other catastrophic events that may occur within the project area during project implementation.

[42] If an area is not projected to be deforested, carbon stock increase in the project scenario cannot be accounted in this methodology, as the project category would be IFM and not AUD.

[43] Ignoring the carbon stocks in the long-lived wood products is conservative under the project scenario.

Optional accounting of significant carbon stock increase

Consideration of carbon stock increase due to planned activities in areas that would be deforested in the baseline case is optional in this methodology and can always be omitted.

However, if the project area includes degraded and secondary forests that in the baseline case would be deforested and due to the project activity these areas will recover and sequester additional carbon, credits for the increased carbon stocks can be claimed. In the case, do the following:

a) Identify within the project area the polygons that are at the same time projected to be deforested in the baseline case and that are currently covered by secondary forests or degraded forests that have the potential to grow and accumulate significant carbon stocks;

b) Identify also the polygons representing areas of forests that will be subject to planned logging, fuel-wood collection and charcoal production activities under the project scenario and that have the potential to grow and accumulate significant carbon stocks after the periodical harvest cycle;

c) Prepare maps showing the annual locations of the polygons identified above;

d) Identify the forest classes existing in the polygons identified above;

e) Calculate activity data (annual areas) for each forest class in the polygons identified above;

f) For each forest class within the polygons, develop conservative growth projections using field data (measurements in plots of different ages), literature, existing databases and other credible and verifiable sources of information;

g) Calculate the projected increase in carbon stocks of each class. If the class is subject to periodical harvesting in the project case, assume that the maximum carbon stock is the long term average carbon stock (the average of a production cycle). Once a class reaches this level of carbon stock, do not allow any more carbon stock increase in the projections; and

h) Summarize the result of the previous assessments and calculations in Tables 26.a –26.d. Tables 26.b and 26.c can only be filled out *ex post* and do not need to be filled out *ex ante* (i.e. their *ex ante* values are 0). These tables are for unpredictable carbon stock increases that may have to be measured and reported *ex post* due to forest regeneration on areas affected by forest fires and catastrophic events.

7.1.2 *Ex ante* estimation of carbon stock changes due to unavoidable unplanned deforestation within the project area

Some unplanned deforestation may happen in the project area despite the AUD project activity. The level at which deforestation will actually be reduced in the project case depends on the effectiveness of the proposed activities, which cannot be measured *ex ante*. *Ex post* measurements of the project results will be important to determine actual emission reductions.

To allow *ex ante* projections to be made, the project proponent shall make a conservative assumption about the effectiveness of the proposed project activities and estimate an Effectiveness Index (EI) between 0 (no effectiveness) and 1 (maximum effectiveness). The estimated value of EI is used to multiply the baseline projections by the factor (1 - EI) and the result shall be considered the *ex ante* estimated emissions from unplanned deforestation in the project case.

$$\Delta CUDdPA_t = \Delta CBSL_t * (1 - EI) \qquad (16)$$

Where:

$\Delta CUDdPA_t$	Total *ex ante* actual carbon stock change due to unavoided unplanned deforestation at year t in the project area; tCO_2-e

7.2 *Ex ante* estimation of actual non-CO_2 emissions from forest fires

Where forest fires have been included in the baseline scenario, non-CO_2 emissions from biomass burning must be included in the project scenario. This is done by multiplying the baseline emissions by the factor (1 – *EI*). The results are presented in table 28.

$$EBBPSPA_t = EBBBSPA_t * (1 - EI) \tag{17}$$

Where:

$EBBPSPA_t$	Total *ex ante* actual non-CO_2 emissions from forest fire due to unavoided unplanned deforestation at year *t* in the project area; tCO_2-e

8 STEP 8: *EX ANTE* ESTIMATION OF LEAKAGE

The goal of this step is to provide an *ex ante* estimate of the possible decrease in carbon stock and increase in GHG emissions (other than carbon stock change) due to leakage. The rationale for estimating leakage *ex ante* is to assist in guiding the design of optimal leakage prevention measures, identify sources of leakage that are potentially significant, and therefore subject to MRV, and to allow making reasonable projections of carbon and other project revenues.

Two sources of leakage are considered in this methodology and must be addressed:

8.1 Decrease in carbon stocks and increase in GHG emissions associated with leakage prevention measures;

8.2 Decrease in carbon stocks and increase in GHG emissions associated with activity displacement leakage.

8.1 *Ex ante* estimation of the decrease in carbon stocks and increase in GHG emissions due to leakage prevention measures

To reduce the risk of activity displacement leakage, baseline deforestation agents should be given the opportunity to participate in activities within the project area and in specially designated leakage management areas (outside the project area) that together will replace baseline income, product generation and livelihood of the agents as much as possible, so that deforestation will be reduced and the risk of displacement minimized.

If leakage prevention measures include tree planting, agricultural intensification, fertilization, fodder production and/or other measures to enhance cropland and grazing land areas, a reduction in carbon stocks and/or an increase in GHG emissions may occur compared to the baseline case. If such decrease in carbon stock or increase in GHG emission is significant, it must be accounted and monitoring will be required. If it is not significant, it must not be accounted and *ex post* monitoring will not be necessary.

If leakage prevention activities are associated to other VCS or UNFCCC registered (and VCS endorsed) project activities, changes in carbon stocks and GHG emissions that are already subject to MRV in such other registered project activities must not be estimated and accounted to avoid double-counting.

The following activities in leakage management areas could occasion a decrease in carbon stocks or an increase in GHG emissions:

8.1.1 Carbon stock changes due to activities implemented in leakage management areas;

8.1.2 Methane (CH_4) and nitrous oxide (N_2O) emissions from livestock intensification (involving a change in the animal diet and/or animal numbers).

Note that nitrous oxide (N_2O) emissions from nitrogen fertilization are considered always insignificant according to the most recent version of the VCS Standard.

Consumption of fossil fuels is considered always insignificant in AUD project activities and must not be considered.

8.1.1 Carbon stock changes due to activities implemented in leakage management areas

Leakage prevention activities generating a decrease in carbon stocks should be avoided, but if such activities are necessary the decrease in carbon stock associated to the leakage prevention activity must be estimated *ex ante* and accounted, if significant.

To estimate carbon stock changes in leakage management areas do the following:

a) Prepare a list of the planned leakage prevention activities and briefly describe each of them in the PD;

b) Prepare a map of the planned leakage prevention activities showing annual areas of intervention and type of intervention;

c) Identify the areas where leakage prevention activities will impact on carbon stocks;

d) Identify the non-forest classes[44] existing within these areas in the baseline case;

e) Measure the carbon stocks in the identified classes or use conservative literature estimates for each of the identified classes. If some classes have changing carbon stocks in the baseline, do carbon stock projections using growths data and other relevant and verifiable sources of information;

f) Report in table 30.a the projected baseline carbon stock changes in the leakage management areas;

g) According to the planned interventions, estimate the projected carbon stocks in the leakage management areas under the project scenario. Use conservative growth projections. Report the result in table 30.b; and

h) Calculate the net carbon stock changes that the planned leakage prevention measures are expected to occasion during the fixed baseline period and, optionally, the project crediting period. Report the results of the calculations in table 30.c

- If the net sum of carbon stock changes within a monitoring period is more than zero, leakage prevention measures are not causing any carbon stock decrease. The net increase shall conservatively be ignored in the calculation of net GHG emission reductions of the project activity.

- If the net sum is negative, determine the significance using the most recent version of the EB-CDM approved "Tool for testing significance of GHG emissions in A/R CDM project activities". If the decrease is significant, it must be accounted in the *ex ante* estimation of leakage and carbon stock changes in the land units where leakage prevention measures are implemented will be subject to MRV. If the decrease is not significant, it must not be accounted and carbon stock changes will not be subject to MRV.

[44] Forest classes cannot be present in leakage management areas at the project start date (see section 1.1.4).

8.1.2 *Ex ante* estimation of CH_4 and N_2O emissions from grazing animals

To estimate the increase in emissions of methane (CH_4) and nitrous oxide (N_2O) from grazing animals in leakage management areas do the following:

a) Specify the annual areas that will have grazing activities in the leakage management areas;

b) Briefly describe the types of animal, forage and manure management. Use table 31 to report the key parameters required to perform the calculation of GHG emissions;

c) Determine the number of animals in the baseline case and under the project scenario based on available areas and forage. The difference must be considered for the calculation of the increase in GHG emissions; and

d) Methods to estimate emissions from enteric fermentation and manure management are given in appendix 4. Perform the final calculations using equation 18 and report the results in table 32.

The GHG emissions are estimated as follows:

$$EgLK_t = ECH4ferm_t + ECH4man_t + EN2Oman_t \qquad (18)$$

Where:

$EgLK_t$	Emissions from grazing animals in leakage management areas at year *t;* tCO_2-e yr^{-1}
$ECH4ferm_t$	CH_4 emissions from enteric fermentation in leakage management areas at year *t*; tCO_2-e yr^{-1}
$ECH4man_t$	CH_4 emissions from manure management in leakage management areas year *t*; tCO_2-e yr^{-1}
$EN2Oman_t$	N_2O emissions from manure management in leakage management areas at year *t*; tCO_2-e yr^{-1}
t	1, 2, 3, … *T* years of the project crediting period; dimensionless

Table 31. Parameters used for the *ex ante* estimation of GHG emissions from grazing activities

Parameter	Value used for calculations	Unit	Description
EF1		kg CH_4 head^{-1} yr^{-1}	Enteric CH_4 emission factor for the livestock group
EF2		kg CH4 head^{-1} yr^{-1}	Manure management CH_4 emission factor for the livestock group
EF3		kg N_2O-N (kg N^{-1}) head^{-1} yr^{-1}	Emission factor for N_2O emissions from manure management for the livestock group
EF4		kg N_2O-N (kg NH_3-N and NO_x-N emitted)$^{-1}$ head^{-1} yr^{-1}	Emission factor for N_2O emissions from atmospheric deposition of forage-sourced nitrogen on soils and water surfaces
DBI		kg d.m. head^{-1} day^{-1}	Daily biomass intake
Nex		kg N head^{-1} yr^{-1}	Annual average N excretion per livestock head
Fracgas		kg NH_3-N and NO_x-N emitted (Kg N)$^{-1}$	Fraction of managed livestock manure nitrogen that volatilizes as NH_3 and NO_x in the manure management phase

8.2 *Ex ante* estimation of the decrease in carbon stocks and increase in GHG emissions due to activity displacement leakage

Activities that will cause deforestation within the project area in the baseline case could be displaced outside the project boundary due to the implementation of the AUD project activity. If carbon stocks in the leakage belt area will decrease more during project implementation than projected in the baseline case, this will be an indication that leakage due to displacement of baseline activities has occurred. Leakage due to activity displacement can thus be estimated by *ex post* monitoring of deforestation in the leakage belt and comparing *ex post* observed deforestation with *ex ante* projected baseline deforestation. A baseline for the leakage belt is therefore necessary and methods to establish this baseline were described in section 6.1.2 and 6.1.3.

Do the *ex ante* baseline assessment of the leakage belt and report the result in tables 21.c (if Method 1 is used) or 22.c (if Method 2 is used):

However, *ex ante*, activity displacement leakage can only be guessed based on the anticipated combined effectiveness of the proposed leakage prevention measures and project activities.

This shall be done by multiplying the estimated baseline carbon stock changes for the project area by a "Displacement Leakage Factor" (*DLF*) representing the percent of deforestation expected to be displaced outside the project boundary[45].

If emissions from forest fires have been included in the baseline, the *ex ante* emissions from forest fires due to activity displacement leakage will be calculated by multiplying baseline forest fire emissions in the project area by the same *DLF* used to estimate the decrease in carbon stocks.

Report the *ex ante* estimated leakage due to activity displacement in table 34.

Table 34. *Ex ante* estimated leakage due to activity displacement

T				

[45] If deforestation agents do not participate in leakage prevention activities and project activities, the Displacement Factor shall be 100%. Where leakage prevention activities are implemented the factor shall be equal to the proportion of the baseline agents estimated to be given the opportunity to participate in leakage prevention activities and project activities.

8.3 *Ex ante* estimation of total leakage

Summarize the result all sources of leakage in table 35.

Table 35. *Ex ante* estimated total leakage

Project year *t*	Total *ex ante* GHG emissions from increased grazing activities		Total *ex ante* increase in GHG emissions due to displaced forest fires		Total *ex ante* decrease in carbon stocks due to displaced deforestation		Carbon stock decrease due to leakage prevention measures		Total net carbon stock change due to leakage		Total net increase in emissions due to leakage

9 STEP 9: *EX ANTE* TOTAL NET ANTHROPOGENIC GHG EMISSION REDUCTIONS

9.1 Significance assessment

All carbon pools and sources of GHG emissions considered in this methodology must be calculated to assess their significance. Use the latest EB-CDM approved “Tool for testing significance of GHG emissions in A/R CDM project activities” to determine the significance of each of the *ex ante* calculated carbon stock changes and GHG emissions. Report the result of the analysis in the PD.

Only significant sources and pools need to be accounted in the calculation of net anthropogenic GHG emission reductions (step 9.2) and only significant sources and pools must be considered in the monitoring plan.

9.2 Calculation of *ex-ante* estimation of total net GHG emissions reductions

The net anthropogenic GHG emission reduction of the proposed AUD project activity is calculated as follows:

$$\Delta REDD_t = (\Delta CBSLPA_t + EBBBSLPA_t) - (\Delta CPSPA_t + EBBPSPA_t) - (\Delta CLK_t + ELK_t) \quad (19)$$

Where:

$\Delta REDD_t$ — *Ex ante* estimated net anthropogenic greenhouse gas emission reduction attributable to the AUD project activity at year t; tCO_2e

$\Delta CBSLPA_t$ — Sum of baseline carbon stock changes in the project area at year t; tCO_2e

Note: The absolute values of $\Delta CBSLPA_t$ shall be used in equation 19.

$EBBBSLPA_t$ — Sum of baseline emissions from biomass burning in the project area at year t; tCO_2e

$\Delta CPSPA_t$ — Sum of *ex ante* estimated actual carbon stock changes in the project area at year t; tCO_2e

Note: If $\Delta CPSPA_t$ represents a net increase in carbon stocks, a negative sign before the absolute value of $\Delta CPSPA_t$ shall be used. If $\Delta CPSPA_t$ represents a net decrease, the positive sign shall be used.

$EBBPSPA_t$ — Sum of (*ex ante* estimated) actual emissions from biomass burning in the project area at year t; tCO_2e

ΔCLK_t — Sum of *ex ante* estimated leakage net carbon stock changes at year t; tCO_2e

Note: If the cumulative sum of ΔCLK_t within a fixed baseline period is > 0, ΔCLK_t shall be set to zero.

ELK_t — Sum of *ex ante* estimated leakage emissions at year t; tCO_2e

t — 1, 2, 3 … T, a year of the proposed project crediting period; dimensionless

9.3 Calculation of *ex-ante* Verified Carbon Units (VCUs)

The number of Verified Carbon Units (VCUs) to be generated through the proposed AUD project activity at year t is calculated as follows:

$VCU_t = \Delta REDD_t - VBC_t$ (20)

$VBC_t = (\Delta CBSLPA_t - \Delta CPSPA_t) * RF_t$ (21)

Where:

VCU_t Number of Verified Carbon Units that can be traded at time *t*; t CO_2-e

Note: If $VCU_t < 0$ no credits (VCUs) will be awarded to the proponents of the AUD project activity. VCUs can only be granted if the following condition is met:

$\sum_{t=0}^{t} \Delta REDD_t > 0$ (22)

$\Delta REDD_t$ *Ex ante* estimated net anthropogenic greenhouse gas emission reduction attributable to the AUD project activity at year *t*; tCO_2-e ha^{-1}

VBC_t Number of Buffer Credits deposited in the VCS Buffer at time *t*; t CO_2-e

$\Delta CBSLPA_t$ Sum of baseline carbon stock changes in the project area at year *t*; tCO_2e

$\Delta CPSPA_t$ Sum of *ex ante* estimated actual carbon stock changes in the project area at year *t*; tCO_2-e ha^{-1}

RF_t Risk factor used to calculate VCS buffer credits; %

Note: RF_t is a risk factor to be determined using the latest version of the VCS-approved AFOLU Non-Permanence Risk Tool.

t 1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless

See also the latest version of the Registration and Issuance Process document for information on this subject matter[46].

Present the result of the calculations in table 36.

[46] Available at: http://www.v-c-s.org

PART 3 – METHODOLOGY FOR MONITORING AND RE-VALIDATION OF THE BASELINE

The *ex post* methodology (to be implemented immediately after project start) includes two main tasks:

1) Monitoring of carbon stock changes and GHG emissions for periodical verifications within the fixed baseline period; and
2) Monitoring of key baseline parameters for revisiting the baseline at the end of the fixed baseline period.

Appendix 6 provides an overview of the tables that should be prepared to report monitoring results.

1 TASK 1: MONITORING OF CARBON STOCK CHANGES AND GHG EMISSIONS FOR PERIODICAL VERIFICATIONS

There are three main monitoring tasks:

1.1 Monitoring of actual carbon stock changes and GHG emissions within the project area;

1.2 Monitoring of leakage; and

1.3 *Ex post* calculation of net anthropogenic GHG emission reduction.

Prepare a Monitoring Plan describing how these tasks will be implemented. For each task the monitoring plan must include the following sections:

a) Technical description of the monitoring tasks.
b) Data to be collected (see appendix 5).
c) Overview of data collection procedures.
d) Quality control and quality assurance procedures.
e) Data archiving.
f) Organization and responsibilities of the parties involved in all the above.

To allow a transparent comparison between *ex ante* and *ex post* estimates, use the same formats and tables presented in Part 2 of the methodology to report the results of monitoring.

1.1 Monitoring of actual carbon stock changes and GHG emissions within the project area

This task involves:

1.1.1 Monitoring of project implementation;

1.1.2 Monitoring of land-use and land-cover change;

1.1.3 Monitoring of carbon stocks and non-CO_2 emissions; and

1.1.4 Monitoring of impacts of natural disturbances and other catastrophic events.

1.1.1 Monitoring of project implementation

Project activities implemented within the project area should be consistent with the management plans of the project area and the PD. All maps and records generated during project implementation should be conserved and made available to VCS verifiers at verification for inspection to demonstrate that the AUD project activity has actually been implemented.

1.1.2 Monitoring of land-use and land-cover change within the project area

The categories of changes that may be subject to MRV are summarized in table 37.

Table 37. Categories subject to MRV

ID	Type	Conditions under which monitoring is mandatory	Explanations
I	Area of forest land converted to non-forest land.	Mandatory in all AUD project activities	
II	Area of forest land undergoing carbon stock decrease.	Mandatory only for AUD project activities having planned logging, fuel-wood collection and charcoal production activities above the baseline.	Change in carbon stock must be significant according to *ex ante* assessment, otherwise monitoring is not required.
III	Area of forest land undergoing carbon stock increase.	Mandatory only for AUD project activities wishing to claim carbon credits for carbon stock increase.	Increase must be significant according to *ex ante* assessment and can only be accounted on areas that will be deforested in the baseline case.

If the project area is located within a region subject to MRV by a jurisdictional program, the MRV data generated by this program must be used.

Similarly, if the project area is located within a region that is subject to a monitoring program that is approved or sanctioned by the national or sub-national government, the data generated by such program must be used, unless they are not applicable according to the criteria listed below:

a) Monitoring occurs in the entire project area and, if the project must monitor a leakage belt, in the leakage belt.

b) If data from the existing monitoring program are used to periodically revisit the baseline, monitoring must occur in the entire reference region at least at the beginning, middle and end of the fixed baseline period.

c) At least category I (table 37) is subject to monitoring (conversion of forest land to non-forest land).

d) It the project must do a monitoring of other categories (II and/or III) and these are not included in the existing program, the existing program can only be used for monitoring category I, and the project proponent must implement a separate monitoring program for category II and/or III.

e) Monitoring will occur during the entire fixed baseline period.

f) Monitoring methods are transparently documented and are similar to those used to determine the baseline of the AUD project activity.

g) Monitoring protocols and data must be accessible for inspection by VCS accredited verifier.

If no existing monitoring program exist or can be used, monitoring must be done by the project proponent or outsourced to a third party having sufficient capacities to perform the monitoring tasks. Methods used to monitor LU/LC change categories and to assess accuracy must be similar to those explained in part 2, step 2.4 and part 2, step 2.5, respectively.

The results of monitoring shall be reported by creating *ex post* tables of activity data per stratum (Tables 9.a, 9.b and 9.c); per initial forest class *icl* (Tables 11.a, 11.b and 11.c); per post-deforestation zone *z* (Tables 13.a, 13.b and 13.c) and, where applicable, per category of land-use change *ct* (Tables 14.a, 14.b and 14.c).or *ctz* (Tables 19.a, 19.b and 19.c).

1.1.3 Monitoring of carbon stock changes and non-CO_2 emissions from forest fires

Monitoring of carbon stock changes

In most cases, the *ex ante* estimated average carbon stocks per LU/LC class (or carbon stock change factors per LU/LC change category) will not change during a fixed baseline period and monitoring of carbon stocks will not be necessary.

However, monitoring of carbon stocks is mandatory in the following cases:

Within the project area:

a) Areas subject to significant carbon stock decrease in the project scenario according to the *ex ante* assessment. These will be areas subject to controlled deforestation and planned harvest activities, such as logging, fuel wood collection and charcoal production. In these areas, carbon stock changes must be estimated at least once after each harvest event.

b) Areas subject to unplanned and significant carbon stock decrease, e.g. due to uncontrolled forest fires and other catastrophic events. In these areas, carbon stock losses must be estimated as soon as possible after the catastrophic event. See section 1.1.4 below for more detailed guidance.

Within leakage management areas:

a) Areas subject to planned and significant carbon stock decrease in the project scenario according to the *ex ante* assessment. In these areas, carbon stocks must be estimated at least once after the planned event that caused the carbon stock decrease.

Monitoring of carbon stocks is optional in the following cases:

Within the project area:

a) Areas subject to carbon stock increase after planned harvest activities, such as logging, fuel wood collection and charcoal production. In these areas, the carbon stock increase occurring after the harvest event can be measured and accounted, when significant.

b) Areas recovering after disturbances, such unplanned forest fires and other catastrophic events. In these areas, the carbon stock increase occurring after the catastrophic event can be measured and accounted, when significant. See section 1.1.4 below for more detailed guidance.

Within leakage management areas:

a) Areas subject to carbon stock increase due to leakage prevention measures. In these areas, the carbon stock increase can be measured and accounted only up to the amount necessary to offset any carbon stock decrease caused by leakage prevention measures in other leakage management areas or in previous years.

Within the leakage belt:

a) Areas undergoing significant changes in carbon stock may be measured at the end of each fixed baseline period in order to update carbon stock information for the subsequent period.

Where carbon stocks are monitored, the methods on sampling and measuring carbon stocks described in appendix 3 must be used.

Some project proponents may wish to do additional carbon stock measurements during project implementation to gain accuracy and credits. If new and more accurate carbon stock data become available, these can be used to estimate the net anthropogenic GHG emission reduction of the subsequent fixed baseline period. For the current fixed baseline period, new data on carbon stocks can only be used if they are validated by an accredited VCS verifier. If new data are used in the current fixed baseline period, the baseline must be recalculated using the new data.

The results of monitoring activity data and carbon stocks must be reported using the same formats and tables used for the *ex ante* assessment:

Table 15	*Ex post* carbon stock per hectare of initial forest classes *icl* existing in the project area and leakage belt

Monitoring of non-CO_2 emissions from forest fires

These are subject to monitoring and accounting, when significant. In this case, under the project scenario it will be necessary to monitor the variables of table 23 within the project area and to report the results in table 24.

1.1.4 Monitoring of impacts of natural disturbances and other catastrophic events

Decreases in carbon stocks and increases in GHG emissions (e.g. in case of forest fires) due to natural disturbances (such as hurricanes, earthquakes, volcanic eruptions, tsunamis, flooding, drought[47], fires, tornados or winter storms) or man-made events, including those over which the project proponent has no control (such as acts of terrorism or war), are subject to monitoring and must be accounted under the project scenario, when significant. Use tables 25.e, 25.f and 25.g to report carbon stock decreases and, optionally, tables 26.e, 26.f and 26.g to report carbon stock increases that may happen on the disturbed lands after the occurrence of an event. Use tables 23 and 24 to report emissions from forest fires.

If the area (or a sub-set of it) affected by natural disturbances or man-made events generated VCUs in past verifications, the total net change in carbon stocks and GHG emissions in the area(s) that generated VCUs must be estimated, and an equivalent amount of VCUs must be cancelled from the VCS buffer.

---

[47] When the 1997-1998 El Niño episode provoked severe droughts in the Amazon and Indonesia, large areas of tropical forest burned, releasing 0.2 to 0.,4 Gt of carbon to the atmosphere (de Mendonça *et al.*, 2004; Siegert *et al.*, 2001; Page *et al*., 2002). If droughts become more severe in the future through more frequent and severe el Niño episodes (Trenberth and Hoar, 1997; Timmermann *et al*., 1999), or the dry season becomes lengthier due to deforestation-induced rainfall inhibition (Nobre *et al*., 1991; Silva-Dias *et al*., 2002) or there are rainfall reductions due to climate change (White *et al*., 1999; Cox *et al*., 2000), then substantial portions of the 200 Gt of carbon stored globally on tropical forest trees could be transferred to the atmosphere in the coming decades (Santilli *et al*., 2005).

No VCUs can be issued to the project until all carbon stock losses and increases in GHG emissions have been offset, i.e. until the following condition is satisfied:

$$\sum_{t=0}^{t} REDD_t > 0 \quad (23)$$

Where:

$\Delta REDD_t$ — *Ex post* estimated net anthropogenic greenhouse gas emission reduction attributable to the AUD project activity at year *t*; tCO_2e

t — 1, 2, 3 … *T,* a year of the proposed project crediting period; dimensionless

1.1.5 Total *ex post* estimated actual net carbon stock changes and GHG emissions in the project area

Summarize the results of all *ex post* estimations in the project area using the same table format used for the *ex ante* assessment:

Table 29: Total *ex post* estimated actual net changes in carbon stocks and emissions of GHG gases in the project area.

1.2 Monitoring of leakage

Monitoring of leakage may not be required if the project area is located within a jurisdiction that is monitoring, reporting, verifying and accounting GHG emissions from deforestation under a VCS or UNFCCC registered (and VCS endorsed) program. In such cases, the most recent VCS JNR Requirements shall be applied.

In all other circumstances, the sources of leakage identified as significant in the *ex ante* assessment are subject to monitoring. Two sources of leakage are potentially subject to monitoring:

1.2.1 Decrease in carbon stocks and increase in GHG emissions associated with leakage prevention activities;

1.2.2 Decrease in carbon stocks and increase in GHG emissions in due to activity displacement leakage.

1.2.1 Monitoring of carbon stock changes and GHG emissions associated to leakage prevention activities

Monitoring of the sources of emissions associated with leakage prevention activities must follow the methods and tools described in part 2, step 8.1 of the methodology.

Results must be reported using the same formats and tables used in the *ex ante* assessment:

Table 30.b *Ex post* carbon stock change in leakage management areas.

Table 30.c *Ex post* net carbon stock change in leakage management areas[48].

[48] Calculations of total net carbon stock changes in Leakage Management Areas use the ex ante estimated baseline carbon stock changes in the Leakage Management Area and the measured ex post carbon stock changes. If the cumulative value of the carbon stock change within a Fixed Baseline Period is > 0, $\Delta CLPMLK_t$ shall be set to zero.

Table 31 *Ex post* parameters for estimating GHG emissions from grazing activities

Table 32 *Ex post* estimation of emissions from grazing animals in leakage management areas.

Table 33 *Ex post* estimation of net carbon stock changes and GHG emissions from leakage prevention activities.

1.2.2 Monitoring of carbon stock decrease and increases in GHG emissions due to activity displacement leakage

Monitoring of carbon stock changes

Deforestation above the baseline in the leakage belt area will be considered activity displacement leakage.

Activity data for the leakage belt area must be determined using the same methods applied to monitoring deforestation activity data (category I, table 37) in the project area. Monitoring of the categories II and III outside the project area is not required because no credits are claimed for avoided degradation under this methodology.

The result of the *ex post* estimations of carbon stock changes must be reported using the same table formats used in the *ex ante* assessment of baseline carbon stock changes in the leakage belt.

Table 21.c *Ex post* total net carbon stock changes in the leakage belt (when using method 1 based on activity data per class).

or

Table 22.c *Ex post* total net carbon stock changes in the leakage belt (when using method 2 based on activity data per category).

Leakage will be calculated as the difference between the *ex ante* and the *ex post* assessment. Report the results in table 21.d

Table 21.d. Total net baseline carbon stock change in the leakage belt
(Calculated with Method 1: Activity data per class)

Project year *t*	Total *ex ante* net baseline carbon stock change		Total *ex post* net actual carbon stock change		Total *ex post* leakage	
	annual	cumulative	annual	cumulative	annual	cumulative
	$\Delta CBSLLK_t$	$\Delta CBSLLK$	$\Delta CBSLLK_t$	$\Delta CBSLLK$	$\Delta CBSLLK_t$	$\Delta CBSLLK$

. . .						
T						

Where strong evidence can be collected that deforestation in the leakage belt is attributable to deforestation agents that are not linked to the project area, the detected deforestation may not be attributed to the project activity and considered leakage. The operational entity verifying the monitoring data shall determine whether the documentation provided by the project proponent represents sufficient evidence to consider the detected deforestation as not attributable to the project activity and therefore not leakage.

Monitoring of increases in GHG emissions

These must only be estimated and accounted if emissions from forest fires are included in the baseline.

To estimate the increased GHG emissions due to forest fires in the leakage belt area the assumption is made that forest clearing is done by burning the forest. The parameter values used to estimate emissions shall be the same used for estimating forest fires in the baseline (table 23), except for the initial carbon stocks (*Cab*, *Cdw*) which shall be those of the initial forest classes burned in the leakage belt area.

Report the result of the estimations using the same table formats used in the *ex ante* assessment of baseline GHG emissions from forest fires in the project area:

Table 23: Parameters used to calculate emissions from forest fires in the leakage belt area

Table 24: *Ex post* estimated non-CO_2 emissions from forest fires in the leakage belt area

1.2.3 Total *ex post* estimated leakage

Summarize the results of all *ex post* estimations of leakage using the same table format used for the *ex ante* assessment:

Table 35. Total *ex post* estimated leakage.

<u>Note:</u> Monitoring of leakage may become obsolete at the date when a VCS or UNFCCC registered (and VCS endorsed) program is monitoring, reporting, verifying and accounting GHG emissions from deforestation in a broader region encompassing the project area. In such cases, the most recent VCS guidelines on this subject matter shall be applied.

1.3 *Ex post* net anthropogenic GHG emission reductions

The calculation of *ex post* net anthropogenic GHG emission reductions is similar to the e*x ante* calculation with the only difference that *ex post* estimated carbon stock changes and GHG emissions must be used in the case of the project scenario and leakage.

Report the *ex post* estimated net anthropogenic GHG emissions and calculation of Verified Carbon Units (VCU_t, and VBC_t) using the same table format used for the *ex ante* assessment:

Table 36: *Ex post* estimated net anthropogenic GHG emission reductions and VCUs**.**

Note: A map showing Cumulative Areas Credited within the project area shall be updated and presented to VCS verifiers at each verification event. The cumulative area cannot generate additional VCUs in future periods.

2 TASK 2: REVISITING THE BASELINE PROJECTIONS FOR FUTURE FIXED BASELINE PERIOD

Baselines, independently from the approach chosen to establish them, must be revisited over time because agents, drivers and underlying causes of deforestation change dynamically. Frequent and unpredicted updating of the baseline can create serious market uncertainties. Therefore, the baseline must be revisited only every 10 years. Where an applicable sub-national or national jurisdictional baseline becomes available, baselines may be reassessed earlier in accordance with section 2.2 below. Tasks involved in revisiting the baseline are:

2.1 Update information on agents, drivers and underlying causes of deforestation.

2.2 Adjust the land-use and land-cover change component of the baseline.

2.3 Adjust, as needed, the carbon component of the baseline.

2.1 Update information on agents, drivers and underlying causes of deforestation

Information on agents, drivers and underlying causes of deforestation in the reference region must be collected periodically, as these are essential for improving future deforestation projections and the design of the project activity.

- Collect information that is relevant to understand deforestation agents, drivers and underlying causes.
- Redo step 3 of the *ex ante* methodology at the beginning of each fixed baseline period.
- Where a spatial model was used to locate future deforestation, new data on the spatial driver variables used to model the deforestation risk must be collected as they become available. These must be used to create updated spatial datasets and new “Factor Maps” for the subsequent fixed baseline period.

2.2 Adjustment of the land-use and land-cover change component of the baseline

If an applicable sub-national or national baseline becomes available during the fixed baseline period, it must be used for the subsequent period. Use the criteria of table 2 to assess the applicability of sub-national or national baselines. If VCS requirements on regional baselines are available, use the most recent version of these guidelines instead of table 2.

If an applicable sub-national or national baseline is not available, the baseline projections must be revisited and adjusted as necessary.

The two components of the baseline projections that must be reassessed are:

2.2.1 The annual areas of baseline deforestation; and

2.2.2 The location of baseline deforestation.

2.2.1 Adjustment of the annual areas of baseline deforestation

At the end of each fixed baseline period, the projected annual areas of baseline deforestation for the reference region need to be revisited and eventually adjusted for the subsequent fixed baseline period. The adjusted baseline rates must be submitted to an independent validation.

Adjustments must be made using the methods described in part 2 of the methodology and using the data obtained from monitoring LU/LC changes in the reference region during the past fixed baseline period, updated information on deforestation agents, drivers and underlying cases of deforestation and, where applicable, any updated information on the variables included in the estimation of the projected areas of baseline deforestation.

2.2.2 Adjustment of the location of the projected baseline deforestation

Using the adjusted projections for annual areas of baseline deforestation and any improved spatial data for the creation of the factor maps included in the spatial model, the location of the projected baseline deforestation must be reassessed using the methods explained in part 2 of the methodology.

All areas credited for avoided deforestation in past fixed baseline periods must be excluded from the revisited baseline projections as these areas cannot be credited again. To perform this exclusion use the map of "cumulative areas credited" that was updated in all previous verification events.

Note: If the boundary of the leakage belt area was assessed using equation (1) or any other spatial model, the boundary of the leakage belt will have to be reassessed at the end of each fixed baseline period using the same methodological approaches used in the first period. This will be required until monitoring of leakage will become unnecessary[49].

2.3 Adjustment of the carbon component of the baseline

Adjusting the carbon component of the baseline will not be necessary in most cases (see section 1.1.3 in Part 3 for more detailed guidance). However, improved carbon stock data are likely to become available over time and if this is the case, they must be used when revisiting the baseline projections. Methods to measure and estimate carbon stocks are described in appendix 3.

---

[49] Monitoring of leakage will become obsolete at the date when a VCS or UNFCCC registered (and VCS endorsed) program is monitoring, reporting, verifying and accounting emissions from deforestation in a broader area encompassing the project area.

APPENDIX 1: DEFINITION OF TERMS FREQUENTLY USED IN THE METHODOLOGY

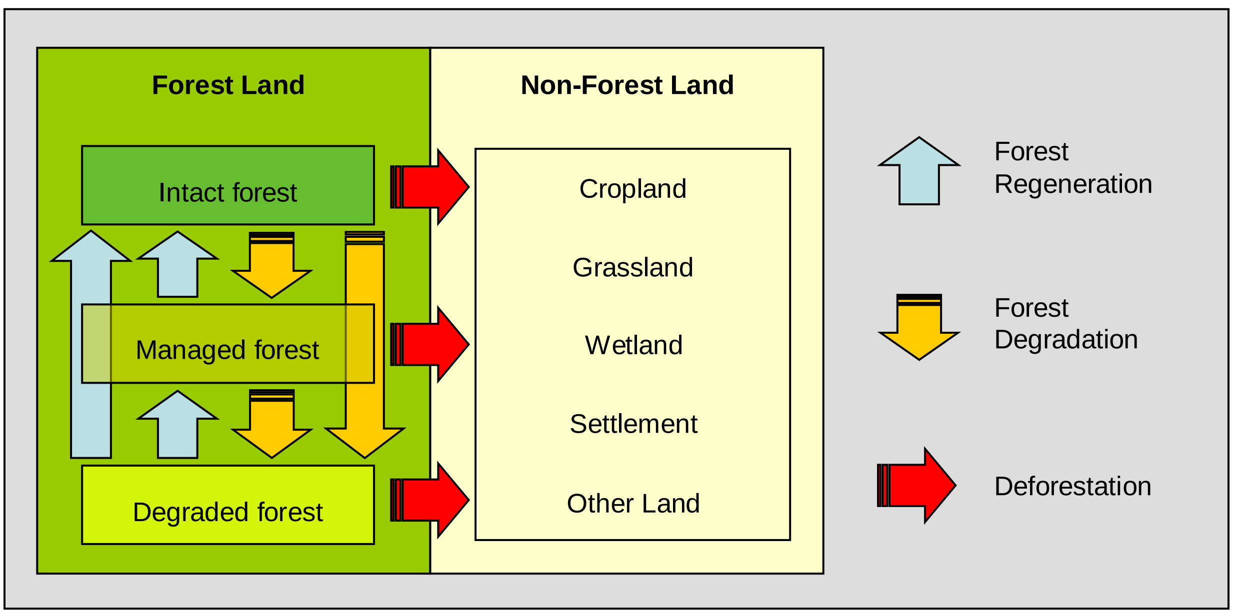
Activity Data is the annual area (ha yr^{-1}) lost or acquired by a *LU/LC class cl* at a given year *t* or the annual area of a *category of LU/LC change ct* for a given year *t*.

Baseline Scenario is the expected change in land use and land cover (LU/LC) in the absence of any *project activity* designed to reduce emissions from *deforestation, forest degradation*, or enhance *carbon stocks*.

Baseline is the sum of *carbon stock* changes and GHG emissions that would occur in the absence of the proposed REDD *project activity*.

Broad Category is the term used in this methodology to identify three main *categories* of LU/LC-change: *deforestation*, *forest degradation* (with carbon stock decrease) and *forest regeneration*(with carbon stock increase) (see figure A1-1):

Figure A1-1. *Broad categories* of land-use and land-cover change



Carbon Density (or *carbon stock* per hectare) is the amount of carbon (as CO_2-e) per hectare (ha^{-1}) estimated to be present in the accounted carbon pools of a *LU/LC Class* at year *t*.

Carbon Stock is the *carbon density* of an area times the number of hectares in the area.

Carbon Stock Change Factor: see "*Emission Factor*".

Category of LU/LC-Change (or simply "*category*") is the change from one *LU/LC class* to another that occurs during a given period of time.

Category is the term used in IPCC reports to refer to specific sources of emissions or removals of greenhouse gases. Under the AFOLU sector, "categories" are land-use / land-cover (LU/LC) transitions. REDD methodologies deal with the following categories:

(a) *Forest* Land to *Forest* Land (degradation and regeneration of *forest* land remaining *forest* land)

(b) *Forest* Land to Crop Land (*deforestation* followed by agriculture)

(c) *Forest* Land to Grass Land (*deforestation* followed by pasture)

(d) *Forest* Land to Settlements (*deforestation* followed by settlements)

(e) *Forest* Land to Wetlands (*deforestation* followed by wetlands)

(f) *Forest* Land to Other Land (*deforestation* followed by other land)

Activities that convert non *forest* land back to *forest* (Crop Land to *Forest* Land, Grass Land to *Forest* Land, etc.) are considered afforestation and reforestation and are excluded from this REDD methodology."

***Class*.** See *LU/LC Class*.

Deforestation is the direct, human-induced and long-term (or permanent) conversion of *forest* land to non-*forest* land[50]. It occurs when at least one of the parameter values used to define "*forest* land" is reduced from above the threshold for defining "*forest*" to below this threshold for a period of time that is longer than the period of time used to define "*temporarily un-stocked*"[51]. For example, if a country defines a *forest* as having a crown cover greater than 30% and "*temporarily un-stocked*" as a maximum period of 3 years, then *deforestation* would not be recorded until the crown cover is reduced below 30% for at least three consecutive years[52]. Country should develop and report criteria by which temporary removal or loss of tree cover can be distinguished from *deforestation*.

Eligible Land. To avoid double counting of emission reductions, land areas registered under the CDM or the VCS or any other carbon trading scheme (both voluntary and compliance-oriented) should be transparently reported and excluded from the *project area*.

Emission Factor (or *Carbon Stock Change Factor*) is the difference between the *carbon density* of the two *LU/LC classes* describing a *category of LU/LC change*.

Fixed baseline period is the period of time for which the validated *baseline* is fixed, which under the VCS can be up to 10 years. After this period of time, the baseline must be reassessed using a VCS approved methodology.

---

[50] Forest area and carbon stock losses due to natural disturbances (landslides, consequences of volcanic eruptions, and see level rise, among other) are not considered "deforestation".

[51] According to IPCC (GPG LUUCF, 2003, Chapter 4.2.6.2.) "The identification of units of land subject to deforestation activities requires the delineation of units of land that:

(a) Meet or exceed the size of the country's minimum forest area (i.e., 0.05 to 1 ha); and

(b) Have met the definition of forest on 31 December 1989; and

(c) Have ceased to meet the definition of forest at some time after 1 January 1990 as the result of direct human-induced deforestation."

[52] Deforestation can be the result of an abrupt event (deforestation = forest → non-forest), in which case the change in land-cover and land-use occurs immediately and simultaneously; or of a process of progressive degradation (deforestation = forest → degraded forest → non-forest), in which case the change in land-cover occurs when one of the parameters used for defining "forest land" falls below its minimum threshold, but the change in land-use may have already occurred or will occur later (e.g. use of the land for the production of crops or grazing animals). Land-use is thus not a reliable indicator for identifying a forest class or for defining a category of change. .

Forest is a land with woody vegetation consistent with the thresholds used to define "*forest* land" in the country where the REDD *project activity* will be implemented. Where the country has adopted a *forest* definition for the Kyoto Protocol, the minimum thresholds of the vegetation indicators (minimum area, tree crown cover and height)[53] used for defining "*forests*", as communicated by the DNA[54]consistent with decision 11/CP.7 and 19/CP.9, should be used. Otherwise, the definition used to define "*Forest* Land" in national GHG inventory should be used.

Land defined as "*forest* land" can include areas that do not, but at maturity *in situ* could potentially reach, the thresholds used to define "*forest* land". To distinguish between "non-*forest*" (and hence "deforested") and "*temporarily un-stocked*" areas in managed *forests*, the definition of "*forest*" should include the maximum period of time that the woody vegetation can remain below the thresholds used to define "*forest* land". This maximum period can be specific for each *category of land-use / land-cover change (LU/LC-change)*. For instance, it could be zero years for conversion from "*forest* land to crop land", but up to 5 or more years for transitions between *forest* classes (e.g. age classes)[55].

Areas covered with planted *forests* as well as with any other anthropogenic vegetation type that meet the definition of "*forest*" since the earliest date of the *historical reference period* used to assess *deforestation* can be considered "*forest* land". Hence, "*forests*" can be natural, semi-natural, or anthropogenic and they may include primary or old-growth *forests* (intact or logged), secondary *forests*, planted *forests*, agro-forestry and silvo-pastoral systems.

Forest degradation is "*forest* land remaining *forest* land" but gradually losing *carbon stocks* as a consequence of direct-human intervention (e.g. logging, fuel-wood collection, fire, grazing, etc.)[56]. Units of *forest* land subject to degradation are allocated to different *forest classes* over time, with each successive *class* having a lower *carbon density* than the previous one. The difference in average *carbon density* between two contiguous *forest classes* should be at least 10%. The difference refers to the upper and lower levels of the confidence intervals of the two contiguous *forest classes* in the degradation sequence (figure A1-2).

Forest management. Areas subject to sustainable *forest management* (with logging activities) represent a particular *class* of "degraded *forest*". An undisturbed natural *forest* that will be subject to

---

[53] "Forest is a minimum area of land of 0.05 – 1.0 hectares with tree crown cover (or equivalent stocking level) of more than 10 – 30 per cent with trees with the potential to reach a minimum height of 2 – 5 meters at maturity *in situ*. A forest may consist either of closed forest formations where trees of various storeys and undergrowth cover a high portion of the ground or open forest. Young natural stands and all plantations which have yet to reach a crown density of 10 – 30 per cent or tree height of 2 – 5 meters are included under forest, as are areas normally forming part of the forest area which are temporarily un-stocked as a result of human intervention such as harvesting or natural causes but which are expected to revert to forest".

[54] DNA = Designated National Authority of the Clean Development Mechanism

[55] Project proponents should report on how they distinguish between deforestation and areas that remain forests but where tree cover has been removed temporarily, notably areas that have been harvested or have been subject to other human or natural disturbance but for which it is expected that forest will be replanted or regenerate naturally. See IPCC GPG LULUCF, 2003, Chapter. 4.2.6.2.1 for further guidance on this issue.

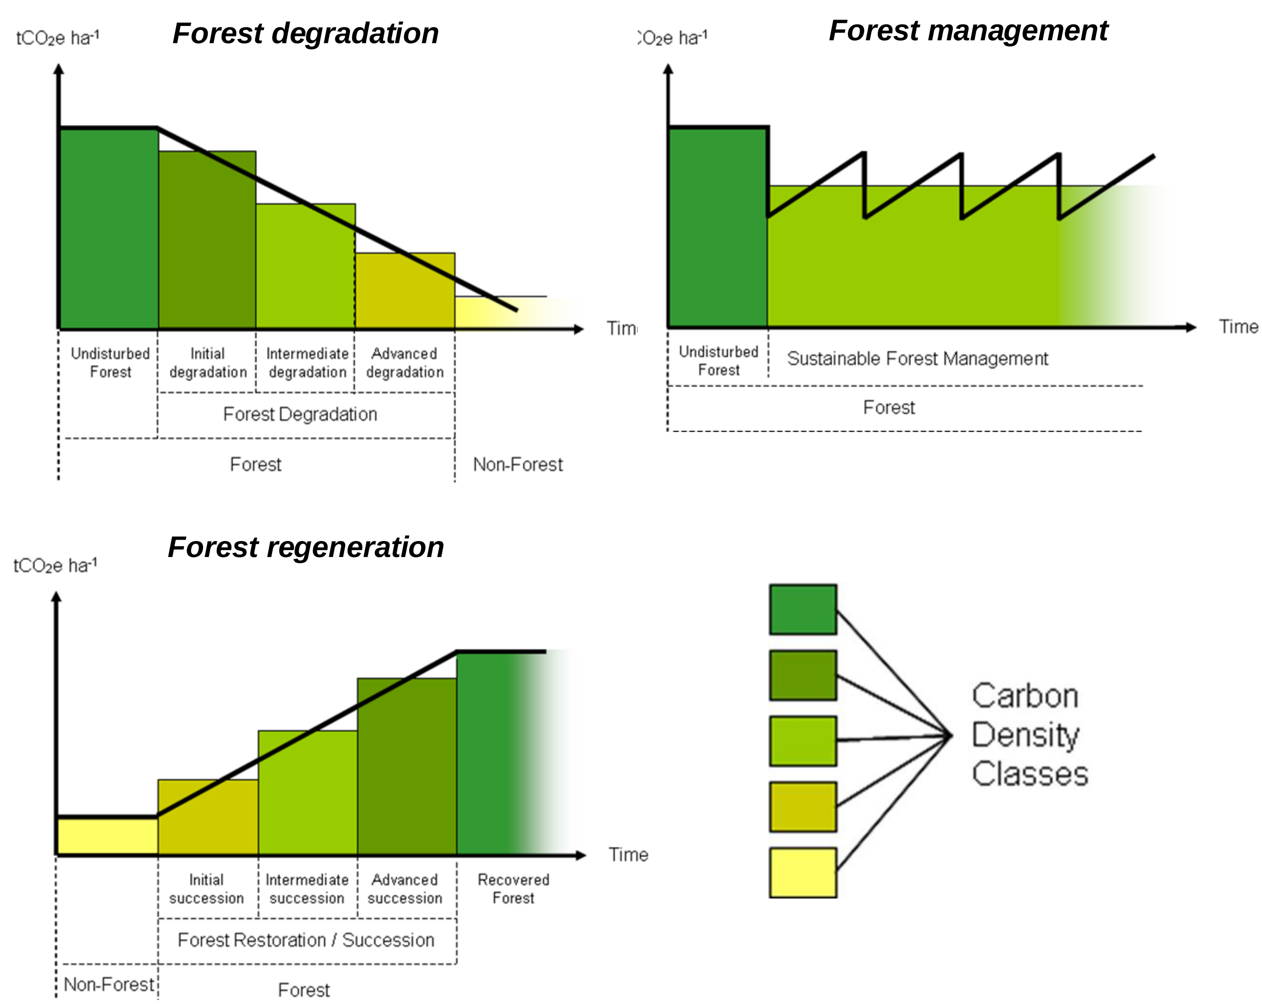
[56] According to IPCC GPG LLUCF "forest degradation" is "a direct, human-induced, long-term (persisting for *X* years or more) or at least *Y%* of forest carbon stock [and forest values] since time *T* and not qualifying as deforestation". Note that *X*, *Y%* and *T* are not quantified. See IPCC 2003 (Report on Definitions and Methodological Options to Inventory Emissions from Direct Human-induced Degradation of Forests and Devegetation of Other Vegetation Types, Chapter 2.2) for a discussion on the definition of "forest degradation", in particular table 2.1 for alternative definitions of direct human-induced forest degradation.

sustainable *forest management* will lose part of its carbon, but the loss will partially recover over time. In the long-term, a sustainable harvesting and re-growth cycle will maintain a constant average *carbon density* in the *forest*. Since this average *carbon density* is lower than in the original *forest*, sustainably managed *forests* can be considered a degraded *forest class*.

Depending on the magnitude and timeframe of the *carbon stock* changes, managed *forests* could be classified into one single "managed *forest*" *class* (with a *carbon density* equivalent to the average of the entire management cycle) or to different sub-*classes* representing different average carbon densities (figure A1-2).

Forest Regeneration is "*forest* land remaining *forest* land" but gradually enhancing its carbon stock as a consequence of direct-human intervention. Units of *forest* land subject to regeneration are allocated to different *forest classes* over time, with each successive *forest* class having a higher *carbon density* than the previous one. The difference in average *carbon density* between two contiguous *forest classes* should be at least 10%. The difference refers to the upper and lower levels of the confidence intervals of the two *forest classes*.

A1-2. *Carbon density* in "*forest* land remaining *forest* land" (living tree biomass)



Frontier Deforestation is the conversion of *forest* land to non-*forest* land occurring when the agricultural frontier expands as a result of improved access to *forest* into areas with relatively little human activity.

Historical Reference Period is a time period preceding the starting date of the proposed REDD project activity. It is analyzed to determine the magnitude of *deforestation* and *forest degradation* in the *reference region* and to identify agents and drivers of DD and the chain of events leading to land-use / land-cover change. In order to be useful for understanding recent and likely future DD trends, the starting date of the *historical reference period* should be selected between 10 and 15 years in the past, and the end date as close as possible to present.

Leakage is the decrease in *carbon stocks* and the increase in GHG emissions attributable to the implementation of the REDD *project activity* that occurs outside the boundary of the *Project area*.

Leakage Belt is the geographical area surrounding or adjacent to the *project area* which activity displacement *leakage* could occur.

Leakage Management Area(s) are areas outside the *project area* in which activities are implemented to avoid *leakage.* At the project start date, leakage management areas must be non-forest land

LU/LC Class (or simply "*class*") is a unique combination of land use and land cover having a specific *carbon density* at time *t*.

LU/LC Polygon is a discrete area falling into a single *LU/LC class*.

Monitoring period is the period of time (in years) between two monitoring and verification events. Typically it is a fraction of the *fixed baseline period*. The minimum duration is one year and the maximum is the duration of the *fixed baseline period*.

Mosaic Deforestation is the conversion of *forest* land to non-*forest* land occurring in a patchy pattern where human population and associated agricultural activities and infrastructure (roads, towns, etc.) are spread out across the landscape and most areas of *forest* within such a configured region or country are practically already accessible.

Planned Deforestation is the legally authorized conversion of *forest* land to non-*forest* land occurring in a discrete area of land. *Deforestation* within an area can be planned (designated and sanctioned) or unplanned (unsanctioned). *Planned deforestation* can include a wide variety of activities such as national resettlement programs from non-forested to forested regions; a component of a national land plan to reduce the *forest* estate and convert it to other industrial-scale production of goods such as soybeans, pulpwood plantations, and oil palm plantations; or plans to convert well-managed community-owned *forests* to other non-*forest* uses. Other forms of *planned deforestation* could also include decisions by individual land owners, whose land is legally zoned for agriculture, to convert their say selectively logged *forest* to crop production. These *planned deforestation* activities would be a component of some land planning or management document and could be readily verified.

Project Activity is the series of planned steps and activities by which the proponent intends to reduce *deforestation* and *forest degradation* and/or enhance forest regeneration.

Project area is the area or areas of land on which the proponent will undertake the *project activities.* No lands on which the *project activity* will not be undertaken can be included in the *project area*.

Project crediting period. Please see current VCS definition.

Project Scenario is the expected change in land use and land cover within the boundary of the *project area* resulting from the undertaking of the *project activity*.

Project Term is the projected lifetime of the REDD *project activity*, which under the VCS is equivalent to the project *crediting period*.

Reference region is the spatial delimitation of the analytic domain from which information about *deforestation* and degradation agents, drivers and LU/LC-change is obtained, projected into the future and monitored. The *reference region* includes the *Project area*[57] and is defined by the project proponent using transparent criteria. It must contain *LU/LC classes* and *deforestation* agents and drivers similar to those found in the *project area* under the *baseline* and *project scenarios*.

Zone is a stratum of the reference region containing a distinctive mix of final post-deforestation classes *fcl*

[57] The methodology thus adopts a so called "Stratified Regional Baseline" (SRB) approach, which has been recommended in recent literature (Sataye and Andrasko, 2007; Brown *et al.*, 2007)

APPENDIX 2: INDICATIVE TABLES

Table 1. Guidance on carbon pool selection depending on the land-use / land-cover change *category* considered[58]

Type of land-use / land-cover transition	Living biomass (trees)		Dead organic matter			Soil
	Above-ground	Below-ground	Wood products	Dead wood	Litter	Organic matter
Forest to cropland	+++	++	+	+	+	+
Forest to pasture	+++	++	+	+	+	
Forest to shifting cultivation	+++	++		+		
Forest to degraded *forest*	+++	++	+			
+++ = include always; ++ = inclusion recommended; + = inclusion possible						

Table 2. Present availability of optical mid-resolution (10-60m) sensors (GOFC-GOLD, 2008)

Nation	Satellite & sensor	Resolution & coverage	Cost (archive[59])	Feature
U.S.A.	Landsat-5 TM	30 m 180×180 km^2	600 US$/scene 0.02 US$/km^2	Images every 16 days to any satellite receiving station. Operating beyond expected lifetime.
U.S.A.	Landsat-7 ETM+	30 m 60×180 km^2	600 US$/scene 0.06 US$/km^2	On April 2003 the failure of the scan line corrector resulted in data gaps outside of the central portion of images, seriously compromising data quality
U.S.A./Japan	Terra ASTER	15 m 60×60 km^2	60 US$/scene 0.02 US$/km^2	Data is acquired on request and is not routinely collected for all areas
India	IRS-P2 LISS-III & AWIFS	23.5 & 56 m		Experimental craft shows promise, although images are hard to acquire
China/Brazil	CBERS-2 HRCCD	20 m		Experimental; Brazil uses on-demand images to bolster their coverage.
Algeria/China/ Nigeria/Turkey/ U.K.	DMC	32 m 160×660 km^2	3000 €/scene 0.03 €/km^2	Commercial; Brazil uses alongside Landsat data
France	SPOT-5 HRVIR	5-20 m 60×60 km^2	2000 €/scene 0.5 €/km^2	Commercial Indonesia & Thailand used alongside Landsat data

[58] Modified from GOFC-GOLD, 2008. See the most recent version of the GOFC-GOLD sourcebook for REDD, as new remote sensing platforms are becoming available.

[59] Some acquisitions can be programmed (e.g., DMC, SPOT). The cost of programmed data is generally at least twice the cost of archived data.

Notes:

- Numbers represent hectares or *activity data* (in this case numbers are for illustrative purposes only, they do not represent any real case).

- Column and rows totals show net conversion of each LU/LC-class.
- "Initial" indicates the area of the LU/LC-class at the starting date of the period assessed, and "Final" the area of the class at the end date of the assessment period.
- Net changes (bottom rows) are the final area minus the initial area for each of the LU/LC-classes shown at the head of the corresponding column.
- Blank entries indicate no LU/LC-change the period assessed.

Box 1: Geomod

Geomod is a land-use land-cover change simulation model implemented in Idrisi, a GIS software developed by Clark University (Pontius *et al.*, 2001; Brown *et al.*, 2007). Geomod has been used frequently to analyze baseline scenarios of deforestation at continental scale for Africa, Asia and Latin America; at the country scale for Costa Rica and India; and at local scale within India, Egypt, Unites States and several countries in Latin America (Pontius and Chen, 2006).

Geomod is a grid-based model that predicts the transition from one *LU/LC class* to another *LU/LC class*, i.e. the location of grid cells that change over time from *class* 1 to *class* 2. Hence, Geomod can be used to predict areas likely to change from *forest class* 1 to non-forest *class* 2 (*deforestation*) over a given time.

Geomod creates the LU/LC-change risk map empirically, by using several driver images and the land-cover map from the beginning time. For example, Geomod's *deforestation* risk maps have relatively high values at location that have biogeophysical attributes similar to those of the deforested land (= "developed land" in Geomod's jargon) of the beginning time, and has relatively low values at locations that have biogeophysical attributes similar to those of forested land ("non-developed" land) of the beginning time.

APPENDIX 3: METHODS TO ESTIMATE CARBON STOCKS

Sampling framework

The sampling framework, including sample size, plot size, plot shape and plot location should be specified in the PD.

Areas to be sampled in forest classes should be at locations expected to be deforested according to the baseline projections.

The sampling areas for non-forest classes should be selected within the reference region at locations that represent a chrono-sequence of 10 to 30 years since the deforestation date.

Temporary or permanent plots

Plots can be temporary or permanent depending on the specific project circumstances, interests and needs, but in general temporary plots should be sufficient.

Where changes in carbon stocks are to be monitored, permanent sampling plots are recommended. Permanent sample plots are generally regarded as statistically efficient in estimating changes in forest carbon stocks because typically there is high covariance between observations at successive sampling events. However, it should be ensured that the plots are treated in the same way as other lands within the project boundary, e.g., during logging operations, and should not be destroyed over the monitoring interval. Ideally, staff involved in forest management activities should not be aware of the location of monitoring plots. Where local markers are used, these should not be visible. If trees markers are required (e.g. if plots are also used for ecological or structural monitoring), these should be as unconspicous as possible and no bias in the treatment of plots compared to the surrounding forest must be granted.

Permanent plots may also be considered to reduce the uncertainty of the average carbon density of a forest class undergoing carbon stock changes due to management and to detect changes in carbon stocks induced by climate change or large-scale natural disturbances.

Definition of the sample size and allocation among LU/LC-classes

The number of sample plots is estimated as dependent on accuracy, variability of the parameter to estimate in each class and costs. The sample size calculation also corresponds to the method of samples drawn without replacement. Where at the beginning of a REDD project activity accurate data for sample size estimation and allocation are not available, the sampling size can initially be estimated by using a desired level of accuracy (10% of sampling error at 90% confidence level), and by allocating the estimated sample size proportionally to the area of each class[61], using respectively equations 1, and 2. Then, once data on carbon stock variability within each class become available, the sample size and allocation is recalculated using the methodology described by Wenger (1984)[62], which also accounts for the cost of sampling (see equations 3 and 4).

Equation 1 was chosen because it works with percentages rather than absolute units (biomass, carbon, or CO_2), and coefficient variation data could be more easy to find in the literature at the beginning of a project activity. The initial allocation of the sample plots shall be proportional to the area of the LU/LC-

[61] Loetsch, F. and Haller, K. 1964. Forest Inventory. Volume 1. BLV-VERLAGS GESE LLSCHAFT, München.

[62] Wenger, K.F. (ed). 1984. Forestry handbook (2nd edition). New York: John Wiley and Sons.

classes, but with minimum of 5 plots per class. The t-student for a 95% confidence level is approximately equal to 2 when the number of sample plot is over 30. As the first step, use 2 as the t –student value, and if the resulting "*n*" is less than 30, use the new "*n*" to get a new t-student value and conduct the new estimation of the sample size. This process can be repeated until the calculated *n* is stabilized.

$$n = \frac{t_{st}^2 \cdot (CV\%)^2}{(E\%)^2 + \frac{t_{st}^2 \cdot (CV\%)^2}{N}} \quad \text{(A3-1)}$$

$$n_{cl} = n \cdot \frac{N_{cl}}{N} \quad \text{(A3-2)}$$

Where:

cl	=	1, 2, 3, …. *Cl* LU/LC classes
Cl	=	Total number of LU/LC classes
t_{st}	=	t-student value for a 90% confidence level (initial value t = 2)
n	=	total number of sample units to be measured (in all LU/LC classes)
E%	=	allowable sample error in percentage (±10%)
CV%	=	the highest coefficient of variation (%) reported in the literature from different volume or biomass forest inventories in forest plantations, natural forests, agro-forestry and/or silvo-pastoral systems.
n_i	=	number of samples units to be measured in LU/LC class *cl* that is allocated proportional to the size of the class. If estimated $n_{cl} < 3$, set $n_{cl} = 3$.
N_i	=	maximum number of possible sample units for LU/LC class *cl*, calculated by dividing the area of *class cl* by the measurement plot area.
N	=	population size or maximum number of possible sample units (all LU/LC classes), $N = \sum_{cl=1}^{Cl} N_{cl}$

In equation A3-2 the standard deviation of each LU/LC class (S_{cl}) shall be determined using the actual data from the latest field measurement. The allowable error is an absolute value, and can be estimated as ±10% of the observed overall average carbon stock per hectare. It is possible to reasonably modify the LU/LC class limits and the sample size after each monitoring event based on the actual variation of the carbon stock changes determined from taking "*n*" sample plots. Where costs for selecting and measuring plots are not a significant consideration then the calculation and allocation of the sample size can be simplified by setting C_{cl} equal to 1 across all LU/LC classes.

$$n = \left(\frac{t_{st}}{E}\right)^2 \left[\sum_{cl=1}^{Cl} W_{cl} \cdot S_{cl} \cdot \sqrt{C_{cl}}\right] \cdot \left[\sum_{cl=1}^{Cl} W_{cl} \cdot S_{cl} \big/ \sqrt{C_{cl}} \cdot\right] \quad \text{(A3-3)}$$

$$n_{cl} = n \cdot \frac{W_{cl} \cdot S_{cl} \Big/ \sqrt{C_{cl}}}{\sum_{cl=1}^{Cl} W_{cl} \cdot S_{cl} \Big/ \sqrt{C_{cl}}} \qquad \text{(A3-4)}$$

Where:

cl	=	1, 2, 3, … *Cl* LU/LC classes
Cl	=	total number of LU/LC classes
t_{st}	=	t-student value for a 95% confidence level, with n-2 degrees of freedom
E	=	allowable error (±10% of the mean)
S_{cl}	=	standard deviation of LU/LC class *cl*
n_{cl}	=	number of samples units to be measured in LU/LC class *cl* that is allocated proportional to $W_{cl} \cdot S_{cl} \Big/ \sqrt{C_{cl}}$. If $n_{cl} < 3$, set $n_{cl} = 3$.
W_{cl}	=	N_{cl}/N
n	=	total number of sample units to be measured (in all LU/LC classes)
N_{cl}	=	maximum number of possible sample units for LU/LC class *cl*, calculated by dividing the area of LU/LC class *cl* by the measurement plot area
N	=	population size or maximum number of possible sample units (all strata), $N = \sum_{cl=1}^{Cl} N_{cl}$
C_i	=	cost to select and measure a plot of the LU/LC class *cl*

Sample plot size

The plot area *a* has major influence on the sampling intensity, time and resources spent in the field measurements. The area of a plot depends on the stand density. Therefore, increasing the plot area decreases the variability between two samples. According to Freese (1962)[63], the relationship between coefficient of variation and plot area can be denoted as follows:

$$CV_2^{\ 2} = \quad CV_1^{\ 2} \sqrt{(a_1 / a_2)} \qquad \text{(A3-5)}$$

Where a_1 and a_2 represent different sample plot areas and their corresponding coefficient of variation (*CV*). Thus, by increasing the sample plot area, variation among plots can be reduced permitting the use of small sample size at the same precision level. Usually, the size of plots is between 100 m^2 for dense

63 Freese, F. 1962. Elementary Forest Sampling. USDA Handbook 232. GPO Washington, DC. 91 pp

stands and 1000 m^2 for open stands[64].

Plot location

To avoid subjective choice of plot locations (plot centers, plot reference points, movement of plot centers to more "convenient" positions), the permanent sample plots shall be located either systematically with a random start (which is considered good practice in IPCC GPG-LULUCF) or completely randomly inside each defined stratum. This can be accomplished with the help of the project GIS platform and a GPS in the field. The geographical position (GPS coordinate), administrative location, stratum and stand, series number of each plot, as well as the procedure used for locating them shall be recorded and archived.

Also, it is recommended that the sampling plots are as evenly distributed as possible. For example, if one stratum consists of three geographically separated sites, then it is proposed to

- Divide the total stratum area by the number of plots, resulting in the average area represented by each plot;
- Divide the area of each site by this average area per plot, and assign the integer part of the result to this site. e.g., if the division results in 6.3 plots, then 6 plots are assigned to this site, and 0.3 plots are carried over to the next site, and so on.

However, remote areas and areas with poor accessibility (either because of physical or social barriers such as unsafe areas) may be excluded for the location of sampling plots, using a transparent and conservative procedure, such as creating a buffer zone along roads, paths or navigable rivers that may be used for reaching the sampling plots. In this case, the representativeness of the plots for the corresponding stratum must be ensured.

The exact total number of plots is unknown at the beginning of the field sampling and thus a perfectly even distribution of sampling plots is not possible. This is also the case if pre existing inventory data is used. In any case, the uneven distribution of sampling plots will be accepted provided that statistical representativeness and the use of standard sampling techniques are granted, clearly reported and archived.

Estimation of carbon stocks

The total average carbon stock per hectare (= carbon density) in a LU/LC class is estimated by the following equation:

$$Ctot_{cl} = Cab_{cl} + Cbb_{cl} + Cdw_{cl} + Cl_{cl} + Csoc_{cl} - Cwp_{cl} \qquad \text{(A3-6)}$$

Where:

$Ctot_{cl}$ = Average carbon stock per hectare in all accounted carbon pools of the LU/LC-class *cl*; tCO_2-e ha^{-1}

Note: *Cwp_{cl}* is subtracted if *cl* is an initial pre-deforestation forest class in the baseline case. It is added if *cl* is a final post-deforestation class or a forest class not deforested in the project scenario.

[64] It is recommended to use sample plots of equal area for the strata. This methodology cannot be used if sample plots area varies within the same stratum. The density of trees to be considered is the one at maturity of the trees.

Cab_{cl}	=	Average *carbon stock* per hectare in the above-ground biomass carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
Cbb_{cl}	=	Average carbon stock per hectare in the below-ground biomass carbon pool of the *LU/LC class cl*; tCO_2.e ha^{-1}
Cdw_{cl}	=	Average carbon stock per hectare in the dead wood carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
Cl_{cl}	=	Average carbon stock per hectare in the litter carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
$Csoc_{cl}$	=	Average carbon stock per hectare in the soil organic carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
Cwp_{cl}	=	Average carbon stock per hectare in the wood products carbon pool of the LU/LC class *cl*;

Note: See methodology Part 2 on mandatory carbon pools.

Estimation of carbon stocks in the living biomass carbon pools (Cab_{cl} and Cbb_{cl})

In a forest most of the carbon is stored in the tree component of the living biomass. Hence, for a majority of forest classes it is sufficient to estimate the carbon stock in the tree component and to ignore the carbon stock in the non-tree vegetation component.

However, there might be situations where carbon stocks in the non-tree vegetation component are significantly increased in the LU/LC-classes adopted after deforestation (e.g. coffee plantations). Under such circumstances, carbon stocks in the non-tree vegetation component should be estimated[65].

The living biomass components that are measured and the minimum diameter at breast height (DBH) above which trees are measured should be specified in the PD.

Carbon stocks in the living biomass are given by the following equations:

$$Cab_{cl} = Cabt_{cl} + Cabnt_{cl} \tag{A3-7}$$

$$Cbb_{cl} = Cbbt_{cl} + Cbbnt_{cl} \tag{A3-8}$$

Where:

Cab_{cl}	=	Average *carbon stock* per hectare in the above-ground biomass carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
$Cabt_{cl}$	=	Average *carbon stock* per hectare in the above-ground tree biomass carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
$Cabnt_{cl}$	=	Average *carbon stock* per hectare in the above-ground non-tree biomass carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}
Cbb_{cl}	=	Average *carbon stock* per hectare in the below-ground biomass carbon pool of the LU/LC class *cl*; tCO_2.e ha^{-1}

65 The same carbon pools are to be estimated for the two classes of a LU/LC-change category

$Cbbt_{cl}$	=	Average *carbon stock* per hectare in the below-ground tree biomass carbon pool of the LU/LC class *cl*; tCO_{2}-e ha^{-1}
$Cbbnt_{cl}$	=	Average carbon stock per hectare in the below-ground non-tree biomass carbon pool of the LU/LC class *cl*; tCO_{2}-e ha^{-1}

Tree component ($Cabt_{cl}$ and Cbb_{cl})

The carbon stock of trees can be estimated using: (a) Existing forest inventory data; or (b) Direct field measurements.

(a) Estimations using *forest* inventory data

(See the most recent version of the GOFC-GOLD sourcebook for REDD for more details)

Forest inventory data typically comes in two different forms: (1) Stand tables and (2) Stock tables.

(a.1) Stand tables provide the number of trees in diameter (DBH) classes. The method basically involves estimating the biomass per average tree of each diameter class of the stand table, multiplying by the number of trees in the class, and summing across all classes. The mid-point diameter of a diameter class should be used in combination with an allometric biomass regression equation (explained later).

Stand tables often include trees with a minimum diameter of 30 cm or more, which essentially ignores a significant amount of carbon particularly for younger *forests* or heavily logged. To overcome this problem Gillespie *et al.* (1992) developed a technique that can be used to estimate the number of trees in lower diameter classes (see Box 1).

Box 1. Adding diameter classes to truncated stand tables

DBH-Class cm	Midpoint Diameter cm	Number of Stems per ha Nr
10-19	15	-
20-29	25	-
30-39	35	35.1
40-49	45	11.8
50-59	55	4.7
…	…	…

DBH class 1 = 30-39 cm, DBH class 2 =40-49 cm

Ratio = 35.1/11.8 = = 2.97

(a.2) Stock tables indicate the volume of merchantable timber by diameter class or total per hectare. If volume data are just for commercial species do not use them for estimating *carbon stock*s, because a large and unknown proportion of the total volume is excluded.

The biomass density can be calculated from Volume Over Bark (*VOB*) by multiplying this value with the Biomass Conversion and Expansion Factor (*BCEF*). When using this approach and default values of the *BCEF* provided in the IPCC GL AFOLU, it is important that the definitions of *VOB* match. The values of *BCEF* for tropical *forests* in the AFOLU report are based on a definition of *VOB* as follows:

> *"Inventoried volume over bark of free bole, i.e. from stump or buttress to crown point or first main branch. Inventoried volume must include all trees, whether presently commercial or not, with a minimum diameter of 10 cm at breast height or above buttress if this is higher"*.

Values of the *BCEF* are given in table 4.5 of the IPCC GL AFOLU guidelines, and those relevant to tropical humid broadleaf and pine *forests* are shown in the table 1.

Table 1. Values of *BCEF* for application to volume data

(Modified by GOFC-GOLD (2008) from table 4.5 in IPCC GL AFOLU)

	Growing stock volume –*average* and range (*VOB*, m^3/ha)						
Forest type	<20	21-40	41-60	61-80	80-120	120-200	>200
Natural broadleaf	4.0 2.5-12.0	2.8 1.8-304	2.1 1.2-2.5	1.7 1.2-2.2	1.5 1.0-1.8	1.3 0.9-1.6	1.0 0.7-1.1
Conifer	1.8 1.4-2.4	1.3 1.0-1.5	1.0 0.8-1.2	0.8 0.7-1.2	0.8 0.6-1.0	0.7 1.6-0.9	0.7 0.6-0.9

In cases where the definition of *VOB* does not match exactly the definition given above, GOFC-GOLD (2008) recommend the following:

- If the definition of *VOB* also includes stem tops and large branches then the lower bound of the range for a given growing stock should be used;
- If the definition of *VOB* has a large minimum top diameter or the *VOB* is comprised of trees with particularly high basic wood density then the upper bound of the range should be used.

Forest inventories often report volumes for trees above a minimum *DBH*. To include the volume of *DBH* classes below the minimum *DBH*, GOFC-GOLD (2008) proposes Volume Expansion Factors (*VEF*). However, due to large uncertainties in the volume of smaller *DBH* classes, inventories with a minimum diameter that is higher than 30 cm should not be used. Volume expansion factors range from about 1.1 to 2.5, and are related to the *VOB*30 as follows to allow conversion of *VOB*30 to a *VOB*10 equivalent:

- For *VOB*30 < 250 m^3/ha use the following equation:

$$VEF = Exp(1.300 - 0.209 * \ln(VOB30)) \quad \text{(A3-9)}$$

- For *VOB*30 > 250 m^3/ha use *VEF* = 1.9

See Box 2 for a demonstration of the use of the *VEF* correction factor and *BCEF* to estimate biomass density.

Box 2. Use of volume expansion factor (*VEF*) and biomass conversion and expansion factor (*BCEF*)

Tropical broadleaf *forest* with a VOB30 = 100 m^3/ha

(1) Calculate the *VEF*:
VEF = Exp(1.300 - 0.209*Ln(100)) = 1.40

(2) Calculate *VOB*10:
*VOB*10 = 100 m^3/ha x 1.40 = 140 m^3/ha

(3) Take the *BCEF* from the table 1 above:
BCEF for tropical hardwood with growing stock of 140 m^3/ha = 1.3

(4) Calculate above-ground biomass density:
= 1.3 x 140 = 182 t/ha

Below-ground tree biomass (roots) is almost never measured, but instead is included through a relationship to above-ground biomass (usually a root-to-shoot ratio). If the vegetation strata correspond with tropical or subtropical types listed in table 2 (modified by GOFC-GOLD, 2008 from table 4.4 in IPCC GL AFOLU to exclude non-*forest* or non-tropical values and to account for incorrect values) then it makes sense to include roots.

Table 2. Root to shoot ratios

(Modified[66] by GOFC-GOLD, 2008) from table 4.4 in IPCC GL AFOLU)

Domain	Ecological Zone	Above-ground biomass	Root-to-shoot ratio	Range
Tropical	Tropical rain*forest*	<125 $t.ha^{-1}$	0.20	0.09-0.25
		>125 $t.ha^{-1}$	0.24	0.22-0.33
	Tropical dry *forest*	<20 $t.ha^{-1}$	0.56	0.28-0.68
		>20 $t.ha^{-1}$	0.28	0.27-0.28
Subtropical	Subtropical humid *forest*	<125 $t.ha^{-1}$	0.20	0.09-0.25
		>125 $t.ha^{-1}$	0.24	0.22-0.33
	Subtropical dry *forest*	<20 $t.ha^{-1}$	0.56	0.28-0.68
		>20 $t.ha^{-1}$	0.28	0.27-0.28

(b) Estimations using direct field measurements

Two methods are available to estimate the carbon stock of trees: (1) Allometric Equations method, and (2) Biomass Expansion Factors (*BEF*). The Allometric Equations method should be favored over the *BEF* method. However, if no biomass equations are available for a given species or *forest* type, the *BEF* method shall be used.

(b.1) <u>Allometric method</u>

1. In the sample plots, identify the plot unique identification number and record the measurement date. Then identify the tree species and identification numbers and measure the diameter at breast height (*DBH*, at 1.3 m above ground), and possibly, depending on the form of the allometric equation, the height of all the trees above a minimum *DBH*.

2. Choose or establish the appropriate allometric equations for each species or species group *j*.

$$TBab_j = f_j(DBH, H)_{ab} \quad \text{(A3-10)}$$

Where:

$TBab_j$ = above-ground biomass of a tree of species, or species group, or forest type *j*, kg $tree^{-1}$

[66] The modification corrects an error in the table based on communications with Karel Mulroney, the lead author of the peer reviewed paper from which the data were extracted.

Note: the unit (Kg $tree^{-1}$) could also be t $tree^{-1}$ or t ha^{-1}, depending on the type of allometric equation

$f_j(DBH,H)_{ab}$ = an allometric equation for species, or group of species, or forest type *j*, linking above-ground tree biomass (in kg $tree^{-1}$ – see the note above) to diameter at breast height (*DBH*) and possibly tree height (*H*).

The allometric equations are preferably local-derived and forest type-specific. When allometric equations developed from a biome-wide database, such as those in Annex 4A.2, Tables 4.A.1 and 4.A.2 of GPG LULUCF, are used, it is necessary to verify by destructively harvesting, within the project area (or within the forest class), but outside the sample plots, a few trees of different species and sizes and estimate their biomass and then compare against the selected equation. The number of trees to be felled will depend on the number of species and the range of size of trees the model(s) will represent. As a general rule, there should be two trees sampled for each 5 cm *DBH* width class. In case of mixed species natural forests, the sample should represent all strata existing in the forest. If the biomass estimated from the harvested trees is within about ±10% of that predicted by the equation, then it can be assumed that the selected equation is suitable for the project; otherwise, it will be required to develop full allometric models valid for the project. In this case, the sample must be increased until obtaining an appropriated statistical fit (all model variables should be statistically significant and the squared r of equation should be at least 0.7). If resources permit, the carbon content can be determined in the laboratory. Finally, allometric equations are constructed relating the biomass with values from easily measured variables, such as basal area or tree diameter and total height (see Chapter 4.3 in GPG LULUCF). Also generic allometric equations can be used, as long as it can be proven that they are conservative.

3. Estimate the carbon stock in the above-ground biomass of all trees measured in the permanent sample plots using the allometric equations selected or established for each species, group of species or forest type.

$$TCab_{tr} = TBab_{tr} \cdot CF_j \qquad \text{(A3-11)}$$

Where:

$TCab_{,tr}$ = *Carbon stock* in above-ground biomass of tree *tr*; kg C $tree^{-1}$(or t C tree-^{1})

$TBab_{tr}$ = Above-ground biomass of tree *tr*; kg $tree^{-1}$(or t tree-^{1})

CF_j = Carbon fraction for tree *tr,* of species, group of species or forest type *j*; t C (t d. m.)$^{-1}$

4. Calculate the carbon stock in above-ground biomass per plot on a per area basis. Calculate by summing the carbon stock in above-ground biomass of all trees within each plot and multiplying by a plot expansion factor that is proportional to the area of the measurement plot. If carbon stock is calculated in kilograms, it is divided by 1,000 to convert from kg to tonnes.

$$PCab_{pl} = \frac{\left(\sum_{tr=1}^{TR_{pl}} TCab_{tr} \cdot XF \right)}{1000} \qquad \text{(A3-12)}$$

$$XF = \frac{10{,}000}{AP} \quad \text{(A3-13)}$$

Where:

$PCab_{pl}$	=	Carbon stock in above-ground biomass in plot *pl*; t C ha^{-1}
$TCab_{tr}$	=	Above-ground biomass of tree *tr*; kg $tree^{-1}$(or t tree-^{1})
XF	=	Plot expansion factor from per plot values to per hectare values; dimensionless
AP	=	Plot area; m^2
tr	=	1, 2, 3, … TR_{pl} number of trees in plot *pl*; dimensionless

5. Calculate the average carbon stock by averaging across all plots within a LU/LC class.

$$Cab_{cl} = 44/12 * \frac{\sum_{pl=1}^{PL_{cl}} PCab_{pl}}{PL_{cl}} \quad \text{(A3-14)}$$

Where:

Ca_{cl}	=	Average carbon stock per hectare in above-ground biomass in LU/LC class *cl*; tCO_2-eha^{-1}.
$PCab_{pl}$	=	Carbon stock in above-ground biomass in plot *pl*; t C ha^{-1}
44/12	=	Ratio converting C to CO_2-e
pl	=	1, 2, 3, … PL_{cl} plots in LU/LC class c*l*; dimensionless
PL_{cl}	=	Total number of plots in LU/LC class c*l*; dimensionless

6. Estimate the carbon stock in the below-ground biomass of tree *tr* using root-shoot ratios and above-ground carbon stock and apply steps 4 and 5 to below-ground biomass.

$$TCbb_{tr} = TCab_{tr} \cdot R_j \quad \text{(A3-15)}$$

$$PCbb_{pl} = \frac{\left(\sum_{tr=1}^{TR} TCbb_{tr} \cdot XF \right)}{1000} \quad \text{(A3-16)}$$

$$Cbb_{cl} = 44/12 * \frac{\sum_{pl=1}^{PL_l} PCbb_{pl}}{PL_l} \quad \text{(A3-17)}$$

Where:

$TCbb_{tr}$	=	Carbon stock in below-ground biomass of tree *tr*; kg C $tree^{-1}$(or t C tree-^{1})
$TCab_{tr}$	=	Carbon stock in above-ground biomass of tree *tr*; kg C $tree^{-1}$(or t C tree-^{1})

R_j	=	Root-shoot ratio appropriate for species, group of species or forest type *j*; dimensionless
$PCbb_{pl}$	=	Carbon stock in below-ground biomass in plot *pl*; t C ha^{-1}
XF	=	Plot expansion factor from per plot values to per hectare values
tr	=	1, 2, 3, … TR_{pl} number of trees in plot *pl*; dimensionless
Cbb_{cl}	=	Average carbon stock per hectare in below-ground biomass in *LU/LC class cl*; tCO_2-eha^{-1}
44/12	=	Ratio converting C to CO_2-e
pl	=	1, 2, 3, … PL_l plots in LU/LC class *cl*; dimensionless
PL_{cl}	=	total number of plots in LU/LC class *cl*; dimensionless

(b.2) Biomass Expansion Factor (*BEF*) Method

1. In the sample plots, identify the plot unique identification number and record the measurement date. Then identify the tree species and identification numbers and measure the diameter at breast height (*DBH*, at 1.3 m above ground), and possibly, depending on the form of the volume equation, the height of all the trees above a minimum *DBH*.
2. Estimate the volume of the commercial component per each tree based on locally derived equations by species, species group or forest type. Then, sum for all trees within a plot, and express it as commercial volume per unit of area (m^3 ha^{-1}). It is also possible to combine step b.1 and step b.2 if there are available field instruments that measure volume per hectare directly (e.g. a Bitterlich relascope). The volume per plot is an ancillary variable, and it may be needed in some cases to estimate the proper biomass expansion factor or the root-shoot ratio.[67]

$$V_{tr} = f_j(DBH, H)_V \tag{A3-18}$$

$$V_{pl} = \sum_{tr=1}^{TR} V_{tr} \cdot XF \tag{A3-19}$$

$$XF = \frac{10{,}000}{AP} \tag{A3-20}$$

Where:

V_{tr}	=	Commercial volume of tree *tr*; m^3 $tree^{-1}$
V_{pl}	=	Commercial volume of plot *pl*; m^3 $plot^{-1}$

[67] See for example: Brown, S. 1997. Estimating Biomass and Biomass Change of Tropical Forests: A primer. FAO Forestry Paper 134, UN FAO, Rome.

$f_j(DBH,H)_V$	=	a commercial volume equation for species or species group *j*, linking commercial volume to diameter at breast height (*DBH*) and possibly tree height (*H*).
tr	=	1, 2, 3, … TR_p number of trees in plot *p*; dimensionless
XF	=	Plot expansion factor from per plot values to per hectare values
AP	=	plot area; m^2

3. Choose a biomass expansion factor (*BEF*) and a root-shoot ratio (*R*). The *BEF* and root-shoot ratio vary with local environmental conditions, forest type, species and age of trees, and the volume of the commercial component of trees, therefore, they should be calculated for each plot in a given *LU/LC class*. Use the result from ‘2’ to choose them.

   These parameters can be determined by either developing a local regression equation or selecting from national inventory, annex 3A.1 table 3A.1.10 of GPG LULUCF, or from published sources.

   If a significant amount of effort is required to develop local *BEFs* and root-shoot ratio, involving, for instance, harvest of trees, then it is recommended not to use this method but rather to use the resources to develop local allometric equations as described in the allometric method above (refers to Chapter 4.3 in GPG LULUCF). If that is not possible either, national species specific defaults for *BEF* and *R* can be used. Since both *BEF* and the root-shoot ratio (*R*) are age or stand density dependent, it is desirable to use age-dependent or stand density-dependent equations (for example, volume per hectare). Stem wood volume can be very small in young stands and *BEF* can be very large, while for old stands *BEF* is usually significantly smaller. Therefore using average *BEF* value may result in significant errors for both young stands and old stands. It is preferable to use allometric equations, if the equations are available, and as a second best solution, to use age-dependent or stand density-dependent *BEFs* (but for very young trees, multiplying a small number for stem wood with a large number for the *BEF* can result in significant error).

4. Convert the volume of the commercial component of each tree in a plot into carbon stock in above-ground biomass and below-ground biomass per tree via basic wood density, BEF, root-shoot ratio and carbon fraction (applicable to the species):

$$TCab_{tr} = V_{tr} \cdot D_j \cdot BEF_{pl} \cdot CF_j \quad \text{(A3-21)}$$

$$TCbb_{tr} = TCab_{tr} \cdot R_{j,pl,tr} \quad \text{(A3-22)}$$

Where:

$TCab_{tr}$	=	Carbon stock in above-ground biomass of tree *tr*; kg C $tree^{-1}$
$TCbb_{tr}$	=	Carbon stock in below-ground biomass of tree *tr*; kg C $tree^{-1}$
V_{tr}	=	Commercial volume of tree *tr*; m^3 $tree^{-1}$
D_j	=	Wood density for species *j*; tonnes d. m. m^{-3} (See IPCC GPG-LULUCF, 2003 table 3A.1.9 or USDA wood density table[68])

68 Reyes *et al.*, 1992. Wood densities of tropical tree species. USDA

BEF_{pl}	=	Biomass expansion factor for converting volumes of extracted round wood to total above-ground biomass (including bark), applicable to tree *tr,* in plot *p*; dimensionless.
CF_j	=	Carbon fraction applicable to tree *tr* of species *j*; tonnes C (tonne d. m.)$^{-1}$.
$R_{j,pl,tr}$	=	Root-shoot ratio, applicable to tree *tr* of species *j* in plot *p*; dimensionless

5. Continue with step a.4 of the allometric equation method to calculate the *carbon stock* in above-ground and below-ground biomass by aggregating successively at the tree, plot, and *LU/LC class* levels.

Non-tree component (*$Cabnt_{cl}$* and *$Cbbnt_{cl}$*)

In tropical forests non-tree vegetation includes palms, shrubs, herbaceous plants, lianas and other epiphytes. These types of plants are difficult to measure. Unless they form a significant component of the ecosystem, they should not be measured, which is conservative as their biomass is usually much reduced in the LU/LC classes adopted after deforestation.

Carbon stock estimations for the non-tree vegetation components are usually based on destructive harvesting, drying and weighting. These methods are described in the Sourcebook for LULUCF projects (Pearson *et al*., 2005) from which most of the following explanations are taken.

For herbaceous plants, a square frame of 1m^2 made from PVC pipe or another appropriated material is sufficient for sampling. For shrubs and other large non-tree vegetation, similar or larger frames should be used (about 1-2 m^2, depending on the size, distribution and frequency of this vegetation). For specific *forest* species (e.g. bamboo) or crop types (e.g. coffee) it is also possible to develop allometric equations. When using destructive sampling, apply the following steps:

a. Place the clip frame at the sampling site. If necessary, open the frame and place around the vegetation.

b. Clip all vegetation within the frame to ground level. Cut everything growing within the quadrate (ground surface not three-dimensional column) and sample this.

c. Weigh the sample and remove a well-mixed sub-sample for determination of dry-to-wet mass ratio. Weight the sub-sample in the field, then oven-dry to constant mass (usually at ~ 70 ^{o}C).

d. Calculate the dry mass of each sample. Where a sub-sample was taken for determination of moisture content use the following equation:

$$Dry\ mass = \left(\frac{subsample\ dry\ mass}{subsample\ fresh\ mass} \right) * fresh\ mass\ of\ whole\ sample \qquad \text{(A3-23)}$$

e. The *carbon stock* in the above-ground non-tree biomass per hectare is calculated by multiplying the dry mass by an expansion factor calculated from the sample-frame or plot size and then by multiplying by the carbon fraction and CO_2/C ratio. For calculating the average *carbon stock* per *LU/LC class*, average over all samples:

$$Cabnt_{cl} = \frac{\sum_{pl=1}^{PLcl} DM_{pl} * XF * CF_{pl} * 44/12}{PL_{cl}} \quad \text{(A3-24)}$$

Where:

$Cabnt_{cl}$	=	Average carbon stock per hectare in the above-ground non-tree biomass carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}
DM_{pl}	=	Dry mass of sample *pl*; tonnes of d.m.
XF	=	Plot expansion factor = [10.000 / Plot Area (m^2)]; dimensionless
CF_{pl}	=	Carbon fraction of sample *pl*; tonnes C (tonne d. m.)$^{-1}$
44/12	=	Ratio converting C to CO_2-e
pl	=	1, 2, 3, … PL_{pl} plots in LU/LC class *cl*; dimensionless
PL_{cl}	=	Total number of plots in LU/LC class *cl*; dimensionless

f. The carbon stock per hectare of the below-ground non-tree biomass is calculated by multiplying the estimated above-ground estimate by and appropriate root to shoot ratio.

Estimation of carbon stocks in the dead wood carbon pool (Cdw_{cl})

Carbon stocks in the dead wood carbon pool can be significant in forest classes although is usually insignificant or zero in most agricultural and pastoral LU/LC classes. However, if burning is used to clear slash, dead wood maybe a significant component of carbon stocks in agricultural/pasture, especially in the short term. Therefore, in most cases it will be conservative to ignore the dead wood carbon pool.

Deadwood comprises two types: standing dead wood and lying dead wood. Different sampling and estimation procedures are used to estimate the carbon stocks of the two components.

$$Cdw_{cl} = Csdw_{cl} + Cldw_{cl} \quad \text{(A3-25)}$$

Where:

Cdw_{cl}	=	Average carbon stock per hectare in the dead wood carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}
$Csdw_{cl}$	=	Average carbon stock per hectare in the standing dead wood carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}
$Cñdw_{cl}$	=	Average carbon stock per hectare in the lying dead wood carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}

Standing dead wood shall be measured using the sampling criteria and monitoring frequency used for measuring live trees. Lying deadwood shall be measured using the transect method as explained below. The description of the method to measure lying deadwood is taken from Harmon and Sexton (1996).

Standing dead wood (*$Csdw_{cl}$*)

a. Within the plots delineated for live trees, the diameter at breast height (*DBH*) of standing dead trees can also be measured. In addition, the standing dead wood is categorized under the following four decomposition classes:

1. Tree with branches and twigs that resemble a live tree (except for leaves);
2. Tree with no twig, but with persistent small and large branches;
3. Tree with large branches only;
4. Bole (trunk) only, no branches.

b. For classes 2, 3 and 4, the height of the tree (*H*) and the diameter at ground level should be measured and the diameter at the top should be estimated. Height can be measured using a clinometer.

c. Top diameter can be estimated using a relascope or through the use of a transparent measuring ruler. Hold the ruler approximately 10-20 cm from your eye and record the apparent diameter of the top of the tree. The true diameter is the equal to:

$$True\ \ diameter - (m) = \frac{Dis\tan ce\ eye\ to\ tree\ (m)}{Dis\tan ce\ eye\ to\ ruler\ (m)} * Ruler\ \ measurment\,(m) \quad \text{(A3-26)}$$

Distance can also be measured with a laser range finder.

d. For decomposition class 1 the carbon content of each dead tree is estimated using the allometric or *BEF* methods applied for live trees and by subtracting out the biomass of leaves (about 2-3% of the above-ground biomass for hardwood/broadleaf species and 5-6% for softwood/conifer species).

e. For classes 2, 3 and 4, where it is not clear what proportion of the original biomass has been lost, it is conservative to estimate the biomass of just the bole (trunk) of the tree.
The volume is calculated using *DBH* and height measurements and the estimate of the top diameter. It is then estimated as the volume of a truncated cone:

$$Volume\ (m3) = 1/3 * \pi * H * \left(r_1^2 + r_2^2 + r_1 * r_2\right) \quad \text{(A3-27)}$$

Where:

H	=	Height of the tree; meters
r_1	=	Radius at the base of the tree; meters
r_2	=	Radius at the top of the tree; meters

The volume is converted to dry biomass using the appropriate wood density D_j and then to carbon dioxide equivalents using the carbon fraction Cu_{ff} and CO_2/C ratio (44/12), as in the *BEF* method, but ignoring the Biomass Expansion Factor.

f. To aggregate the carbon stock of each standing dead tree at the plot level and then at the LU/LC class level, continue with step a.4 of the allometric equation method.

Lying dead wood (*$Cldw_{cl}$*)

Lying dead wood is most efficiently measured using the line-intersect method. Only coarse dead wood above a predefined minimum diameter (e.g. > 10 cm) is measured with this method – dead wood with smaller diameter can be measured with litter.

a. At each plot location, lay out two lines of 50 meters either in a single line or at right angles. The lines should be outside the boundaries of the plot to avoid damage to seedlings in the plots during measurement, and also to biasing the dead wood pool by damaging during tree measurement. Alternatively, separate and independent sampling of lying deadwood may be used, in which case deadwood transects must be randomly located (to avoid subjective choice of plots locations), without sample replacement, using the same procedure used for live trees[69]. Their location must also be permanently marked and their coordinates reported.

b. Along the length of the lines, measure the diameter of each intersecting piece of coarse dead wood above a predefined minimum diameter (e.g. > 10 cm). Calipers work best for measuring the diameter. A piece of dead wood should only be measured if: (a) more than 50% of the log is above-ground and (b) the sampling line crosses through at least 50% of the diameter of the piece. If the log is hollow at the intersection point, measure the diameter of the hollow: the hollow portion in the volume estimates should be excluded.

c. Assign each piece of dead wood to one of the three following density classes:

   1. Sound
   2. Intermediate
   3. Rotten

   To determine what density class a piece of dead wood fits into, each piece should be struck with a machete. If the blade does not sink into the piece (that is, it bounces off), it is classified as sound. If it sinks partly into the piece and there has been some wood loss, it is classified as intermediate. If the blade sinks into the piece, there is more extensive wood loss and the piece is crumbly, it is classified as rotten.

d. At least 10 random dead wood samples of each three density classes, representing a range of species present, should be collected for density determination. This determination can be accomplished using the maximum moisture content method (Smith 1954), which does not require sample volume determination. Using a chainsaw or a handsaw, cut a compete disc or a piece of reasonable size from the selected piece of dead wood and bring to the laboratory for wood density determination.

e. Submerge wood samples in water until saturation is reached. Weight saturated samples. Then, dry samples at 105°C for 26 hours. Extract and weight samples again. Do this last weight quickly, withdrawing samples from oven immediately before weighting them, so that no moisture is absorbed by dried samples before obtaining weights.

---

[69] Using this alternate approach, transects may be located in places distant to live trees plots, increasing sampling costs. Even if lying deadwood stocks are very homogeneous in all the strata, implying that fewer samples will be required, the cost of additional displacements and work won't probably compensate for the decrease in samples number.

f. Calculate the wood density for each density class (sound, intermediate, rotten) from the pieces of dead wood collected. Density is calculated by the following equation:

$$Dm = \frac{1}{\frac{ps - po}{po} + \frac{1}{1.53}} \quad \text{(A3-28)}$$

Where:

Dm	= Deadwood density; g cm^{-3}
Ps	= Saturated weight of sample; g
Po	= Anhydrous weight of sample, g
1.53	= Wood density constant

Average the densities to get a single density value for each class.

g. For each density class, the volume is calculated separately as follows:

$$Volume\ (m^3/ha) = \pi^2 * \left(\frac{d_1^2 + d_2^2 + ...d_n^2}{8 * L} \right) \quad \text{(A3-29)}$$

Where:

$d_1, d_2, ..., d_n$	=	Diameters of intersecting pieces of dead wood; cm
L	=	Length of the line; meters

h. The per hectare carbon stock in the lying dead wood carbon pool of each LU/LC class is calculated as follows:

$$Cldw_{cl} = \frac{\sum_{pl=1}^{PL_{cl}} \left(\sum_{dc=1}^{DC} Volume_{dc} * D_{dc} * CF_{dc} * 44/12 \right)_{pl}}{PL_{cl}} \quad \text{(A3-30)}$$

Where:

$Cldw_{cl}$	=	Average carbon stock per hectare in the lying dead wood carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}
$Volume_{dc}$	=	Volume of lying dead wood in the density class *dc*; m^3
D_{dc}	=	Dead wood density of class *dc*; tonnes d. m. m^{-3}
CF_{dc}	=	Carbon fraction of the density class *dc*; tonnes C (tonne d. m.)$^{-1}$
44/12	=	Ratio converting C to CO_2-e
pl	=	1, 2, 3, … PL_{cl} plots in LU/LC class *cl*; dimensionless
PL_{cl}	=	Total number of plots in LU/LC class *cl*; dimensionless
dc	=	1, 2, 3 dead wood density classes; dimensionless
DC	=	Total number of density classes (3); dimensionless

Estimation of carbon stocks in the litter carbon pool (CL_{cl})

In some forest ecosystem litter carbon stocks in the litter carbon pool can be a significant component of the total carbon stock while in anthropogenic ecosystem, particularly in agricultural or pastoral systems, litter is almost absent.

Litter is defined as all dead organic surface material on top of the mineral soil not considered in the lying dead wood pool. Some of this material is recognizable (for example dead leaves, twigs, dead grasses and small branches) and some is unidentifiable (decomposed fragments of different components of originally live biomass. To differentiate small woody debris from the lying dead wood it is necessary to define a diameter (i.e. 10 cm) below which small dead wood pieces are classified as litter and above which they are considered dead wood.

If litter is measured, it should be sampled at the same time of the year at each monitoring event in order to eliminate seasonal effects. The sampling technique is similar to the one used for non-tree vegetation: a square frame of 1.0 m^2 made from PVC pipe or another suitable material can be used. The following description of the sampling and data analysis techniques is taken from the sourcebook for LULUCF projects (Pearson *et al.*, 2005).

a. Place the sampling frame at the sample site.

b. Collect all the litter inside the frame. Pieces of twigs or wood that cross the border of the frame should be cut using a knife or pruning scissors. Place all the litter on a tarpaulin beside the frame or inside a weighting bag. Weigh the sample on-site, then oven-dry to a constant weight.

c. Where sample bulk is excessive, the fresh weight of the total sample should be recorded in the field and a sub-sample of manageable size (approximately 80-100 g) taken for moisture content determination, from which the total dry mass can be calculated.

d. Calculate the dry mass of the sample. Where a sub-sample was taken for determination of the moisture content use equation 23 to estimate the dry mass of the whole sample.

e. The carbon stock per hectare in the litter carbon pool is calculated by multiplying the dry mass by an expansion factor calculated from the sample-frame or plot size and then by multiplying by the carbon fraction and CO_2/C ratio. For calculating the average carbon stock per LU/LC class, average over all samples (see equation 24).

Estimation of carbon stocks in soil organic carbon pool ($Csoc_{cl}$)

Methods to estimate *carbon stocks* in the soil organic carbon pool are described in the sourcebook for LULUCF projects (Pearson *et al.*, 2006) from which the following explanations have been taken.

Three types of variables must be measured to estimate soil organic carbon stocks: (1) depth, (2) bulk density (calculated from the oven-dried weight of soil from a known volume of sampled material), and (3) the concentrations of organic carbon within the sample.

The sample depth should be constant, 30 cm is usually a sufficient sampling depth.

a. Steadily insert the soil probe to a 30 cm depth. If the soil is compacted, use a rubber mallet to fully insert. If the probe will not penetrate to the full depth, do not force it as it is likely a stone or root that is blocking its route and, if forced, the probe will be damaged. Instead, withdraw the probe, clean out any collected soil and insert in a new location.

b. Carefully extract the probe and place the sample into a bag. Because the carbon concentration of organic materials is much higher than that of the mineral soil, including even a small amount of surface material can result in a serious overestimation of soil *carbon stocks*.

c. To reduce variability, aggregate four samples from each collection point for carbon concentration analysis.

d. At each sampling point, take two additional aggregated cores for determination of bulk density. When taking the cores for measurements of bulk density, care should be taken to avoid any excess or loss of soil from the cores.

e. Soil samples can be sent to a professional laboratory for analysis. Commercial laboratories exist throughout the world and routinely analyze plant and soil samples using standard techniques. It is recommended the selected laboratory be checked to ensure they follow commonly accepted standard procedures with respect to sample preparation (for example, mixing and sieving), drying temperatures and carbon analysis methods.

For bulk density determination, ensure the laboratory dries the samples in an oven at 105 ^{o}C for a minimum of 48 hours. If the soil contains coarse, rocky fragments, the coarse fragments must be retained and weighted. For soil carbon determination, the material is sieved through a 2 mm sieve, and then thoroughly mixed. The well-mixed sample should not be oven-dried for the carbon analysis, but only air-dried; however, the carbon concentration does need to be expressed on an oven dry basis at 105 ^{o}C. The dry combustions method using o controlled temperature furnace (for example, a LECO CHN-2000 or equivalent) is the recommended method for determining total soil carbon, but the Walkley-Black method is also commonly used.

f. Calculate the bulk density of the mineral soil core:

$$Bulk\ density\ (g/cm^3) = \frac{oven\, dry\, mass\,(g/cm^3)}{core\, volume\,(cm^3) - \dfrac{mass\, of\ coarse\ fragments\,(cg)}{density\ of\ rock\ fragments\,(cg/m^3)}} \quad \text{(A3-31)}$$

Where the bulk density is for the < 2 mm fraction, coarse fragments are > 2 mm. The density of rock fragments is often given as 2.65 g/cm^3.

g. Using the carbon concentration data obtained from the laboratory, the amount of carbon per unit area is given by:

$$Csoc_{cl}\,(t/ha) = [(soil\ bulk\ density\ (g/cm^3) * soil\ depth\ (cm) * C)] * 100 \qquad \text{(A3-32)}$$

In the above equation, C must be expressed as a decimal fraction. For example, 2.2% carbon is expressed as 0.022 in the equation.

h. The *carbon stock* per hectare in the soil organic carbon pool is calculated by averaging the *carbon stock* estimates per each *LU/LC class*:

$$Csoc_{cl} = \frac{\sum_{pl=1}^{PL_{pl}} Csoc_{pl}}{PL_{pl}} \qquad \text{(A3-33)}$$

Where:

$Csoc_{cl}$	=	Average carbon stock per hectare in the soil organic carbon pool of the LU/LC class *cl*; tCO_2-e ha^{-1}
$Csoc_{pl}$	=	***Carbon stock*** per hectare in the soil organic carbon pool estimated for the plot *pl*; tCO_2-e ha^{-1}
pl	=	1, 2, 3, … PL_{pl} plots in LU/LC class *cl*; dimensionless
PL_{pl}	=	Total number of plots in LU/LC class *cl*; dimensionless

Estimation of *carbon stocks* in the harvested wood products carbon pool (Cwp_{cl})

The wood products carbon pool must be included where there is timber harvest in the baseline scenario prior to or in the process of deforestation and where project activities may significantly reduce the pool. The wood products carbon pool may (optionally) be included where baseline activities may significantly reduce the pool. In this case, Cwp_{cl} must be subtracted in the calculation of $Ctot_{cl}$ in the baseline case and can be added in the calculation of $Ctot_{cl}$ in the project case.

Carbon stocks in wood products are those stocks that become wood products pool at the time of deforestation. They are divided in three fractions, as follows:

- Short-term wood products: wood products and waste that would decay within 3 years; all carbon shall be assumed to be lost immediately;
- Medium-term wood products: wood products that are retired between 3 and 100 years; for this group of wood products, a 20-year linear decay function shall be applied;
- Long-term wood products: wood products that are considered permanent (i.e. carbon is stored for 100 years or more); it may be assumed that no carbon is released.

Accounting for carbon stocks in wood products in the baseline case should only take place at the time of deforestation (year *t*). In the project case, Cwp_{cl} can be accounted at the years of planned timber harvest, in which case monitoring is mandatory.

The proportion of carbon stock stored in each fraction of the wood products carbon pool must be obtained from specific studies applicable to the local conditions or from country-specific data about the volume of timber harvested per forest classes. If data on the proportion of carbon stocks in each fraction of the wood product carbon pool are unavailable, it is conservative to assume that 100% of the carbon is stored in the long-term fraction in the baseline case (in which case no carbon is released into the atmosphere in the baseline case), and that 100% of the carbon is stored in short-term fraction in the project case (in which case all carbon is emitted immediately in the project case).

If data on carbon stocks in each fraction of wood products are available and if timber harvest plans, specifying harvest intensity per forest class in terms of volume extracted per ha, are available for the Project area use Method 1. If approved harvest plans are not available use Method 2.

Method 1: Direct Volume Extraction Estimation

Step 1: Calculate the biomass carbon of the commercial volume extracted since the project start date and in the process of deforestation as follows:

$$CXB_{w,icl,t} = \frac{1}{ABSLPA_{icl,t}} * (\sum_{t=1}^{t*}\sum_{j=1}^{J}(VEX_{w,j,icl,t} * D_j * CF_j * \frac{44}{12}) \quad \text{(A3-34)}$$

Where:

$CXB_{w,icl,t}$	=	Mean carbon stock per hectare of extracted biomass carbon by class of wood product *w* from forest class *icl* at time *t*; tCO_2-e ha^{-1}
icl	=	1, 2, 3, …*Icl* initial pre-deforestation forest classes; dimensionless
w	=	1, 2, 3 … *W* Wood product class (sawn-wood, wood-based panels, other industrial round-wood, paper and paper board, and other); dimensionless
t	=	1, 2, 3… *T* years, a year of the project crediting period; dimensionless
*t**	=	the year at which the area A$BSLPA_{icl,t}$ is deforested in the baseline case; dimensionless
j	=	1, 2, 3 … *J* tree species; dimensionless
$ABSLPA_{icl,t}$	=	Area of forest class *icl* deforested at year *t**; ha
$VEX_{,w,j,fcl,t}$	=	Volume of timber for product class *w*, of species *j*, extracted from within forest class *fcl* at time *t*; m^3
D_j	=	Mean wood density of species *j*; t d.m.m^{-3}
CF_j	=	Carbon fraction of biomass for tree species *j*; t C t^{-1}d.m.
44/12	=	Ratio of molecular weight of CO_2 to carbon; dimensionless

Step 2: Calculate the carbon stock in the wood products carbon pool extracted from the biomass at time *t* (year of deforestation).

$$Cwp_{icl,t} = \sum_{w=1}^{W} CXB_{w,icl,t} * (1 - STF_w) \quad \text{(A3-35)}$$

Where:

$Cwp_{icl,t}$	=	Carbon stock in the wood products carbon pool in initial forest class *icl* at time *t*; tCO_2-e ha^{-1}
icl	=	1, 2, 3, …*Icl* forest classes; dimensionless
w	=	1, 2, 3 … *W* Wood product class (sawn-wood, wood-based panels, other industrial round-wood, paper and paper board, and other); dimensionless
t	=	1, 2, 3… *T* years, a year of the project crediting period; dimensionless
$CXB_{w,icl,t}$	=	Mean stock of extracted biomass carbon by class of wood product *w* from forest class *icl* at time *t*; tCO_2-e ha^{-1}
STF_w	=	Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless

Step 3: Calculate the biomass carbon extacted at time *t* that becomes the medium-term wood products at the time of deforestation.

$$Cwp_{mt,icl,t} = Cwp_{icl,t} - (Cwp_{icl,t} * (1 - STF_w) * (1 - LTF_w)) \quad \text{(A3-36)}$$

Where:

$Cwp_{mt,icl,t}$ = Carbon stock in the medium-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}

$Cwp_{icl,t}$ = Carbon stock in the wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}

STFw = Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless

LTFw = Fraction of wood products that are considered permanent (i.e. carbon is stored for 100 years or more); it may be assumed no carbon is released

Step 4: Calculate the biomass carbon extacted at time *t* that becomes the long-term wood products at the time of deforestation.

$$Cwp_{lt,icl,t} = Cwp_{icl,t} - (Cwp_{icl,t} * (1 - STF_w) * (1 - MTF_w)) \quad \text{(A3-37)}$$

Where:

$Cwp_{lt,icl,t}$ = Carbon stock in the long-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}

$Cwp_{icl,t}$ = Carbon stock in the wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}

STFw = Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless

MTFw = Fraction of wood products that are retired between 3 and 100 years; for this group of wood products, a 20-year linear decay function shall be applied

Method 2: Commercial inventory estimation

Step 1: Calculate the biomass carbon of the commercial volume extracted prior to or in the process of deforestation:

$$CXB_{icl,t} = Cab_{icl,t} * \frac{1}{BCEF} * Pcom_{icl} \quad \text{(A3-38)}$$

Where:

$CXB_{icl,t}$ = Mean stock of extracted biomass carbon from initial forest class *icl* at time *t*; tCO_2-e ha^{-1}

$Cab_{icl,t}$ = Mean above-ground biomass carbon stock in initial forest class *icl* at time *t*; tCO_2-e ha^{-1}

BCEF	=	Biomass conversion and expansion factor for conversion of merchantable volume to total aboveground tree biomass; dimensionless
$Pcom_{icl}$	=	Commercial volume as a percent of total aboveground volume in initial forest class *icl*; dimensionless
t	=	1, 2, 3… *T* years, a year of the project crediting period; dimensionless
icl	=	1, 2, 3, …*Icl* forest classes; dimensionless

Step 2: Identify the wood product class(es) (*w,* defined here as sawn-wood, wood-based panels, other industrial round-wood, paper and paper board, and other) that are the anticipated end use of the extracted carbon calculated in step 1. It is acceptable practice to assign gross percentages of volume extracted to wood product classes on the basis of local expert knowledge of harvest activities and markets.

Step 3: Calculate the biomass carbon extracted at time *t* that becomes the wood products at the time of deforestation.

$$Cwp_{icl,t} = \sum_{w=1}^{W} CXB_{w,icl,t} * (1 - STF_w) \qquad \text{(A3-39)}$$

Where:

$Cwp_{icl,t}$	=	Carbon stock in wood products pool in initial forest class *icl* at time *t*; tCO_2-e ha^{-1}
icl	=	1, 2, 3, …*Icl* forest classes; dimensionless
w	=	Wood product class (sawn-wood, wood-based panels, other industrial round-wood, paper and paper board, and other); dimensionless
t	=	1, 2, 3 … *T* years, a year of the project crediting period; dimensionless
$CXB_{w,icl,t}$	=	Mean stock of extracted biomass carbon by class of wood product *w* from initial forest class *icl* at time *t*; tCO_2-e ha^{-1}
STF_w	=	Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless

Step 4: Calculate the biomass carbon extacted at time *t* that becomes the medium-term wood products at the time of deforestation.

$$Cwp_{mt,icl,t} = Cwp_{icl,t} - (Cwp_{icl,t} * (1 - STF_w) * (1 - LTF_w)) \qquad \text{(A3-40)}$$

Where:

$Cwp_{mt,icl,t}$	=	Carbon stock in the medium-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}
$Cwp_{icl,t}$	=	Carbon stock in the wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}
STFw	=	Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless
LTFw	=	Fraction of wood products that are considered permanent (i.e. carbon is stored for 100 years or more); it may be assumed no carbon is released

Step 5: Calculate the biomass carbon extacted at time *t* that becomes the long-term wood products at the time of deforestation.

$$Cwp_{lt,icl,t} = Cwp_{icl,t} - (Cwp_{icl,t} * (1 - STF_w) * (1 - MTF_w)) \quad \text{(A3-41)}$$

Where:

$Cwp_{lt,icl,t}$	=	Carbon stock in the long-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}
$Cwp_{icl,t}$	=	Carbon stock in the wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*; tCO_2-e ha^{-1}
STFw	=	Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless
MTFw	=	Fraction of wood products that are retired between 3 and 100 years; for this group of wood products, a 20-year linear decay function shall be applied

APPENDIX 4: METHODS TO ESTIMATE EMISSIONS FROM ENTERIC FERMENTATION AND MANURE MANAGEMENT

Estimation of CH_4 emissions from enteric fermentation ($ECH4ferm_{,t,t}$)

The amount of methane[70] emitted by a population of animals is calculated by multiplying the emission rate per animal by the number of animals above the baseline case. To reflect the variation in emission rates among animal types, the population of animals is divided into subgroups, and an *emission factor* per animal is estimated for each subgroup. As per IPCC GPG 2000 and IPCC 2006 Guidelines for AFOLU, use the following equation[71]:

$$ECH4ferm_t = EF_1 * Population_t * 0{,}001 * GWP_{CH4} \quad \text{(A4-1)}$$

$$Population_t = Pforage_t / (DBI * 365) \quad \text{(A4-2)}$$

Where:

$ECH4ferm_t$	=	CH_4 emissions from enteric fermentation at year *t*; tCO_2e
EF_1	=	Enteric CH_4 emission factor for the livestock group; kg CH_4 head^{-1} yr^{-1}
$Population_t$	=	Equivalent number of forage-fed livestock at year *t*; heads
$Pforage_t$	=	Production of forage at year *t*; kg d.m. yr^{-1}
DBI	=	Daily biomass intake; kg d.m. head^{-1} day^{-1}
GWP_{CH4}	=	Global warming potential for CH_4 (with a value of 21 for the first commitment period); dimensionless
0.001	=	Conversion factor of kilograms into tonnes; dimensionless
365	=	Number of day per year; dimensionless
t	=	1, 2, 3, … *T* years of the project crediting period

The production of forage can be estimated by collecting production rates from the literature that represents the shrub species, climate, soil conditions and other features of the areas in which forage will be produced. Sampling surveys is also a good option.

Country-specific emission factors for enteric CH_4 emissions are documented in peer reviewed literature or can be obtained from national GHG inventories. Default values are given in table 10.10 and 10.11 in the

---

[70] Methane is produced in herbivores as a by-product of enteric fermentation, a digestive process by which carbohydrates are broken down by microorganisms into simple molecules for absorption into the bloodstream. Both ruminant animals (e.g., cattle, sheep) and some non-ruminant animals (e.g., pigs, horses) produce CH_4, although ruminants are the largest source since they are able to digest cellulose, due to the presence of specific micro organisms in their digestive tracts. The amount of CH_4 that is released depends on the type, age, and weight of the animal, the quality and quantity of the feed, and the energy expenditure of the animal.

[71] Refer to equation 10.19 and equation 10.20 in IPCC 2006 GL AFOLU or equation 4.12 and equation 4.13 in GPG 2000 for agriculture.

IPCC 2006 Guidelines for AFOLU. When selecting emission factors it is important to select those from a region that is similar to the Project area. The tables in Annex 10A.1 of the IPCC 2006 Guidelines for AFOLU specify the animal characteristic such as weight, growth rate and milk production used to estimate the emission factors. These tables should be consulted in order to ensure that the local conditions are similar. In particular, data on average milk production by dairy livestock should be analyzed when selecting an emission factor for dairy livestock. To estimate the emission factor, the data in table 10A.1 can interpolated using the data on the local average milk production.

For data on daily biomass intake use local data or data that are applicable to the local conditions according to peer-reviewed literature or the national GHG inventory. When selecting a value for daily biomass intake, ensure that the chosen data are applicable to both the forage types to be produced and the livestock group (see also table 5 in appendix 2).

Estimation of CH_4 emissions from manure management (*$ECH4man_t$*) [72]

The storage and treatment of manure under anaerobic conditions produces CH_4. These conditions occur most readily when large numbers of animals are managed in confined area (e.g. dairy farms, beef feedlots, and swine and poultry farms), and where manure is disposed of in liquid based systems. The main factors affecting CH_4 emissions are the amount of manure produced and the portion of manure that decomposes anaerobically. The former depends on the rate of waste production per animal and the number of animals, and the latter on how the manure is managed. When manure is stored or treated as a liquid (e.g. in lagoons, ponds, tanks, or pits), it decomposes anaerobically and can produce a significant quantity of CH_4. The temperature and the retention time of storage greatly affect the amount on methane produced. When manure is handled as a solid (e.g. in stacks or piles), or when it is deposited on pastures and rangelands, it tends to decompose under more aerobic conditions and less CH_4 is produced.

CH_4 emissions from manure management for the forage-fed livestock can be estimated using IPCC methods[73].

$$ECH4man_t = EF_2 * Population_t * 0{,}001 * GWP_{CH4} \qquad \text{(A4-3)}$$

Where:

$ECH4man_{t,t}$	=	CH_4 emissions from manure management at year *t*; tCO_2e
EF_2	=	Manure management CH_4 emission factor for the livestock group; kg CH_4 $head^{-1}$ yr^{-1}
$Population_t$	=	Equivalent number of forage-fed livestock at year *t*; heads
GWP_{CH4}	=	Global warming potential for CH_4 (with a value of 21 for the first commitment period); dimensionless
0.001	=	Conversion factor of kilograms into tonnes; dimensionless
t	=	1, 2, 3, … *T* years of the project crediting period

[72] Taken from AR-AM0006 version 1

[73] Refer to equation 10.22 in AFOLU volume of the IPCC 2066 Guidelines or equation 4.15 in GPG 2000 for agriculture.

The best estimate of emissions will usually be obtained using country-specific emission factors that have been published in peer-reviewed literature or in the national GHG inventory. It is recommended that country-specific emission factors be used that reflect the actual duration of storage and type of treatment of animal manure in the management system used. If appropriate country-specific emission factors are unavailable, default emission factors presented in table 10.14-10.16 of IPCC 2006 Guidelines for AFOLU may be used. These emission factors represent those for a range of livestock types and associated management systems, by regional management practices and temperature. When selecting a default factor, be sure to consult the supporting tables in Annex 10A.2 of IPCC 2006 Guidelines for AFOLU, for the distribution of manure management systems and animal waste characteristics used to estimate emissions. Select an emission factor for a region that most closely matches the circumstances of the livestock that are fed forage from the project area.

Estimation of N_2O emissions from manure management (*$EN2Oman_t$*) [74]

Nitrous oxide emissions from manure management vary significantly between the type of management system used, and can also result in indirect emissions due to other forms of nitrogen loss from the system. The N_2O emissions from manure management can be estimated using method provided in the IPCC 2006 Guidelines for AFOLU, or in IPCC GPG 2000[75]

$$EN2Oman_t = EdirN2Oman_t + EindN2Oman_t \quad \text{(A4}$$

$$EdirN2Oman_t = Population_t * Nex * EF_3 \cdot 0{,}001 * 44/28 * GWP_{N20} \quad \text{(A4-5)}$$

$$EindN2Oman_t = Population_t * Nex * Frac_{gas} * EF_4 * 0{,}001 * 44/28 * GWP_{N2O} \quad \text{(A4-6)}$$

Where:

$EN2Oman_{fcl,t}$	=	N_2O emissions from manure management at year *t*; tCO_2e[1]
$EdirN_2Oman_t$	=	Direct N_2O emissions from manure management at year *t*; tCO_2e
$EindNOman_t$	=	Indirect N_2O emissions from manure management at year *t*; tCO_2e
$Population_t$	=	Equivalent number of forage-fed livestock at year *t*; heads
Nex	=	Annual average N excretion per livestock head; kg N $head^{-1}$ yr^{-1}
EF_3	=	Emission factor for N_2O emissions from manure management for the livestock group; kg N_2O-N (kg N^{-1}) $head^{-1}$ yr^{-1}
EF_4	=	Emission factor for N_2O emissions from atmospheric deposition of forage-sourced nitrogen on soils and water surfaces; kg N_2O-N (kg NH_3-N and NO_x-N emitted)$^{-1}$ $head^{-1}$ yr^{-1} **<u>Note:</u>** The use of the IPCC default factor 0.01 is recommended.

74 Taken from AR-AM0006 version 1

75 Refer to equations 10.25, 10.26 and 10.27 in AFOLU volume of the IPCC 2006 Guidelines and/or equation 4.18 in GPG 2000 for agriculture.

$Frac_{gas}$	=	Fraction of managed livestock manure nitrogen that volatilizes as NH3 and NOx in the manure management phase; kg NH_3-N and NO_x-N emitted (Kg N)$^{-1}$
GWP_{N2O}	=	Global warming potential for N_2O (310 for the first commitment period); dimensionless
44/28	=	Conversion of N_20-N emissions to N_2O emissions
0.001	=	Conversion factor of kilograms into tonnes; dimensionless

The best estimate of the annual nitrogen excretion rates for each livestock group will usually be obtained using country-specific rates from published peer reviewed literature or from the national GHG inventory. If country-specific data cannot be collected or derived, or appropriate data are not available from another country with similar conditions, default nitrogen excretion rates can be obtained from table 10.19 of IPCC 2006 Guidelines for AFOLU.

The possible data sources for emission factors are similar. Default emission factors are given in table 10.21 and 11.3 of the IPCC 2006 Guidelines for AFOLU and default values for volatilization of NH_3 and NO_x ($Frac_{gas}$) in the manure management system are presented in table 10.22 of the same IPCC 2006 Guidelines. For $EF_4$the IPCC default value 0.01 is recommended (equation 10.27, IPCC 2006 Guidelines for AFOLU).

APPENDIX 5: DATA AND PARAMETERS USED IN THIS METHODOLOGY

Notation	Description	Unit	Equation	Observation	Source	Monitoring
±90%CI	90% Confidence Interval					
A	Area of error due to observed change predicted as persistence	ha	9		calculated	each renewal of fixed baseline period
a	Estimated intercept of the regression line	ha yr^{-1}	4a,		calculated	each renewal of fixed baseline period
a_1 and a_2	sample plot areas	ha	A3-5		calculated	each renewal of fixed baseline period
$Aaverage_i$	Area of "average" forest land suitable for conversion to non-forest land within stratum	ha	6		calculated	each renewal of fixed baseline period
ABSLLK	Cumulative area of baseline deforestation within the leakage belt at year *t*	ha	Table 9c, Table 11c, Table 13c, Table 14c, Table 19c		calculated	each renewal of fixed baseline period
$ABSLLK_{ct,t}$	Area of category *ct* deforested at time *t* within the leakage belt in the baseline case	ha			measured or estimated from literature	each renewal of fixed baseline period
$ABSLLK_{fcl,t}$	Area of final (post-deforestation) forest class *fcl* deforested at time *t* within the leakage belt in the baseline case	ha			calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$ABSLLK_{i,t}$	Annual area of baseline deforestation in stratum *i* within the leakage belt at year *t*;	ha	Table 9.c		calculated	each renewal of fixed baseline period
$ABSLLK_{icl,t}$	Area of initial (pre-deforestation) forest class *icl* deforested at time *t* within the leakage belt in the baseline case	ha	Table 30a		calculated	each renewal of fixed baseline period
$ABSLLK_t$	Annual area of baseline deforestation within the leakage belt at year *t*;	ha	Table 9c, Table 11c, Table 13c, Table 14c, Table 19c		calculated	each renewal of fixed baseline period
$ABSLPA$	Cumulative area of baseline deforestation in the project area at year *t*	ha	Table 9b, Table 11b, Table 13b, Table 14b, Table 19b		calculated	each renewal of fixed baseline period
$ABSLPA_{ct,t}$	Area of category *ct* deforested at time *t* within the project area in the baseline case	ha	Table 22b1		measured or estimated from literature	each renewal of fixed baseline period
$ABSLPA_{i,t}$	Annual area of baseline deforestation in stratum *i* within the project area at year *t*;	ha	Table 9b		calculated	each renewal of fixed baseline period
$ABSLPA_{icl,t}$	Area of initial (pre-deforestation) forest class *icl* deforested at time *t* within the project area in the baseline	ha	10		calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	case					
$ABSLPA_t$	Annual area of baseline deforestation in the project area at year *t*	ha	Table 9b, Table 11b, Table 13b, Table 14b, Table 19b		calculated	each renewal of fixed baseline period
ABSLPAz,t	Area of the zone *z* "deforested" at time *t* within the project area in the baseline case; ha	ha	10		calculated	each renewal of fixed baseline period
ABSLRR	cumulative area of baseline deforestation in the reference region at year t	ha	Table 9.a, Table 11a, Table 13a, Table 14a, Table 19a		calculated	each renewal of fixed baseline period
$ABSLRR_{ct,t}$	Area of category *ct* deforested at time *t* within the reference region in the baseline case	ha	Table 22.a.1		measured or estimated from literature	each renewal of fixed baseline period
$ABSLRR_{i,t}$	Annual area of baseline deforestation in stratum *i* within the reference region at year *t*	ha	3, 4a, 4b, 4c, 5, 6, 7, 8a, 8b, 8c,		calculated	each renewal of fixed baseline period
ABSLRRtaverage,i	Annual area of baseline deforestation in stratum *i* within the Reference region at a year $taverage_i$	ha	7		calculated	each renewal of Fixed Baseline Period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$ABSLRR_t$	Annual area of baseline deforestation in the reference region at year t	ha	Table 9.a, Table 11a, Table 13a, Table 14a, Table 19a		calculated	each renewal of fixed baseline period
$ACPA_{icl,t}$	Annal area within the Project Area affected by catastrophic evens in class *icl* at year *t*	ha	Table 25f, Table 26f		measured *ex post*	each time a catastrophic event occurs
$Aforage_t$	Area under forege above the baseline in leakage management areas	ha	Table 32		calculated *ex ante*, measured *ex post*	annually
$Aoptimal_i$	Area of "optimal" forest land suitable for conversion to non-forest land within stratum *i*	ha	5		calculated	each renewal of fixed baseline period
AP	Plot area	m^2	A3-13		measured or estimated from literature	only once at project start and when mandatory
$APDPA_{icl,t}$	Areas of planned deforestation in forest class *icl* at year *t* in the project area	ha	Table 25a	*ex ante* and *ex post*	measured or estimated from literature	annually
$APFPA_{icl,t}$	Annual area of planned fuel-wood and charcoal activities in forest class *icl* at year *t* in the project area	ha	Table 25, Table 26c	*ex ante* and *ex post*	calculated *ex ante*, measured *ex post*	annually
$APLPA_{icl,t}$	Areas of planned logging activities in forest class *icl* at year *t* in the project area	ha	Table 25b, Table 26b	*ex ante* and *ex post*	calculated ex *ante*, measured *ex post*	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$APNiPA_{icl,t}$	Annual area of forest class *icl* with increasing carbon stock without harvest at year *t* in the project area	ha	Table 26a	*ex ante* and *ex post*	calculated ex *ante*, measured *ex post*	annually
$APSLK_{fcl,t}$	Annual area of class *fcl* with decreasing carbon stock in leakage management areas in the project case at year *t*	ha	Table 30b		measured *ex post*	annually
ARR_i	Total forest area in stratum *i* within the reference region at the project start date	ha	4.b, 8.c		measured or estimated from literature	each renewal of fixed baseline period
$ARR_{i,t-1}$	Area with forest cover in stratum *i* within the reference region a year *t-1*	ha	3		calculated	each renewal of fixed baseline period
$AUFPA_{icl,t}$	Areas affected by forest fires in class *icl* in which carbon stock recovery occurs at year *t*	ha	Table 25e, Table 26e		measured *ex post*	annually
B	Area correct due to observed change predicted as change	ha	9		measured or estimated from literature	each renewal of fixed baseline period
b	Estimated coefficient of the time variable (or slope of the linear regression)	dimensionless	4.a, 7, 8.a, 8.b		calculated	each renewal of fixed baseline period
BCEF	Biomass conversion and expansion factor for conversion of merchantable volume to total aboveground tree biomass	dimensionless	A3-9, A3-36		measured or estimated from literature	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
BEFpl	Biomass expansion factor for converting volumes of extracted round wood to total above-ground biomass (including bark), applicable to tree tr, in plot pl	dimensionless	A3-21		measured or estimated from literature	only once at project start
BLDA, BLDB, … BLDN	Total area of projected baseline deforestation during the fixed baseline period of Project A	ha	2.a, 2.b, 2.n		PD of project A; PD of project B, … PD of Project N;	each renewal of fixed baseline period
C	Area of error due to observed persistence predicted as change	ha	9		calculated	
Cab_{fcl}	Average carbon stock per hectare in the above-ground biomass carbon pool of final post-deforestation class *fcl*	t CO_2e ha^{-1}	Table 16, Table 17		measured or estimated from literature	
Cab_{cl}	Average carbon stock per hectare in the above-ground biomass carbon pool of LU/LC class *cl*	t CO_2e ha^{-1}	A3-6, A3-14,A3-36		measured or estimated from literature	only once at project start and when mandatory
Cab_{icl}	Average carbon stock per hectare in the above-ground biomass carbon pool of initial forest class *icl*	t CO_2e ha^{-1}	Table 15a, A3-38		measured or estimated from literature	Cab_{icl}
$Cabnt_{cl}$	Average carbon stock per hectare in the above-ground non-tree biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-7, A3-24		measured or estimated from literature	only once at project start and when mandatory

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$Cabt_{cl}$	Average carbon stock per hectare in the above-ground tree biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-7		measured or estimated from literature	only once at project start and when mandatory
Cabz	Average carbon stock per hectare in the above-ground biomass carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
Ca_{cl}	Average carbon stock per hectare in above-ground biomass in LU/LC class *cl*	tCO_2-eha^{-1}	A3-14			
Cbb_{cl}	Average carbon stock per hectare below-ground biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6, A3-17		measured or estimated from literature	only once at project start and when mandatory
Cbb_{fcl}	Average carbon stock per hectare below-ground biomass carbon pool of final post-deforestation class *fcl*	t CO_2-e ha^{-1}	Table 16, Table 17		measured or estimated from literature	
Cbb_{icl}	Average carbon stock per hectare below-ground biomass carbon pool of initial forest class *icl*	t CO_2-e ha^{-1}	Table 15		measured or estimated from literature	
$Cbbnt_{cl}$	Average carbon stock per hectare below-ground non-tree biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-8		measured or estimated from literature	only once at project start and when mandatory
Cbb_{fcl}	Average carbon stock per hectare below-ground biomass carbon pool of final post-	t CO_2-e ha^{-1}			measured or estimated from literature	

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	deforestation class *fcl*					
$Cbbt_{cl}$	Average carbon stock per hectare below-ground tree biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-8		measured or estimated from literature	only once at project start and when mandatory
Cbbz	Average carbon stock per hectare below-ground tree biomass carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
Cdw_{fcl}	Average carbon stock per hectare in the in the dead wood biomass carbon pool of final post-deforestation class *fcl*	t CO_2-e ha^{-1}	Table 16, Table 17		measured or estimated from literature	only once at project start and when mandatory
Cdw_{cl}	Average carbon stock per hectare in the in the dead wood biomass carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6, A3-25		measured or estimated from literature	only once at project start and when mandatory
Cdw_{icl}	Average carbon stock per hectare in the in the dead wood biomass carbon pool of initial forest class *icl*	t CO_2-e ha^{-1}	Table 15		measured or estimated from literature	
Cdwz	Average carbon stock per hectare in the in the dead wood biomass carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
$CE_{p,icl}$	Average combustion efficiency of the carbon pool *p* in the forest class	dimensionless	14		measured or estimated from literature	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
CF_{dc}	Carbon fraction of the density class *dc*	tonnes C (tonne d. m.)$^{-1}$	A3-30		measured or estimated from literature	only once at project start and when mandatory
CF_j	Carbon fraction for tree *tr*, of species, group of species or forest type *j*	tonnes C (tonne d. m.)$^{-1}$	A3-11, A3-21, A3-24		measured or estimated from literature	only once at project start
CF_{pl}	Carbon fraction of sample *pl*	tonnes C (tonne d. m.)$^{-1}$	A3-24		calculated	only once at project start and when mandatory
C_i	Cost to select and measure a plot of the LU/LC class *cl*		A3-3; A3-4		estimated	each renewal of fixed baseline period
cl	1, 2, 3 … *Cl* LU/LC classes	dimensionless	A3-3		measured or estimated from literature	each renewal of fixed baseline period
$Cldw_{fcl}$	Average carbon stock per hectare in the lying dead wood carbon pool of final post-deforestation class *fcl*	t CO_2-e			measured or estimated from literature	$Cldw_{fcl}$
Cl_{cl}	Average carbon stock per hectare in the litter carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6		measured or estimated from literature	only once at project start and when mandatory
$Cldw_{cl}$	Average carbon stock per hectare in the lying dead wood carbon pool of the LU/LC class *cl*	t CO_2-e	A3-25, A3-30		measured or estimated from literature	only once at project start and when mandatory
$Cldw_{icl}$	Average carbon stock per hectare in the lying dead wood carbon pool of initial forest	t CO_2-e			measured or estimated from literature	

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	class *icl*					
Clfcl	Average carbon stock per hectare in the litter carbon pool of LU/LC class f*cl*	t CO_2-e ha^{-1}	Table 16, Table 17		measured or estimated from literature	only once at project start and when mandatory
Clicl	Average carbon stock per hectare in the litter carbon pool of LU/LC class i*cl*	t CO_2-e ha^{-1}	Table 15		measured or estimated from literature	only once at project start and when mandatory
Clz	Average carbon stock per hectare in the litter carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
Cp	Average carbon stock per hectare in the carbon pool *p*	t CO_2-e ha^{-1}	Table 7b		calculated	only once at project start
$Cp_{,icl,t}$	Average carbon stock per hectare in the carbon pool *p* burnt at year *t* in the forest class *icl*;	t CO_2-e ha^{-1}	14		calculated	only once at project start
$Csoc_{fcl}$	Average carbon stock per hectare in the soil organic carbon pool of final post-deforestation class *fcl*	t CO_2-e ha^{-1}	Table 16, table 17		measured or estimated from literature	
Csocz	Average carbon stock per hectare in the soil organic carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
$Csdw_{cl}$	Average carbon stock per hectare in the standing dead wood carbon pool of the LU/LC class *cl*	t CO_2-e ha^{-1}	A3-25		measured or estimated from literature	only once at project start and when mandatory

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$Csoc_{icl}$	Average carbon stock per hectare in the soil organic carbon pool of initial forest class *icl*	t CO_2-e ha^{-1}	Table 15		measured or estimated from literature	only once at project start and when mandatory
$Csoc_{cl}$	Average carbon stock per hectare in the soil organic carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6, A3-33		measured or estimated from literature	only once at project start and when mandatory
$Csoc_{p}l$	Carbon stock per hectare in the soil organic carbon pool estimated for the plot *pl*;	t CO_2-e ha^{-1}	A3-33		measured or estimated from literature	only once at project start
ct	1, 2, 3 … *Ct* categories of LU/LC change (from initial forest classes *icl* to final post-deforestation classes *fcl*)	dimensionless			calculated	each renewal of fixed baseline period
$Ctot_{cl}$	Average carbon stock per hectare in all accounted carbon pools of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6		calculated	only once at project start and when mandatory
$Ctot_{fcl,t}$	Average carbon stock of all accounted carbon pools in non-forest class *fcl* at time *t*;	CO_2-e ha^{-1}	Table 30b		calculated	only once at project start
$Ctot_{icl}$	Average carbon stock of all accounted carbon pools in forest class *icl*	t CO_2-e ha^{-1}	Table 15		calculated	only once at project start and when mandatory
$Ctot_{icl,t}$	Average carbon stock of all accounted carbon pools in forest class *icl* at time *t*	t CO_2-e ha^{-1}	Table 25a, Table 30a		calculated	only once at project start and when mandatory
Ctotz	Average carbon stock of all accounted carbon pools per zone z	t CO_2-e ha^{-1}	Table 17		calculated	only once at project start and when mandatory

Notation	Description	Unit	Equation	Observation	Source	Monitoring
ctz	1, 2, 3 … *Ctz* categories of LU/LC change (from initial forest classes *icl* to post deforestation zones *z*)	dimensionless			calculated	each renewal of fixed baseline period
CV%	The highest coefficient of variation (%) reported in the literature from different volume or biomass forest inventories in forest plantations, natural forests, agro-forestry and/or silvo-pastoral systems	%	A3-1, A3-5		literature	only once at project start and when mandatory
Cwp_{fcl}	Average carbon stock per hectare in the harvested wood products carbon pool of final post-deforestation class *fcl*	t CO_2-e ha^{-1}	Table 16, Table 17			only once at project start and when mandatory
Cwp_{cl}	Average carbon stock per hectare in the harvested wood products carbon pool of LU/LC class *cl*	t CO_2-e ha^{-1}	A3-6, A3-35, A3-37		measured or estimated from literature	only once at project start and when mandatory
Cwp_{icl}	Average carbon stock per hectare in the harvested wood products carbon pool of initial forest class *icl*	t CO_2-e ha^{-1}	Table 15, A3-35,A3-36, A3-37, A3-39, A3-40, A3-41			only once at project start and when mandatory
$Cwp_{lt,icl,t}$	Carbon stock in the long-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*		A3-37, A3-41			

Notation	Description	Unit	Equation	Observation	Source	Monitoring
Cwpmt,icl,t	Carbon stock in the medium-term wood products carbon pool at the time of deforestation *t* of the initial forest class *icl*		A3-36, A3-40			
Cwpz	Average carbon stock per hectare in the harvested wood products carbon pool per zone z	t CO_2-e ha^{-1}	Table 17		measured or estimated from literature	only once at project start and when mandatory
$CXB_{w,icl,t}$	Mean carbon stock per hectare of extracted biomass carbon by class of wood product *w* from forest class *icl* at time *t*	t CO_2-e ha^{-1}	A3-34, A3-35, A3-39		measured or estimated from literature	only once at project start and when mandatory
d1, d2, ..., dn	Diameters of intersecting pieces of dead wood	cm	A3-29		measured or estimated from literature	only once at project start and when mandatory
DBH	Diameter at Breast Height	cm	A3-18		measured or estimated from literature	only once at project start and when mandatory
DBI	Daily biomass intake	kg d.m. $head^{-1}$ day^{-1}	A4-2, Table 31		measured or estimated from literature	each renewal of fixed baseline period
dc	1, 2, 3 dead wood density classes	dimensionless	A3-30		defined	
DC	Total number of density classes (3)	dimensionless	A3-30		defined	

Notation	Description	Unit	Equation	Observation	Source	Monitoring
ΔCab_{ct}	Average carbon stock change factor in the above-ground biomass carbon pool of category *ct*	t CO_2-e ha^{-1}	Table 22.a.1		calculated	only once at project start and when mandatory
$\Delta CabBSLLK_t$	Total baseline carbon stock changes for the above-ground biomass pool in the leakage belt	t CO_2-e	Table 22.c.1		calculated	each renewal of fixed baseline period
$\Delta CabBSLLK_t$	Cumuativel baseline carbon stock changes for the above-ground biomass pool in the leakage belt	t CO_2-e	Table 22.c.1		calculated	each renewal of fixed baseline period
$\Delta CabBSLPA$	Cumulative baseline carbon stock changes for the above-ground biomass pool in the project area	t CO_2-e	Table 22.b.1		calculated	each renewal of fixed baseline period
$\Delta CabBSLPA_t$	Total baseline carbon stock changes for the above-ground biomass pool in the project area	t CO_2-e	Table 22.b.1		calculated	each renewal of fixed baseline period
$\Delta CabBSLRR$	Cumulative baseline carbon stock changes for the above-ground biomass pool in the reference region	t CO_2-e	Table 22.a.1		calculated	each renewal of fixed baseline period
$\Delta CabBSLRR_t$	Total baseline carbon stock changes for the above-ground biomass pool in the reference region	t CO_2-e	Table 22.a.1		calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$\Delta CADLK$	Cumulative total decrease in carbon stocks due to displaced deforestation	t CO_2-e	Table 34, Table 35		calculated	annually
$\Delta CADLK_t$	Total decrease in carbon stocks due to displaced deforestation at year *t*	t CO_2-e	Table 34, Table 35		calculated	annually
ΔCbb_{ct}	Average carbon stock change factor in the below-ground biomass carbon pool of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta CBSLPAf_t$	Total baseline carbon stock change in final classes within the project area at year *t*	t CO_2-e			calculated	each renewal of fixed baseline period
$\Delta CBSLPA$	Total baseline carbon stock changes in the project area	t CO_2-e	Table 36		calculated	each renewal of fixed baseline period
$ABSLPA_{ct,t}$	Area of category *ct* deforested at time *t* within the project area in the baseline case	ha	Table 22.b.1		calculated	each renewal of fixed baseline period
$\Delta CBSLLK$	Cumulative carbon stock changes in leakage management areas in the baseline case	t CO_2-e	Table 21d, Table 30a, Table 30c		calculated	each renewal of fixed baseline period
$\Delta CBSLLK_t$	Annual carbon stock changes in leakage management areas in the baseline case at year *t*	t CO_2-e	Table 21d, Table 30a, Table 30c		calculated	each renewal of fixed baseline period
$\Delta CBSLPAf$	Total cumulative baseline carbon stock change in final classes within the project area	t CO_2-e			calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	at year *t*					
$\Delta CBSLPAf_t$	Total annual baseline carbon stock change in final classes within the project area at year *t*	t CO_2-e			calculated	each renewal of fixed baseline period
$\Delta CBSLPA$	Total net cumulative baseline carbon stock change in final classes within the project area at year *t*	t CO_2-e	10		calculated	each renewal of fixed baseline period
$\Delta CBSLPAi$	Total cumulative baseline carbon stock change in initial forest classes within the project area at year *t*	t CO_2-e			calculated	each renewal of fixed baseline period
$\Delta CBSLPAi_t$	Total baseline carbon stock change in initial forest classes within the project area at year *t*	t CO_2-e			calculated	each renewal of fixed baseline period
$\Delta CBSLPA_t$	Total baseline carbon stock change within the project area at year *t*	t CO_2-e	19, 21, Table 36		calculated	each renewal of fixed baseline period
$\Delta CBSL_t$	Total baseline carbon stock change at year *t* in the project area	tCO_2-e	16		calculated	each renewal of fixed baseline period
ΔCdw_{ct}	Average carbon stock change factor in the dead wood biomass carbon pool of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta CFCdPA$	Cumulative decrease in carbon stock due to forest fires	t CO_2-e	Table 25g, Table 27	*ex post*	calculated	$\Delta CFCdPA$

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	and catastrophic events at year *t* in the project area					
$\Delta CFCdPA_t$	Total decrease in carbon stock due to forest fires and catastrophic events at year *t* in the project area	t CO_2-e	Table 25g, Table 27	*ex post*	calculated	annually
$\Delta CFCiPA$	Cumulative increase in carbon stock due to forest fires and catastrophic events at year *t* in the project area	t CO_2-e	Table 26g, Table 27	*ex post*	calculated	annually
$\Delta CFCiPA_t$	Total increase in carbon stock due to forest fires and catastrophic events at year *t* in the project area	t CO_2-e	Table 26g, Table 27	*ex post*	calculated	annually
ΔCl_{ct}	Average carbon stock change factor in the litter carbon pool of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
ΔCLK	Total cumulative decrease in carbon stocks within the leakage belt at year *t*	t CO_2-e	Table 35, Table 36		calculated	each renewal of fixed baseline period
ΔCLK_t	Total decrease in carbon stocks within the leakage belt at year *t*	t CO_2-e	19,Table 35, Table 36		calculated	each renewal of fixed baseline period
$\Delta CLPMLK$	Cumulative carbon stock decrease due to leakage prevention measures		Table 30c, Table 33, Table 35	*ex ante* and *ex post*	calculated	annually
$\Delta CLPMLKt$	Carbon stock decrease due to leakage prevention measures		Table 30c, Table 33,	*ex ante* and *ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	at year *t*		Table 35			
ΔCp_t	Carbon stock change factor applicable to pool *p* at time *t*	t CO_2-e			calculated	each renewal of fixed baseline period
$\Delta CPAdPA$	Cumulative decrease in carbon stock due to all planned activities at year *t* in the project area	t CO_2-e	Table 25d, Table 27, Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CPAdPA_t$	Total decrease in carbon stock due to all planned activities at year *t* in the project area	t CO_2-e	Table 25d, Table 27, Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CPAiPA$	Cumulative increase in carbon stock due to all planned activities at year *t* in the project area	t CO_2-e	Table 26d, Table 27, Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CPAiPA_t$	Total increase in carbon stock due to all planned activities at year *t* in the project area	t CO_2-e	Table 26d, Table 27, Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CPDdPA$	Cumulative decrease in carbon stock due to planned deforestation at year *t* in the project area	t CO_2-e	Table 25a	*ex ante* and *ex post*	calculated	annually
$\Delta CPDdPA_t$	Total decrease in carbon stock due to planned deforestation at year *t* in the project area	t CO_2-e	Table 25a	*ex ante* and *ex post*	calculated	annually
$\Delta CPFdPA$	Cumulative decrease in carbon stock due to planned fuel-wood and charcoal	t CO_2-e	Table 25c, Table 25d	*ex ante* and *ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	activities at year *t* in the project area					
$\Delta CPFdPA_t$	Total decrease in carbon stock due to planned fuel-wood and charcoal activities at year *t* in the project area	t CO_2-e	Table 25c, Table 25d	*ex ante* and *ex post*	calculated	annually
$\Delta CPFiPA$	Cumulative increase in carbon stock due to planned fuel-wood and charcoal activities at year *t* in the project area	t CO_2-e	Table 26c, Table 26d	*ex ante* and *ex post*	calculated	annually
$\Delta CPFiPA_t$	Total increase in carbon stock due to planned fuel-wood and charcoal activities at year *t* in the project area	t CO_2-e	Table 26c, Table 26d	*ex ante* and *ex post*	calculated	annually
$\Delta\ Cp_{icl,t=t*}$	Average carbon stock change factor for carbon pool *p* in the initial forest class *icl* applicable at time *t*	tCO_2-e ha^{-1}	10			
$\Delta CPLdPA$	Cumulative decrease in carbon stock due to planned logging activities at year *t* in the project area	t CO_2-e	Table 25b, Table 25d	*ex ante* and *ex post*	calculated	annually
$\Delta CPLdPA_t$	Total decrease in carbon stock due to planned logging activities at year *t* in the project area	t CO_2-e	Table 25b, Table 25d	*ex ante* and *ex post*	calculated	annually
$\Delta CPLiPA$	Cumulative increase in carbon stock due to planned logging activities at year *t* in the	t CO_2-e	Table 26b, Table 26d	*ex ante* and *ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	project area					
$\Delta CPLiPA_t$	Total increase in carbon stock due to planned logging activities at year *t* in the project area	t CO_2-e	Table 26b, Table 26d	*ex ante* and *ex post*	calculated	annually
$\Delta CPNiPA$	Cumulative increase in carbon stock due to planned protection of growing forest classes in the project area at year *t*	t CO_2-e	Table 26a, Table 26d	*ex ante* and *ex post*	calculated	annually
$\Delta CPNiPA_t$	Total increase in carbon stock due to planned protection of growing forest classes in the project area at year *t*	t CO_2-e	Table 26a, Table 26d	*ex ante* and *ex post*	calculated	annually
$\Delta CPSLK$	Total cumulative carbon stock change in leakage management areas in the project case	t CO_2-e	Table 30b, Table 30c	*ex ante* and *ex post*	calculated	annually
$\Delta CPSLK_t$	Total annual carbon stock change in leakage management areas in the project case	t CO_2-e	Table 30b, Table 30c	*ex ante* and *ex post*	calculated	annually
$\Delta CPSPA$	Cumulative project carbon stock change within the project area at year *t*	t CO_2-e	Table 27, Table 29, Table 36	*ex ante* and *ex post*	calculated	annually
$\Delta CPSPA_t$	Total project carbon stock change within the project area at year *t*	t CO_2-e	19, 21, Table 27, Table 29, Table 36	*ex ante* and *ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$\Delta Cp_{z,t=t*}$	Average carbon stock change factor for carbon pool *p* in zone *z* applicable at time *t* = *t**	tCO_2-e ha^{-1}	10		calculated	each renewal of tha baseline
$\Delta Csoc_{ct}$	Average carbon stock change factor in the soil organic carbon pool of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta Ctot_{ct,t}$	Carbon stock change factor (also called emission factor) for all accounted carbon pools in category *ct* at time *t*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta Ctot_{ct}$	Average carbon stock change factor in all accounted carbon pools of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta Ctot_{icl,t}$	Average carbon stock change of all accounted carbon pools in forest class *icl* at time t	t CO_2-e ha^{-1}	Table 25b, Table 25c, Table 25e, Table 25f, Table 26a, Table 26b, Table 26c, Table 26e, Table 26f		calculated	each renewal of tha baseline
$\Delta CUCdPA$	Cumulative decrease in carbon stock due to catastrophic events at year *t* in the project area	t CO_2-e	Table 25f, Table 25g	*ex post*	calculated	annually
$\Delta CUCdPA_t$	Total decrease in carbon stock due to catastrophic events at year *t* in the project area	t CO_2-e	Table 25f, Table 25g	*ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$\Delta CUCiPA$	Cumulative increase in carbon stock in areas affected by catastrophic events (after such events) at year **t** in the project area	t CO_2-e	Table 26f, Table 26g	*ex post*	calculated	annually
$\Delta CUCiPA_t$	Total increase in carbon stock in areas affected by catastrophic events (after such events) at year **t** in the project area	t CO_2-e	Table 26f, Table 26g	*ex post*	calculated	annually
$\Delta CUDdPA$	Cumulative actual carbon stock change due to unavoided unplanned deforestation at year *t* in the project area	t CO_2-e	Table 27, Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CUDdPA_t$	Total actual carbon stock change due to unavoided unplanned deforestation at year *t* in the project area	t CO_2-e	16,Table 27 Table 29	*ex ante* and *ex post*	calculated	annually
$\Delta CUFdPA$	Cumulative otal decrease in carbon stock due to unplanned (and planned – where applicable) forest fires in the project area	t CO_2-e	Table 25e, Table 25g	*ex post*	calculated	annually
$\Delta CUFdPA_t$	Total decrease in carbon stock due to unplanned (and planned – where applicable) forest fires at year *t* in the project area	t CO_2-e	Table 25e, Table 25g	*ex post*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$\Delta CUFiPA$	Cumulative increase in carbon stock in areas affected by forest fires (after such events) in the project area	t CO_2-e	Table 26e, Table 26g	*ex post*	calculated	annually
$\Delta CUFiPA_t$	Total increase in carbon stock in areas affected by forest fires (after such events) at year *t* in the project area	t CO_2-e	Table 26e, Table 26g	*ex post*	calculated	annually
ΔCwp_{ct}	Average carbon stock change factor in the harvested wood products carbon pool of category *ct*	t CO_2-e ha^{-1}			calculated	only once at project start and when mandatory
$\Delta REDD$	Cumulative met anthropogenic greenhouse gas emission reduction attributable to the AUD project activity	t CO_2-e	21	*ex ante* and *ex post*	calculated	annually
$\Delta REDD_t$	Net anthropogenic greenhouse gas emission reduction attributable to the AUD project activity at year *t*	t CO_2-e	19, 20, 23, Table 36	*ex ante* and *ex post*	calculated	annually
D_{dc}	Dead wood density of class *dc*	tonnes d. m. m^{-3}	A3-30		measured or estimated from literature	only once at project start and when mandatory
D_j	Mean wood density of species *j*	t d.m.m^{-3}	A3-34		measured or estimated from literature	only once at project start
DLF	Displacement Leakage Factor	%			defined	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
Dm	Deadwood density	g cm-3	A3-28		measured or estimated from literature	only once at project start and when mandatory
DM_{pl}	Dry mass of sample $_{pl}$;	tonnes of d.m.	A3-24		measured or estimated from literature	only once at project start and when mandatory
e	Euler number (2,71828)	dimensionless	4.b, 8.c			
E%	allowable sample error in percentage (±10%)	%	A3-1			
E	allowable error (±10% of the mean)	%	A3-3			
EADLK	Cumulative total increase in GHG emissions due to displaced forest fires	t CO_2-e	Table 34, Table 35	*ex ante* and *ex post*	calculated	annually
$EADLK_t$	Total *ex ante* increase in GHG emissions due to displaced forest fires at year *t*	t CO_2-e	Table 34, Table 35	*ex ante* and *ex post*	calculated	annually
EBBBSPA	Cumulative baseline non-CO_2 emissions from forest fire at year *t* in the project area	t CO_2-e	17, 19, Table 24, Table 36	*ex ante* and *ex post*	calculated	annually
$EBBBSLPA_t$	Sum of (or total) baseline non-CO_2 emissions from forest fire at year *t* in the project area	t CO_2-e	19, Table 24, Table 36	*ex ante* and *ex post*	calculated	annually
$EBBBSLtot_{icl}$	Sum of (or total) actual non-	t CO_2-e	Table 24	*ex ante* and *ex*	calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	CO_2 emissions from forest fire at year *t* in strata *i* in forest class *icl*			*post*		
$EBBCH4_{icl}$	CH_4 emission from biomass burning in forest class *icl*	t CO_2-e	11, 13	*ex ante* and *ex post*	calculated	annually
$EBBCO2_{icl}$	Per hectare CO_2 emission from biomass burning in slash and burn in forest class *icl*	t CO_2-e ha^{-1}	12, 13, 14		calculated	only once at project start
$EBBN2O_{icl}$	N_2O emission from biomass burning in forest class *icl*	t CO_2-e	11, 12	*ex ante* and *ex post*	calculated	annually
EBBPSPA	Cumulative (or total) actual non-CO_2 emissions from forest fire at year *t* in the project area	t CO_2-e	Table 28, Table 29, Table 36	*ex ante* and *ex post*	calculated	annually
$EBBPSPA_t$	Sum of (or total) actual non-CO_2 emissions from forest fire at year *t* in the project area	t CO_2-e	17,19, Table 28, Table 29, Table 36	*ex ante* and *ex post*	calculated	annually
$EBBtot_{icl}$	Total GHG emission from biomass burning in forest class *icl*	t CO_2-e	11	*ex ante* and *ex post*	calculated	annually
$ECH4ferm_t$	CH_4 emissions from enteric fermentation at year *t*	t CO_2-e	18, A4-1		calculated	annually
$ECH4man_t$	CH_4 emissions from manure management at year *t*	t CO_2-e	18, A4-3		calculated	annually
$EdirN2Oman_t$	Direct N_2O emissions from manure management at year *t*	t CO_2-e	A4-4, A4-5, Table 32		calculated	annually
EF1	Enteric CH_4 emission factor for the livestock group	kg CH_4 $head^{-1}$ yr^{-1}	A4-1, Table 31		calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
EF2	Manure management CH_4 emission factor for the livestock group	kg CH_4 head^{-1} yr^{-1}	A4-3, Table 31		measured or estimated from literature	each renewal of fixed baseline period
EF3	Emission factor for N_2O emissions from manure management for the livestock group	kg N_2O-N (kg N^{-1}) head^{-1} yr^{-1}	A4-5, Table 31		measured or estimated from literature	each renewal of fixed baseline period
EF4	Emission factor for N_2O emissions from atmospheric deposition of forage-sourced nitrogen on soils and water surfaces	kg N_2O-N (kg NH_3-N and NO_x-N emitted)-1 head^{-1} yr^{-1}	A4-6, Table 31		measured or estimated from literature	each renewal of fixed baseline period
EgLK	Cumulative Emissions from grazing animals in leakage management areas at year *t*	t CO_2-e	Table 32, Table 33, Table 35		calculated	annually
$EgLK_t$	Emissions from grazing animals in leakage management areas at year *t*	t CO_2-e	18, Table 32, Table 33, Table 35		calculated	annually
EI	Ex ante estimated Effectiveness Index	%	16		defined	annually
$EindNOman_t$	Indirect N_2O emissions from manure management at year *t*	t CO_2-e	A4-4, A4-5		calculated	annually
ELK	Cumulative sum of ex ante estimated leakage emissions at year *t*	t CO2-e	19, Table 35, Table 36		calculated	annually
ELK_t	Sum of *ex ante* estimated leakage emissions at year *t*	t CO_2-e	19, Table 35, Table 36		calculated	annually

Notation	Description	Unit	Equation	Observation	Source	Monitoring
ELPMLK	Cumulative otal *ex* increase in GHG emissions due to leakage prevention measures	t CO_2-e	Table 33		calculated	annually
$ELPMLK_t$	Annual total increase in GHG emissions due to leakage prevention measures at year *t*	t CO_2-e	Table 33		calculated	annually
$EN2Oman_t$	N_2O emissions from manure management at year *t*	t CO_2-e	18, A4-4, Table 32		calculated	annually
ERCH4	Emission ratio for CH_4 (IPCC default value = 0.012)	dimensionless	13		defined	each renewal of fixed baseline period
ERN2O	Emission ratio for N2O (IPCC default value = 0.007)	dimensionless	12		defined	each renewal of fixed baseline period
$Fburnt_{icl}$	Proportion of forest area burned during the historical reference period in the forest class *icl*	%	14, Table 23		measured or estimated from literature	only once at project start
fcl	1, 2, 3 … *Fcl* final (post-deforestation) non-forest classes	dimensionless			measured or estimated from literature	each renewal of fixed baseline period
$f_j(DBH,H)_{ab}$	an allometric equation for species, or group of species, or forest type *j*, linking above-ground tree biomass (in kg $tree^{-1}$) to diameter at breast height (*DBH*) and possibly tree height (*H*).		A3-10		measured or estimated from literature	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
FOM	"Figure of Merit"	dimensionless	9	This is measure of goodness of fit between observed and predicted deforestation	calculated	each renewal of fixed baseline period
Fracgas	Fraction of managed livestock manure nitrogen that volatilizes as NH_3 and NO_x in the manure management phase	kg NH_3-N and NO_x-N emitted $(Kg\ N)^{-1}$	Table 31		calculated	each renewal of fixed baseline period
$f_j(DBH,H)_V$	a commercial volume equation for species or species group j, linking commercial volume to diameter at breast height (DBH) and possibly tree height (H)		A3-20		calculated	each renewal of fixed baseline period
f(t)	A function of time		4.c		calculated	each renewal of fixed baseline period
GWP_{CH4}	Global Warming Potential for CH_4 (IPCC default value = 21 for the first commitment period)	dimensionless	13		defined	each renewal of fixed baseline period
GWP_{N2O}	Global Warming Potential for N_2O (IPCC default value = 310 for the first commitment period)	dimensionless	12		defined	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
H	Height of the tree	meters	A3-27		measured or estimated from literature	only once at project start and when mandatory
i	1, 2, 3 .. I_{RR} A stratum within the reference region	dimensionless	In most equations		defined	each renewal of fixed baseline period
icl	1, 2, 3 … *Icl* initial (pre-deforestation) forest classes	dimensionless	10		measured or estimated from literature	each renewal of fixed baseline period
ID_{cl}	Identifier of a land-use/land-cover class					
ID_{ct}	Identifier of a land-use/ land-cover change category (from initial class *icl* to final class *fcl)*					
ID_{ctz}	Identifier of a land-use/ land-cover change category (from initial class *icl* to zone *z)*					
ID_{fcl}	Identifier of a final post-deforestation class *fcl*					
ID_i	Identifier of a strtum *i* in the reference region					
ID_{icl}	Identifier of an initial forest class *icl*					
ID_z	Identifier of a zone					
j	number of organic fertilizer types	dimensionless			defined	annually
k	Estimated parameter of the logistic regression	dimensionless	4.b, 8.c		calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
L	Length of the line	m	A3-29		measured or estimated from literature	only once at project start and when mandatory
LTFw	Fraction of wood products that are considered permanent (i.e. carbon is stored for 100 years or more); it may be assumed no carbon is released		A3-36, A3-40			
%LKB	Percentage of the overlapping leakage belts area to be assigned to project, A, B…..N	%	2.a,2.b,2.n		calculated	At each verification
MTFw	Fraction of wood products that are retired between 3 and 100 years		A3-37, A3-41			
n	total number of sample units to be measured (in all LU/LC classes)	dimensionless	A3-1, A3-2		calculated	each renewal of fixed baseline period
N	Population size or maximum number of possible sample units (all LU/LC classes)	dimensionless	A3-2		measured	each renewal of fixed baseline period
n_{cl}	number of samples units to be measured in LU/LC class *cl* that is allocated proportional to $W_{cl} \cdot S_{cl} / \sqrt{C_{cl}}$.	dimensionless	A3-2, A3-4			each renewal of fixed baseline period
NCR	Nitrogen/Carbon ratio (IPCC default value = 0.01)	dimensionless	12		defined	each renewal of fixed baseline period
Nex	Annual average N excretion per livestock head	kg N head^{-1} yr^{-1}	A4-6, Table 31		measured or estimated from	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
					literature	
n_i	Number of samples units to be measured in LU/LC class cl that is allocated proportional to the size of the class. If estimated ncl < 3, set *ncl* = 3		A3-2			
N_i	Maximum number of possible sample units for LU/LC class *cl*, calculated by dividing the area of class *cl* by the measurement plot area		A3-2			
OFw	Fraction of wood products that will be emitted to the atmosphere between 5 and 100 years of timber harvest	dimensionless	A3-35, A3-37		measured or estimated from literature	only once at project start
p	Carbon pool that could burn (above-ground biomass, dead wood, litter)	dimensionless	10		defined	each renewal of fixed baseline period
$Pburnt_{p,icl}$	Average proportion of mass burnt in the carbon pool *p* in the forest class *icl*;	%	14		measured or estimated from literature	only once at project start
$PCab_{pl}$	Carbon stock in above-ground biomass in plot *pl*	tC ha^{-1}	A3-13		calculated	only once at project start and when mandatory
$PCbb_{pl}$	Carbon stock in below-ground biomass in plot *pl*	tC ha^{-1}	A3-16		calculated	only once at project start and when mandatory

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$Pcom_{icl}$	Commercial volume as a percent of total aboveground volume in initial forest class *icl*	dimensionless	A3-36, A3-38		measured or estimated from literature	only once at project start and when mandatory
PCx_i	Average in situ production costs for one ton of product *Px* in stratum *i*	$/t	1	This variable may have different values within different strata of the reference region	measured or estimated from literature	each renewal of fixed baseline period
$Pforage_t$	Production of forage at year *t*	kg d. m. yr^{-1}	A4-2, Table 32		calculated *ex ante*, measured *ex post*	each renewal of fixed baseline period
pl	1, 2, 3, … *PLcl* plots in LU/LC class *cl*	dimensionless	A3-14, A3-17, A3-24, A3-33		calculated	only once at project start and when mandatory
PL_{cl}	Total number of plots in LU/LC class *cl*	dimensionless	A3-14, A3-17, A3-24, A3-34		calculated	only once at project start and when mandatory
Po	Anhydrous weight of sample	g	A3-28		measured or estimated from literature	only once at project start and when mandatory
$Population_t$	Equivalent number of forage-fed livestock at year *t*	number of heads	A4-1, Table 32		calculated *ex ante*, measured *ex post*	annually
$PP_{i,t}$	Proportion of stratum *i* that is within the project area at time *t*	%			calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
PPx_l	Potential profitability of product *Px* at the location *l* (pixel or polygon)	$/t	1		calculated	each renewal of fixed baseline period
Ps	Saturated weight of sample	g	A3-28		measured or estimated from literature	only once at project start and when mandatory
Px	Product x produced in the reference region	dimensionless	1		measured or estimated from literature	each renewal of fixed baseline period
r1	Radius at the base of the tree	meters	A3-27		measured or estimated from literature	only once at project start and when mandatory
r2	Radius at the top of the tree	meters	A3-27		measured or estimated from literature	only once at project start and when mandatory
$RBSLRR_{i,t}$	Percentage of remaining forest area at year t -1 in stratum *i* to be deforested at year *t*	%	3	Used as an alternative to $ABSLRR_{i,t}$ in baseline approach "c"	calculated	each renewal of fixed baseline period
RF_t	Risk factor used to calculate VCS buffer credits	%	21		estimated	each renewal of fixed baseline period
R_j	Root-shoot ratio appropriate for species, group of species or forest type *j*	dimensionless	A3-18		measured or estimated from literature	only once at project start
$R_{j,pl,tr}$	Root-shoot ratio, applicable to tree *tr* of species *j* in plot *pl*	dimensionless	A3-22		measured or estimated from literature	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
S_{cl}	standard deviation of LU/LC class *cl*		A3-4			
$S\$_x$	Selling price of product *Px*	$/t	1		measured or estimated from literature	each renewal of fixed baseline period
SLF_w	Fraction of wood products that will be emitted to the atmosphere within 5 years of timber harvest	dimensionless	A3-35, A3-37		measured or estimated from literature	only once at project start
SPx_l	Selling point *l* of product *Px*	map	1		measured or estimated from literature	each renewal of fixed baseline period
STF_w	Fraction of wood products and waste that will be emitted to the atmosphere within 3 years; all carbon shall be assumed to be lost immediately; dimensionless		A3-35, A3-37, A3-40, A3-41			
t	1, 2, 3 … *T* a year of the proposed project crediting period	dimensionless	almost all equations		defined	
*t**	the year at which the area $ABSLPA_{icl,t}$ is deforested in the baseline case	dimensionless	10, A3-34		defined	
t1	Start date of the historical reference period	dimensionless				
t2	End date of the historical reference period	dimensionless				

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$Taverage_i$	Number of years in which $Aaverage_i$ is deforested in the baseline case	yr			calculated	each renewal of fixed baseline period
$taverage_i$	Year at which $Taverage_i$ ends	yr	6, 7		calculated	each renewal of fixed baseline period
$TBab_j$	above-ground biomass of a tree of species, or species group, or forest type *j*	kg $tree^{-1}$ or t $tree^{-1}$	A3-10		calculated	only once at project start
$TBab_{tr}$	Above-ground biomass of tree *tr*	kg $tree^{-1}$ or t $tree^{-1}$	A3-11, A3-13, A3-21		calculated	only once at project start
$TCab_{tr}$	Carbon stock in above-ground biomass of tree $_{tr}$	kg C $tree^{-1}$ or t C $tree^{-1}$	A3-11, A3-21		calculated	only once at project start
$TCbb_{tr}$	Carbon stock in below-ground biomass of tree $_{tr}$	kg C $tree^{-1}$	A3-16, A3-22		calculated	only once at project start and when mandatory
TC_v	Average Transport Cost per kilometer for one ton of product *Px* on land, river or road of type *v*	$/t/km	1		measured or estimated from literature	each renewal of fixed baseline period
TD_v	Transport Distance on land, river or road of type *v*	$/t/km	1		calculated	each renewal of fixed baseline period
Thrp	Duration of the historical reference period	yr			defined	only once at project start
$Toptimal_i$	Number of years since the start of the AUD project activity in which *Aoptimal* in stratum *i* is deforested in the baseline case	yr			calculated	each renewal of fixed baseline period

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$toptimal_i$	Year at which $Toptimal_i$ ends	yr	5, 6		calculated	each renewal of fixed baseline period
tr	1, 2, 3, … *TRpl* number of trees in plot *pl*	dimensionless	A3-13		measured or estimated from literature	only once at project start and when mandatory
t_{st}	t-student value for a 95% confidence level (initial value t = 2)	dimensionless	A3-1			t_{st}
$Tsub\text{-}optimal_i$	Number of years in which $Asub\text{-}optimal_i$ is deforested in the baseline case	yr			calculated	each renewal of fixed baseline period
v	1,2,3, …*V* type of surface on which transport occurs	dimensionless	1		measured or estimated from literature	each renewal of fixed baseline period
$V1_{i,t}$; $V2_{i,t}$; ...;$Vn_{i,t}$	Variables included in a deforestation model		8	Unit of each variable to be specified by the project proponent	measured or estimated from literature	each renewal of fixed baseline period
VBC_t	Number of Buffer Credits deposited in the VCS Buffer at time *t*;	t CO_2-e	20, 21, Table 36		calculated	annually
VCU_t	Number of Verified Carbon Units (VCUs) to be made available for trade at time *t*	t CO_2-e	20,Table 36		calculated	annually
VEF	Volume Expansion Factor	dimensionless	A3-9		measured or estimated from literature	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
$VEX_{w,j,fcl,t}$	Volume of timber for product class *w*, of species *j*, extracted from within forest class *fcl* at time *t*	m^3	A3-34		measured or estimated from literature	only once at project start and when mandatory
VOB10	Volume Over Bark above 10 cm *DBH*	m^3	A3-9		measured or estimated from literature	only once at project start
VOB30	Volume Over Bark above 30 cm *DBH*	m3	A3-9		measured or estimated from literature	only once at project start
$Volume_{dc}$	Volume of lying dead wood in the density class *dc*	m^3	A3-30		measured or estimated from literature	only once at project start and when mandatory
V_{pl}	Commercial volume of plot *pl*	m^3 $plot^{-1}$	A3-19		measured or estimated from literature	only once at project start and when mandatory
V_{tr}	Commercial volume of tree *tr*	m^3	A3-18, A3-21		measured or estimated from literature	only once at project start and when mandatory
w	1, 2, 3 … *W* Wood product class (sawn-wood, wood-based panels, other industrial round-wood, paper and paper board, and other);	dimensionless	A3-34		defined	only once at project start and when mandatory
W_{cl}	N_{cl}/N		A3-4			
WW_w	Wood waste for wood product class *w*. The fraction	dimensionless	A3-35, A3-37		measured or estimated from	only once at project start

Notation	Description	Unit	Equation	Observation	Source	Monitoring
	immediately emitted through mill inefficiency				literature	
XF	Plot expansion factor from per plot values to per hectare values	dimensionless	A3-12, A3-13, A3-16, A3-19, A3-20, A3-24		calculated	only once at project start and when mandatory
z	1, 2, 3, … Z post deforestation zones having a characteristic mixture of final post-deforestation classes (*fcl*)					

APPENDIX 6: LIST OF TABLES USED IN THIS METHODOLOGY

Table		*Ex ante*	*Ex post*	
		At validation	At verification	At baseline update
Table 1	Scope of the methodology	I		
Table 2	Criteria determining the applicability of existing baselines	I		
Table 3	Carbon pools included or excluded within the boundary of the proposed AUD project activity	Y		Y
Table 4	Sources and GHG included or excluded within the boundary of the proposed AUD project activity	Y		Y
Table 5	Data used for historical LU/LC change analysis	Y	Y	Y
Table 6	List of all land use and land cover classes existing at the project start date within the reference region	Y		Y
Table 7.a	Potential land-use and land-cover change matrix (initial forest classes *icl* to final post-deforestation classes *fcl*)	Y-M2,ct		Y-M2,ct
Table 7.b	List of land-use and land-cover change categories *ct* (initial forest classes *icl* to final post-deforestation classes *fcl*)	Y-M2,ct		Y-M2,ct
Table 8	Stratification of the reference region	Y		Y
Table 9.a	Annual areas of baseline deforestation in the reference region	Y		Y
Table 9.b	Annual areas of baseline deforestation in the project area	Y	Y	Y
Table 9.c	Annual areas of baseline deforestation in the leakage belt	Y	Y	Y
Table 10	List of variables, maps and factor maps	Y		Y
Table 11.a	Annual areas deforested per forest class *icl* within the reference region in the baseline case (baseline activity data per forest class)	Y		Y

DOCUMENT HISTORY

Version	Date	Comment
v1.0	12 Jun 2011	Initial version released.
v1.1	3 Dec 2012	The methodology was revised to account for the decay of carbon from the below-ground biomass, dead wood, soil carbon and meditum-term harvested wood products pools Revisions were made to section 6.1.2 and Appendix 3. Additional revisions have also been incorporated into the methodology. Specifically, litter is included as an optional pool, sampling techniques are provided as an option for developing land-use/land cover maps, the steps to analyse deforestation constraints is removed, and a process to project future land-use/land cover with zones is provided. The following minor updates have also been incorporated into the methodology: • The word “guidelines” when referring to Jurisdictional and Nested REDD was changed to “requirements”. • Equations 6.a, 6.b and 6.c were corrected to avoid negative areas. • Equations 7.b and 12.c were corrected (“e” is the Euler Number). • The minimum threshold requirements for the Figure of Merit (FOM) were changed and made consistent with the corresponding module of VM0007. • The definition of the minimum mapping unit was updated to be consistent with the definition found in the VCS *JNR Requirements*. • An error was corrected in equation A3-17 (the factor 44/12 to convert tons of C to tons of CO_2-e was missing).

1 SOURCES

This methodology refers to the latest version of the following approved methodologies:

- Climate Action Reserve (CAR) methodology *U.S. Ozone Depleting Substances Project Protocol, Destruction of U.S. Ozone Depleting Substances Banks*
- Climate Action Reserve (CAR) methodology *Article 5 Ozone Depleting Substances Project Protocol, Destruction of Article 5 Ozone Depleting Substances Banks*
- RAL Deutsches Institut für Gütesicherung: Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment

This methodology refers to the latest version of the following approved tools and modules:

- CDM tool *Tool for the demonstration and assessment of additionality*
- CDM tool *Tool to calculate the emission factor for an electricity system*
- VCS module *VMD0048 Activity method for the determination of additionality for recovered and stockpiled ODS refrigerant projects*

The following have also informed the development of the methodology:

- CDM tool *Tool to calculate project or leakage CO2 emissions from fossil fuel combustion*
- CDM tool *Tool to calculate baseline, project and/or leakage emissions from electricity consumption and monitoring of electricity generation*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

Additionality and Crediting Method	
Additionality	Project / Activity Method
Crediting Baseline	Project

This methodology quantifies the GHG emission reductions from activities that recover and destroy Ozone-Depleting Substances (ODS) from products where a partial or total atmospheric release of ODS occurs in the baseline scenario. Project activities can be implemented in Montreal Protocol Article 5 and Non-Article 5 countries.

Project activities may recover and destroy ODS refrigerants, ODS blowing agents or both.

3 DEFINITIONS

In addition to the definitions set out in VCS document *Program Definitions*, the following definitions and acronyms apply to this methodology:

Article 5 Country

Any party to the Montreal Protocol that is a developing country and whose annual calculated level of consumption of the controlled substances in Annex A (of the Montreal Protocol) is less than 0.3 kilograms per capita

Non Article 5 Country

Any party to the Montreal Protocol which is not an Article 5 country

Destruction Facility

The facility where the destruction of the ODS takes place and which meets the screening criteria for destruction technologies set out in the report, as may be updated from time to time, by the UNEP Technology and Economic Assessment Panel (TEAP) Task Force on Destruction Technologies. *UNEP Technology and Economic Assessment Panel (TEAP) Report of the Task Force on Destruction Technologies*, UNEP, 2002.

Ozone-Depleting Substance (ODS)

A family of man-made compounds that includes, but is not limited to, chlorofluorocarbons (CFCs), bromofluorocarbons (halons), methyl chloroform, carbon tetrachloride, methyl bromide, and hydrochlorofluorocarbons (HCFCs). These compounds have been shown to deplete stratospheric ozone, and therefore are typically referred to as ODS. Many Ozone-Depleting Substances also have a Global Warming Potential (GWP) and are therefore Greenhouse Gases (GHG).

> CFC ODS: An ODS listed in Annex A, Group 1 or Annex B, Group 1 of Appendix I of this methodology.
>
> HCFC ODS: An ODS listed in Annex C, Group 1 of Appendix I of this methodology.

ODS blowing agent

A chemical (being an ODS) added to plastics and rubbers that generates inert gases on heating, causing the resin to assume a cellular structure

ODS refrigerant

A chemical (being an ODS) used or intended for use in a cooling mechanism, such as an air conditioner or refrigerator, as the heat carrier which changes from gas to liquid and then back to gas in the refrigeration cycle

Product

Any of the following: refrigeration, air conditioning or fire suppression equipment, systems or appliances, or thermal insulation foams

Recovery

To remove ODS refrigerants and blowing agents in any condition from a system and store it in an external container

Recovery Facility
The facility where the project proponent recovers ODS refrigerants and blowing agents from appliances, or the facility where collected refrigerant is aggregated by the project proponent in preparation for destruction. The location where refrigerant is recovered from stationary equipment, such as a chiller, is not a recovery facility.

Recycle
To extract ODS refrigerants from an appliance and clean it using oil separation and single or multiple passes through filter-driers, which reduce moisture, acidity, and particulate matter

Reclaim
To reprocess used ODS refrigerants or blowing agents, typically by distillation, to specifications similar to that of virgin product specifications

Refrigerator appliance
Any appliance whose main purpose is the cooling of foodstuffs and other temperature-sensitive products and which are further defined as following *(according to RAL Deutsches Institut für Gütesicherung: Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment):*

Domestic fridges: These are refrigerators of a typical domestic design with a storage capacity of up to 180 litres. The appliances may or may not be equipped with a separate deep-freeze compartment. (Type 1 appliances).

Domestic fridge-freezers: These are refrigeration appliances of a typical domestic design with a storage capacity ranging from 180 to 350 litres. Generally, these appliances have a separate deep-freeze compartment. (Type 2 appliances).

Domestic chest freezers and upright freezers: These are deep-freeze appliances of a typical domestic design with a storage capacity up to 500 litres. (Type 3 appliances).

Stockpile
A CFC ODS refrigerant stored in an external container(s) by a single person or entity (including but not limited to private companies, organizations, and/or government agencies), or by multiple people or entities at a single location. A stockpile may be composed of one or more containers of any size. Containers in a stockpile may consist of recovered, reclaimed, recycled, or unused (manufactured for use but never so used) CFC ODS.

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that recover and destroy ODS where the baseline scenario is the partial or total atmospheric release of ODS. This methodology does not apply to ODS refrigerant or ODS blowing agents that are manufactured for the sole purpose of their subsequent destruction.

Project activities can be implemented in Article 5 as well as in Non-Article 5 countries[1].

Only ODS listed in Appendix I of this methodology, and for which the VCS rules (as may be updated from time to time) apply**,** are eligible. ODS in a stockpile must be CFC ODS in order to be eligible under this methodology.

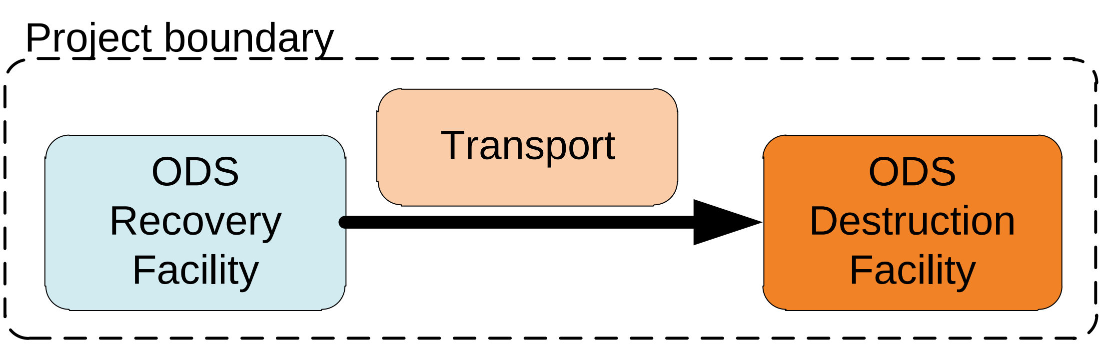
The methodology can be applied to either ODS refrigerants and/or ODS blowing agents. In the case of ODS blowing agents the methodology is only applicable to project activities recovering and destroying ODS blowing agents contained in insulation foam of end-of-life refrigerator appliances. The ODS blowing agent must be extracted from the foam to a concentrated form prior to destruction. This must be done under negative pressure to ensure that fugitive release of ODS cannot occur.

All ODS must be collected, stored, and transported in cylinders or other hermetically sealed containers.

5 PROJECT BOUNDARY

The spatial extent of the project boundary encompasses:

- The recovery facility
- Transportation from the recovery facility to the destruction facility
- The destruction facility



The greenhouse gases included in or excluded from the project boundary are shown in Table below.

[1] For the avoidance of doubt: Recovery and destruction activities can take place in separate countries.

Table 1: GHG Sources Included In or Excluded From the Project Boundary

	Source	Gas	Included?	Justification/Explanation
Baseline	Emissions through the release of ODS refrigerants into the atmosphere	$\sum_{i=1}^{n} ODS_i$	Yes	Main emission source in the baseline
	Emissions through the release of ODS blowing agent into the atmosphere	$\sum_{i=1}^{n} ODS_i$	Yes	Main emission source in the baseline
Project	Emissions through on-site fossil fuel and electricity consumption at the recovery facility	CO_2	Yes	May be an important emission source
		CH_4	No	Excluded for simplification. This emission source is assumed to be very small
		N_2O	No	Excluded for simplification. This emission source is assumed to be very small
	Emissions through transportation of ODS from the recovery facility to the destruction facility	CO_2	Yes	May be an important emission source
		CH_4	No	Excluded for simplification. This emission source is assumed to be very small
		N_2O	No	Excluded for simplification. This emission source is assumed to be very small
	Emissions associated to the destruction process of ODS	CO_2	Yes	May be an important emission source
		CH_4	No	Excluded for simplification. This emission source is assumed to be very small
		N_2O	No	Excluded for simplification. This emission source is assumed to be very small
		$\sum_{i=1}^{n} ODS_i$	Yes	May be an important emission source

6 BASELINE SCENARIO

The project proponent must use Step 1 of the latest version of the CDM *Tool for the demonstration and assessment of additionality*, to identify all realistic and credible baseline alternatives. In doing so, relevant policies and regulations related to the management of ODS banks should be taken into account. Such policies or regulations may include mandatory ODS capture or destruction requirements because of regional or local environmental regulations. In addition, the assessment of alternative scenarios should take into account regional economic and technological circumstances.

For ODS refrigerants the realistic and credible alternative(s) may include, *inter alia*

R1 Project activity not performed as emission reduction project

R2 Products are disposed of into an incineration facility and thereby ODS refrigerants are destroyed

R3 Atmospheric release of the ODS refrigerant or partial capture and destruction

R4 Atmospheric release of the ODS refrigerant or partial capture and reuse in existing products or continued storage in stockpile

For ODS blowing agents the realistic and credible alternative(s) may include, *inter alia*

BAF1 Project activity not performed as emission reduction project

BAF2 The refrigerators containing foams (blowing agents) are disposed of into an incineration facility and thereby ODS blowing agents are destroyed

BAF3 The refrigerators containing foams (blowing agents) are disposed of at a landfill/dump

BAF4 Before final disposal, the refrigerators containing foam are shredded. The foams are subsequently:

BAF4.1 disposed of at an incineration facility

BAF4.2 disposed of at a landfill/dump

BAF4.3 disposed of by open burning

BAF4.4 extracted and ODS blowing agents are partly captured and destroyed

The methodology is only applicable for ODS refrigerants if the most plausible baseline scenario for the ODS refrigerant is either R3 or R4 or a combination of both. In respect of ODS blowing agents the methodology is only applicable if the most plausible baseline scenario for ODS blowing agents from foam is either one of BAF4.1, BAF4.2, BAF4.3 or BAF4.4 or any combination of these scenarios.

7 ADDITIONALITY

The project proponent should use the two-step process set out in Section 7.1 for the demonstration of additionality for projects that destroy CFC refrigerant and fulfill the applicability conditions of VCS activity method module *Activity method for the determination of additionality for recovered and stockpiled ODS refrigerant projects*. The project proponent must use the project method set out in Section 7.2 for all other projects eligible under this methodology.

7.1 Destruction of CFC refrigerant

Step 1: Regulatory surplus

The project proponent must demonstrate regulatory surplus in accordance with the rules and requirements regarding regulatory surplus set out in the latest version of the *VCS Standard*.

Step 2: Positive list

The applicability conditions of VCS activity method module *Activity method for the determination of additionality for recovered and stockpiled ODS refrigerant projects* represent the positive list. The positive list was established using the revenue streams option (Option C in the *VCS Standard*). Projects that meet all of the applicability conditions of this methodology and the VCS activity method module *Activity method for the determination of additionality for recovered and stockpiled ODS refrigerant projects* are deemed additional.

7.2 Destruction of ODS refrigerant and/or ODS blowing agents

This methodology uses a project method for the demonstration of additionality of all project activities that are not eligible to apply the activity method described above. Such projects include the destruction of ODS blowing agents and the destruction of other ODS refrigerants where the activity method is not applicable or preferred, in which case project proponents shall apply the latest version of the CDM *Tool for the demonstration and assessment of additionality*.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

Baseline emissions from existing ODS contained in products and/or stockpiles are determined with the following equation:

$$BE_{ODS,y} = BE_{ODS\_ref,y} + BE_{ODS\_foam,y} \quad (1)$$

Where:

$BE_{ODS,y}$	=	Total quantity of baseline emissions from ODS refrigerants and blowing agents (foam) which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
$BE_{ODS\_ref,y}$	=	Baseline emissions from ODS refrigerants which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
$BE_{ODS\_foam,y}$	=	Baseline emissions from ODS blowing agents contained in insulation foams of refrigeration appliances which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]

Baseline emissions from ODS refrigerants are determined as follows:

$$BE_{ODS\_ref,y} = \sum_{i=1}^{n}\Big(\big(M_{DESTR,refr,i,y} \times VR_{refr} \times EF_{VR}\big) + \big(M_{DESTR,refr,i,y} \times RR_{refr,i,y} \times EF_{RR,refr,i,y}\big) + \big(M_{DESTR,refr,i,y} \times DR_{refr} \times EF_{DR}\big)\Big) \times GWP_{refr,i} \quad (2)$$

$$1 = VR_{refr} + RR_{refr,i,y} + DR_{refr} \quad (3)$$

Where:

$BE_{ODS\_ref,y}$	=	Baseline emissions from ODS refrigerants which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
$M_{DESTR,refr,i,y}$	=	Quantity of ODS refrigerant i destroyed by the project activity in year y [$tODS_i$]
VR_{refr}	=	Rate of ODS refrigerants (destroyed) which would be vented into the atmosphere in the baseline [%,0-100%]
EF_{VR}	=	Emission factor for the rate of ODS refrigerants (destroyed) which would be vented into the atmosphere [1]
DR_{refr}	=	Rate of ODS refrigerants (destroyed) by the project activity which would also be destroyed in the baseline [%,0-100%]
EF_{DR}	=	Emission factor for the rate of ODS refrigerants (destroyed) by the project activity which would also be destroyed in the baseline [0]
$RR_{refr,i,y}$	=	Rate of ODS refrigerants i which would be used, reused or remain in storage in the baseline [%,0-100%]
$EF_{RR,refr,i,y}$	=	Emission factor for the rate of ODS refrigerant i (destroyed) which would be reused in the baseline [0-1.0]
$GWP_{refr,i}$	=	Global warming potential of ODS refrigerant type i that converts 1 ton of ODS i to tons of CO_2 equivalents. [$tCO_2e/tODS_i$]

$$EF_{VR} = 1 \tag{4}$$

$$EF_{DR} = 0 \tag{5}$$

$$EF_{RR,refr,i} = 1 - \left(1 - LR_{refr,i}\right)^{tcp} \tag{6}$$

Where:

$EF_{RR,refr,i}$	=	Emission factor for the rate of ODS refrigerant i (destroyed) which would be reused in the baseline [0-1.0]
$LR_{refr,i}$	=	Leak rate of ODS refrigerant i (destroyed), which would be used as refrigerant for existing equipment or remain in storage in the baseline [%,0-100%]
tcp	=	Project crediting period [10]

When destruction of the ODS refrigerants by the project activity is mandated by law, statute or other regulatory framework applying in the host country, the baseline shall be the gradually increasing compliance with such law, statute or other regulatory framework, and the baseline GHG emissions shall be calculated as follows:

$$BE_{ODS\_ref,y,a} = BE_{ODS\_ref,y} \times \left(1 - CR_y\right) \tag{7}$$

Where:

$BE_{ODS\_ref,y}$	=	Baseline emissions from ODS refrigerants which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
$BE_{ODS\_ref,y,a}$	=	Adjusted baseline emissions to be used for the calculation of emission reductions in year y [tCO_2e]
CR_y	=	Host country-level compliance rate of the law, statute or other regulatory framework in the year y. Calculation of the compliance rate shall exclude other projects implemented under GHG programs. If the compliance rate exceeds 50%, the project shall receive no further credit [%, 0-100%]

Baseline emissions from ODS blowing agents are determined as follows:

$$BE_{ODS\_foam,y} = \sum_{i=1}^{n} \left(\left(M_{APPLIANCE,foam,i,y} \times ER_{foam,i} - \left(M_{APPLIANCE,foam,i,y} - M_{DESTR,foam,i,y} \right) \right) \times GWP_{foam,i} \right) \tag{8}$$

Where:

$BE_{ODS\_foam,y}$	=	Baseline emissions from ODS blowing agents contained in insulation foams of refrigeration appliances which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
$M_{DESTR,foam,i,y}$	=	Quantity of ODS blowing agent i destroyed by the project activity in year y [$tODS_i$]
$M_{APPLIANCE,foam,i,y}$	=	Total quantity of ODS blowing agent i contained in the total number of refrigerator appliances from which ODS is recovered in year y [$tODS_i$]
$ER_{foam,i}$	=	Rate by which ODS blowing agent i contained in foam of refrigeration appliances would be released into atmosphere based on the disposal practice (baseline) in the respective host country [%,0-100%]
$GWP_{foam,i}$	=	Global warming potential of ODS blowing agent type i that converts 1 ton of ODS i to tons of CO2 equivalents. [$tCO_2e/tODS_i$]

$$M_{APPLIANCE,foam,i,y} = M_{APPLIANCE,1,foam,i,y} + M_{APPLIANCE,2,foam,i,y} + M_{APPLIANCE,3,foam,i,y} \quad (9)$$

Where:

$M_{APPLIANCE,1,foam,i,y}$	=	Total quantity of ODS blowing agent i contained in the total number of type 1 refrigerator appliances from which ODS is recovered in year y [$tODS_i$]
$M_{APPLIANCE,2,foam,i,y}$	=	Total quantity of ODS blowing agent i contained in the total number of type 2 refrigerator appliances from which ODS is recovered in year y [$tODS_i$]
$M_{APPLIANCE,3,foam,i,y}$	=	Total quantity of ODS blowing agent i contained in the total number of type 3 refrigerator appliances from which ODS is recovered in year y [$tODS_i$]

$$M_{APPLIANCE,1,foam,i,y} = \sum_{1}^{J} M_{app,1,foam,i,y} \quad (10)$$

Where:

$M_{APPLIANCE,1,foam,i,y}$	=	Quantity of ODS blowing agent i contained in <u>one</u> type 1 refrigerator appliance from which ODS is recovered during year y [$tODS_i$]
J	=	Total number of type 1 refrigerator appliances from which ODS blowing agent i is recovered in year y [Number]

$$M_{APPLIANCE,2,foam,i,y} = \sum_{1}^{K} M_{app,2,foam,i,y} \quad (11)$$

Where:

$M_{app,2,foam,i,y}$	=	Quantity of ODS blowing agent i contained in one type 2 refrigerator appliance from which ODS is recovered during year y [$tODS_i$]
K	=	Total number of type 2 refrigerator appliances from which ODS blowing agent i is recovered in year y [Number]

$$M_{APPLIANCE,3,foam,i,y} = \sum_{1}^{L} M_{app,3,foam,i,y} \quad (12)$$

Where:

$M_{app,3,foam,i,y}$	=	Quantity of ODS blowing agent i contained in one type 3 refrigerator appliance from which ODS is recovered during year y [$tODS_i$]
L	=	Total number of type 3 refrigerator appliances of which ODS blowing agent i is recovered in year y [Number]

For baseline scenarios BAF4.1 and BAF4.2 the following default factors shall be used for $ER_{foam,i}$

Table 2: Default Factors

Disposal Practice (Baseline)	Applicable default factor		
BAF4.1: disposed of at an incineration facility	ODSi	$ER_{foam,i}$	Source
	CFC-11	0.24	Same as used in CAR U.S. Ozone Depleting Substances Project Protocol Table 5.3 and 5.4 Based on Scheutz, C. et al. (2007a)
	CFC-12	0.24	
	HCFC-22	0.24	
	HCFC-141b	0.24	
BAF4.2: disposed of at a landfill/dump	CFC-11	0.44	Same as used in CAR U.S. Ozone Depleting Substances Project Protocol Table 5.3 and 5.4 Based on Scheutz, C. et al. (2007a/b) Fredenslund, A. et al. (2005)
	CFC-12	0.55	
	HCFC-22	0.75	
	HCFC-141b	0.5	

For BAF4.3 and BAF4.4, $ER_{foam,i}$ shall be based on host country officially published data, research studies or industry data.

When destruction of the ODS blowing agents by the project activity is mandated by law, statute or other regulatory framework applying in the host country, the baseline shall be the gradually increasing compliance with such law, statute or other regulatory framework, and the baseline GHG emissions shall be calculated as follows:

$$BE_{ODS\_foam,y,a} = BE_{ODS\_foam,y} \times (1 - CR_y) \quad (13)$$

Where:

$BE_{ODS\_foam,y,a}$	=	Adjusted baseline emissions to be used for the calculation of emission reductions in year y [tCO_2e]
$BE_{ODS\_foam,y}$	=	Baseline emissions from ODS blowing agents contained in insulation foams of refrigeration appliances which would be released into the atmosphere in the absence of the project activity in year y [tCO_2e]
CR_y	=	Host country-level compliance rate of the law, statute or other regulatory framework in the year y. Calculation of the compliance rate shall exclude other projects implemented under GHG programs. If the compliance rate exceeds 50%, the project shall receive no further credit [%,0-100%]

8.2 Project Emissions

Project emissions in year y are:

- Emissions that are caused by the project activity due to energy consumption at the ODS recovery facility
- Emissions that are caused by the project activity due to ODS transportation
- Emissions that are caused by the project activity due to ODS destruction

$$PE_y = PE_{Energy\_Consump,y} + PE_{ODS\_Transport,y} + PE_{ODS\_Destruction,y} \quad (14)$$

PE_y	=	Project emissions during year y [tCO_2e]
$PE_{Energy\_Consump,y}$	=	Project emissions from energy consumption at the ODS recovery facility during year y [tCO_2e]
$PE_{ODS\_Transport,y}$	=	Project emission from ODS transportation during year y [tCO_2e]
$PE_{ODS\_Destruction,y}$	=	Project emission from ODS destruction during year y [tCO_2e]

Determination of $PE_{Energy\_Consump,y}$:

$$PE_{Energy\_Consump,y} = PE_{EC,y} + PE_{FC,j,y} \quad (15)$$

Where:

$PE_{Energy\_Consump,y}$	=	Project emissions from energy consumption attributable to the ODS recovery facility during year y [tCO_2e]
$PE_{EC,y}$	=	Project emissions from electricity consumption from the grid at the ODS recovery facility during year y [tCO_2e]
$PE_{FC,j,y}$	=	Project emissions from fossil fuel consumption attributable to the ODS recovery facility including third party used fossil fuel to generate energy for the ODS recovery facility during year y [tCO_2e]

Determination of $PE_{EC,y}$:

$$PE_{EC,y} = EC_{PJ,y} \times EF_{grid,y} \times (1 + TDL_y) \quad (16)$$

Where:

$PE_{EC,y}$	=	Project emissions from electricity consumption from the grid at the ODS recovery facility during year y [tCO_2e]
$EC_{PJ,y}$	=	Amount of electricity consumed at the ODS recovery facility from the grid during year y [MWh]
$EF_{grid,y}$	=	Grid emission factor during monitoring period y [tCO_2e /MWh]
TDL_y	=	Average technical transmission and distribution losses in the grid for the voltage level at which electricity is obtained from the grid at the project site during year y [%,0-100%]

For determination of $EF_{grid,y}$ the project proponent shall choose one of the following options:

- Calculate the combined margin emission factor, using the procedures in the latest approved version of the CDM “Tool to calculate the emission factor for an electricity system”; or
- Use a conservative default value of 1.3 tCO_2/MWh

For determination of TDL_y

- Use recent, accurate and reliable data available within the country; or
- Use a conservative default value of 20%

Determination of $PE_{FC,j,y}$:

$$PE_{FC,j,y} = \sum_i FC_{i,j,y} \times COEF_{i,y} \quad (17)$$

Where:

$PE_{FC,j,y}$ = Project emissions from fossil fuel consumption attributable to the ODS recovery facility including third party used fossil fuel to generate energy for the ODS recovery facility during year y [tCO_2e]

$FC_{i,j,y}$ = Amount of fuel type i combusted in process j at the ODS recovery facility or at any third party generating energy for the ODS recovery facility during year y [mass or volume unit]

$COEF_{i,y}$ = CO_2 emission coefficient of fuel type i in year y [tCO_2e / mass or volume unit] i are the fuel types combusted in process j

The CO_2 emission coefficient $COEF_{i,y}$ can be calculated according to two different procedures, depending on the available data about the fossil fuel type *i*,:

- **Option A:** The CO_2 emission coefficient $COEF_{i,y}$ is calculated based on the chemical composition of the fossil fuel type *i*, using the following approach:

If $FC_{i,j,y}$ is measured in a mass unit: $COEF_{i,y} = w_{C,i,y} \times 44/12$

If $FC_{i,j,y}$ is measured in a volume unit: $COEF_{i,y} = w_{C,i,y} \times \rho_{i,y} \times 44/12$

Where:

$COEF_{i,y}$ = CO_2 emission coefficient of fuel type i during year y [tCO_2e / mass or volume unit]

$w_{C,i,y}$ = Weighted average mass fraction of carbon in fuel type i during year y [tC / mass unit of the fuel]

$\rho_{i,y}$ = Weighted average density of fuel type i during year y [mass unit / volume unit of the fuel]

- **Option B:** The CO_2 emission coefficient $COEF_{i,y}$ is calculated based on net calorific value and CO_2 emission factor of the fuel type i, as follows:

$$COEF_{i,y} = NCV_{i,y} \times EF_{CO2,i,y} \tag{18}$$

Where:

$COEF_{i,y}$ = CO_2 emission coefficient of fuel type i during year y [tCO_2e / mass or volume unit]

$NCV_{i,y}$ = Weighted average net calorific value of the fuel type i during year y [GJ/mass or volume unit]

$EF_{CO2,i,y}$	=	Weighted average CO_2 emission factor of fuel type i during year y [tCO_2e /GJ]

Where necessary data is available option A should be used.

Determination of $PE_{ODS\_Transport,y}$ and $PE_{ODS\_Destruction,y}$:

For project emissions due to ODS transportation and destruction, the project proponent shall apply the default factors provided by the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol: (Calculating Default Project Emissions from ODS Destruction and Transportation)*

$$PE_{ODS_{Transport},y} + PE_{ODS_{Destruction},y} = \left(M_{DESTR,refr,i,y} + M_{DESTR,foam,i,y}\right) \times EF_{ODS\_Transport+Destruction,y} \tag{19}$$

Where:

$PE_{ODS\_Transport,y}$	=	Project emission from ODS transportation during year y [tCO_2e]
$PE_{ODS\_Destruction,y}$	=	Project emission from ODS destruction during year y [tCO_2e]
$M_{DESTR,refr,i,y}$	=	Quantity of ODS refrigerant i sent for destruction by the project activity, including eligible and ineligible material, during year y [tODSi]
$M_{DESTR,foam,i,y}$	=	Quantity of ODS blowing agent i sent for destruction by the project activity, including eligible and ineligible material, during year y [$tODS_i$]
$EF_{ODS\_Transport+Destruction,y}$	=	Default emission factor aggregating both transportation and destruction emissions [tCO_2] (sourced from CAR, as above)

8.3 Leakage

Leakage emissions occur where in the baseline ODS refrigerant would have been re-used and in the project scenario must be substituted by other chemicals. Reuse may result in a gradual release of ODS over the project crediting period. When refrigerant ODS are destroyed, continued demand for refrigeration will lead to the production and consumption of other refrigerant chemicals whose production is still legally allowed.

$$LE_{ODS\_Substitute,y} = \sum_i^n M_{Destr,refr,i,y} \times TLR_{substitute,i} \times GWP_{substitute,i} \tag{20}$$

Where:

$LE_{ODS\_Substitute,y}$	=	Leakage emissions through ODS substitute i during year y [tCO_2e]

$M_{Destr,refr,i,y}$	=	Quantity of ODS refrigerant i which is sent to destruction by the project activity in year y [tODSi]
$TLR_{substitute,i}$	=	Total leakage of substitute chemical i over the project crediting period [0-1]
$GWP_{substitute,i}$	=	Global warming potential of substitute chemical i [tonsCO_2e/substitute,i]

$$TLR_{substitute,i} = 1 - \left(1 - LR_{substitute,i;y}\right)^{tcp} \quad (21)$$

Where:

$TLR_{substitute,i}$	=	Total leakage of substitute chemical i over the project crediting period [0-1]
$LR_{substitute,i;y}$	=	Leak rate of substitute chemical i in year y [0-1]
tcp	=	Project crediting period

For project activities taking place in Article 5 countries, the project proponent shall apply a substitute chemical derived from either official published data, research, industry studies, or default values provided in the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol*. The leak rate $LR_{substitute,i;y}$ shall be obtained from either official published data, research, industry studies, or default values provided in the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol*.

For project activities taking place in Non-Article 5 countries, the project proponent shall apply substitute chemicals derived from either official published data, research, industry studies, or default values provided in the latest version of the CAR *U.S. Ozone Depleting Substances Project Protocol*. The leak rate $LR_{substitute,i;y}$ shall be obtained from either official published data, research, industry studies, or default values provided in the latest version of the CAR *U.S. Ozone Depleting Substances Project Protocol.*

8.4 Net GHG Emission Reduction and Removals

Emission reductions are calculated as follows:

$$ER_{ODS,y} = BE_{ODS\_refr,y} + BE_{ODS\_foam,y} - PE_y - LE_y \quad (22)$$

Where:

$ER_{ODS,y}$	=	means total emission reductions during year y [tCO_2e]

$BE_{ODS\_refr,y}$	=	means the baseline emissions from ODS refrigerants banks which would be released into the atmosphere in the absence of the project activity during year y [tCO_2e]
$BE_{ODS\_foam,y}$	=	means baseline emissions from ODS blowing agents contained in insulation foams of refrigeration appliances which would be released into the atmosphere in the absence of the project activity during year y [tCO_2e]
PE_y	=	means the project emissions by the project activity during year y [tCO_2e]
LE_y	=	means the leakage emissions by the project activity during year y [tCO_2e]

9 MONITORING

9.1 Data and Parameters Available at Validation

Data / Parameter:	GWP_{ODSi} (refrigerants, blowing agents and substitute chemical)
Data unit:	tCO2e/tODS$_i$
Description:	Global Warming Potential of ODS$_i$
Source of data:	IPCC
Description of measurement methods and procedures to be applied:	See value Appendix I of this methodology for the first commitment period. Shall be updated according to any future COP/MOP decisions.
Comments:	

Data / Parameter:	VR_{refr}
Data unit:	% expressed as number [0-100%]
Description:	Rate of ODS refrigerants (destroyed) which would be vented into the atmosphere in the baseline
Source of data:	Default value(s) given below or project-specific rate(s) sourced from officially published country data, research studies, industry data, etc. In non-Article 5 countries, it is conservatively assumed that no intentional venting occurs and all ODS refrigerant is either used, reused or stored as a stockpile. As such, the default rate is 0%.

	In Article 5 countries, the default rate is similarly 0% unless the project proponent demonstrates that all or a portion of the ODS refrigerant destroyed as part of the project was recovered from products at end-of-life. In the absence of any regulatory prohibition on venting, all ODS refrigerant recovered from products at end-of-life is assumed to be vented directly to the atmosphere (100%) in the baseline.
Description of measurement methods and procedures to be applied:	In Article 5 countries, maintain point of origin documentation to demonstrate the portion of ODS refrigerant sourced from products at end-of-life.
Comments:	Calculated as a cumulative rate over the 10-year period following ODS destruction.

Data / Parameter:	DR_{refr}
Data unit:	% expressed as number [0-100%]
Description:	Rate of ODS refrigerants (destroyed) which would be destroyed in the baseline
Source of data:	Default value given below or project-specific rate(s) sourced from officially published data, research studies, industry data, etc. In the absence of a government mandate, product stewardship scheme, or other program that creates an incentive or mechanism for ODS refrigerant destruction in the country(ies) where the project activity occurs, the default rate is 0%.
Description of measurement methods and procedures to be applied:	
Comments:	Calculated as a cumulative rate over the 10-year period following ODS destruction.

Data / Parameter:	$RR_{refr,i}$
Data unit:	% expressed as number [0-100%]
Description:	Rate of ODS refrigerant i (destroyed) which would be used, reused or remain in storage in the baseline

Source of data:	Default value(s) given below or project-specific rate(s) sourced from officially published data, research studies, industry data, etc. In non-Article 5 countries, it is conservatively assumed that all ODS refrigerant recovered from products is recycled or reclaimed for reuse. If in a stockpile, it is assumed that the ODS refrigerant is used to recharge existing equipment, or in the case of a government stockpile of ODS refrigerant that cannot legally be sold into the commercial refrigerant market, remains in storage. As such, the default rate is 100%. In Article 5 countries, the default rate is similarly 100% unless the project proponent demonstrates that all or a portion of the ODS refrigerant destroyed as part of the project was recovered from products at end-of-life. The portion of ODS refrigerant not recovered from products at end-of-life is assumed to be recycled or reclaimed, used in existing equipment and/or remain in storage (as in the case of a government stockpile of ODS refrigerant that cannot legally be sold into the commercial refrigerant market).
Description of measurement methods and procedures to be applied:	Maintain point of origin documentation to demonstrate the quantity of ODS refrigerant sourced from a government stockpile that cannot legally be sold into the commercial refrigerant market. In Article 5 countries, maintain point of origin documentation to demonstrate the quantity of ODS refrigerant not sourced from products at end-of-life.
Comments:	Calculated as a cumulative rate over the 10-year period following ODS destruction.

Data / Parameter:	$LR_{refr,i}$
Data unit:	% expressed as number [0-100%]
Description:	Leak rate of ODS refrigerant i (destroyed), which would be used as refrigerant for existing equipment or remain in storage in the baseline
Source of data:	Default value(s) given below or project-specific rate(s) sourced from officially published data, research studies, industry data, etc. In non-Article 5 countries, default values for ODS refrigerant used or reused in existing equipment are the annual weighted average emission rates given in the latest version of the Climate Action Reserve's *U.S. ODS Project Protocol*.

	In Article 5 countries, default values for ODS refrigerant used or reused in existing equipment are the applicable annual emission rates given in the latest version of the Climate Action Reserve's *Article 5 ODS Project Protocol*. In the case of government stockpiles of ODS refrigerant that cannot legally be sold into the commercial refrigerant market and therefore remain in storage in either non-Article 5 or Article 5 countries, the default rate is 10%[2].
Description of measurement methods and procedures to be applied:	
Comments:	

Data / Parameter:	$ER_{foam,i}$
Data unit:	% expressed as number [0-100%]
Description:	Rate by which ODS blowing agents contained in foam of refrigeration appliances would be released into atmosphere based on the disposal practice (baseline) in the respective host country
Source of data:	Depending on baseline scenario (BAF1-4). For BAF4.1-4.2 see scientific sources Appendix II to this methodology and/or default values provided by the latest version of the *Climate Action Reserve (CAR): U.S. Ozone Depleting Substances Project Protocol*. For baseline scenarios BAF4.3 and BAF4.4 officially published data, research studies or industry data shall be used.
Description of measurement methods and procedures to be applied:	
Comments:	

[2] United Nations Environment Programme. (2013). Report on Progress and Experiences gained in Demonstration Projects for the Disposal of Unwanted ODS, Annex III. Executive Committee of the Multilateral Fund. Document No. 7054, Bangkok. Available at: http://www.multilateralfund.org/70/English/1/7054.pdf

Data / Parameter:	$LR_{substitute,i}$
Data unit:	% expressed as number [0-100%]
Description:	Leak rate of substitute chemical I in year y [0-1]
Source of data:	For project activities taking place in Article 5 countries, the leak rate shall be obtained from either official published data, research, industry studies, or default values provided in the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol*. For project activities taking place in Non Article 5 countries, officially published data, research studies, industry data, or default values from the latest version of the *CAR U.S. Ozone Depleting Substances Project Protocol* shall be used.
Description of measurement methods and procedures to be applied:	
Comments:	

Data / Parameter:	Substitute chemical i
Data unit:	
Description:	Chemical i substituting ODS refrigerant i where in the baseline refrigerant ODS would have been re-used and in the project scenario must be substituted by other chemicals
Source of data:	For project activities taking place in Article 5 countries, the project proponent shall apply a substitute chemical derived from either official published data, research, industry studies, or default values provided in the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol*. For project activities taking place in Non-Article 5 countries, officially published data, research studies, industry data, or the latest version of the *CAR U.S. Ozone Depleting Substances Project Protocol* shall be used.
Description of measurement methods and procedures to be applied:	
Comments:	

Data / Parameter:	$M_{app,1,foam,i,y}$, $M_{app,2,foam,i,y}$, $M_{app,3,foam,i,y}$
Data unit:	t ODSi/appliance type 1, 2 and 2
Description:	Amount of blowing agent ODSi contained in foam of refrigeration appliance types 1-3 in host country • Type 1 appliances, Domestic fridges: These are refrigerators of a typical domestic design with a storage capacity of up to 180 litres. The appliances may or may not be equipped with a separate deep-freeze compartment. • Type 2 appliances, Domestic fridge-freezers: These are refrigeration appliances of a typical domestic design with a storage capacity ranging from 180 to 350 litres. Generally, these appliances have a separate deep-freeze compartment. • Type 3 appliances, Domestic chest freezers and upright freezers: These are deep-freeze appliances of a typical domestic design with a storage capacity up to 500 litres.
Source of data:	If official national values are available those national values shall be used. In cases where no such official values are available it shall be determined by RAL *RAL Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment*
Description of measurement methods and procedures to be applied:	
Comments:	

Data / Parameter:	$EF_{ODS\_Transport+Destruction,y}$
Data unit:	tCO_2
Description:	Default emission factor aggregating both transportation and destruction emissions
Source of data:	Provided by the latest version of the *CAR Article 5 Ozone Depleting Substances Project Protocol: (Calculating Default Project Emissions from ODS Destruction and Transportation)*
Description of measurement methods	

and procedures to be applied:	
Comments:	

9.2 Data and Parameters Monitored

Data / Parameter:	$M_{DESTR,refr,i,y}$
Data unit:	tODSi
Description:	Quantity of ODS refrigerant i destroyed by the project activity in year y
Source of data:	• Operation logbook of recovery facility • Identification note for each individual ODS container by a bill of lading • Certificate of Destruction for each individual ODS container (refer to Section 9.3 of this methodology "Monitoring Methodology")
Description of measurement methods and procedures to be applied:	Refer to Section 9.3 of this methodology "Monitoring Methodology"
Frequency of monitoring/recording:	Each container with ODS sent to destruction
QA/QC procedures to be applied:	All measurements should be conducted with calibrated measurement equipment according to relevant industry standards (refer to Section 9.3 of this methodology "Monitoring Methodology")
Comments:	

Data / Parameter:	$M_{DESTR,foam,i,y}$
Data unit:	tODSi
Description:	Quantity of ODS blowing agent i contained in insulation foams of refrigeration appliances destroyed by the project activity in year y
Source of data:	• Operation logbook of recovery facility • Identification note for each individual ODS container by a bill of lading

	• Certificate of Destruction for each individual ODS container (refer to Section 9.3 of this methodology “Monitoring Methodology”)
Description of measurement methods and procedures to be applied:	Refer to Section 9.3 of this methodology “Monitoring Methodology”
Frequency of monitoring/recording:	Each container with ODS sent to destruction
QA/QC procedures to be applied:	All measurements should be conducted with calibrated measurement equipment according to relevant industry standards (refer to section 9.3 of this methodology “Monitoring Methodology”)
Comments:	

Data / Parameter:	Input flow of appliances (and types) J, K, L into the section of the recovery facility where removal of foams and extraction of ODS blowing agents from foams takes place
Data unit:	Number of refrigeration appliances [Number] and mass unit [e.g. kg]
Description:	Documentation of all input flows into the section of the recovery facility where removal of foams and extraction of ODS from foams takes place according to appliance types (type 1 domestic fridges; type 2 domestic fridge-freezers; type 3 domestic chest freezers and upright freezers;) and by weight.
Source of data:	Operation logbook of recovery facility
Description of measurement methods and procedures to be applied:	Weight measured by calibrated weighing scales.
Frequency of monitoring/recording:	Continuous monitoring, recording monthly, once annually: Test of 1000 appliances
QA/QC procedures to be applied:	All measurements should be conducted with calibrated measurement equipment according to relevant industry standards
Comments:	

Data / Parameter:	Total weight of output fractions from the section of the recovery facility where removal of foams and extraction of ODS blowing agents from foams takes place (test procedure)
Data unit:	Mass unit [e.g. kg]
Description:	Documentation of output flows (type and weight) The following fractions shall be documented: • Polyurethane • Ferrous metals • Non-ferrous metals • Plastics • Non-ferrous/plastic fraction • Residual waste • Process water • ODS blowing agents • Other components
Source of data:	Operation logbook of the recovery facility
Description of measurement methods and procedures to be applied:	Weight measured by calibrated weighing scales.
Frequency of monitoring/recording:	Continuous monitoring, recording monthly, once annually: Test of 1000 appliances
QA/QC procedures to be applied:	All measurements should be conducted with calibrated measurement equipment according to relevant industry standards
Comments:	

Data / Parameter:	$CR_{ODSi,y}$
Data unit:	Number
Description:	Host country-level compliance rate of the law, statute or other regulatory framework in the year y in relation to ODSi. Calculation of the compliance rate shall exclude other projects implemented under GHG programs. If the compliance rate exceeds 50%, the project shall receive no further credit.
Source of data:	Officially published data, research studies, industry data etc…

Description of measurement methods and procedures to be applied:	
Frequency of monitoring/recording:	Annually
QA/QC procedures to be applied:	
Comments:	

Data / Parameter:	$FC_{i,j,y}$
Data unit:	Mass or volume unit per year (e.g. ton/y or m³/y)
Description:	Quantity of fuel type i combusted in process j
Source of data:	Onsite measurements
Description of measurement methods and procedures to be applied:	Use utility bills or invoices for purchased fuel, or alternatively, either mass or volume meters onsite. In cases where fuel is supplied from small daily tanks, rulers can be used to determine mass or volume of the fuel consumed, with the following conditions: The ruler gauge must be part of the daily tank and calibrated at least once a year and have a book of control for recording the measurements (on a daily basis or per shift); Accessories such as transducers, sonar and piezoelectronic devices are accepted if they are properly calibrated with the ruler gauge and receiving a reasonable maintenance; In case of daily tanks with pre-heaters for heavy oil, the calibration will be made with the system at typical operational conditions.
Frequency of monitoring/recording:	Continuously
QA/QC procedures to be applied:	If onsite measurements are used, the consistency of metered fuel consumption quantities should be cross-checked by an annual energy balance that is based on purchased quantities and stock changes. Where the purchased fuel invoices can be identified specifically for the project activity, the metered fuel consumption quantities should also be cross-checked with available purchase invoices from the financial records.
Comments:	

Data / Parameter:	$W_{C,i,y}$
Data unit:	ton C/mass unit of the fuel
Description:	Weighted average mass fraction of carbon in fuel type i in year y
Source of data:	The following data sources may be used if the relevant conditions apply: **Data source** — **Conditions for using the data source** a) Values provided by the fuel supplier in invoices — Where relevant information is available use option a) b) Measurements by the project proponent — If a) is not available
Description of measurement methods and procedures to be applied:	Measurements should be undertaken in line with national or international fuel standards.
Frequency of monitoring/recording:	The mass fraction of carbon should be obtained for each fuel delivery, from which weighted average annual values should be calculated.
QA/QC procedures to be applied:	Verify if the values under a) and b) are within the uncertainty range of the IPCC default values as provided in Table 1.2, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements. The laboratories in b) should have ISO17025 accreditation or justify that they can comply with similar quality standards.
Comments:	Applicable where option A is used

Data / Parameter:	$\rho_{i,y}$
Data unit:	Mass unit/volume unit
Description:	Weighted average density of fuel type i in year y
Source of data:	The following data sources may be used if the relevant conditions apply: **Data source** — **Conditions for using the data source** a) Values provided by the fuel supplier in invoices — Where relevant information is available use option a)

	b) Measurements by the project proponent — If a) is not available c) Regional or national default values — If a) is not available. These sources can only be used for liquid fuels and should be based on well documented, reliable sources (such as national energy balances).
Description of measurement methods and procedures to be applied:	Measurements should be undertaken in line with national or international fuel standards.
Frequency of monitoring/recording:	The density of the fuel should be obtained for each fuel delivery, from which weighted average annual values should be calculated.
QA/QC procedures to be applied:	
Comments:	Applicable where option A is used and where $FC_{i,j,y}$ is measured in a volume unit. Preferably the same data source should be used for $W_{C,i,y}$ and $\rho_{i,y}$.

Data source	Conditions for using the data source
b) Measurements by the project proponent	If a) is not available
c) Regional or national default values	If a) is not available These sources can only be used for liquid fuels and should be based on well documented, reliable sources (such as national energy balances).

Data / Parameter:	$NCV_{i,y}$
Data unit:	GJ per mass or volume unit (e.g. GJ/m³, GJ/ton)
Description:	Weighted average net calorific value of fuel type i in year y
Source of data:	The following data sources may be used if the relevant conditions apply:

Data source	Conditions for using the data source
a) Values provided by the fuel supplier in invoices	Where relevant information is available use option a)
b) Measurements by the project proponent	If a) is not available
c) Regional or national default values	If a) is not available. These sources can only be used for liquid fuels and should be based on well documented,

	<table><tr><td></td><td>reliable sources (such as national energy balances).</td></tr><tr><td>d) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in Table 1.2 of Chapter 1 of Vol. 2 (Energy) of the 2006 IPCC Guidelines on National GHG Inventories</td><td>If a) is not available</td></tr></table>
Description of measurement methods and procedures to be applied:	For a) and b): Measurements should be undertaken in line with national or international fuel standards
Frequency of monitoring/recording:	For a) and b): The NCV should be obtained for each fuel delivery, from which weighted average annual values should be calculated For c): Review appropriateness of the values annually For d): Any future revision of the IPCC Guidelines should be taken into account
QA/QC procedures to be applied:	Verify if the values under a), b) and c) are within the uncertainty range of the IPCC default values as provided in Table 1.2, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements. The laboratories in a), b) or c) should have ISO17025 accreditation or justify that they can comply with similar quality standards.
Comments:	Applicable where option B of this methodology is used

Data / Parameter:	$EF_{CO2,i,y}$
Data unit:	tCO_2/GJ
Description:	Weighted average CO_2 emission factor of fuel type i in year y
Source of data:	The following data sources may be used if the relevant conditions apply: <table><tr><td>**Data source**</td><td>**Conditions for using the data source**</td></tr><tr><td>a) Values provided by the fuel supplier in invoices</td><td>Where relevant information is available use option a).</td></tr></table>

	b) Measurements by the project proponents	If a) is not available
	c) Regional or national default values	If a) is not available These sources can only be used for liquid fuels and should be based on well documented, reliable sources (such as national energy balances).
	d) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in table 1.4 of Chapter1 of Vol. 2 (Energy) of the 2006 IPCC Guidelines on National GHG Inventories	If a) is not available
Description of measurement methods and procedures to be applied:	For a) and b): Measurements should be undertaken in line with national or international fuel standards.	
Frequency of monitoring/recording:	For a) and b): The CO_2 emission factor should be obtained for each fuel delivery, from which weighted average annual values should be calculated For c): Review appropriateness of the values per monitoring interval y For d): Any future revision of the IPCC Guidelines should be taken into account	
QA/QC procedures to be applied:		
Comments:	Applicable where option B is used. For a): If the fuel supplier does provide the NCV value and the CO_2 emission factor on the invoice and these two values are based on measurements for this specific fuel, this CO_2 factor should be used. If another source for the CO_2 emission factor is used or no CO_2 emission factor is provided, options b), c) or d) should be used	

Data / Parameter:	$EC_{PJ,y}$

Data unit:	MWh
Description:	Amount of electricity consumed at the ODS recovery facility from the grid during year y
Source of data:	Onsite measurements and recorded by a computer system and/or by printed journals; or, alternatively, utility bills or invoices for purchased electricity
Description of measurement methods and procedures to be applied:	Directly measured by calibrated electricity meter installed at the project site.
Frequency of monitoring/recording:	Continuously, aggregated at least annually
QA/QC procedures to be applied:	If onsite measurements are used, cross check measurement results with invoices for purchased electricity if relevant
Comments:	

Data / Parameter:	$EF_{grid,y}$
Data unit:	tons CO_2/MWh
Description:	Grid emission factor during the monitoring period y
Source of data:	Choose one of the following options: • Calculate the combined margin emission factor, using the procedures in the latest approved version of the CDM "Tool to calculate the emission factor for an electricity system"; Use a conservative default value of 1.3 tCO_2/MWh.
Description of measurement methods and procedures to be applied:	
Frequency of monitoring/recording:	
QA/QC procedures to be applied:	If the "Tool to calculate the emission factor for an electricity system" will be used the source and/or the calculation shall be available by printed journals.
Comments:	

Data / Parameter:	TDL_y
Data unit:	
Description:	Average technical transmission and distribution losses in the grid for the voltage level at which electricity is obtained from the grid at the project site during year y
Source of data:	Choose one of the following options: a) Use recent, accurate and reliable data available within the country; b) Use a default value of 20%
Description of measurement methods and procedures to be applied:	For a) TDL_y should be estimated for the distribution and transmission networks of the electricity grid of the same voltage as the connection where the proposed project activity is connected to. The technical distribution losses should not contain other types of grid losses (e.g. commercial losses/theft). The distribution losses can either be calculated by the project proponent or be based on references from utilities, network operators or other official documentation.
Frequency of monitoring/recording:	
QA/QC procedures to be applied:	In the absence of data from the relevant year, most recent figures should be used, but not older than 5 years.
Comments:	

9.3 Description of the Monitoring Plan[3]

Composition and Quantity Analysis Requirements

The requirements of this section must be followed to determine the quantities of both ODS refrigerants and ODS blowing agents. Prior to destruction, the precise mass and composition of ODS to be destroyed must be determined. The following analysis must be conducted:

Mass shall be determined by individually measuring the weight of each container of ODS:

1. When it is full prior to destruction; and

[3] This section is mainly based on Climate Action Reserve (CAR): U.S. Ozone Depleting Substances Project Protocol Version 2 February 27 2012 and on RAL Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment version: 2007/09

2. After it has been emptied and the contents have been fully purged and destroyed. The mass of ODS and any contaminants is equal to the difference between the full and empty weight, as measured

The following requirements must be met when weighing the containers of ODS:

1. A single scale must be used for generating both the full and empty weight tickets at the destruction facility
2. Weighing instruments must comply with the relevant national requirements and/or international standards – such as EC Directive 2009/23/EC or International Organization for Legal Metrology OIML R 76-1 – and be subject to regular calibration, as set out in the relevant national requirements and/or international standards to accuracy appropriate to its accuracy class. These instruments shall have a measuring range corresponding to the capacity of containers and tanks weighed. If a scale is found to be out of tolerance, it must be recalibrated.
3. The full weight must be measured no more than two days prior to commencement of destruction per the Certificate of Destruction
4. The empty weight must be measured no more than two days after the conclusion of destruction per the Certificate of Destruction

Composition and concentration of ODS shall be established for each individual container by taking a sample from each container of ODS and having it analyzed for composition and concentration at a lab accredited to perform analyses in compliance with the applicable International Organization for Standardization (ISO) standard or equivalent standards. Further, where national standards exist they may be used in lieu of ISO standards provided that they have been the subject of a verification or validation process addressing their accuracy and representativeness. In the case where no such standards exist, the US Air-Conditioning, Heating and Refrigeration Institute *700-2006* standard shall be applied.

The laboratory performing the composition analysis must not be affiliated with the project proponent or the project activities beyond performing these services.

The following requirements must be met for each sample:

1. The sample must be taken while ODS is in the possession of the company that will destroy the ODS
2. Samples must be taken by a technician unaffiliated with the project developer
3. Samples must be taken with a clean, fully evacuated sample bottle that meets applicable U.S. DOT requirements or an equivalent national (host country) or ISO standard
4. The technician must ensure that the sample is representative of the contents of the container

5. Each sample must be taken in liquid state
6. A minimum sample size of 0.453592 kg (1 pound) must be drawn for each sample
7. Each sample must be individually labeled and tracked according to the container from which it was taken, and the following information recorded:
    - Time and date of sample
    - Name of project developer
    - Name of technician taking sample
    - Employer of technician taking sample
    - Volume of container from which sample was extracted
    - Ambient air temperature at time of sampling
8. Chain of custody for each sample from the point of sampling lab must be documented by paper bills of lading or electronic, third-party tracking that includes proof of delivery

All project samples shall be analyzed using the International Organization for Standardization (ISO) standard applicable. Further, where national standards exist they may be used in lieu of ISO standards provided that they have been the subject of a verification or validation process addressing their accuracy and representativeness. In the case where no such standards exist, the US Air-Conditioning, Heating and Refrigeration Institute *700-2006* standard shall be applied. The analysis shall provide:

1. Identification of the refrigerant
2. Purity (%) of the ODS mixture by weight using gas chromatography
3. Moisture level in parts per million. The moisture content of each sample must be less than 75% of the saturation point for the ODS based on the temperature recorded at the time the sample was taken. For containers that hold mixed ODS, the sample's saturation point shall be assumed to be that of the ODS species in the mixture with the lowest saturation point that is at least 10 percent of the mixture by mass.
4. Analysis of high boiling residue, which must be less than 10% by mass
5. Analysis of other ODS in the case of mixtures of ODS, and their percentage by mass

If any of the requirements above are not met, no GHG reductions may be verified for ODS destruction associated with that container. If a sample is tested and does not meet one of the requirements as defined above, the project proponent may elect to have the material re-sampled and re-analyzed. The project proponent may sample for moisture content and perform any necessary de-watering prior to the required sampling and laboratory analysis.

If the container holds non-mixed ODS (defined as greater than 90% composition of a single ODS species) no further information or sampling is required to determine the mass and composition of the ODS. If the container holds mixed ODS, which is defined as less than 90% composition of a single ODS species, the project proponent must meet additional requirements as provided below.

Composition and Quantity Analysis Requirements for Mixed ODS

If a container holds mixed ODS, its contents must also be processed and measured for composition and concentration according to the requirements of this section. The sampling required under this section may be conducted at the final destruction facility or prior to delivery to the destruction facility. However, the circulation and sampling activities must be conducted by a third-party organization (i.e., not the project proponent), and by individuals who have been properly trained for the functions they perform. Circulation and sampling may be conducted at the project proponent's facility, but all activities must be directed by a properly trained and contracted third-party. The project description must specify the procedures by which mixed ODS are analyzed.

The composition and concentration of ODS on a mass basis must be determined using the results of the analysis of this section for each container. The results of the composition analysis in the section above shall be used by verifiers to confirm that the destroyed ODS is in fact the same ODS that is sampled under these requirements. Prior to sampling, the ODS mixture must be circulated in a container that meets all of the following criteria:

1. The container has no solid interior obstructions[4]
2. The container was fully evacuated prior to filling
3. The container must have sampling ports to sample liquid and gas phase ODS
4. The liquid port intake must be at the bottom of the container, and the vapor port intake must be at the top of the container. For horizontally-oriented mixing containers, the intakes must be located in the middle third of the container
5. The container and associated equipment can circulate the mixture via a closed loop system from the bottom to top

If the original mixed ODS container does not meet these requirements, the mixed ODS must be transferred into a temporary holding tank or container that meets all of the above criteria. The weight of the contents placed into the temporary container shall be calculated and recorded. During transfer of ODS into and out of the temporary container, ODS shall be recovered to the vacuum levels required by the U.S. EPA for that ODS (see 40 CFR 82.156) or any national (host country) or ISO standard.

[4] Mesh baffles or other interior structures that do not impede the flow of ODS are acceptable.

Once the mixed ODS is in a container or temporary storage unit that meets the criteria above, circulation of mixed ODS must be conducted as follows:

1. Liquid mixture shall be circulated from the liquid port to the vapor port.
2. A volume of the mixture equal to two times the volume in the container shall be circulated
3. Circulation must occur at a rate of at least 113.6l/minute
4. Start and end times shall be recorded

Within 30 minutes of the completion of circulation, a minimum of two samples shall be taken from the bottom liquid port and analyzed according to the procedures above. The mass composition and concentration of the mixed ODS shall be equal to the lesser of the two GWP-weighted concentrations.

Determination of Recovery Efficiency of Blowing Agents Contained in Foam of Refrigeration Appliances

An annual test shall be conducted in which at least 1000 refrigeration appliances with ODS containing insulation materials are processed at the recovery facility of the project proponent.

Every appliance used in the test shall be intact, i.e. there shall be no damage to the appliance carcass and the doors typical of that appliance type shall still be attached. No other doors, appliance components or other products containing foam insulation shall be processed during the test. Systematically sorting out refrigeration appliances from the mass flow of incoming devices for the purpose of manipulating the quantity of recovered ODS is strictly forbidden.

To compile a mass balance analysis, the total weight of all the appliances used in the test shall be determined and recorded. In addition, the weight of all material fractions recovered from the processing plant during the test shall be determined.

- Polyurethane
- Ferrous metals
- Non-ferrous metals
- Plastics
- Non-ferrous/plastic fraction
- Residual waste
- Process water
- ODS
- Other components

The gas cylinders used to store the recovered ODS are weighed when empty (i.e. before processing commences) and again when filled (i.e. after processing has been completed). The dry weight in kilograms of ODS recovered is divided by the number of appliances processed. The result is recorded as the quantity of ODS recovered in grams per appliance.

The quantities of ODS blowing agents to be recovered for each appliance type (domestic fridge, domestic fridge-freezers, domestic chest freezers and upright freezers) as specified in Section 3, “Definitions” shall be sourced from official national values. In cases where no such official values are available it shall be determined by RAL *RAL Quality Assurance and Test Specifications for the Demanufacture of Refrigeration Equipment*. The recovery facility must achieve a recovery efficiency of at least 90% otherwise no credits can be generated for the respective monitoring period.

The RAL test protocol shall be used for the annual test.

Since this methodology requires the extraction of ODS from the foam to a concentrated form prior to destruction the overall Recovery and Destruction Efficiency will be achieved when the destruction facility meets the requirements of *UNEP Technology and Economic Assessment Panel (TEAP) Report of the Task Force on Destruction Technologies*, UNEP, 2002. A minimum Recovery and Destruction Efficiency (RDE) of 85% shall be achieved otherwise no credits can be generated for the respective monitoring period.

Destruction Facility Requirements

Destruction of ODS must occur at a facility that has a valid host country permit for ODS destruction and meets the screening criteria for destruction technologies set out in the report, as may be updated from time to time, by the UNEP Technology and Economic Assessment Panel (TEAP) Task Force on Destruction Technologies (reproduced in full in Appendix III from TEAP *Report of the Task Force on Destruction Technologies*, Chapter 2 (2002)).

Operating parameters of the destruction unit while destroying ODS material shall be monitored and recorded as described in the Code of Good Housekeeping[5] (as reproduced in full in Appendix II) approved by the Montreal Protocol.

APPENDIX II: CODE OF GOOD HOUSEKEEPING[6]

To provide additional guidance to facility operators, in May 1992 the Technical Advisory Committee prepared a "Code of Good Housekeeping" as a brief outline of measures that should be considered to ensure that environmental releases of ozone-depleting substances (ODS) through all media are minimized. This Code, updated by the Task Force on Destruction Technologies and amended by the Parties at their Fifteenth Meeting, in 2003, is also intended to provide a framework of practices and measures that should normally be adopted at facilities undertaking the destruction of ODS.

Not all measures will be appropriate to all situations and circumstances and, as with any code, nothing specified should be regarded as a barrier to the adoption of better or more effective measures if these can be identified.

Pre-delivery

This refers to measures that may be appropriate prior to any delivery of ODS to a facility.

The facility operator should generate written guidelines on ODS packaging and containment criteria, together with labelling and transportation requirements. These guidelines should be provided to all suppliers and senders of ODS prior to agreement to accept such substances.

The facility operator should seek to visit and inspect the proposed sender's stocks and arrangements prior to movement of the first consignment. This is to ensure awareness on the part of the sender of proper practices and compliance with standards.

Arrival at the facility

This refers to measures that should be taken at the time ODS are received at the facility gate. These include an immediate check of documentation prior to admittance to the facility site, coupled with a preliminary inspection of the general condition of the consignment. Where necessary, special or "fast-track" processing and repackaging facilities may be needed to mitigate risk of leakage or loss of ODS. Arrangements should exist to measure the gross weight of the consignment at the time of delivery.

Unloading from delivery vehicle

This refers to measures to be taken at the facility in connection with the unloading of ODS. It is generally assumed that ODS will normally be delivered in some form of container, drum or other vessel that is removed from the delivery vehicle in total. Such containers may be returnable.

---

[6] Reproduced in full from: TEAP, Code of Good Housekeeping in *Handbook for the Montreal Protocol on Substances that Deplete the Ozone Layer - 7th Edition* (2006)

All unloading activities should be carried out in properly designated areas, to which restricted access of personnel applies. Areas should be free of extraneous activities likely to lead to, or increase the risk of, collision, accidental dropping, spillage, etc. Materials should be placed in designated quarantine areas for subsequent detailed checking and evaluation.

Testing and verification

This refers to the arrangements made for detailed checking of the ODS consignments prior to destruction.

Detailed checking of delivery documentation should be carried out, along with a complete inventory, to establish that delivery is as advised and appears to comply with expectations.

Detailed checks of containers should be made both in respect of accuracy of identification labels, etc, and of physical condition and integrity. Arrangements must be in place to permit repackaging or “fast-track” processing of any items identified as defective. Sampling and analysis of representative quantities of ODS consignments should be carried out to verify material type and characteristics. All sampling and analysis should be conducted using approved procedures and techniques.

Storage and stock control

This refers to matters concerning the storage and stock control of ODS.

ODS materials should be stored in specially designated areas, subject to the regulations of the relevant local authorities. Arrangements should be put in place as soon as possible to minimize, to the extent practicable, stock emissions prior to destruction.

Locations of stock items should be identified through a system of control that should also provide a continuous update of quantities and locations as stock is destroyed and new stock delivered. In regard to storage vessels for concentrated sources of ODS, these arrangements should include a system for regular monitoring and leak detection, as well as arrangements to permit repackaging of leaking stock as soon as possible.

Measuring quantities destroyed

It is important to be aware of the quantities of ODS processed through the destruction equipment. Where possible, flow meters or continuously recording weighing equipment for individual containers should be employed. As a minimum, containers should be weighed “full” and “empty” to establish quantities by difference.

Residual quantities of ODS in containers that can be sealed and are intended to be returned for further use, may be allowed. Otherwise, containers should be purged of residues or destroyed as part of the process.

Facility design

This refers to basic features and requirements of plant, equipment and services deployed in the facility.

In general, any destruction facility should be properly designed and constructed in accordance with the best standards of engineering and technology and with particular regard to the need to minimize, if not eliminate, fugitive losses.

Particular care should be taken when designing plants to deal with dilute sources such as foams. These may be contained in refrigeration cabinets or may be part of more general demolition waste. The area in which foam is first separated from other substrates should be fully enclosed wherever possible and any significant emissions captured at that stage.

Pumps: Magnetic drive, sealers or double mechanical seal pumps should be installed to eliminate environmental releases resulting from seal leakage.

Valves: Valves with reduced leakage potential should be used. These include quarter-turn valves or valves with extended packing glands.

Tank vents (including loading vents): Filling and breathing discharges from tanks and vessels should be recovered or vented to a destruction process.

Piping joints: Screwed connections should not be used and the number of flanged joints should be kept to the minimum that is consistent with safety and the ability to dismantle for maintenance and repair.

Drainage systems: Areas of the facility where ODS are stored or handled should be provided with sloped concrete paving and a properly designed collection system. Water that is collected should, if contaminated, be treated prior to authorized discharge.

Maintenance

In general, all maintenance work should be performed according to properly planned programmes and should be executed within the framework of a permit system to ensure proper consideration of all aspects of the work.

ODS should be purged from all vessels, mechanical units and pipework prior to the opening of these items to the atmosphere. The contaminated purge should be routed to the destruction process or treated to recover the ODS.

All flanges, seals, gaskets and other sources of minor losses should be checked routinely to identify developing problems before containment is lost. Leaks should be repaired as soon as possible.

Consumable or short-life items, such as flexible hoses and couplings, must be monitored closely and replaced at a frequency that renders the risk of rupture negligible.

Quality control and quality assurance

All sampling and analytical work connected with ODS, the process and the monitoring of its overall performance should be subject to quality assessment and quality control measures in line with current recognized practices. This should include at least occasional independent verification and confirmation of data produced by the facility operators.

Consideration should also be given to the adoption of quality management systems and environment quality practices covering the entire facility.

Training

All personnel concerned with the operation of the facility (with “operation” being interpreted in its widest sense) should have training appropriate to their task. Of particular relevance to the ODS destruction objectives is training in the consequences of unnecessary losses and in the use, handling and maintenance of all equipment in the facility. All training should be carried out by suitably qualified and experienced personnel and the details of such training should be maintained in written records. Refresher training should be conducted at appropriate intervals.

Code of transportation

In the interest of protecting the stratospheric ozone layer, it is essential that used ODS and products containing ODS are collected and moved efficiently to facilities practising approved destruction technologies. For transportation purposes, used ODS should receive the same hazard classification as the original substances or products. In practice, this may introduce restrictions on hazardous waste shipment under the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and their Disposal and this should be consulted separately. In the absence of such specific restrictions, the following proposed code of transportation for ODS from customer to destruction facilities is provided as a guide to help minimize damage caused to the ozone layer as a result of ODS transfers. Additional guidance is contained in the United Nations Transport of Dangerous Goods Model Regulations.

It is important to supervise and control all shipments of used ODS and products containing ODS according to national and international requirements to protect the environment and human health. To ensure that ODS and products containing ODS do not constitute an unnecessary risk, they must be properly packaged and labelled. Instructions to be followed in the event of danger or accident must accompany each shipment to protect human beings and the environment from any danger that might arise during the operation.

Notification of the following information should be provided at any intermediate stage of the shipment from the place of dispatch until its final destination. When making notification, the notifier should supply the information requested on the consignment note, with particular regard to:

a. The source and composition of the ODS and products containing ODS, including the customer’s identity;

b. Arrangements for routing and for insurance against damage to third parties;

c. Measures to be taken to ensure safe transport and, in particular, compliance by the carrier with the conditions laid down for transport by the States concerned;

d. The identity of the consignee, who should possess an authorized centre with adequate technical capacity for the destruction;

e. The existence of a contractual agreement with the consignee concerning the destruction of ODS and products containing ODS.

This code of transportation does not necessarily apply to the disposal of ODS-containing rigid insulation foams. The most appropriate way to dispose of such products may be by direct incineration in municipal waste incinerators or rotary kiln incinerators.

Monitoring

The objectives of monitoring should be to provide assurance that input materials are being destroyed with an acceptable efficiency generally consistent with the destruction and removal efficiency (DRE) recommendations listed in annex II to the present report and that the substances resulting from destruction yield environmentally acceptable emission levels consistent with, or better than, those required under national standards or other international protocols or treaties.

As there are as yet no International Organization for Standardization (ISO) standards applicable for the sampling and analysis of ODS or the majority of the other pollutants listed in annex IV to the present report, where national standards exist they should be employed. Further, where national standards exist they may be used in lieu of ISO standards provided that they have been the subject of a verification or validation process addressing their accuracy and representativeness.

As ISO develops international standards for pollutants listed in annex IV to the present report, the technical bodies charged with developing such standards should take note of the existing national standards including those identified in appendix F to the report of the Technology and Economic Assessment Panel (TEAP) of April 2002 (volume 3, report of the Task Force on Destruction Technologies) and strive to ensure consistency between any new ISO standards and the existing standard test methods, provided that there is no finding that those existing methods are inaccurate or unrepresentative.

Where national standards do not exist, the Technical Advisory Committee recommends adoption of the following guidelines for monitoring of destruction processes operating using an approved technology.

Recognizing that the Unites States of America Environmental Protection Agency (EPA) methods have been the subject of verification procedures to ensure that they are reasonably accurate and representative, that they cover all of the pollutants of interest (although not all ODS compounds have been the specific subject of verification activities), that they provide a comprehensive level of detail that should lead to replicability of the methods by trained personnel in other jurisdictions and that they are readily available for reference and downloading from the Internet without the payment of a fee, applicable EPA methods as described in appendix F to the 2002 report of TEAP may be employed.

In the interest of ensuring a common international basis of comparison for those pollutants or parameters where ISO standards exist (currently particulates, carbon monoxide, carbon dioxide and oxygen), use of those standards is encouraged and jurisdictions are encouraged to adopt them as national standards or acceptable alternatives to existing national standards.

The use of EPA or other national standards described in appendix F is also considered acceptable, however. The precedence given to the EPA methods in the present code is based on the relative comprehensiveness of the methods available (both in scope and content), and the relative ease of access to those methods.

Measurement of ODS

Operators of destruction facilities should take all necessary precautions concerning the storage and inventory control of ODS-containing material received for destruction. Prior to feeding the ODS to the approved destruction process, the following procedures are recommended:

a. The mass of the ODS-containing material should be determined, where practicable;

b. Representative samples should be taken, where appropriate, to verify that the concentration of ODS matches the description given on the delivery documentation;

c. Samples should be analysed by an approved method. If no approved methods are available, the adoption of United States EPA methods 5030 and 8240 is recommended;

d. All records from these mass and ODS-concentration measurements should be documented and kept in accordance with ISO 9000 or equivalent.

Control systems

Operators should ensure that destruction processes are operated efficiently to ensure complete destruction of ODS to the extent that it is technically feasible for the approved process. This will normally include the use of appropriate measurement devices and sampling techniques to monitor the operating parameters, burn conditions and mass concentrations of the pollutants that are generated by the process.

Gaseous emissions from the process need to be monitored and analysed using appropriate instrumentation. This should be supplemented by regular spot checks using manual stack-sampling methods. Other environmental releases, such as liquid effluents and solid residues, require laboratory analysis on a regular basis.

The continuous monitoring recommended for ongoing process control, including off-gas cleaning systems, is as follows:

a. Measurement of appropriate reaction and process temperatures;

b. Measurement of flue gas temperatures before and after the gas cleaning system;

c. Measurement of flue gas concentrations for oxygen and carbon monoxide.

Any additional continuous monitoring requirements are subject to the national regulatory authority that has jurisdiction. The performance of online monitors and instrumentation systems must be periodically checked and validated. When measuring detection limits, error values at the 95 per cent confidence level should not exceed 20 per cent.

Approved processes must be equipped with automatic cut-off control systems on the ODS feed system, or be able to go into standby mode whenever:

a. The temperature in the reaction chamber falls below the minimum temperature required to achieve destruction;

b. Other minimum destruction conditions stated in the performance specifications cannot be maintained.

Performance measurements

The approval of technologies recommended by TEAP is based on the destruction capability of the technology in question. It is recognized that the parameters may fluctuate during day-to-day operation from this generic capability. In practice, however, it is not possible to measure against performance criteria on a daily basis. This is particularly the case for situations where ODS only represents a small fraction of the substances being destroyed, thereby requiring specialist equipment to achieve detection of the very low concentrations present in the stack gas. It is therefore not uncommon for validation processes to take place annually at a given facility.

With this in mind, TEAP is aware that the measured performance of a facility may not always meet the criteria established for the technology. Nonetheless, TEAP sees no justification for reducing the minimum recommendations for a given technology. Regulators, however, may need to take these practical variations into account when setting minimum standards.

The ODS destruction and removal efficiency[7] for a facility operating an approved technology should be validated at least once every three years. The validation process should also include an assessment of other relevant stack gas concentrations identified in annex II to decision XV/[…] and a comparison with maximum levels stipulated in relevant national standards or international protocols/treaties.

Determination of the ODS destruction and removal efficiency and other relevant substances identified in annex IV to the present report should also be followed when commissioning a new or rebuilt facility or

[7] Destruction and removal efficiency has traditionally been determined by subtracting from the mass of a chemical fed into a destruction system during a specific period of time the mass of that chemical alone that is released in stack gases and expressing that difference as a percentage of the mass of that chemical fed into the system

when any other significant change is made to the destruction procedures in a facility to ensure that all facility characteristics are completely documented and assessed against the approved technology criteria.

Tests shall be done with known feed rates of a given ODS compound or with well-known ODS mixtures. In cases where a destruction process incinerates halogen-containing wastes together with ODS, the total halogen load should be calculated and controlled. The number and duration of test runs should be carefully selected to reflect the characteristics of the technology.

In summary, the destruction and removal efficiency recommended for concentrated sources means that less than 0.1 gram of total ODS should normally enter the environment from stack-gas emissions when 1,000 grams of ODS are fed into the process. A detailed analysis of stack test results should be made available to verify emissions of halogen acids and polychlorinated dibenzodioxin and dibenzofuran (PCDD/PCDF). In addition, a site-specific test protocol should be prepared and made available for inspection by the appropriate regulatory authorities. The sampling protocol shall report the following data from each test:

a. ODS feed rate;
b. Total halogen load in the waste stream;
c. Residence time for ODS in the reaction zone;
d. Oxygen content in flue gas;
e. Gas temperature in the reaction zone;
f. Flue gas and effluent flow rate;
g. Carbon monoxide in flue gas;
h. ODS content in flue gas;
i. Effluent volumes and quantities of solid residues discharged;
j. ODS concentrations in the effluent and solid residues;
k. Concentration of PCDD/PCDF, particulates, HCl, HF and HBr in the flue gases;
l. Concentration of PCDD/PCDF in effluent and solids.

APPENDIX III: TECHNOLOGY SCREENING PROCESS[8]

Criteria for Technology Screening

The following screening criteria were developed by the UNEP TFDT. Technologies for use by the signatories to the Montreal Protocol to dispose of surplus inventories of ODS were assessed on the basis of:

1. Destruction and Removal Efficiency (DRE)
2. Emissions of dioxins/furans
3. Emissions of other pollutants (acid gases, particulate matter, & carbon monoxide)
4. Technical capability

The first three refer to technical performance criteria selected as measures of potential impacts of the technology on human health and the environment. The technical capability criterion indicates the extent to which the technology has been demonstrated to be able to dispose of ODS (or a comparable recalcitrant halogenated organic substance such as PCB) effectively and on a commercial scale.

For convenience, the technical performance criteria are summarized in Table 3-1. These represent the minimum destruction and removal efficiencies and maximum emission of pollutants to the atmosphere permitted by technologies that qualify for consideration by the TFDT for recommendation to the Parties of the Montreal Protocol for approval as ODS destruction technologies. The technologies must also satisfy the criteria for technical capability as defined below.

Table 3-1: Summary of Technical Performance Qualifications[9]

Performance Qualification	Units	Diluted Sources	Concentrated Sources
DRE	%	95	99.99
PCDDs/PCDFs	ng-ITEQ/NM^3	0.5	0.2
HCL/CL_2	mg/NM^3	100	100

[8] Reproduced in full from: *UNEP Technology and Economic Assessment Panel (TEAP) Report of the Task Force on Destruction Technologies*, UNEP, 2002. Available at: http://ozone.unep.org/teap/Reports/Other_Task_Force/TEAP02V3b.pdf

[9] All concentrations of pollutants in stack gases and stack gas flow rates are expressed on the basis of dry gas at normal conditions of 0ºC and 101.3 kPa, and with the stack gas corrected to 11% O2.

HF	mg/NM^3	5	5
HBr/Br_2	mg/NM^3	5	5
Particulates	mg/NM^3	50	50
CO	mg/NM^3	100	100

Destruction and Removal Efficiency

Destruction Efficiency (DE)[10] is a measure of how completely a particular technology destroys a contaminant of interest – in this case the transformation of ODS material into non-ODS by-products. There are two commonly used but different ways of measuring the extent of destruction – DE and Destruction and Removal Efficiency (DRE)[11]. For a more detailed explanation of how DRE is calculated, see section 4.2.1. The terms are sometimes interchanged or used inappropriately. DE is a more comprehensive measure of destruction than DRE, because DE considers the amount of the chemical of interest that escapes destruction by being removed from the process in the stack gases and in all other residue streams. Most references citing performance of ODS destruction processes only provide data for stack emissions and thus, generally, data is only available for DRE and not DE.

Because of the relatively volatile nature of ODS and because, with the exception of foams, they are generally introduced as relatively clean fluids, one would not expect a very significant difference between DRE and DE. For these reasons this update of ODS destruction technologies uses DRE as the measure of destruction efficiency. For the purposes of screening destruction technologies, the minimum acceptable DRE is:

- 95% for foams; and,
- 99.99% for concentrated sources.

It should be noted that measurements of the by-products of destruction of CFCs, HCFCs and halons in a plasma destruction process have indicated that interconversion of ODS can occur during the process. For example, under some conditions, the DRE of CFC-12 (CCl_2F_2) was measured as 99.9998%, but this was accompanied by a conversion of 25% of the input CFC-12 to CFC-13 ($CClF_3$), which has the same

---

[10] Destruction Efficiency (DE) is determined by subtracting from the mass of a chemical fed into a destruction system during a specific period of time the mass of that chemical that is released in stack gases, fly ash, scrubber water, bottom ash, and any other system residues and
expressing that difference as a percentage of the mass of the chemical fed into the system.
[11] Destruction and Removal Efficiency (DRE) has traditionally been determined by subtracting from the mass of a chemical fed into a destruction system during a specific period of time the mass of that chemical alone that is released in stack gases, and expressing that difference as a percentage of the mass of that chemical fed into the system.

ozone-depleting potential. The interconversion is less severe when hydrogen is present in the process, but can nonetheless be significant.[12] For this reason, it is important to take into account all types of ODS in the stack gas in defining the DRE.

For the reasons described in the previous paragraph, the Task Force recommends that future calculations of DRE use the approach described below[13].

DRE of an ODS should be determined by subtracting from the number of moles of the ODS fed into a destruction system during a specific period of time, the total number of moles of all types of ODS that are released in stack gases, and expressing that difference as a percentage of the number of moles of the ODS fed into the system.

In mathematical terms, $DRE = \frac{N_I^{in} - \sum_i N_i^{out}}{N_I^{in}}$ where N_I^{in} is the number of moles of the ODS fed into the destruction system and N_i^{out} is the number of moles of the *i*th type of ODS that is released in the stack gases.

Emissions of Dioxins and Furans

Any high temperature process used to destroy ODS has associated with it the potential formation (as by-products) of polychlorinated dibenzo-paradioxins (PCDDs) and polychlorinated dibenzofurans (PCDFs). These substances are among the products of incomplete combustion (or PICs) of greatest concern for potential adverse effects on public health and the environment. The internationally recognized measure of the toxicity of these compounds is the toxic equivalency factor (ITEQ),[14] which is a weighted measure of

---

Soc.: Chem. Commun.* No. 3 (1995) 347-348; A. B. Murphy, A. J. D. Farmer, E. C. Horrigan, and T. McAllister, Plasma destruction of ozone depleting substances, *Plasma Chem. Plasma Process.* **22** (2002) 371-385.

[13] Since different ODS have different ODP, consideration should be given to taking into account the ODP of each type of ODS present in the stack gas in calculating the DRE. An appropriate definition that takes into account the differences in ODP is: *DRE of an ODS is determined by subtracting from the number of moles of the ODS fed into a destruction system during a specific period of time, the total number of moles of all types of ODS that are released in stack gases, weighted by their ODP relative to that of the feed ODS, and expressing that difference as a percentage of the number of moles of the ODS fed into the system.*

[14] There are 75 chlorinated dibenzo-p-dioxins and 135 chlorinated dibenzofurans that share a similar chemical structure but that have a wide range in degree of chlorination and a corresponding wide range in toxicity. Of these, one specific dioxin [2,3,7,8- Tetrachlorodibenzo-p-dioxin, or (TCDD)] is the most toxic and best characterized of this family of compounds. Since PCDDs and PCDFs are generally released to the environment as mixtures of these compounds, the scientific community has developed a system of toxic equivalency factors (TEFs) which relate the biological potency of compounds in the dioxin/furan family to the reference TCDD compound. The concentration of each specific compound is multiplied by its corresponding TEF value, and the resulting potency-weighted concentration values are summed to form an expression of the mixture's overall toxic equivalence (TEQ). The result of this exercise is a standardized expression of toxicity of a given mixture in terms of an equivalent amount of TCDD (the reference compound). The internationally accepted protocol for determining TEQ – *i.e.,* ITEQ – was established by NATO in 1988. [*Scientific Basis for the Development of International Toxicity Equivalency Factor (I-TEF), Method of Risk Assessment for Risk Assessment of Complex Mixtures of Dioxins and Related Compounds*. North Atlantic Treaty Organization/Committee on the Challenge of Modern Society. Report No. 176, Washington, D.C. 1988.]

the toxicity for all the members of the families of these toxic compounds that are determined to be present.

The task force members note that the World Health Organization has developed a new system for calculating TEQs, however, most of the existing data on emissions is expressed in the former ITEQ system established in 1988.

For purposes of screening destruction technologies, the maximum concentration of dioxins and furans in the stack gas from destruction technologies is:

- 0.5 ng-ITEQ/Nm^3 for foams; and,
- 0.2 ng-ITEQ/Nm^3 for concentrated sources.

These criteria were determined to represent a reasonable compromise between more stringent standards already in place in some industrialized countries [for example, the Canada-Wide Standard of 0.08 ng/m^3 (ITEQ)], and the situation in developing countries where standards may be less stringent or non-existent. Although a previous standard of 1.0 ng/m^3 (ITEQ) had been suggested in the UNEP 1992 report, advances in technology in recent years, and the level of concern for emissions of these highly toxic substances justified a significantly more stringent level.

Emissions of Acid Gases, Particulate Matter and Carbon Monoxide

Acid gases are generally formed when ODS are destroyed and these must be removed from the stack gases before the gases are released to the atmosphere. The following criteria for acid gases have been set for purposes of screening destruction technologies:

- A maximum concentration in stack gases of 100 mg/Nm^3 HCl/Cl_2
- A maximum concentration in stack gases of 5 mg/Nm^3 HF; and,
- A maximum concentration in stack gases of 5 mg/Nm^3 HBr/Br_2.

Particulate matter is generally emitted in the stack gases of incinerators for a variety of reasons and can also be emitted in the stack gases of facilities using non-incineration technologies. For the purposes of screening technologies, the criterion for particulate matter is established as:

- A maximum concentration of total suspended particulate (TSP) of 50 mg/Nm^3.

Carbon monoxide (CO) is generally released from incinerators resulting from incomplete combustion and may be released from some ODS destruction facilities because it is one form by which the carbon content of the ODS can exit the process. Carbon monoxide is a good measure of how well the destruction process is being controlled. For the purposes of screening technologies, the following criterion has been established:

- A maximum CO concentration in the stack gas of 100 mg/Nm^3.

These maximum concentrations apply to both foams and concentrated sources. They were set to be achievable by a variety of available technologies while ensuring adequate protection of human health and the environment.

Technical Capability

As well as meeting the above performance requirements it is necessary that the destruction technologies have been demonstrated to be technically capable at an appropriate scale of operation. In practical terms, this means that the technology should be demonstrated to achieve the required DRE while satisfying the emissions criteria established above. Demonstration of destruction of ODS is preferred but not necessarily required. Destruction of halogenated compounds that are refractory, *i.e.,* resistant to destruction, is acceptable. For example, demonstrated destruction of polychlorinated biphenyls (PCBs) was often accepted as an adequate surrogate for demonstrated ODS destruction.

For this evaluation, an ODS destruction technology is considered technically capable if it meets the following minimum criteria:

- It has been demonstrated to have destroyed ODS to the technical performance standards, on at least a pilot scale or demonstration scale (designated in Table 2-2 as “Yes”).
- *It has been demonstrated to have destroyed a refractory chlorinated* organic compound other than an ODS, to the technical performance standards, on at least a pilot scale or demonstration scale (designated in Table 2-2 as “P,” which indicates that the technology is considered to have a high potential for application with ODS, but has not actually been demonstrated with ODS).
- The processing capacity of an acceptable pilot plant or demonstration plant must be no less than 1.0 kg/hr of the substance to be destroyed, whether ODS or a suitable surrogate.

These criteria of technical capability will minimize the risk associated with technical performance and ensure that destruction of ODS will be performed in a predictable manner consistent with protecting the environment.

Adoption of Sustainable Agricultural Land Management

Table of Contents

Section I: Summary and applicability of the baseline and monitoring methodology

Acknowledgements: The BioCarbon Fund acknowledges the lead author of this methodology: Neil Bird. We are also grateful to external reviewers, Timm Tennigkeit, Matthias Seebauer, Giuliana Zanchi, and internal reviewers from the World Bank, Neeta Hooda and Rama Chandra Reddy that contributed to the development of this methodology.

I.1 Brief description

This methodology proposes to estimate and monitor greenhouse gas emissions of project activities that reduce emissions in agriculture through adoption of sustainable land management practices (SALM) in the agricultural landscape. In this methodology, SALM is defined as any practice that increases the carbon stocks on the land. Examples of SALM are (but are not limited to) manure management, use of cover corps, and returning composted crop residuals to the field and the introduction of trees into the landscape. The methodology is applicable to areas where the soil organic carbon would remain constant or decrease in the absence of the project.

The methodology in its current form is applicable only for use of Roth-C model. The estimates of uncertainty and Activity Baseline and Monitoring Survey (ABMS[a]) in the current methodology are adapted for the Roth-C model only. Application of the methodology for use of other models will require at a minimum, revisions to estimates of uncertainty and ABMS specific to the model applied. If however, the parameters used by another model correspond to some or all parameters included in this methodology, then the methodology is applicable, provided applicability conditions of the methodology are met.

This methodology is based on the project "Western Kenya Smallholder Agriculture Carbon Finance project" in Kenya. The baseline study, monitoring and project document are being prepared by the Foundation Vi Planterar trad ("We plant trees") with assistance from Unique Forestry Consultants ltd., the Swedish International Agency (Sida) and the International Bank for Reconstruction and Development as Trustee of the Biocarbon Fund.

I.2 Applicability conditions

This methodology is applicable to projects that introduce sustainable agriculture land management practices (SALM) into an agricultural landscape subject to the following conditions:

a) Land is either cropland or grassland at the start of the project;
b) The project does not occur on wetlands;
c) The land is degraded and will continue to be degraded or continue to degrade;
d) The area of land under cultivation in the region is constant or increasing in absence of the project;
e) Forest land, as defined by the national CDM forest definition, in the region is constant or decreasing over time;
f) There must be studies (for example: scientific journals, university theses, local research studies or work carried out by the project proponent) that demonstrate that the use of the Roth-C model[1] is appropriate for: (a) the IPCC climatic regions of 2006 IPCC AFOLU

[1] For ROTH-C see http://www.rothamsted.bbsrc.ac.uk/aen/carbon/rothc.htm.

Guidelines[b,] or (b) the agroecological zone (AEZ) in which the project is situated, using one of options presented below:[2]

Option 1: The studies used in support of the project should meet the guidance on model applicability as outlined in IPCC AFOLU 2006 guidelines in order to show that the model is applicable for the relevant IPCC climatic region. The guidance notes that an appropriate model should be capable of representing the relevant management practices and that the model inputs (i.e., driving variables) are validated from country or region-specific locations that are representatives of the variability of climate, soil and management systems in the country.

Option 2: Where available, the use of national, regional or global[3] level agroecological zone (AEZ) classification is appropriate to show that the model has been validated for similar AEZs. It is recognized that national level AEZ classifications are not readily available; therefore this methodology allows the use of the global and regional AEZ classification[4].

Where a project area consists of multiple sites, it is recognized that studies demonstrating model validity using either Option 1 or Option 2 may not be available for each of the sites in the project area. In such cases the study used should be capable of demonstrating that the following two conditions are met:

(i) The model is validated for at least 50% of the total project area where the project area covers up to 50,000 ha[5]; or at least 75% of the total project area where project area covers greater than 50,000 ha; and

(ii) The area for which the model is validated generates at least two-thirds of the total project emission reductions.

Explanation / justification

Applicability conditions (a) - (d) allow for the simplification of the baseline. With these conditions we conservatively assume that the lands of a given land use type are degrading in absence of the project.

Specifically it is likely that:

a) if the land is cropland, then it will remain cropland in absence of the project; otherwise
b) the land is grasslands that will remain grassland or be converted to croplands in absence of the project.

[2] The IPCC climatic regions are shown in Figure 3A.5.1 page 3.38.
[3] The agro-ecological zone (AEZ) methodology is standardized framework for the characterization of climate, soil and terrain conditions relevant to agricultural production. Crop modelling and environmental matching procedures are used to identify crop-specific limitations of prevailing climate, soil and terrain resources, under assumed levels of inputs and management conditions.
[4] The details of global agroecological zones classification outlined by Food and Agricultural Organization of United Nations (FAO), Rome, Italy and International Institute for Applied Systems Analysis, Laxenburg, Austria are available at: http://www.iiasa.ac.at/Research/LUC/GAEZ/index.htm
[5] The project area of 50,000 ha is reasonable taking into account the wide range of soil carbon sequestration rates, which depend on climate, soil and land use characteristics. The project area is also influenced by the rates of SALM adoption that are in turn influenced by factors such as farmer awareness to SALM, institutional support and extension systems. Assuming a conservative soil sequestration rate of 0.5 tC/ ha/ yr applied in CDM A/R methodologies, a project of 50, 000 ha is likely to generate 25,000 tC/ ha/yr, and is considered reasonable taking into account the implementation, monitoring and verification costs.

Degradation shall be demonstrated using the latest version of the CDM EB approved tool *Tool for the identification of degraded or degrading lands for consideration in implementing CDM A/R project activities*.[c]

Applicability condition (e) ensures that, in absence of the project, the land would likely not have been:

a) abandoned and allowed to naturally regenerate to forest, or
b) afforested or reforested.

With these applicability conditions we can conservatively assume that the soil organic carbon would remain constant or decrease with time in absence of the project.

Finally, the methodology relies on modelled soil organic carbon. To assure that the model results are reasonable, there must be studies (for example; scientific journals, university theses, local research studies or work carried out by the project proponent) that demonstrate the use of the selected model is valid for the project region. This is fulfilled with applicability condition (f) in accordance with the VCS guidance included in Section 2.3 of the VCS Standard Version 3.1 on quantification of GHG emissions and/or removals related to the methodology.

I.3 Selected carbon pools and emission sources

Table 1: Selected carbon pools

Carbon pools	Selected (answer with Yes or No)	Explanation / justification
Above ground	Yes	A carbon pool covered by SALM practices. The increase in above ground biomass of woody perennials planted as part of the SALM practices is part of the methodology. The increase in above ground biomass of annual crops is not considered since in the IPCC accounting system, annual crops are ignored. The above ground biomass is calculated using the CDM A/R Tool *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities*[d] and *Simplified baseline and monitoring methodologies for small-scale afforestation and reforestation project activities under the clean development mechanism implemented on grasslands or croplands* AR-AMS0001[e]
Below ground	Yes	Below-ground biomass stock is expected to increase due to the implementation of the SALM activities. The increase in below ground biomass of woody perennials planted as part of the SALM practices is part of the methodology. The increase in below ground biomass of annual crops is not considered since in the IPCC accounting system, annual crops are ignored. The below ground biomass is calculated using the CDM A/R Tool *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities*[d] and *Simplified baseline and monitoring methodologies for small-scale afforestation and reforestation project activities under the clean development mechanism implemented on*

		grasslands or croplands AR-AMS0001[e]
Dead wood	No	None of the applicable SALM practices decrease dead wood. It can be conservatively ignored.
Litter	No	None of the applicable SALM practices decrease the amount of litter. It can be conservatively ignored.
Soil organic carbon	Yes	A major carbon pool covered by SALM practices.
Wood products	No	None of the applicable SALM practices decrease the amount of wood products. It can be conservatively ignored.

Table 2: Emissions sources included in or excluded from the project boundary

Sources	Gas	Included/ excluded	Explanation / justification
Use of fertilizers	CO_2	Excluded	Not applicable
	CH_4	Excluded	Not applicable
	N_2O	Included	Main gas for this source. These are calculated using the CDM A/R Tool *Estimation of direct nitrous oxide emission from nitrogen fertilization (version 01)*[f]
Use of N-fixing species	CO_2	Excluded	Not applicable
	CH_4	Excluded	Not applicable
	N_2O	Included	Main gas for this source. These are calculated using the tool *Estimation of direct nitrous oxide emission from N-fixing species and crop residues* (Section VI.1)
Burning of biomass	CO_2	Excluded	However, carbon stock decreases due to burning are accounted as a carbon stock change
	CH_4	Included	Non-CO_2 emissions from the burning of biomass. These are calculated using the tool *Estimation of non-CO2 emissions from the burning of crop residues* (Section VI.3)
	N_2O	Included	Non-CO_2 emissions from the burning of biomass. These are calculated using *Estimation of non-CO2 emissions from the burning of crop residues* (Section VI.3)
Burning of fossil fuels	CO_2	Included	CO_2 and non-CO_2 emissions are calculated using the tool *Estimation of emissions from the use of fossil fuels in agricultural management*
	CH_4	Included	
	N_2O	Included	

I.4 Summary description of major baseline and project methodological steps

I.4.1 Baseline methodology

The baseline emissions and removals are estimated using the following steps:

1. Identify and delineate the project boundary;

2. Identify the baseline scenario and demonstrate additionality;
3. Estimate the annual emissions from the use of synthetic fertilizers;
4. Estimate the annual emissions from the use of N-fixing species;
5. Estimate the annual emissions from the burning of agricultural residues;
6. Estimate the annual removals from existing woody perennials;
7. Estimate the annual emissions from the use of fossil fuels for agricultural management; and
8. Estimate the equilibrium soil organic carbon in the baseline assuming no changes in agricultural management or agricultural inputs.

I.4.2 Project methodology

The project emissions and removals are estimated using the following steps:

1. Estimate the annual emissions from the use of synthetic fertilizers;
2. Estimate the annual emissions from the use of N-fixing species;
3. Estimate the annual emissions from the burning of agricultural residues;
4. Estimate the annual emissions and removals from woody perennials;
5. Estimate the annual emissions from the use of fossil fuels for agricultural management;

Using the model estimate the parameters in 6, 7 and 8 below:

6. Estimate the equilibrium soil organic carbon in the project based on estimated or measured changes in agricultural management or agricultural inputs;
7. Convert the equilibrium soil organic carbon in the project to transient soil organic carbon assuming a linear transition period;
8. Estimate the annual emissions and removals from soil organic carbon; and
9. Estimate leakage from the increase in the use of non-renewable biomass that occurs from the displacement of biomass used for energy to agricultural inputs.

I.4.3 Monitoring methodology

The following steps are required as part of the monitoring methodology:

1. Record the amount of fossil fuels used in the project;
2. Record the amount of synthetic fertilizers used in the project;
3. Estimate the amount of production of biomass by N-fixing species in the project;
4. Estimate the amount of agricultural residues burnt in the project;
5. Record the production from areas of various types of agricultural land management;
6. Measure the changes in biomass in woody perennials;
7. Estimate the reduction in the amount of biomass used for energy that is a result of the project.

The summary description of major baseline and project methodological steps noted above has been elaborated in the sections II, III and IV of the methodology.

Section II: Baseline methodology description

II.1 Project boundary

The "project boundary" geographically delineates all lands that are under the control of the project proponent for the proposed sustainable agricultural land management (SALM) activities[6].

The SALM project activities may contain more than one discrete area of land.

II.2 Procedure for selection of most plausible baseline scenario

The baseline scenario is identified as existing or historical land management practices. The project proponent shall use the most recent version of the *Combined tool to identify the baseline scenario and demonstrate the additionality in A/R CDM project activities*[g], *mutatis mutandis*.

II.3 Additionality

The project proponent shall use the most recent version of the *Combined tool to identify the baseline scenario and demonstrate the additionality in A/R CDM project activities, mutatis mutandis*.

II.4 Estimation of baseline GHG emissions and removals

II.4.1 Baseline emissions due to fertilizer use

The baseline emissions from synthetic fertilizer use, BEF_t, are calculated using the latest version of the CDM A/R Tool *Estimation of direct nitrous oxide emission from nitrogen fertilization*[f].

Emissions from manure application are not expected to change with the project, as the project activity does not result in a change in animal population. For this reason the baseline emissions from manure application can be ignored.

II.4.2 Baseline emissions due to the use of N-fixing species

The baseline emissions from the use of N-fixing species, BEN_t, are not calculated, but the project proponent shall record the area under N-fixing species prior to project implementation.

II.4.3 Baseline emissions due to burning of biomass

The baseline emissions due to burning of biomass, $BEBB_t$, are calculated using the tool *Estimation of non-CO2 emissions from the burning of crop residues* (Section VI.3).

II.4.4 Baseline removals from existing woody perennials

The baseline removals from woody perennials, $BRWP_t$, are calculated using the latest version of the CDM A/R Tool *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities*[d].

II.4.5 Baseline emissions from use of fossil fuels in agricultural management

The baseline emissions due to combustion of fossil fuels in agricultural management in baseline, $BEFF_t$, is calculated using the tool *Estimation of emissions from combustion the use of fossil fuels in agricultural management* (Section VI.2).

[6] In accordance with the VCS rules.

II.4.6 Equilibrium soil organic carbon density in management systems

Using an analytic model that has been accepted in scientific publications (for example: Roth-C soil organic carbon model[h]) estimate the soil organic carbon (SOC) density to a depth of 30 cm, at equilibrium in identified management practices on cropland and grassland. Soil carbon modelling should count only biomass inputs to soil from within the project boundary.

The SOC density should be estimated using area-weighted average values of model input parameters for each management practice identified in Step 4 under uncertainty analysis.

The baseline soil organic carbon at equilibrium can be estimated using:

$$BS_{equil,t} = \sum_{m_C} BA_{C,m_C,t} \bullet SOC_{C,m_C} + \sum_{m_G} BA_{G,m_G,t} \bullet SOC_{G,m_G} \qquad 1$$

Where:

$BS_{equil,t}$	Baseline SOC in equilibrium year t, tC
$BA_{C,m_C,t}$	Baseline areas in cropland with management practice, m_C, year t, ha
SOC_{C,m_C}	Soil organic carbon density at equilibrium for cropland with management practice, m_C, tC/ha
m_C	An index for cropland management types, unit less
$BA_{G,m_G,t}$	Baseline areas in grassland with management practice, m_G, year t, ha
SOC_{G,m_G}	Soil organic carbon density to a depth of 30 cm, at equilibrium for grassland with management practice, m_G, tC/ha
m_G	An index for grassland management types, unit less

II.4.7 Baseline removals due to changes in soil organic carbon

Since the applicability conditions limit the project to lands that are under agricultural pressure and are degrading, it can be conservatively assumed that the baseline removals due to changes in SOC are zero. Therefore

$$BRS_t = 0 \qquad 2$$

Where:

BRS_t	Baseline removals due to changes in soil organic carbon in year t, t CO_2e.

II.4.8 Total baseline emissions and removals

The total baseline emissions and removals are given by:

$$BE_t = BEF_t + BEFF_t + BEBB_t - BRWP_t \qquad 3$$

Where:

BE_t	Baseline emissions in year t, t CO_2e
BEF_t	Baseline emissions due to nitrogen fertilizer use in year t, t CO_2e.

$BEFF_t$	Baseline emissions due to use of fossil fuels in agricultural management in year t, t CO_2e.
$BEBB_t$	Baseline emissions due to biomass burning in year t, t CO_2e.
$BRWP_t$	Baseline removals due to changes in woody perennials in year t, t CO_2e.

Section III: Project methodology description

III.1 Estimation of project GHG emissions and removals

Where the sum of increase in greenhouse gas emissions from each of the identified emission sources in the methodology and leakage due to displacement of renewable biomass is insignificant these can be ignored[7].

III.1.1 Project emissions due to fertilizer use

The project emissions from synthetic fertilizer use, PEF_t, are calculated using the latest version of the CDM A/R Tool *Estimation of direct nitrous oxide emission from nitrogen fertilization (version 01)*[f.]

Emissions from manure application are not expected to change with the project, as the project activity does not result in a change in the animal population. For this reason the project emissions from manure application can be ignored.

III.1.2 Project emissions due to the use of N-fixing species

Only the emissions due to increased area under N-fixing species shall be accounted.

If the area cropped with N-fixing species in the project is more than 50% larger than the area under N-fixing species in the baseline then the project emissions from the use of N-fixing species, PEN_t, are calculated using the tool *Estimation of direct nitrous oxide emission from N-fixing species and crop residues* (Section VI.1).

In all other cases estimation of emissions from N-fixing species is not required.

This differentiation is based on the assumption that:

a) the project does not occur on wetlands;

b) the project occurs on degraded lands so that the lands are likely nitrogen deficient.

These assumptions mean that the nitrogen emissions tend to be smaller than estimated by the Tier 1 IPCC estimation methodology.

III.1.3 Project emissions due to burning of biomass

The project emissions due to burning of biomass, $PEBB_t$, are calculated using the tool *Estimation of non-CO2 emissions from the burning of crop residues* (Section VI.3).

[7] Significance is defined so that the sum of increase in greenhouse gas emissions from the displacement of renewable biomass and each of emission sources identified in the methodology is less than 5% of the emission reductions by the project. The significance of the emission will be tested using the latest version of the CDM EB approved *Tool for testing significance of GHG emissions in A/R CDM project activities* (http://cdm.unfccc.int/methodologies/ARmethodologies/tools/ar-am-tool-04-v1.pdf

III.1.4 Project removals from woody perennials

The project removals from woody perennials, $PRWP_t$, are calculated using portions of CDM A/R *Simplified baseline and monitoring methodologies for small-scale afforestation and reforestation project activities under the clean development mechanism implemented on grasslands or croplands* AR-AMS0001e.

III.1.5 Project emissions due to use of fossil fuels for agricultural management

The project emissions due to the use of fossil fuels for agricultural management, $PEFF_t$, are calculated using the tool *Estimation of emissions from the use of fossil fuels in agricultural management* (Section VI.2)

III.1.6 Project equilibrium soil organic carbon density in management systems

Undertake an Activity Baseline and Monitoring Survey (ABMS) to identify the dominant agricultural management practices for croplands and grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record;

1. its area;
2. the average annual biomass production from within the project boundary;
3. the average biomass left on site or input;
4. the average number and type of grazing animals;
5. the amount of manure input; and
6. the amount of nitrogen fertilizers input.

Using an analytic model that has been accepted in scientific publications and validated for the project region (for example: Roth-C soil organic carbon model[i]) estimate the soil organic carbon (SOC) density, to a depth of 30 cm, at equilibrium in each of the identified management practices in each of the land use categories (cropland and grassland). The soil carbon modelling should count only biomass inputs to soil from within the project boundary.

The details of each management practice that are recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)[8]
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should also record:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)[9]
- Existing manure management practices and their frequency

[8] Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines
[9] Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.

- Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record:

- Area under tillage (ha)
- Type and depth of tillage
- Existing tilling practices and their frequency
- Future tilling practices that will be implemented with the project

If the project activity includes agroforestry, then, for use with the Roth-C model, the ABMS should record:

- Area of agroforestry (ha)
- Number and species of trees used
- Diameter at breast height (DBH) of trees
- Future numbers of trees that will be implemented with the project

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

The SOC density should be estimated using area-weighted average values of model input parameters for each management practice identified.

The project soil organic carbon at equilibrium can be estimated using:

$$PS_{equil,t} = \sum_{m_C} PA_{C,m_C,t} \bullet SOC_{C,m_C,t} + \sum_{m_G} PA_{G,m_G,t} \bullet SOC_{G,m_G,t} \quad (4)$$

Where:

$PS_{equil,t}$	Project SOC in equilibrium year t, tC
$PA_{C,m_C,t}$	Project areas in cropland with management practice, m_C, year t, ha
$SOC_{C,m_C,t}$	Soil organic carbon density at equilibrium for cropland, to a depth of 30 cm, with management practice, m_C, at year t, tC/ha
m_C	An index for cropland management types, unit less
$PA_{G,m_G,t}$	Project areas in grassland with management practice, m_G, year t, ha
$SOC_{G,m_G,t}$	Soil organic carbon density at equilibrium, to a depth of 30 cm, for grassland with management practice, m_G, at year t, tC/ha
m_G	An index for grassland management types, unit less

III.1.7 Project estimate of soil organic carbon with transitions

The estimate of soil organic carbon with transitions can be estimated using:

$$PS_t = \frac{1}{D} \sum_{t-D+1}^{t} PS_{equil,t} \bullet \Delta t \quad (5)$$

Where:

PS_t	Estimate of the project SOC in year t, tC
$PS_{equil,t}$	Estimate of the project SOC in equilibrium year t, tC
D	The transition period required for SOC to be at equilibrium after a change in land use or management practice, year
Δt	Time increment = 1 year

For values of t-D+1 less than zero (the start of the project) assume that $PS_{equil,t} = BS_{equil,t=0}$.

These values are required if one is trying to estimate the absolute soil organic carbon in the baseline. Since the ultimate goal of the methodology is the increase or decrease in SOC with the project these values are not required since they appear in both the baseline and project estimation technique.

Value of D may be chosen from published data from local or regional studies or the modelling exercise. In absence of such data, the IPCC Tier 1 methodology default factor of 20 years may also be used.

III.1.8 Estimate of project removals due to changes in soil organic carbon

The estimate of project removals due to changes in soil organic carbon is given by:

$$PRS_t = \left(PS_t - PS_{t-1}\right) \bullet \frac{44}{12} \quad 6$$

Where:

PRS_t	Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.
PS_t	Estimate of the project SOC in year t, tC
PS_{t-1}	Estimate of the project SOC in year t-1, tC

III.1.9 Actual net GHG emissions and removals by sinks

The actual net GHG emissions and removals by sinks are given by:

$$PE_t = PEF_t + PEFF_t + PEN_t + PEBB_t - PRWP_t - PRS_t \quad 7$$

Where:

PE_t	Estimate of actual net project GHG emissions and removals by sinks in year t, t CO_2e
PEF_t	Estimate of project emissions due to nitrogen fertilizer use in year t, t CO_2e.
$PEFF_t$	Estimate of project emissions due to burning of fossil fuels for agricultural management in year t, t CO_2e.
PEN_t	Estimate of project emissions due to the increase use of N-fixing species in year t, t CO_2e.
$PEBB_t$	Estimate of project emissions due to biomass burning in year t, t CO_2e.
$PRWP_t$	Estimate of project removals due to changes in biomass of woody perennials in year t, t CO_2e.

PRS_t Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.

III.2 Estimation of leakage

The one potential source of leakage is an increase in the use of fuel wood and/or fossil fuels from non-renewable sources for cooking and heating purposes due to the decrease in the use of manure and/or residuals as an energy source.

Leakage due to the increase in the use of fuel wood from non-renewable sources for cooking and heating purposes may be a significant source of leakage if manure or other agricultural residuals used for cooking and heating are transferred to the fields as part of the project. In the project, this could be minimized by the introduction of woody perennials for fuel in the landscape and/or improvement of energy efficiency of biomass for cooking and heating. In situations of this form of leakage, the leakage from a switch to non-renewable biomass use, $LNRB_t$, is calculated in accordance with Section IV.2.6 (which is adapted from the small scale methodology AMS-I.E. *Switch from Non-Renewable Biomass for Thermal Applications by the User* [j]*.)*

However, where this is significant, leakage due to switch to fossil fuels (LFF_t) shall be estimated in accordance with Equation 11 in Section IV.2.6.

Table 3: Emissions sources included in or excluded from leakage

Sources	**Gas**	**Included/ excluded**	**Justification / Explanation of choice**
Soil organic carbon stock changes	CO_2	Excluded	Applicability condition
	CH_4	Excluded	Not applicable
	N_2O	Excluded	Not applicable
Increase fossil fuel for cooking	CO_2	Included	
	CH_4	Excluded	Not applicable
	N_2O	Excluded	Not applicable
Increase non-renewable biomass for cooking	CO_2	Included	
	CH_4	Excluded	Not applicable
	N_2O	Excluded	Not applicable

III.3 Estimation of net anthropogenic GHG emissions and removals

The estimation of net anthropogenic GHG removal by sinks is made using:

$$\Delta R_t = BE_t - PE_t - LHE_t \qquad 8$$

Where:

ΔR_t Estimate of net anthropogenic GHG emissions and removals in year t, t CO_2e

PE_t Estimate of actual net project GHG emissions and removals in year t, t CO_2e

BE_t Baseline emissions and removals in year t, t CO_2e

LHE_t The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year t, t CO_2e

Section IV: Monitoring methodology description

IV.1 Baseline GHG emissions and removals

IV.1.1 Sampling design

The project proponent shall use the CDM EB approved *General Guidelines For Sampling And Surveys For Small-Scale CDM Project Activities*[k] for sampling and survey design. At the start of the project, the project proponent shall undertake an Activity Baseline and Monitoring Survey (ABMS) to identify the dominant agricultural management practices for croplands and grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record;

1. its area;
2. the annual biomass production from within the project boundary;
3. the annual biomass left on the fields;
4. the number and type of grazing animals;
5. the amount of manure input;
6. the amount of nitrogen fertilizers input;
7. the amount of N-fixing species;
8. the amount of biomass burnt; and
9. the existence and amount of woody perennials (trees and bushes).

The information recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the project activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record in the baseline:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)[10]
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should record in the baseline:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)[11]

[10] Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines.
[11] Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.

- Existing manure management practices and their frequency
- Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record in the baseline:

- Area under tillage (ha)
- Type and depth of tillage
- Existing tilling practices and their frequency
- Future tilling practices that will be implemented with the project

If the project activity includes agroforestry, then for use with the Roth-C model, the ABMS should record in the baseline:

- Area of agroforestry (ha)
- Number and species of trees used
- Diameter at breast height (DBH) of trees
- Future numbers of trees that will be implemented with the project

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

Other model input parameters that may be required by the selected model, such as climatic data, clay content and texture of soils[l] can be acquired from global or national data sets and do not need to be measured by the project proponent. The project proponent may use climatic data collected by the meteorological station/s in proximity to the project area or use published data and determine the relevance of this data to the project in the following ways:

- The data being applied to the project has been obtained from one or more meteorological station/s whose meteorological coverage includes the project area.
- The data being applied to the project has been obtained from one or more meteorological station/s whose meteorological coverage can be shown to be applicable to the project area based on expert opinion.
- Where data from a meteorological station/s is not available, project entities may use published climatic data by demonstrating that such data is applicable to the project area, using expert opinion.

It is recommended that the project proponent stratifies by crop system, tillage system, use of crop residues, application of manure and clay content of soils and relevant climatic variables as a minimum.

IV.1.2 Data to be collected and archived for baseline GHG emissions and removals

Section	Data / Parameter	Unit	Description	Recording frequency	Source
II.4.1	$BSN_{t=0}$	kg	Synthetic fertilizer use	Project start	ABMS
II.4.2	$Crop_{i,t=0}$	kg d.m./ha	Harvested annual dry matter yield for crop *i*	Project start	ABMS
II.4.2	$Area_{i,t=0}$	ha	total annual area harvested of crop *i* or N-fixing trees *i*	Project start	ABMS
II.4.2	$Areaburnt_{i,t=0}$	ha	annual area of crop *i* or N-fixing trees *i* burnt	Project start	ABMS

II.4.3	$MB_{C,t=0}$	t d.m.	Mass of crop residues burnt	Project start	ABMS
II.4.3	$MB_{G,t=0}$	t d.m.	Mass of grasslands residues burnt	Project start	ABMS
II.4.3	C_F	unitless	Combustion factors that depend on vegetation type	Project start	National or regional studies
II.4.4	See A/R Methodological Tool *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities* [d] for a complete list of data and parameters collected and archived.				
II.4.5	$FC_{j,t}$	Litres	Fossil fuel consumed in vehicle or equipment recorded by vehicle and fuel type	Project start	ABMS
II.4.6	$BA_{C,m_C,t=0}$	ha	Baseline areas in cropland with management practice, m_C	Project start	ABMS
II.4.6	$SOC_{C,m_C,t=0}$	tC/ha	Soil organic carbon density, to a depth of 30 cm, at equilibrium for cropland with management practice, m_C	Project start	Modelled
II.4.6	$BP_{C,m_C,t=0}$	t/ha/month	Baseline production in cropland per month with management practice from within the project , m_C	Project start	ABMS
II.4.6	$BR_{C,m_C,t=0}$	t/t prod/ month	Baseline fraction of production returned as residues per month (calculated from $BP_{C,m_C,t=0}$) in cropland with management practice, m_C	Project start	ABMS
II.4.6	$BM_{C,m_C,t=0}$	t/ha/month	Baseline manure input in cropland per month with management practice, m_C	Project start	ABMS
II.4.6	$BCC_{C,m_C,t=0}$		Baseline cover crop flag per month in cropland per month with management practice, m_C	Project start	ABMS
II.4.6	$BA_{G,m_G,t=0}$	ha	Baseline areas in grassland with management practice, m_G,	Project start	ABMS
II.4.6	$SOC_{G,m_G,t=0}$	tC/ha	Soil organic carbon density, to a depth of 30 cm, at equilibrium for grassland with management practice, m_G	Project start	Modelled

II.4.6	$BP_{G,m_G,t=0}$	t/ha/month	Baseline production in grassland per month with management practice from within the project, m_G	Project start	ABMS
II.4.6	$BR_{G,m_G,t=0}$	t/t prod/ month	Baseline fraction of production returned as residuals per month (calculated from $BP_{G,m_G,t=0}$) in grassland with management practice, m_G	Project start	ABMS
II.4.6	$BM_{G,m_G,t=0}$	t/ha/month	Baseline manure input in grassland per month with management practice, m_G	Project start	ABMS
II.4.6	$BCC_{G,m_G,t=0}$		Baseline cover crop flag per month in grassland per month with management practice, m_G	Project start	ABMS
II.4.6	$\overline{Temp}_m$	°C	Average temperature per month	Project start	Data relevant to the project* area
II.4.6	$\overline{Prec}_m$	mm	Average precipitation per month	Project start	Data relevant to the project*area
II.4.6	$\overline{Evap}_m$	mm/day	Average evapotranspiration per month	Project start	Data relevant to the project area*

*IV.2 *Ex-ante and ex-post net anthropogenic GHG emissions and removals*

IV.2.1 Data to be collected and archived for *ex-ante* project GHG emissions and removals

Record all assumptions and sources of assumptions.

IV.2.2 Data to be collected and archived for *ex-ante* leakage

The only source of leakage possible as a result of the project is the leakage from a switch to non-renewable biomass use or fossil fuels. Procedures to estimate leakage have been included ex-post; the ex-ante estimate of leakage is zero.

IV.2.3 Monitoring of project implementation

The project proponent should record when each farmer within the project area enters into agreement to adopt sustainable agricultural land management practices.

Each farmer should be given a unique ID. Their name, location of their lands, and date of entering into the agreement and leaving the agreement should be recorded.

IV.2.4 Sampling design

The project proponent shall use the CDM EB approved *General Guidelines For Sampling And Surveys For Small-Scale CDM Project Activities*[m] for sampling and survey design. They should undertake an Activity Baseline and Monitoring Survey (ABMS) on a regular basis (annually or bi-annually) to identify the actual agricultural management practices adopted on croplands and grasslands. The ABMS should estimate or record details of each management practice. For example when using the Roth-C model, one should record;

1. its area;
2. the annual biomass production;
3. the annual biomass left on the fields;
4. the number and type of grazing animals;
5. the amount of manure input;
6. the amount of nitrogen fertilizers input;
7. the amount of N-fixing species;
8. the amount of biomass burnt; and
9. the biomass of woody perennials (trees and bushes).

The following parameters need to be recorded annually.

1. Regional total biomass production;
2. Annual temperature, precipitation and evapotranspiration and
3. Fertilizer price.
4. The amount of fossil fuel used for agricultural management

The information recorded will depend on the choice of soil model selected and the type of activity being promoted. For example, if the activity is improving the use of crop residues then for use with the Roth-C model, the ABMS should record:

- Area of each crop (ha)
- Productivity of each crop (kg/ha)
- The amount of crop residues (kg/ha)[12]
- Existing crop residue management practices and their frequency
- Future crop residue management practices that will be implemented with the project

If the project activity includes improving the management of manure, then for use with the Roth-C model, the ABMS should record:

- Area of grazing (ha)
- The number of livestock per animal type
- The amount of manure produced (kg/ha or kg/an)[13]
- Existing manure management practices and their frequency
- Future manure management practices that will be implemented with the project

If the project activity includes improved tillage practices, then for use with the Roth-C model, the ABMS should record:

- Area under tillage (ha)
- Type and depth of tillage
- Existing tilling practices and their frequency
- Future tilling practices that will be implemented with the project

[12] Amount of crop residues need not be measured directly. It can also be estimated from the crop production using equations listed in Table 11.2 in Volume 4 of the 2006 IPCC Guidelines.
[13] Amount of manure need not be measured directly. It can also be estimated from the number and type of animal using values from Table 10A-4 in Chapter 10 of the 2006 IPCC Guidelines.

If the project activity includes agroforestry, then for use with the Roth-C model, the ABMS should record:

- Area of agroforestry (ha)
- Number and species of trees used
- Diameter at breast height (DBH) of trees
- Future numbers of trees that will be implemented with the project

It is recommended that the project proponent stratifies the project area by crop system, tillage system, use of crop residues, application of manure and clay content of soils and relevant climatic variables as a minimum.

The applicability of the selected model and parameters recorded for the various activities, and soil and climate types are dependent on the actual project. Since these are project specific and not methodology specific, they should be discussed in detail in the project description.

Other model input parameters that may be required by the selected model, such as climatic data, clay content and texture of soils[1] can be acquired from global or national data sets and do not need to be measured by the project proponent.

IV.2.5 Data to be collected and archived for project GHG emissions and removals

Section	Data / Parameter	Unit	Description	Recording frequency	Source
III.1.1	PSN_t	kg/year	Synthetic fertilizer use per year	Annually	ABMS
III.1.1	$PA_{C,t}$	ha/year	Areas in cropland	Annually	ABMS
III.1.1	$PA_{G,t}$	ha/year	Areas in grassland	Annually	ABMS
III.1.1	PF_t	USD/kg	the price of inorganic fertilizer	Annually	National or regional studies
III.1.2	$Crop_{i,t}$	kg d.m./ha	Harvested annual dry matter yield for crop *i*	Annually	ABMS
III.1.2	$Area_{i,t}$	Ha/year	total annual area harvested of crop *i* or N-fixing trees *i*	Annually	ABMS
III.1.2	$Areaburnt_{i,t}$	Ha/year	annual area of crop *i* or N-fixing trees *i* burnt	Annually	ABMS
III.1.3	$MB_{C,t}$	t d.m./year	Mass of crop residues burnt	Annually	ABMS
III.1.3	$MB_{G,t}$	t d.m./year	Mass of grasslands residues burnt	Annually	ABMS
III.1.3	C_F	unitless	Combustion factors that depend on vegetation type	Project start	National or regional studies
III.1.4	See *Simplified baseline and monitoring methodologies for small-scale afforestation and reforestation project activities under the clean development mechanism implemented on grasslands or croplands* AR-AMS0001e for a complete list of data and parameters collected and archived.

III.1.6	$\overline{Evap}_m$	mm/day	Average evapotranspiration per month	Over the previous five years	Data relevant to the project area
III.1.6	D	Years	Transition period	Every five years	National or regional studies

IV.2.6 Data to be collected and archived for leakage

The only source of leakage possible as a result of the project is the leakage from a switch to non-renewable biomass use attributable to the project. If the project plan includes the diversion of biomass used for cooking and heating to the fields (for example, manure or agricultural residuals) then the project proponent should estimate the possible leakage.

The project proponent should record the amount of biomass used for cooking and heating purposes that is diverted to the agricultural system. It is conservatively assumed that this is replaced by non-renewable biomass or locally used fossil fuels.

The ABMS survey is expected to provide information to assess whether or not non-renewable biomass from outside the project or fossil fuels are used for the purpose of cooking or heating by the surveyed project households to replace the biomass diverted to agricultural fields. If the ABMS survey data shows that 10% or fewer project households use non-renewable biomass from outside the project or fossil fuels to replace the biomass diverted to agricultural fields, then the leakage is considered insignificant and ignored.

In situations where ABMS survey data shows that more than 10% of the project households use non-renewable biomass from outside the project or fossil fuels to replace the biomass diverted to agricultural fields, then the leakage is considered significant and shall be estimated based on the household energy use information collected through the ABMS Survey to calculate the leakage.

$$LHE_t = LNRB_t + LFF_t \qquad 9$$

Where:

LHE_t The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year t, t CO2e

$LNRB_t$ Leakage from a switch to non-renewable biomass use in year t, , t CO_2e

LFF_t Leakage from switch to fossil fuel in year t , t CO_2e

$$LNRB_t = B_{biomass,t} * fNRB * NCV_{biomass} * EF_{fossil\ fuel} \quad 10$$

$LNRB_t$ Leakage from a switch to non-renewable biomass use in year t, t CO_2e

$B_{biomass,t}$ Quantity of biomass from outside the project that replaces biomass used for cooking/heating diverted to agricultural system in year t, tonnes

$fNRB$ Fraction of non-renewable biomass from outside the project in year t

$NCV_{biomass}$ Net calorific value of the non-renewable biomass from outside the project

$EF_{fossil\ fuel}$ Emission factor of fossil fuel as substitute for non-renewable biomass

$$LFF_t = B_{fossil\ fuel\ t} * NCV_{fossil\ fuel} * EF_{fossil\ fuel} \quad 11$$

$B_{fossilfuel,\ t}$ Quantity of fossil fuel that replaces the biomass used for cooking/heating diverted to agricultural system in year t, tonnes

$NCV_{fossil\ fuel}$ Net calorific value of the fossil fuel that is substituted

$EF_{fossil\ fuel}$ Emission factor of fossil fuel as a substitution for non-renewable biomass

Section	Data / Parameter	Unit	Description	Recording frequency	Source
III.2	$B_{biomass,t}$ $B_{fossilfuel,\ t}$	tonnes/ year	Quantity of biomass from outside the project or fossil fuel used in place of the amount of biomass used in cooking and heating diverted to the agricultural system in the project	Annually	ABMS

III.2	$f_{NRB,t}$	dimension less	Fraction of biomass that comes from non-renewable sources	Start of the project	If the data on $f_{NRB,t}$ is available, it is calculated as per the procedure of AMS I.E methodology. For situations, where the data on $f_{NRB,t}$ is not available $fNRB_{,t}$ =1 shall be used (i.e., $fNRB_{,t}$ value is fixed at 1), which is conservative.
III.2	$NCV_{biomass}$/ $NCV_{fossil\ fuel}$	TJ/ tonne	Net calorific value of the non-renewable biomass or fossil fuel substituted	Start of the project	IPCC defaults, National or regional studies
III.2	$EF_{fossilfuel}$	tCO2/ TJ	Emission factor for the projected fossil fuel consumption	Start of the project	Default value of 81.6 tCO2/TJ I as per AMS I.E

IV.2.7 Conservative approach

Since emissions reduced are calculated as the baseline emissions minus project emissions, an approach that:

1) ignores emissions in the baseline; and/or
2) ignores emission removals (sequestration) in the project

is conservative. Ignoring either of these two items will mean that emission reductions are underestimated.

The methodology uses a conservative approach because applicability conditions limit its use to:

a) Land is either cropland or grassland at the start of the project
b) The project does not occur on wetlands
c) The land is degraded and will continue to be degraded or continue to degrade
d) The area of land under cultivation is constant or increasing in absence of the project
e) Forest land, as defined by the national CDM forest definition, in the area is constant or decreasing over time

With these assumptions the methodology conservatively ignores emissions from SOC in the baseline.

The methodology uses a conservative approach because it assumes that leakage caused by the displacement of biomass used for cooking and heating purposes to the fields as the result of the project, causes an increase in the use of non-renewable biomass or fossil fuels.

IV.2.8 Uncertainty analysis

The project proponent shall use the CDM EB approved *General Guidelines for Sampling and Surveys for Small-Scale CDM Project Activities*[o] with a view to reducing uncertainty of model input parameters. The generation of model parameters follows the standard procedures on surveys and quality assurance in the collection and organization of data.

The project proponent will estimate the uncertainty of the agricultural input parameters to the soil organic model using the ABMS as required under Section 4.1 of VCS standard v3.1.

If the project area is stratified, the sampling effort should represent the relevant strata in the sample frame. Where there is no specific survey guidance from national institutions, the project proponent shall use a precision of 15% at the 95% confidence level as the criteria for reliability of sampling efforts. This reliability specification shall be applied to determine the sampling requirements for assessing parameter values. The sampling intensity could be increased to ensure that the model parameters estimated from the ABMS lead to the achievement of a desired precision of 15% at the 95% confidence level) for the estimate of greenhouse gas emission reductions from the project. The project proponent should calculate the soil model response using the model input parameters with the upper and lower confidence levels. The range of model responses demonstrates the uncertainty of the soil modelling.

Step 1: Calculate the values for all input parameters at the upper and lower confidence limit.

Calculate the mean, X_p and standard deviation, ∂_p for all parameters measured in ABMS, and then the standard error in the mean is given by:

$$SE_p = \frac{\partial_p}{\sqrt{n_p}} \qquad 12$$

Where:

SE_p	Standard error in the mean of parameter, *p* in year *t*
∂_p	The standard deviation of the parameter p in year t
n_p	Number of samples used to calculate the mean and standard deviation of parameter p

Assuming that values of the parameter are normally distributed about the mean, the minimum and maximum values for the parameters are given by.

$$P_{\min} = \overline{X_p} - 1.96 * SE_p$$
$$P_{\max} = \overline{X}_p + 1.96 * SE_p \qquad 13$$

Where:

$P_{\min}$	The minimum value of the parameter at the 95% confidence interval
$P_{\max}$	The maximum value of the parameter at the 95% confidence interval
SE_p	Standard error in the mean of parameter, *p* in year *t*
1.96	The value of the cumulative normal distribution at 95% confidence interval

Step 2: Calculate the project removals due to changes in soil organic carbon with the minimum and maximum values of the input parameters

The project removals due to changes in soil organic carbon using the minimum and maximum values of the parameters is given by

$$PRS_{\min,t} = Model(P_{\min}, Temperature_{\max}, Precipitation_{\max}, ClayContent_{\min})$$
$$PRS_{\max,t} = Model(P_{\max}, Temperature_{\min}, Precipitation_{\min}, ClayContent_{\max}) \quad 14$$

Where:

$PRS_{\min,t}$	The minimum value of project removals due to changes in soil organic carbon at the 95% confidence interval
$PRS_{\max,t}$	The maximum value of project removals due to changes in soil organic carbon at the 95% confidence interval

Step 3: Calculate the uncertainty in the model output

The uncertainty in the output model is given by:

$$UNC_t = \frac{\left|PRS_{\max,t} - PRS_{\min,t}\right|}{2 * PRS_t} \quad 15$$

Step 4: Adjust the estimate of soil sequestration based on the uncertainty in the model output

If the uncertainty of soil models is less than or equal to 15% of the mean value then the project proponent may use the estimated value without any deduction for conservativeness or increase in sampling.

If the uncertainty of soil models is greater than 15% but less than or equal to 30% of the mean value, then the project proponent may use the estimated value subject to a deduction calculated as

$$PRS_{Deduction,t} = PRS_t * (UNC_t - 15\%) \quad 16$$

And the following term will be used in equation 7 in place of PRS_t

$$PRS_{Adj,t} = PRS_t - PRS_{Deduction,t} \quad 17$$

Where:

PRS_t	Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.
PRS_{Unc}	Estimate of uncertainty in the mean of changes in soil organic carbon in year t, t CO_2e.
$PRS_{Deduction,t}$	A calculated deduction to the estimate of the change in soil organic removals year t, t CO_2e.
$PRS_{Adj,t}$	An adjusted estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.

In this way, when the uncertainty is 15% or less than 15% there is no deduction and when the uncertainty is between 15 and 30% a deduction as calculated in Step 4 above will apply.

If the uncertainty of soil models is greater than 30% of the mean value then the project proponent should increase the sample size of the input parameters until the soil model uncertainty is better than ± 30%.

IV.2.9 Other information

Every five years the means of parameters will be tested for significant difference using t-tests. If the means are significantly different then the soil model shall be updated based on the new data and relevant data such as studies conducted in the region. It is not incumbent that the project proponent shall undertake such studies as part of the project activity but shall make use of data generated elsewhere as part of ongoing research/other efforts in the region for updating the model. Such data can be used to refine the model over time and decrease uncertainty.

Section V: Lists of variables, acronyms and references

V.1 Variables used in equations

Equation 1

$BS_{equil,t}$	Baseline SOC in equilibrium year t, tC
$BA_{C,m_C,t}$	Baseline areas in cropland with management practice, m_C, year t, ha
SOC_{C,m_C}	Soil organic carbon density at equilibrium for cropland with management practice, m_C, tC/ha
m_C	An index for cropland management types, unit less
$BA_{G,m_G,t}$	Baseline areas in grassland with management practice, m_G, year t, ha
SOC_{G,m_G}	Soil organic carbon density at equilibrium for grassland with management practice, m_G, tC/ha
m_G	An index for grassland management types, unit less

Equation 2

BRS_t	Baseline removals due to changes in soil organic carbon in year t, t CO_2e.

Equation 3

BE_t	Baseline emissions in year t, t CO_2e
BEF_t	Baseline emissions due to nitrogen fertilizer use in year t, t CO_2e.
$BEFF_t$	Baseline emissions due to use of fossil fuels in agricultural management in year t, t CO_2e.
BEN_t	Baseline emissions due to the use of N-fixing species in year t, t CO_2e.
$BEBB_t$	Baseline emissions due to biomass burning in year t, t CO_2e.
$BRWP_t$	Baseline removals due to changes in woody perennials in year t, t CO_2e.

Equation 4

$PS_{equil,t}$	Project SOC in equilibrium year t, tC
$PA_{C,m_C,t}$	Project areas in cropland with management practice, m_C, year t, ha
$SOC_{C,m_C,t}$	Soil organic carbon density at equilibrium for cropland with management practice, m_C, at year *t*, tC/ha
m_C	An index for cropland management types, unit less
$PA_{G,m_G,t}$	Project areas in grassland with management practice, m_G, year t, ha
$SOC_{G,m_G,t}$	Soil organic carbon density at equilibrium for grassland with management practice, m_G, at year *t*, tC/ha
m_G	An index for grassland management types, unit less

Equation 5

PS_t	Project estimate of the project SOC in year t, tC
$PS_{equil,t}$	Project estimate of the project SOC in equilibrium year t, tC
D	The transition period required for SOC to be at equilibrium after a change in land use or management practice, year
Δt	Time increment = 1 year

Equation 6

PRS_t	Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.
PS_t	Estimate of the project SOC in year t, tC

Equation 7

PE_t	Estimate of actual net GHG emissions and removals by sinks in year t, t CO_2e
PEF_t	Estimate of project emissions due to nitrogen fertilizer use in year t, t CO_2e.
$PEFF_t$	Estimate of project emissions due to burning of fossil fuels for agricultural management in year t, t CO_2e.
PEN_t	Estimate of project emissions due to the use of N-fixing species in year t, t CO_2e.
$PEBB_t$	Estimate of project emissions due to biomass burning in year t, t CO_2e.
$PRWP_t$	Estimate of project due to changes in biomass of woody perennials in year t, t CO_2e.
PRS_t	Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.

Equation 8

ΔR_t Estimate of net anthropogenic GHG emissions and removals in year t, t CO_2e

PE_t Estimate of actual net GHG emissions and removals in year t, t CO_2e

BE_t Baseline emissions and removals in year t, t CO_2e

LHE_t The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year t, t CO_2e

Equation 9

LHE_t The leakage from a switch to non-renewable biomass or fossil fuel in place of the biomass used for cooking/heating diverted to agricultural system in year t, t CO2e

$LNRB_t$ Leakage from a switch to non-renewable biomass use in year t, , t CO_2e

LFF_t Leakage from switch to fossil fuel in year t , t CO_2e

Equation 10

$LNRB_t$ Leakage from a switch to non-renewable biomass use in year t, t CO_2e

$B_{biomass,t}$ Quantity of biomass from outside the project used in place of the biomass used for cooking/heating diverted to agricultural system in year t, tonnes

$fNRB$ Fraction of non-renewable biomass from outside the project in year t

$NCV_{biomass}$ Net calorific value of the non-renewable biomass from outside the project

$EF_{fossil\,fuel}$ Emission factor of fossil fuel as substitute for non-renewable biomass

Equation 11

$B_{fossilfuel,t}$ Quantity of fossil fuel used in place of the biomass used for cooking/heating diverted to agricultural system in year t, tonnes

$NCV_{fossil\,fuel}$ Net calorific value of the fossil that is substituted

$EF_{fossil\,fuel}$ Emission factor of fossil fuel as a substitution for non-renewable biomass

Equation 12

SE_p Standard error in the mean of parameter, *p* in year *t*

∂_p The standard deviation of the parameter p in year t

n_p Number of samples used to calculate the mean and standard deviation of parameter p

SE_p	Standard error in the mean of parameter, *p* in year *t*

Equation 13

$P_{\min}$	The minimum value of the parameter at the 95% confidence interval
$P_{\max}$	The maximum value of the parameter at the 95% confidence interval
SE_p	Standard error in the mean of parameter, *p* in year *t*
1.96	The value of the cumulative normal distribution at 95% confidence interval

Equation 14, 15

$PRS_{\min,t}$	The minimum value of project removals due to changes in soil organic carbon at the 95% confidence interval
$PRS_{\max,t}$	The maximum value of project removals due to changes in soil organic carbon at the 95% confidence interval

Equation 16, 17

PRS_t	Estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.
PRS_{Unc}	Estimate of uncertainty in the mean of changes in soil organic carbon in year t, t CO_2e.
$PRS_{Deduction,t}$	A calculated deduction to the estimate of the change in soil organic removals year t, t CO_2e.
$PRS_{Adj,t}$	An adjusted estimate of project removals due to changes in soil organic carbon in year t, t CO_2e.

A/R	Afforestation / reforestation
CDM	Clean Development Mechanism
ABMS	Activity Baseline and Monitoring Survey
SALM	sustainable agricultural land management
SOC	soil organic carbon

Section VI: Tools

VI.1 Estimation of direct nitrous oxide emission from N-fixing species and crop residues

This tool can be used for both ex ante and ex post estimation of the nitrous oxide emissions from the use of nitrogen fixing species and crop residues within the boundary of a VCS project. For *ex post* estimation purposes, activity data (quantities of crop residues) are monitored or estimated.

It is important to note that for the project emissions, it is only the new area under N-fixing crop that is input to the formulae.

As the project proponent may use various N-fixing species, it is important to identify and record the species type and estimate the amount of inputs from each species. The direct nitrous oxide emissions from the use of nitrogen-fixing species and crop residues can be estimated using equations as follows:

$$N_2O_{direct-N,t} = F_{CR,t} \cdot EF_1 \cdot MW_{N_2O} \cdot GWP_{N_2O} \cdot 10^{-3} \quad 18$$

$$F_{CR,t} = \sum_{i=1}^{I} Crop_{i,t} \cdot \left(Area_{i,t} - Areaburnt_{i,t} \cdot C_f\right) \cdot Frac_{Renew} \cdot \left[R_{AG,i,t} \cdot N_{AG,i,t} \cdot \left(1 - Frac_{Removed}\right) + R_{BG,i,t} \cdot N_{BG,i,t}\right] \quad 19$$

Where:

$N_2O_{direct-N,t}$	Direct N_2O emission as a result of nitrogen application within the project boundary, t-CO_2-e in year t
$F_{CR,t}$	Amount of N in crop residues (above and below ground), including N-fixing crops returned to soils annually, kg N yr^{-1} in year t
EF_1	Emission Factor for emissions from N inputs, tonne-N_2O-N (tonne-N input)$^{-1}$ As noted in IPCC 2006 Guidelines (table 11.1), the default emission factor (EF_1) is 1% of applied N, and this value should be used when country-specific factors are unavailable. The project proponent may use emission factors from the peer reviewed scientific literature that are specific for the project area.
MW_{N_2O}	Ratio of molecular weights of N_2O and N (44/28), tonne-N_2O (t-N)$^{-1}$
GWP_{N2O}	Global Warming Potential for N_2O, kg-CO_2-e (kg-N_2O)$^{-1}$ (IPCC default = 310, valid for the first commitment period).
$Crop_{i,t}$	Harvested annual dry matter yield for crop i in year t, kg d.m. ha^{-1} For N-fixing trees use the above ground biomass.
$Area_{i,t}$	total annual area harvested of N-fixing crop i or trees i in year t, ha yr^{-1}
$Areaburnt_{i,t}$	annual area of N-fixing crop i or trees burnt in year t, ha yr^{-1}
C_f	combustion factor (dimensionless) (see *2006 IPCC Guidelines*, Table 2.6)
$Frac_{Renew}$	fraction of total area under crop that is renewed annually. For countries where pastures are renewed on average every X years, $Frac_{Renew}$ = 1/X. For annual crops $Frac_{Renew}$ = 1. For N-fixing trees assume that they shed their

	leaves every year are similar to annual crops
$R_{AG,i,t}$	ratio of above-ground residues dry matter ($AG_{DM,i,t}$) to harvested yield for crop i in year t ($Crop_{i,t}$), kg d.m. (kg d.m.)$^{-1}$ (see *2006 IPCC Guidelines*, Table 11.2) For NB-fixing trees use the ratio of leaf biomass to above ground biomass. For deciduous trees 0.02 is a reasonable value
$N_{AG,i,t}$	N content of above-ground residues for crop i, kg N (kg d.m.)$^{-1}$ (see *2006 IPCC Guidelines*, Table 11.2) For N-fixing trees assume 0.027 (default value for N-fixing forages) This value should be used when country-specific factors are unavailable.
$Frac_{Removed}$	Fraction of above-ground residues of crop i removed annually for purposes such as feed, bedding and construction, kg N (kg crop-N)$^{-1}$. Survey of experts in country is required to obtain data. If data for $Frac_{Removed}$ are not available, assume no removal.
$R_{BG,i,t}$	Ratio of below-ground residues to harvested yield for crop i, kg d.m. (kg d.m.)$^{-1}$. (see *2006 IPCC Guidelines*, Table 11.2) For N-fixing trees assume 0.01 (assumes that fine roots are 7% of total root biomass, that total root biomass is 25% of above ground biomass and there is a 50% fine root turnover). This value should be used when country-specific factors are unavailable.
$N_{BG,i,t}$	N content of below-ground residues for crop i, kg N (kg d.m.)$^{-1}$. (see *2006 IPCC Guidelines*, Table 11.2) For N-fixing trees assume 0.022 (default value for N-fixing forages) This value should be used when country-specific factors are unavailable.

VI.2 Estimation of emissions from the use of fossil fuels in agricultural management

The following tool is derived from the A/R Methodological Tool *Estimation of GHG emissions related to fossil fuel combustion in A/R CDM project activities*[n]. The CO_2 emissions are calculated using the following equations:

$$EFF_t = \sum_{j=1J} ET_{j,t} \qquad (20)$$

Where:

EFF_t Emissions due to the use of fossil fuels in agricultural management, t CO_2e
Note: in the methodology there is a prefix B or P depending on whether they are baseline or project emissions

$ET_{j,t}$ Emission from fossil fuel combustion in vehicle/equipment type *j* during year *t*, t CO_2e/yr

j Type of vehicle/equipment

J Total number of types of vehicle/equipment used in the project activity

It is assumed that the amount of fuel combusted is available. The method may be used in estimating vehicle/equipment emission, when the vehicle/equipment is captive (i.e. controlled by the project proponent) and the entire fuel consumptions can be monitored. If this is not available, the amount of fuel combusted can be estimated using fuel efficiency (for example l/100 km, l/t-km, l/hour) of the vehicle and the appropriate unit of use for the selected fuel efficiency (for example km driven if efficiency is given in l/100 km). The equation is as follows.

$$ET_{j,t} = FC_{j,t} \cdot EF_{CO2,j}$$

Where:

$ET_{j,t}$	Emission from fossil fuel combustion in vehicle/equipment type *j* during year *t*, t CO_2e/yr
$FC_{j,t}$	Consumption of fossil fuel in vehicle/equipment type *j* during year *t*, litres/yr
$EF_{CO2,j}$	Emission factor for the type of fossil fuel combusted in vehicle or equipment, *j*
	For gasoline EF_{CO2e} = 0.002810 t per litre. For diesel EF_{CO2e} = 0.002886 t per litre[14]
j	Type of vehicle/equipment
J	Total number of types of vehicle/equipment used in the project activity

VI.3 Estimation of non-CO_2 emissions from the burning of crop residues

The CO_2 emissions from the burning of crop residues and grasslands are not included in the methodology as per IPCC convention. The non-CO_2 emissions burning this biomass, EBB_t are calculated using the following equations:

$$EBB_t = \begin{bmatrix} MB_{C,t} \bullet C_F \bullet \left(2.7 \bullet GWP_{CH4} + 0.07 \bullet GWP_{N2O}\right) \\ + MB_{G,t} \bullet C_F \bullet \left(2.3 \bullet GWP_{CH4} + 0.21 \bullet GWP_{N2O}\right) \end{bmatrix} \bullet 10^{-3} \quad (20)$$

Where:

EBB_t	Emissions due to biomass burning in year t, t CO_2e
$MB_{C,t}$	Mass of crop residues burnt in year t, tonnes
2.7, 0.07	Emissions factors for the burning of cropland, g CH_4 / kg and g N_2O / kg, respectively From Table 2.5, 2006 IPCC Guidelines for National Greenhouse Gas Inventories
$MB_{G,t}$	Mass of grasslands residues burnt in year t, tonnes
2.3, 0.21	Emissions factors for the burning of grassland, g CH_4 / kg and g N_2O / kg, respectively
	From Table 2.5, 2006 IPCC Guidelines for National Greenhouse Gas Inventories
GWP_{CH4}	Global warming potential of CH_4 (IPCC default: 21 for the first commitment period of the Kyoto Protocol); t CO_2e / t $_{CH4}$
C_F	Combustion factors that depend on vegetation type (see Table 4), unit less

[14] These values calculated from IPCC 2006 Table 3.3.1 assuming 2-stroke gasoline engine for gasoline combustion and default values for energy content of 47.1 GJ/t and 45.66 GJ/t for gasoline and diesel respectively (IEA. 2004. Energy Statistics Manual. http://www.iea.org/stats/docs/statistics_manual.pdf)

Table 4: Combustion factor values for fires in a range of vegetation types

Vegetation type	Subcategory	Mean Value
Savanna Grasslands/ Pastures (early dry season burns)	Tropical/sub-tropical grassland	0.74
	Grassland	-
All savanna grasslands (early dry season burns)		**0.74**
Savanna Grasslands/ Pastures (mid/late dry season burns)*	Tropical/sub-tropical grassland	0.92
	Tropical pasture~	0.35
	Savanna	0.86
All savanna grasslands (mid/late dry season burns)		**0.77**
Other vegetation types	Peatland	0.50
	Tropical Wetlands	0.70
Agricultural residues (Post harvest field burning)	Wheat residues	0.90
	Maize residues	0.80
	Rice residues	0.80
	Sugarcane	0.80

From Table 2.6, 2006 IPCC Guidelines for National Greenhouse Gas Inventories

Version 1.0

Sectoral Scopes 3, 13

Energy Efficiency and Solid Waste Diversion Activities within a Sustainable Community

Scope

This methodology provides a procedure to determine the net CO_2, N_2O and CH_4 emissions reductions associated with grouped projects that focus on energy efficiency and solid waste diversion activities for an assortment of facilities within a set territory.

Methodology Developer

The methodology was developed by Will Solutions, Inc. (formerly Gedden Inc.), in collaboration with ICF Marbek and CertiConseil Inc.

Authors

- Methodology Process and Project Director - Martin Clermont, Eng. M.Sc. Env., B. Tech. Mec. Will Solutions, Inc. – Business Solutions
- Christophe Kaestli LEED AP, DBA - CertiConseil Inc.
- Duncan Rotherham, Chad Hamre, Braydon Boulanger – ICF Marbek

Relationship to Approved or Pending Methodologies

No approved or pending methodology under the VCS Program or an approved GHG program can reasonably be revised to meet the objective of this proposed methodology. All existing and pending VCS, CDM and CAR methodologies under sectoral scopes 3 and 13 have been reviewed. All corresponding methodologies have been grouped and listed below. None of the similar methodologies listed below could be revised without the addition of new procedures or scenarios to more than half of its sections.

Program	Sectoral Scope	Title	Similarity
CDM	3	*AM0025 - Avoided emissions from organic waste through alternative waste treatment processes*	Similar
CDM	3	*AM0041 - Mitigation of Methane Emissions in the Wood Carbonization Activity for Charcoal Production*	Not Similar
CDM	3	*AM0049 - Methodology for gas based energy generation in an industrial facility*	Not Similar
CDM	3	*AM0046 - Distribution of efficient light bulbs to households*	Not Similar
CDM	3	*AM0055 - Baseline and Monitoring Methodology for the recovery and utilization of waste gas in refinery facilities*	Not Similar
CDM	3	*AM0086- Installation of zero energy water purifier for safe drinking water application*	Not Similar
CDM	3	*AM0091- Energy efficiency technologies and fuel switching in new buildings*	Similar
CDM	3	*AM065 - Replacement of SF6 with alternate cover gas in the magnesium industry*	Not Similar
CDM	3	*AM0070 - Manufacturing of energy efficient domestic refrigerators*	Not Similar
CDM	3	*ACM003 - Emissions reduction through partial substitution of fossil fuels with alternative fuels or less carbon intensive fuels in cement manufacture*	Not Similar
CDM	3	*AM0007 - Analysis of the least-cost fuel option for seasonally-operating biomass cogeneration plants*	Not Similar
CDM	3	*AM0014 - Natural gas-based package cogeneration*	Not Similar
CDM	3	*ACM0012 - Consolidated baseline methodology for GHG emission reductions from waste energy recovery projects*	Not Similar
CDM	3	*AM0024 - Methodology for greenhouse gas reductions through waste heat recovery and utilization for power generation at cement plants*	Not Similar

Program	Sectoral Scope	Title	Similarity
CDM	4	*ACM0015 - Consolidated baseline and monitoring methodology for project activities using alternative raw materials that do not contain carbonates for clinker production in cement kilns*	Not Similar
CDM	3	*AM0020 - Baseline methodology for water pumping efficiency improvements --- Version 2.0*	Not Similar
CDM	3	*AM0044 - Energy efficiency improvement projects: boiler rehabilitation or replacement in industrial and district heating sectors --- Version 1.0*	Similar
CDM	3	*AM0060 - Power saving through replacement by energy efficient chillers --- Version 1.1*	Similar
CDM	3	*AM0068 - Methodology for improved energy efficiency by modifying ferroalloy production facility --- Version 1.0*	Not Similar
CDM	3	*AM0088 - Air separation using cryogenic energy recovered from the vaporization of LNG --- Version 1.0*	Not Similar
CDM	3	*AM0017 - Steam system efficiency improvements by replacing thermal energy traps and returning condensate --- Version 2.0*	Similar
CDM	3	*AM0018 - Baseline methodology for thermal energy optimization systems --- Version 2.2*	Similar
CDM	3	*AMS-I.I. - Biogas/biomass thermal applications for households/small users --- Version 1.0*	Not Similar
CDM	3	*AMS-II.C.- Demand-side energy efficiency activities for specific technologies --- Version 13.0*	Similar
CDM	3	*AMS-II.F. - Energy efficiency and fuel switching measures for agricultural facilities and activities --- Version 9.0*	Similar
CDM	3	*AMS-II.G. - Energy Efficiency Measures in Thermal Applications of Non-Renewable Biomass --- Version 2.0*	Not Similar
CDM	3	*ACM0005 - Consolidated Baseline Methodology for Increasing the Blend in Cement Production --- Version 5.0*	Not Similar
CDM	3	*AMS-III.B. - Switching fossil fuels --- Version 15.0*	Similar
CDM	3	*AMS-II.E. - Energy efficiency and fuel switching measures for buildings*	Similar
CDM	*3*	*AMS-II.J. - Demand-side activities for efficient lighting technologies*	Similar
CDM	*3*	*AMS-II.K. - Installation of co-generation or tri-generation systems supplying energy to commercial building*	Not Similar

Program	Sectoral Scope	Title	Similarity
CDM	3	*AMS-II.L. - Demand-side activities for efficient outdoor and street lighting technologies*	Similar
CDM	*3*	*AMS-II.M. - Demand-side energy efficiency activities for installation of low-flow hot water savings devices*	Similar
CDM	3	*AMS-III.AE. - Energy efficiency and renewable energy measures in new residential buildings*	Similar
CDM	3	*AMS-III.AL. - Conversion from single cycle to combined cycle power generation*	Similar
CDM	3	*AMS-III.AV. - Low greenhouse gas emitting water purification systems*	Similar
CDM	3	*AMS-III.X. - Energy Efficiency and HFC-134a Recovery in Residential Refrigerators*	Not Similar
CDM	13	*AM0039 - Methane emissions reduction from organic waste water and bioorganic solid waste using co-composting*	Similar
CDM	13	*AM0057 - Avoided emissions from biomass wastes through use as feed stock in pulp and paper production or in bio-oil production*	Similar
CAR	13	*CAR - Organic Waste Composting Project Protocol*	Similar
CDM	13	*AM0073 - GHG emission reductions through multi-site manure collection and treatment in a central plant*	Not Similar
CDM	13	*AM0083 - Avoidance of landfill gas emissions by in-situ aeration of landfills*	Not Similar
CDM	13	*ACM0014 - Mitigation of greenhouse gas emissions from treatment of industrial wastewater*	Not Similar
CAR	13	*CAR - Landfill Project Protocol*	Not Similar
CDM	13	*AMS-III.AJ. - Recovery and recycling of materials from solid wastes*	Similar
CDM	13	*AM0025 - Avoided emissions from organic waste through alternative waste treatment processes*	Similar

1 SOURCES

These documents have been drawn upon heavily in the development of this methodology. Throughout the text the short form reference (PUBLISHER, YEAR) will be used to indicate areas where the sources were drawn upon most heavily.

This methodology complies with the principles of:

- *ISO 14064*: Part 2, "Specification with guidance at the project level for the quantification, monitoring and reporting of greenhouse gas emission reductions and removal enhancements*"* (ISO, 2006).
- VCS, *VCS Standard*, Version 3 (VCS, Version 3)

This methodology also draws ideas from the latest approved version of the following CDM tools:

- CDM, *Tool to Calculate the Emission Factor for an Electricity System* (Version 2.2.0) (CDM, 2011) and
- CDM, *Combined Tool to Identify the Baseline Scenario and Demonstrate Additionality* (Version 3.0.1) (CDM, 2011).

The energy efficiency approach within has been based on elements of the following methodologies:

- Direct Energy's, *GHG Quantification Protocol for Energy Efficiency in Commercial and Institutional Buildings* (Direct Energy, 2009);
- Alberta Offset System, Protocol, *GHG Quantification Protocol for Energy Efficiency in Commercial and Institutional Buildings* (AENV, 2010);
- Alberta Offset System, Protocol, *Quantification Protocol For Energy Efficiency Projects* (Version 01) (AENV, 2007);
- IPMVP - Efficiency Valuation Organization (EVO-1000-1, 2010) in its International Performance Measurement and Verification Protocol (IPMVP) (www.evo-world.org) for guidance on methods determining energy savings.[1]

This waste diversion approach within has been based on elements of the following methodologies:

- CDM, AM0039, *Methane Emissions Reduction from Organic Waste Water and Bioorganic Solid Waste using Co-composting* (Version 02) (CDM, 2007).
- CDM, *Tool to Determine Methane Emissions Avoided from Disposal of Waste at a Solid Waste Disposal Site* (Version 6.0) (CDM, 2011)
- CCX "Avoided Emissions from Organic Waste Disposal Offset Project Protocol" (CCX, 2009);

[1] IPMVP is a recognized international standard for measuring, monitoring, and verifying energy savings.

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology provides a framework for the quantification of emission reductions for grouped projects[2], where energy efficiency and solid waste diversion activities have been initiated by a Sustainable Community Service Promoter for an assortment of Client Facilities grouped in a Territory. This methodology requires that the SCSP uses a consolidated, Information and Communication Technology-enabled data monitoring and collection system to track project activity data. Even though the activities of Client Facilities vary, energy consumption and waste management are similar across many businesses and organizations. This methodology is meant to work with and support the provision of single window reporting and measurement provided by a third party to capture the information required to quantify emissions reductions.

3 DEFINITIONS

This sub-section introduces important terminology to ensure the project proponent and validation/verification bodies (VVBs) share common understandings of the various roles, parties and grouping systems involved in this methodology.

Client Facility	A large range of small companies or business units that contract the Sustainable Community Service Promoter to manage their GHG emitting services. Client Facilities may include commercial, institutional, residential and industrial buildings/facilities including but not limited to warehouses, apartment buildings, hotels, restaurants, educational buildings, shopping malls, food manufacturing plants, chemical manufacturing facilities, and light industrial plants. Client Facilities are typically located in regional or state clusters.
Sustainable Community (SC)	A Sustainable Community is as a collection of Client Facilities that have undertaken common actions (usually initiated by the SCSP) to reduce their overall GHG emissions.

[2] See *VCS Standard* for grouped project requirements.

Sustainable Community Service Promoter (SCSP)	An independent entity, which acts as the project proponent, providing essential consultation services in the fields of energy and waste to Client Facilities to stimulate greenhouse gas (GHG) reduction activities. SCSPs add value to Client Facilities by implementing Information and Communication Technology-enabled electronic tracking platforms, monitoring technologies, and emission reduction activities. In providing services to Client Facilities, SCSPs contractually maintain ownership of the environmental attributes associated with actions that reduce the Client Facilities overall GHG emissions.
Territory	A grouping of Client Facilities which belong to a common industrial or geographic cluster, where the regional conditions (i.e. electricity source, climate, waste processing schemes, etc.) and regulations (i.e. waste and emission regulations, etc.) are similar for the different facilities; where homogeneous emission factors for fossil combustibles and identifiable emission factor for the electricity grid can be applied; and where common energy efficiency activities and waste processing activities are possible. The Territory concept has been applied to facilitate VVB sampling procedures, though sampling resolutions are ultimately to be determined by the VVB based on a risk assessment of the project and project controls.

This sub-section introduces data, sampling, and conceptual terminologies that are important to how emission reductions are quantified and monitored under this methodology.

Baseline Adjustments	The non-routine adjustments arising during the monitoring period from changes in: 1) any energy governing characteristic of the facility within the measurement boundary, except the named independent variables used for routine adjustments (EVO 10000-1, 2010); or 2) any waste governing characteristic of the facility within the measurement boundary (for example, total production).
Baseline Period	The period of time chosen to represent operation of the facility or system before implementation of an Energy Conservation Measure or waste reduction/diversion activities. This period may be as short as the time required for an instantaneous measurement of a constant quantity, or long enough to reflect one full operating cycle of a system or facility with variable operations.

Confidence Interval	A confidence interval (CI) is a particular kind of interval estimate of a population parameter and is used to indicate the reliability of an estimate. It is an observed interval (i.e. it is calculated from the observations), in principle different from sample to sample, that frequently includes the parameter of interest, if the experiment is repeated. How frequently the observed interval contains the parameter is determined by the confidence interval or confidence coefficient.
Estimate	A process of determining a parameter used in a savings calculation through methods other than measuring it in the baseline and monitoring periods. These methods may be based on secondary data or engineering assumptions and estimates derived from manufacturer's rating of equipment performance. Equipment performance tests that are not made in the place where they are used during the monitoring period shall be considered as estimates.
Facility	The collection of units, excluding the Project Unit. As such, the greenhouse emissions from the facility are defined to remain constant as only the Project Unit is impacted by the project. Where the Project Unit encompasses the entire site, there may be no components defined as the Facility at the site.
Functional Equivalence	The project and the baseline shall provide the same function and quality of products or services. This type of comparison requires a common metric or unit of measurement (such as the mass of cardboard diverted from landfill for mass of finished furniture, energy use/per unit of product) for comparison between the project and baseline activity.
Information and Communication Technology (ICT)	Information and Communication Technology that is applied through an electronic tracking platform for each Client Facility. An electronic account and the effective electronic link between all Client Facilities inside a Territory to stimulate, to support and measure their GHG related activities. SCSPs employ an ICT-enabled GHG monitoring system.

Measurement Boundary	A notional boundary drawn around equipment and/or systems to segregate those which are relevant to savings determination from those which are not. All energy uses of equipment or systems within the measurement boundary must be measured or estimated, whether the energy uses are within the boundary or not (EVO 10000-1, 2010)
Non-Routine Adjustments	Calculations that account for changes in Static Factors within the measurement boundary since the baseline period. Examples of changes in Static Factors that require non-routine adjustments include the facility size, product types, building envelope characteristics, indoor environment and occupancy characteristics. Non-routine adjustments applied to the baseline are sometimes referenced as “baseline adjustments” (EVO 10000-11, 2010). For this quantification protocol, non-routine adjustments also account for changes in the “surplus” characteristics of the project.
Primary Data	Observed data from specific facilities linked to the SCSP tracking system.
Project Unit	A project activity instance wherein the equipment, processes and facilities are being serviced and impacted by the energy efficiency and waste diversion processing project. The Project Unit must be clearly defined and justified by the project proponent. All non-Project Unit items are covered under the heading of facility operation.
Routine Adjustments	The calculations made by a formula, as shown in the energy efficiency and waste diversion monitoring plans, to account for changes in selected independent variables within the measurement boundary since the baseline period (EVO 10000-11, 2010), not including any changes to Static Factors.
Secondary Data	Generic- or industry-average data from published sources that are representative of Project unit Activities and Client Facility products.
Static Factors	Those characteristics of a Client Facility which affect energy use and waste volume produced, within the chosen measurement boundary. These characteristics include fixed, environmental, operational and maintenance characteristics. They may be constant or varying (EVO 10000-11, 2010).

Standard Deviation — The standard deviation, denoted by *s* and is defined as follows:

$$s = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}(x_i - \overline{x})^2},$$

where $\{x_1, x_2, \ldots, x_N\}$ are the observed values of the sample items and $\overline{x}$ is the mean value of these observations.

Suggested Sample Size — While the ultimate level of sampling must be determined by the VVB, the project proponent may provide a suggested number of Sustainable Community Project Units to be physically verified.

Unit of Productivity — The unit of productivity is to be defined by the project proponent as a basis for incorporating Functional Equivalence within the calculation methodology. Examples of units of productivity could be: energy requirements for residential buildings, per square foot of front of house commercial space, per kg/L/m2/m3 of output from manufacturing facilities, etc. The unit of productivity shall be defined to account for any non-production sensitive components. In all cases the project proponent must thoroughly justify their assessment of the appropriate unit of productivity.

Verified Data Feedback Loop — After each verification cycle, verified SCSP Client Facility data may be used to increase the confidence interval on any estimated values included in the baseline or project scenarios. Examples of such situations could include replacing regional factors for a specific facility with a more accurate waste or energy profile of the specific Client Facility based on measured data, providing it can still be related to the baseline period. This verified data feedback loop could ultimately result in adjustments that both increase or decrease emission reduction assertions in future years. The adjustments would not be retroactive to previously serialized offsets.

These definitions apply to the energy efficiency components of GHG quantification described herein.

Adjusted-baseline energy — The energy use of the baseline period, adjusted to a different set of operating conditions (EVO 10000-11, 2010).

Baseline Energy — The energy use occurring during the baseline period without adjustments (EVO 10000-11, 2010).

Cycle	The period of time between the start of successive similar operating modes of a facility or piece of equipment whose energy use varies in response to operating procedures or independent variables. For example, the cycle of most buildings is 12 months, since their energy use responds to outdoor weather which varies on an annual basis. Another example is the weekly cycle of an industrial process which operates differently on Sundays than during the rest of the week (EVO 10000-11, 2010).
Energy Conservation Measure (ECM)	An activity or set of instances designed to increase the energy efficiency of a facility, system or piece of equipment. ECMs may also conserve energy without changing efficiency. Several ECMs may be carried out in a facility at one time, each with a different thrust. An ECM may involve one or more of: physical changes to facility equipment, revisions to operating and maintenance procedures, software changes, or new means of training or managing users of the space or operations and maintenance staff. An ECM may be applied as a retrofit to an existing system or facility, or as a modification to a design before construction of a new system or facility.

These definitions apply to the waste diversion components of GHG quantification described herein.

Alternative Processing	Refers to recycling, reusing, reduction and re-processing activities which are applied as part of the project to divert waste from reaching a landfill.
Biodegradability	Biodegradability is the capability of a substance to break down into simpler substances, especially into innocuous products, by the actions of living organisms (that is, microorganisms).
Composting	The process of collecting, grinding, mixing, piling, and supplying sufficient moisture and air to organic materials to speed natural decay. The finished product of a composting operation is compost, a soil amendment suitable for incorporating into topsoil and for growing plants. Compost is different than mulch, which is a shredded or chipped organic product placed on top of soil as a protective layer.
Destinations	The ultimate destination for waste being shipped by the project. This is the location where the waste would be unloaded from a truck after having been shipped from project Origins.

Disposal	Final stage in the management of waste, which includes: treatment of waste prior to disposal, incineration of waste, with or without energy recovery, deposit of waste to land or water, discharge of liquid waste to sewer, and permanent, indefinite or long term storage of waste.
Diversion	For waste measurement purposes, diversion is any combination of waste prevention (source reduction), recycling, reuse and composting instances that reduces waste disposed at authorized landfills and transformation facilities.
Landfill Gas (LFG)	Gas generated by biological decomposition of waste material in a landfill. The gas is typically comprised of methane, carbon dioxide, other trace gases and water vapor.
Origins	Starting points for waste being shipped by the project. This is the location where the waste would be loaded onto a truck or train for ultimate delivery to Destinations.
Producer	Refers to the Client Facility that produces the waste to be disposed of.
Process Emissions	Process emissions are direct emissions from sources directly associated with production that involve chemical or physical reactions, other than combustion, and where the primary purpose of the process is not energy production.
Recycling	The process of collecting, sorting, cleansing, treating, and reconstituting materials that would otherwise become solid waste, and returning them to the economic mainstream in the form of raw material for new, reused, or reconstituted products that meet the quality standards necessary to be used in the marketplace.

Waste	All type of wastes, regulated or not regulated, hazardous or non-hazardous and generated by citizens under the municipal umbrella (Municipal Solid Waste (MSW)) or by others sources such as an Industrial, Commercial and Institutional (ICI) business unit. This definition of the wastes defined by the Basel Convention http://www.basel.int/ in the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal in the article 2 and referred to Annex I and II, shall apply for all types of wastes. Notice this UN international convention respect the full right of country to define their wastes (article 2 item 1).
Waste Transformation	Incineration, pyrolysis, distillation, gasification, or biological conversion other than composting.
Waste Management	All types of waste management operations, disposal and recycling applied for all types of wastes shall refer to the definition used by the Basel Convention http://www.basel.int/ in the Basel Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal in article 2 and referred to Annex IV. Notice this UN international convention respect the full right of country to define their management wastes operations (article 2).

4 APPLICABILITY CONDITIONS

This methodology is applicable for grouped projects for the quantification of direct and indirect reductions of GHG emissions arising from energy efficiency and waste management project activity instances at client facilities (project units).

The requirements of this methodology have been designed to meet micro energy efficiency and/or waste diversion project units where the maximum emission reductions from an individual project unit is 5,000 tCO_2e/year. Therefore, through a combination of energy efficiency and waste management activities, project units within a grouped project could have a maximum combined abatement threshold of 10,000 tCO_2e/year. While each client facility, or project unit, may only contribute a modest abatement (10,000 tCO_2e/year or less), the total sum of abatement from all project units within this entire grouped project may exceed the combined threshold of 10,000 tCO_2e/year.

This methodology is applicable for grouped projects for the quantification of direct and indirect reductions of GHG emissions arising from energy-efficiency and waste-diversion projects at client facilities. Projects can be located in residential, commercial, institutional, or industrial buildings/facilities. The project proponent must demonstrate right of use in respect of the project's GHG emission reductions, which may, for example, entail securing right of use from client facilities.

<u>Energy Efficiency</u>

This methodology is applicable to ECMs where the project activity is the construction of new facilities, the retrofit of existing facilities, or process/management changes of existing facilities that result in a reduction of energy use per unit of productivity. The ECMs must occur in conjunction with the following:

- Building envelope modifications
- Heating, ventilation and air conditioning (HVAC)
- Heat generation (including industrial thermal energy systems)
- Chilling/cooling systems
- Lighting and lighting control
- Building mechanical infrastructure
- Appliances and industrial processes (including heating and cooling requirements and process modification)
- Electric motors
- Equipment optimization

The following guidance provides further clarification on energy efficiency activities, approach and applicability:

a. The project proponent must document the useful life of the ECMs and the remaining useful life of the existing baseline equipment and ensure that the project unit(s) is not credited beyond the useful life of the ECM or remaining useful life of the existing technology in the baseline scenario. If capital stock equipment that was originally measured in the baseline for a given project crediting period is replaced during a project crediting period, it can only be considered additional, and in turn be able to generate GHG credits, if it was retired prior to its natural capital stock rotation as indicated in the initial documentation of useful life. If capital stock enters the end of its useful life prior to the end of a project crediting period and is replaced, any emission reduction attributable to this replacement technology must not be considered towards generating credits, and shall lower the facility baseline by a sum equal to the difference in emissions between the previous capital stock equipment and the replacement capital stock equipment.

b. By reducing energy consumption, applicable projects will reduce GHG emissions associated with the conversion of primary energy sources to secondary forms of energy (e.g., electricity, heat, mechanical energy, etc.).

c. This methodology is also applicable to activities generating GHG emission reductions related to improvements in combustion efficiency[3]. This applies to projects involving switching from one energy generation method to a less GHG-intensive energy generation method. In this case, this methodology only quantifies emissions reductions from fuel switching that occur within the project boundary. Fuel switching associated with large energy suppliers, which

[3] There must not be double counting between activities related to improvements in combustion efficiency and any energy efficiency activities within the project.

have emission reductions that exceed the established threshold of this methodology, are not intended to be quantified using this protocol. Only small on-site power sources, with emission reductions within the threshold limit of this methodology, are applicable for inclusion within the methodology. This separation of large offsite generation and the project removes risk of double counting. A net emission reduction and efficiency improvement would be achieved by such activities so long as a net reduction in overall greenhouse gas emissions per unit of productivity is achieved. The production of energy, particularly from fossil energy sources, has significant associated GHG emissions (typically combustion-related), including both direct and indirect sources.

d. Biological or chemical components of the operation must not yield any increase in non-biogenic greenhouse gas emissions compared to the baseline scenario, unless these are accounted for under the applicable flexibility mechanisms as indicated by an affirmation from the project proponent.

Waste Diversion

This methodology is applicable where the project activity is the diversion of waste for other productive uses and alternative disposal options. This methodology is only applicable to quantify emission reductions associated with methane avoidance. This methodology is not approved for quantifying emission reductions associated with landfill gas flaring or electricity/energy production. This methodology is applicable to the following activities:

- Card board recycling
- Organic composting
- Aerobic decomposition

5 PROJECT BOUNDARY

5.1 Project

The project proponent shall identify all GHG sources and sinks (SS) relevant to the project such as:

- Production of electricity
- Maintenance, construction and decommissioning
- Decomposition of solid waste in landfills.

The process set out in Diagram 1 identifies, illustrates and organizes SS for a typical project applicable under this methodology. Table 1 describes each SS identified in Diagram 1, discusses the SS relevance and characterizes the SS as controlled, related or affected by the project activity.

Since this methodology has been written to work for various types of project activities, one single project boundary cannot be provided. The project proponent shall use the requirements set out in this section to clearly define the most appropriate boundary for each grouping of client facilities with appropriate justifications for the inclusion or exclusion of SS. This shall include unique geo-coordinates if the projects are implemented across several dispersed locations.

For energy efficiency activities, it is important to note that the site boundaries are determined by whether the project proponent elects to quantify using “Option A – Isolation Parameter Measurement” or “Option B – Whole Facility Measurement.”

If Option A, Isolation Parameter Measurement, is selected, savings are determined by measuring the energy use of the ECM affected system, rather than the entire building. As such the boundary chosen is the ECM affected system. In this case, clear justification must be provided at the Territory level by the project proponent that the ECM affected system would have no material impact on the operation and emissions of the whole or remaining facility. Functional equivalence and unit of productivity adjustments for the ECM affected system must be made to the baseline of the system.

If Option B, Whole Facility Measurement, is selected, energy use for the entire facility is measured and any savings are calculated accordingly and therefore the boundary chosen is the entire facility. In this case, clear justification must be provided at the Territory level by the project proponent that the entire building’s baseline meets functional equivalence and has been adjusted by units of productivity.

Regardless of which option is selected, the project energy use calculations shall be done according to the methodology documents in IPMVP’s “Concepts and Options for Determining Energy and Water Savings (Volume 1)” (EVO, 2010). For waste diversion activities, the project proponent must use “Whole Facility Measurement” to determine the site boundaries. This means that if the project proponent is including waste diversion activities, then an isolated component of the facility cannot be used, the entire facility’s facility and waste stream must be included in the boundary. The project and baseline element life cycle charts are shown in Diagrams 1 and 2, respectively. Project documentation shall include diagrams that disclose the locations and processes of metering equipment used in determining the mass energy flows.

Diagram1: Project Element Life Cycle Chart

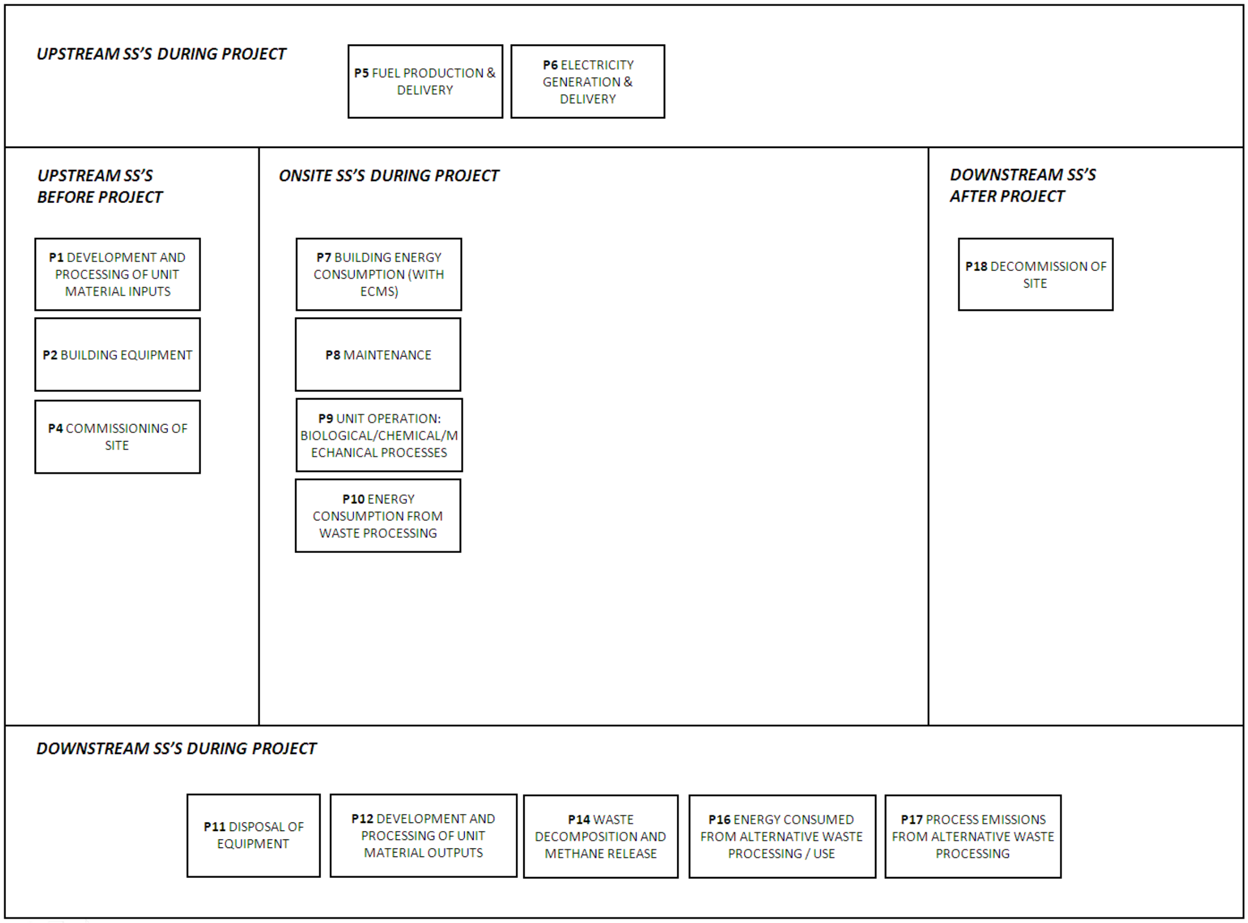

Table 1: Project Life Cycle SS Descriptions

SS	Description	Controlled, Related or Affected
Upstream Before Project		
P1 Development and Processing of Unit Material Inputs	The material inputs to the unit process need to be transported, developed and/or processed prior to the unit process. This may require any number of mechanical, chemical or biological processes. All relevant characteristics of the material inputs would need to be tracked to prove functional equivalence with the baseline scenario.	Related
P2 Building Equipment	GHG emissions arise from the manufacturing process of the equipment to implement the ECMs and conventional building/facility operation in the project. Such emissions are likely associated with the fossil fuels and electricity consumed during the manufacturing process.	Related

P4 Commissioning of Site	The development of the site (technically onsite before project) and installation of equipment result in GHG emissions, primarily from the use of fossil fuels and electricity during this process.	Related
Upstream During Project		
P5 Fuel Production & Delivery	The production and distribution of fuel used during building/facility operations result in GHG emissions. The volume and type of fuel shall be required for GHG emission calculations, as is the distribution distance.	Related
P6 Electricity Generation & Delivery	Building/facility operations could require significant amounts of electricity. The generation and distribution of electricity results in GHG emissions.	Related
Onsite During Project		
P7 Building/System Energy Consumption (with ECMs)	Energy (including fossil fuel and electricity) is likely required on-site to operate the building/facility. Equipment utilizing this energy could include boilers, lighting systems, HVAC Systems, ventilation systems, equipment, etc.	Controlled
P8 Maintenance	The facility and systems within the facility likely requires maintenance. GHG emissions arise from the use of fuels and electricity in maintenance procedures.	Controlled
P9 Unit Operation: Biological/Chemical /Mechanical Processes	Greenhouse gas emissions may occur that are associated with the operation and maintenance of the biological processes (biological, chemical, and mechanical) within the unit at the project site. All relevant characteristics of the biological processes would need to be identified.	Controlled
P10 Energy Consumption from Waste Processing	Energy may be required to power waste processing or handling equipment (i.e. compacters, etc.)	Controlled
Downstream During Project		
P11 Disposal of Equipment	The disposal of some materials/equipment which compose all or a component of the ECM or waste diversion systems may result in GHG emissions.	Related
P12 Development and Processing of Unit Material Outputs	The material outputs from the unit process need to be transported, developed, and/or processed subsequent to the unit process. This may require any number of mechanical, chemical or biological processes. All relevant characteristics of the material outputs would need to be identified to prove functional equivalence with the baseline scenario.	Related

P14 Waste Decomposition and Methane Release	Waste may decompose in the disposal facility (typically a landfill site) resulting in the production of methane. A methane collection and destruction system may be in place at the disposal site. If such a system is active in the landfill or the area of the landfill where this material is being disposed, then its characteristics must be identified and the efficiency (ie, percent of total methane generation that is capture and destroyed) must be accounted for in a reasonable manner. Disposal site characteristics, mass disposed at each site, and methane collection and destruction system characteristics may need to be identified.	Related
P16 Energy Consumed from alternative processing of waste/use	Energy may be consumed by the alternative processing waste diversion activity. The related energy inputs for fueling this equipment are identified under this SS, for the purpose of calculating the resulting GHG emissions.	Related
P17 Process Emissions from Alternative Processing of Waste	This SS encompasses any process emissions associated with the new method of handling waste. Any process emissions related to the alternative use or disposal of the solid waste must be measured or estimated. All relevant characteristics of these processes would need to be identified.	Related
Downstream After Project		
P12 Decommission of Site	Once the facility is no longer operational, the site may need to be decommissioned. This may involve the disassembly of the equipment, demolition of on-site structures, disposal of some materials, environmental restoration, re-grading, planting or seeding, and transportation of materials off-site. Greenhouse gas emissions would be primarily attributed to the use of fossil fuels and electricity used to power equipment required to decommission the site.	Related

5.2 Baseline

All SS relevant to the baseline, including on-site, upstream and downstream SS shall be identified.

The process set out in Diagram 2 identifies, illustrates and organizes SS for a typical baseline applicable under this methodology. Table 2 describes each SS identified in Diagram 2, discusses the SS relevance and characterizes the SS as controlled, related, or affected by the project activity.

Diagram 2: Baseline Life Cycle Chart

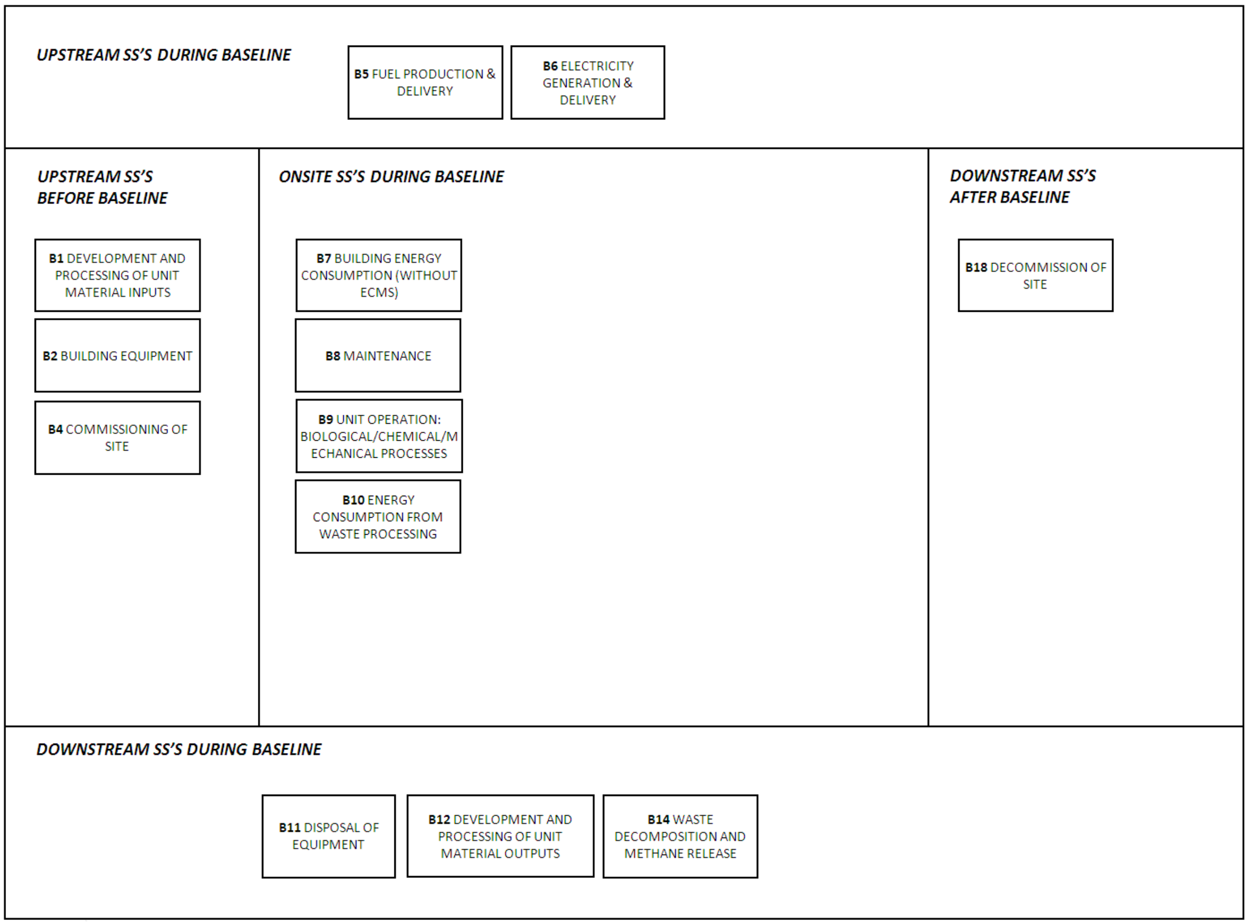

Table 2: Baseline Element Life Cycle SS Descriptions

SS	Description	Controlled, Related or Affected
	Upstream During Baseline	
B1 Development and Processing of Unit Material Inputs	The material inputs to the unit process need to be transported, developed and/or processed prior to the unit process. This may require any number of mechanical, chemical or biological processes. All relevant characteristics of the material inputs would need to be identified to prove functional equivalence with the baseline scenario.	Related
B2 Building Equipment	GHG emissions arise from the manufacturing process of the equipment to implement the ECMs and conventional building/facility operation in the project. Such emissions are likely associated with the fossil fuels and electricity consumed during the manufacturing process.	Related
B4 Commissioning of Site	The development of the site (before project) and installation of equipment results in GHG emissions, primarily from the use of fossil fuels and electricity during this process.	Related
	Upstream Before Baseline	
B5 Fuel Production & Delivery	The production and distribution of fuel used during building/facility operations results in GHG emissions. The volume and type of fuel shall be required for GHG emission calculations, as is the distribution distance.	Related
B6 Electricity Generation & Delivery	Building/facility operations could require significant amounts of electricity. The generation and distribution of electricity results in GHG emissions.	Related
	Onsite During Baseline	
B7 Building/System Energy Consumption (without ECMs)	Energy (including fossil fuel and electricity) is likely required on-site to operate the building/facility. Equipment utilizing this energy could include boilers, lighting systems, HVAC Systems, ventilation systems, equipment, etc.	Controlled
B8 Maintenance	The facility and systems within the facility likely requires maintenance. GHG emissions arise from the use of fuels and electricity in maintenance procedures.	Controlled
B9 Unit Operation: Biological/Chemical/ Mechanical Processes	GHG emissions may occur that are associated with the operation and maintenance of the biological processes (biological, chemical, and mechanical) within the unit at the project site. All relevant characteristics of the biological processes would need to be identified.	Controlled

B10 Energy Consumption from Waste Processing	Energy may be required to power waste processing or handling equipment (i.e. compacters, etc.)	Controlled
Downstream During Baseline		
B11 Disposal of Equipment	The disposal of some materials/equipment which compose all or a component of the ECM or waste diversion systems may result in GHG emissions.	Related
B12 Development and Processing of Unit Material Outputs	The material outputs from the unit process need to be transported, developed, and/or processed subsequent to the unit process. This may require any number of mechanical, chemical or biological processes. All relevant characteristics of the material outputs would need to be identified to prove functional equivalence with the baseline scenario.	Related
B14 Waste Decomposition and Methane Release	Waste may decompose in the disposal facility (typically a landfill site) resulting in the production of methane. A methane collection and destruction system may be in place at the disposal site. If such a system is active in the landfill or the area of the landfill where this material is being disposed, then its characteristics must be identified and the efficiency (ie, percent of total methane generation that is capture and destroyed) must be accounted for in a reasonable manner. Disposal site characteristics and mass disposed of at each site may need to be identified.	Related
Downstream After Baseline		
B15 Decommission of Site	Once the facility is no longer operational, the site may need to be decommissioned. This may involve the disassembly of the equipment, demolition of on-site structures, disposal of some materials, environmental restoration, re-grading, planting or seeding, and transportation of materials off-site. Greenhouse gas emissions would be primarily attributed to the use of fossil fuels and electricity used to power equipment required to decommission the site.	Related

5.3 SS Selection

Each of the SS from the project and baseline scenario shall be compared and evaluated as to their relevancy. The justification for the potential exclusion or conditions upon which the SS may be excluded is provided in Table 3. Negligible emissions have been defined as being less than 1% of the project's lifetime emissions (calculated on an annual basis). Where the SS are to be excluded, they must fall below this threshold. Table 3 includes a generalized assessment that is expected to be accurate for most facilities. However, the project proponent must make an assessment for their specific project and may only exclude emissions that do not exceed the 1% threshold.

Table 3: Process for Selection of SS

Source		**Gas**	**Included?**	**Justification/Explanation**
Baseline	B1 Development and Processing of Unit Material Inputs	CO_2	[Excluded]	Expected to be excluded as they must be functionally equivalent to allow for the application of the methodology.
		CH_4	[Excluded]	
		N_2O	[Excluded]	
	B2 Building Equipment	CO_2	[Excluded]	Expected to be excluded since emissions from manufacturing of building equipment are expected to be negligible over the lifetime of the project.
		CH_4	[Excluded]	
		N_2O	[Excluded]	
	B4 Commissioning of Site	CO_2	[Excluded]	Expected to be excluded since emissions from site development are expected to be negligible given the minimal site development typically required.
		CH_4	[Excluded]	
		N_2O	[Excluded]	
	B5 Fuel Production & Delivery	CO_2	[Excluded]	Expected to be excluded since emissions from fuel production and delivery are expected to be greater under the baseline scenario.

		CH_4	Included	
		N_2O	Included	
	P8 Maintenance	CO_2	Included	Must be included, though can be excluded if the baseline and project scenario operations would involve immaterial difference in energy consumed for maintenance activities. If however maintenance activities included major overhauls that would not have been included in the baseline scenario, evidence must be provided by the project proponent to show the SS is below the negligible emissions threshold.
		CH_4	Included	
		N_2O	Included	
	P9 Unit Operation: Biological/Chemical/Mechanical Processes	CO_2	Included	Must be included, though can be excluded if prescribed to be functionally equivalent.
		CH_4	Included	
		N_2O	Included	
	P10 Energy Consumption from Waste Processing	CO_2	Included	Must be included, though can be excluded if the facility or group of facilities is not quantifying emission reductions associated with waste diversion activities and if the ECM activities would not affect the energy consumed for waste processing.
		CH_4	Included	
		N_2O	Included	
	P11 Disposal of Equipment	CO_2	[Excluded]	Expected to be excluded since emissions from disposal of equipment are expected to be negligible
		CH_4	[Excluded]	
		N_2O	[Excluded]	

Source		Gas	Included?	Justification/Explanation
	P12 Development and Processing of Unit Material Outputs	CO_2	[Excluded]	Expected to be excluded as they must be functionally equivalent to allow for the application of the methodology.
		CH_4	[Excluded]	
		N_2O	[Excluded]	
	P14 Waste Decomposition and Methane Release	CO_2	Included	Must be included, though can be excluded if the facility or group of facilities is not quantifying emission reductions associated with waste diversion activities and if the ECM activities would not affect the amount methane emitted from decomposition.
		CH_4	Included	
		N_2O	Included	
	P16 Energy Consumed from Alternative Processing of Waste / Use	CO_2	Included	Must be included, though can only be excluded if the facility or group of facilities is not quantifying emission reductions associated with alternative processing of waste / use in the project scenario at the Territory level.
		CH_4	Included	
		N_2O	Included	
	P17 Process Emissions from Alternative Processing of Waste	CO_2	Included	Must be included, though can be excluded if the facility or group of facilities is not quantifying emission reductions associated with the alternative processing of waste at the Territory level.
		CH_4	Included	
		N_2O	Included	
	P18 Decommission of Site	CO_2	[Excluded]	Expected to be excluded since emissions from decommissioning are not expected to differ highly between the baseline and project scenarios.
		CH_4	[Excluded]	
		N_2O	[Excluded]	

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO AND DEMONSTRATING ADDITIONALITY

Regardless of the specific project type being proposed, the project proponent must follow the step-wise approach specified in the CDM *Combined Tool to Identify the Baseline Scenario and Demonstrate Additionality* to identify the baseline scenario and demonstrate additionality. The tool shall be applied with baseline alternatives and project scenarios categorized by project units. The cost savings associated with energy efficiency shall be included in the investment analysis.

When selecting the baseline period for waste diversion and energy efficiency activities, the appropriateness of baseline period shall be analyzed for the two activities separately. While one baseline period for both may be deemed appropriate, it is also possible that different baseline periods and approaches are required for the different activities. As one example, the best unit of productivity for the waste diversion baseline period may be different from that for the energy efficiency baseline period depending on the selected unit of productivity and the quality of data available for each.

The baseline scenario shall be determined by analyzing, at minimum, the following potential alternatives:

a. Each business owner proactively exceeds the current regulations and decreases their per unit energy consumption. Additionally, each business owner could also purchase new capital equipment prior to the natural turnover rate of their existing stock, for the purposes of energy efficiency savings, without installing the added monitoring equipment as required to quantify GHG emission reductions. This step is essentially the implementation of the energy efficiency project activity without carbon financing.

b. Each business owner proactively puts into place a system to treat waste in a manner other than anaerobic decomposition in a landfill. This step is essentially the implementation of the waste diversion project activity without carbon financing.

c. The government or industrial sector enforces minimum building codes, not only for new facilities but for the current stock of buildings. These codes could mandate certain levels of efficiency or waste handling that could achieve the anticipated results of this protocol without the use of VCUs.

d. The continuation of the current situation (ie, no project activity or other alternatives undertaken). Comparable outputs of the project – constant energy intensity per production unit and anaerobic decomposition of waste in landfill – will continue. Currently, technologies/ practices that provide outputs/services of comparable qualities, properties and application areas as the proposed project activity, are not incentivized and are not introduced to the market for dispersed client facilities. These facilities do not have the economies of scale necessary to develop and operate the necessary monitoring systems to achieve affordable gains similar to the goals of this protocol.

7 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

Quantification of the reductions, removals and reversals of relevant SS for each of the greenhouses gases must be completed by using the baseline and project emissions equations specified for energy efficiency and waste diversion activities.

If the project proponent chooses to exclude any of the sources from the SS selection (Table 3: Process for Selection of SS

), a detailed justification must be provided for each exclusion.

7.1 Baseline Emissions

$\text{Emissions}_{\text{Adjusted Baseline EE}}$	= the energy efficiency activities related baseline emissions plus any adjustments needed to adjust it to the conditions of the monitoring period
$\text{Emissions}_{\text{Adjusted Baseline EE}}$	$= \text{Emissions}_{\text{Adjusted Building/System Energy Consumption w/o ECM}} + \text{Emissions}_{\text{Adjusted Maintenance}} + \text{Emissions}_{\text{Adjusted Unit Operation}}$

$\text{Emissions}_{\text{Adjusted Building Energy Consumption w/o ECM}}$ = Emissions under SS **B7** Adjusted Building/System Energy Consumption (w/o ECMs)

$\text{Emissions}_{\text{Adjusted Maintenance}}$ = Emissions under SS **B8** Adjusted Maintenance

$\text{Emissions}_{\text{Adjusted Unit Operation}}$ = Emissions under SS **B9** Adjusted Unit Operation: Biological/Chemical/Mechanical Processes

$\text{Emissions}_{\text{Adjusted Baseline WASTE}}$	= the waste related baseline emissions plus any adjustments needed to adjust it to the conditions of the monitoring period
$\text{Emissions}_{\text{Adjusted Baseline WASTE}}$	$= \text{Emissions}_{\text{Adjusted Energy Consumption from Waste Processing}} + \text{Emissions}_{\text{Adjusted Waste Decomposition and Methane Release}}$

$\text{Emissions}_{\text{Adjusted Energy Consumption from Waste Processing}}$ = Emissions under SS **B10** Adjusted Energy Consumption from Waste Processing

$\text{Emissions}_{\text{Adjusted Waste Decomposition and Methane Release}}$ = Emissions under SS **B14** Adjusted Waste Decomposition and Methane Release

7.2 Adjustments

The project proponent may conduct emission adjustments for measuring functional equivalence as well as unit of productivity. The baseline scenario identified for the projects using this methodology may require adjustments to ensure functional equivalence with the project.

In order for this comparison between the project scenario and baseline scenario to be meaningful, the project and the baseline must provide the same function and quality of products or services. This consistency in metrics and units of production provides an ability to quantify actual emissions reductions achieved in the project scenario.

Table 4 provides SS-specific equations for the baseline component of the comparison. Table 5 provides project SS emission adjustment quantification.

In some cases, the project scenario cannot have the same units as the baseline. An example of this would be where the project seeks to displace conventional natural gas with landfill gas. In this case, the common metric would be the energy content of each fuel, reported as energy content/liter of fuel[4].

The project proponent is strongly encouraged to review IPMVP volumes for examples of how to make adjustments for functional equivalence and productivity.

The unit of productivity must be used by the project proponent as a basis for incorporating functional equivalence within the calculation methodology. Examples of units of productivity could be: energy requirements for residential buildings, per square foot of front of house commercial space, per kg/L/m^2/m^3 of output from manufacturing facilities, etc. The unit of productivity shall be defined to account for any non-production sensitive components. In all cases the project proponent must thoroughly justify their assessment of the appropriate unit of productivity.

The project proponent must also justify the selection of data used for deriving the unit of productivity.

Functional equivalence adjustments are usually performed when the energy savings are quantified. In many cases, the quantification and claims of GHG emission reductions shall occur on a yearly basis; therefore, these adjustments need to be performed according to that same schedule. Typical adjustment includes routine adjustments and non-routine adjustments as explained below:

Routine Adjustments of the Baseline

IPMVP provides the following guidance on performing routine adjustments: “For any energy governing factors expected to change routinely during the monitoring period such as weather… a variety of techniques can be used to perform the adjustments. Techniques may be as simple as a constant value (no adjustment) or as complex as a several multiple parameter non-linear equations, each correlating energy with one or more independent variables. Valid mathematical techniques must be used to derive

[4] Ibid.

the adjustment method." The quantification of routine baseline adjustments should reflect best practice set out in the latest IPMVP volume[5].

Non-Routine Adjustments of the Baseline

IPMVP provides examples of non-routine adjustments. The quantification of non-routine baseline adjustments should reflect best practice set out in the latest IPMVP volume.

Table 4: Baseline SS Emission Adjustment Quantification

[5] IPMVP contains examples of routine and non-routine adjustments.

SS	Units	Baseline SS Formula
B7 Building/System Energy Consumption (without ECMs)	kgCO2e	Emissions $_{Building/System\ Energy\ Consumption\ w/o\ ECM}$ = ∑ [(Vol. Fuel $_i$ * EF Fuel $_{i\ CO2}$) ; (GWP_{CH4} * Vol. Fuel $_i$ * EF Fuel $_{i\ CH4}$) ; (GWP_{N2O} * Vol. Fuel $_i$ * EF Fuel $_{i\ N20}$)] + [Electricity * EF $Grid_{CO2e}$] + [Thermal Energy * EF Thermal $Energy_{CO2e}$]

P10 Energy Consumption from Waste Processing	kgCO2e	Emissions $_{\text{Energy Consumption from Waste Processing}}$ = ∑ [(Vol. Fuel $_i$ * EF Fuel $_{i\ CO2}$) ; (GWP_{CH4} * Vol. Fuel $_i$ * EF Fuel $_{i\ CH4}$) ; (GWP_{N2O} * Vol. Fuel $_i$ * EF Fuel $_{i\ N20}$)] + [Electricity * EF $Grid_{CO2e}$] + [Thermal Energy * EF Thermal $Energy_{CO2e}$]
P14 Waste Decomposition and Methane Release	kgCO2e	Emissions $_{\text{Waste Decomposition and Methane Release}}$ $= 1000 * \phi * (1-f) * GWP_{CH4} * (1-OX) * \left(\frac{16}{12}\right) * F * DOC_f * MCF * \sum_{x=1}^{y}\sum_{j} W_{j,x} * DOC_j * e^{-k_j(y-x)} * \left(1-e^{-k_j}\right)$
P16 Energy Consumed from alternative processing of waste / use	kgCO2e	Emissions $_{\text{Energy Consumed from alternative processing of waste / use}}$ = ∑ [(Vol. Fuel $_i$ * EF Fuel $_{i\ CO2}$) ; (GWP_{CH4} * Vol. Fuel $_i$ * EF Fuel $_{i\ CH4}$) ; (Vol. Fuel $_i$ * EF Fuel $_{i\ N20}$)] + [Electricity * EF $Grid_{CO2e}$] + [Thermal Energy * EF Thermal $Energy_{CO2e}$]
P17 Process Emissions from Alternative Processing of Waste	kgCO2e	Emissions $_{\text{Process Emissions from Alternative Processing of Waste}}$ = ∑ [(Mass $_{CO2}$) ; (Mass $_{N2O}$) ; (Mass $_{CH4}$)]

7.4 Leakage

The project proponent must assess the likelihood of leakage based on the specific project activities. If it cannot be shown that no plausible material leakage would occur based on the specific project activities, then this methodology shall not be applied.

The project proponent must quantify GHG emissions sources occurring outside the project boundary as a result of implementation of the project activities, which are expected to contribute more than 1% of the overall average emission reductions.

7.5 Summary of GHG Emission Reduction and/or Removals

Quantification of the net GHG reductions must be calculated using the equation set out below.

Emission Reductions = [Emission $_{\text{Adjusted Baseline EE}}$ – Emissions $_{\text{Project EE}}$] + [Emission $_{\text{Adjusted Baseline WASTE}}$ – Emissions $_{\text{Project WASTE}}$]

Where:

Emissions $_{\text{Adjusted Baseline EE}}$ = the energy efficiency related baseline emissions plus any adjustments needed to adjust it to the conditions of the monitoring period

Emissions $_{\text{Adjusted Baseline WASTE}}$ = the waste related baseline emissions plus any adjustments needed to adjust it to the conditions of the monitoring period

Emissions $_{\text{Project EE}}$ = sum of the energy efficiency related emissions under the project scenario

Emissions $_{\text{Project WASTE}}$ = sum of the waste related emissions under the project scenario

8 Monitoring

8.1 Parameters Available at Validation

The following data units/parameters are referred to numerous times in the formulas presented in Section 6. Actual measured or local data are to be used when available. If not available, regional data must be used. The data sources for each parameter are offered below, however; in their absence, IPCC defaults can be used from the most recent version of the IPCC Guidelines for National Greenhouse Gas Inventories.

Parameter:	EF Thermal Energy$_{CO2e}$
Data unit:	Kg CO_2e per GJ
Description:	CO_2e emissions factor for local generation of thermal energy
Source of data:	For the Territory of interest, the project proponent must identify the most appropriate CO2e emission factor for the source of thermal energy used under the project scenario. Regional data (for example: US Department of Energy's Form EIA-1605 Appendix N. Emission factors for Steam and Chilled/Hot Water) shall be used. In its absence, IPCC defaults must be used from the most recent version of *IPCC Guidelines for National Greenhouse Gas Inventories* providing they are deemed to reasonably represent local circumstances. The project proponent must choose the values in a conservative manner and justify the choice.
Justification of choice of data or description of measurement methods and procedures applied:	Thermal Energy generation characteristics are likely to remain relatively stable over a year's time.

Parameter:	EF Fuel $_{i\ N20}$
Data unit:	Kg N_2O per L, m^3, or other
Description:	N_2O emissions factor for combustion of each type of fuel (EF Fuel $_{i\ N2O}$)
Source of data:	For both mobile and stationary fuel combustion for the Territory of interest, the project proponent must identify the most appropriate emission factors for the source of thermal energy used under the project condition. Regional data (for example: EPA's AP 42, *Compilation of Air Pollutant Emission Factors*) shall be used. In its absence, IPCC defaults must be used from the most recent version of *IPCC Guidelines for National Greenhouse Gas Inventories* providing they are deemed to reasonably represent local circumstances. The project proponent must choose the values in a conservative manner and justify the choice.
Justification of choice of data or description of measurement methods and procedures applied:	This is one of the most comprehensive fuel emission factor databases available.

Parameter:	EF Fuel $_{i\ CH4}$
Data unit:	Kg CH_4 per L, m^3, or other
Description:	CH_4 emissions factor for combustion of each type of fuel (EF Fuel $_{i\ CH4}$)
Source of data:	For both mobile and stationary fuel combustion for the Territory of interest, the project proponent must identify the most appropriate emission factors for the source of thermal energy used under the project scenario. Regional data (for example: EPA's AP 42, *Compilation of Air Pollutant Emission Factors*) shall be used. In its absence, IPCC defaults can be used from the most recent version of *IPCC Guidelines for National Greenhouse Gas Inventories* providing they are deemed to reasonably represent local circumstances. The project proponent must choose the values in a conservative manner and justify the choice.
Justification of choice of data or description of measurement methods and procedures applied:	This is one of the most comprehensive fuel emission factor databases available.

Parameter:	EF Fuel $_{i\ CO2}$
Data unit:	Kg CO_2 per L, m^3, or other
Description:	CO_2 Emissions Factor for combustion of each type of fuel (EF Fuel $_{i\ CO2}$)
Source of data:	For both mobile and stationary fuel combustion for the Territory of interest, the project proponent must identify the most appropriate emission factors for the source of thermal energy used under the project scenario. Regional data (for example: EPA's AP 42, *Compilation of Air Pollutant Emission Factors*) shall be used. In its absence, IPCC defaults can be used from the most recent version of *IPCC Guidelines for National Greenhouse Gas Inventories* providing they are deemed to reasonably represent local circumstances. The project proponent must choose the values in a conservative manner and justify the choice.
Justification of choice of data or description of measurement methods and procedures applied:	This is one of the most comprehensive fuel emission factor databases available.

Parameter:	ϕ
Data unit:	-
Description:	Model correction factor to account for model uncertainties (0.9)
Source of data:	This factor is determined using the CDM's "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)" (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Parameter:	OX
Data unit:	-
Description:	Oxidation factor (reflecting the amount of soil or other material covering the waste)
Source of data:	This factor is determined using the CDM's "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)" (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Parameter:	DOC_f
Data unit:	-
Description:	Fraction of degradable organic carbon (DOC) that can decompose
Source of data:	This factor is determined using the CDM's "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)" (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Parameter:	DOC_j
Data unit:	-
Description:	Fraction of degradable organic carbon (by weight)
Source of data:	This factor is determined using the CDM’s “Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)” (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Parameter:	MCF
Data unit:	-
Description:	Methane correction factor
Source of data:	This factor is determined using the CDM’s “Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)” (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Parameter:	k_j
Data unit:	-
Description:	Decay rate for the waste type j
Source of data:	IPCC 2006 Guidelines for National Greenhouse Gas Inventories (adapted from Volume 5, Table 3.3)
Justification of choice of data or description of measurement methods and procedures applied:	Apply the following default values for the different waste types j

Waste type *j*		**Boreal and Temperate (MAT≤20°C)**		**Tropical (MAT>20°C)**	
		Dry (MAP/PET <1)	Wet (MAP/PET >1)	Dry (MAP< 1000mm)	Wet (MAP> 1000mm)
Slowly degrading	Pulp, paper, cardboard (other than sludge), textiles	0.04	0.06	0.045	0.07
Slowly degrading	Wood, wood products and straw	0.02	0.03	0.025	0.035
Moderately degrading	Other (non-food) organic putrescible garden and park waste	0.05	0.10	0.065	0.17
Rapidly degrading	Food, food waste, beverages and tobacco (other than sludge)	0.06	0.185	0.085	0.40

NB: MAT – mean annual temperature, MAP – Mean annual precipitation, PET – potential evapotranspiration. MAP/PET is the ratio between the mean annual precipitation and the potential evapotranspiration.

If a waste type, prevented from disposal by the proposed CDM project activity, cannot clearly be attributed to one of the waste types in the table above, project participants choose among the waste types that have similar characteristics that waste type where the values of *DOCj* and *kj* result in a conservative estimate (lowest emissions), or request a revision of / deviation from this methodology.

Document in the CDM-PDD the climatic conditions at the SWDS site (temperature, precipitation and, where applicable, evapotranspiration). Use long-term averages based on statistical data, where available. Provide references.

8.2 Data and Parameters Monitored

The specific data and parameters associated with each SS are identified below.

Data Unit / Parameter:	Vol. $Fuel_i$
Data unit:	L, m^3, or other
Description:	Volume of each type of fuel combusted. This volume of fuel is adjusted for both functional equivalence and units of productivity.
Source of data:	The volume of fuel is determined by third party custody invoices, consolidated monthly. Un-calibrated internal meters cannot be used.
Description of measurement methods and procedures to be applied:	Monthly invoices filed for verification.
Frequency of monitoring/recording:	Monthly.
QA/QC procedures to be applied:	Manual transcription is avoided where possible.

Data Unit / Parameter:	Electricity
Data unit:	kWh
Description:	The amount of electricity consumed from the grid.
Source of data:	The amount of electricity consumed from the grid is determined by third party custody invoices, consolidated monthly. If internal meters are required for the Isolation Parameter Measurement option, calibration records is provided as per the manufacturer's schedule.
Description of measurement methods and procedures to be applied:	Monthly.
Frequency of monitoring/recording:	Manual transcription is avoided where possible.
QA/QC procedures to be applied:	Cross reference when possible.

Data Unit / Parameter:	EF $Grid_{CO2e}$
Data unit:	Kg CO2e per kWh
Description:	CO_2e Emissions Factor for electricity from the grid.
Source of data:	For the Territory of interest, the project proponent must calculate the emission factor for the appropriate emission factor using the CDM's "Tool to calculate the emission factor for an electricity system (Version 2.2.1)" (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	Refer to the latest version of the CDM tool.

Data Unit / Parameter:	Thermal Energy
Data unit:	GJ
Description:	Thermal Energy consumed at the facility. This amount is adjusted for both functional equivalence and units of productivity.
Source of data:	Thermal energy crossing the boundary is measured with monthly invoices. If the thermal energy crosses the boundary without a custody caliber meter, only calibrated internal meters is relied upon. Calibration records must be made available during verification.
Description of measurement methods and procedures to be applied:	Continuous Metering or invoice reconciliation
Frequency of monitoring/recording:	Frequency of metering and reconciliation is most frequent as possible.
QA/QC procedures to be applied:	Cross-checked with the quantity of heat invoiced if relevant

Data Unit / Parameter:	$W_{j,x}$
Data unit:	kg
Description:	Mass of Waste Material Sent to Landfill
Source of data:	Direct measurement of mass of waste sent for disposal.
Description of measurement methods and procedures to be applied:	Continuous metering or invoice reconciliation. The mass of material diverted from conventional landfill disposal may be measured by invoice reconciliation from a sight appropriate for no anaerobic disposal of waste. The mass of organic material sent to landfill may be measured upon departure from the composting site or at the waste disposal site. Care must be taken to ensure no material is then diverted to landfill without being accounted for.
Frequency of monitoring/recording:	Both methods are standard practice. Frequency of metering is highest level possible.
QA/QC procedures to be applied:	As per the latest version of the "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)" (CDM, 2011).

Data Unit / Parameter:	f
Data unit:	-
Description:	Fraction of methane captured in the SWDS gas
Source of data:	This factor is determined using the CDM's "Tool to determine methane emissions avoided from disposal of waste at a solid waste disposal site (Version 05.1.0)" (CDM, 2011).
Justification of choice of data or description of measurement methods and procedures applied:	The most used tool for calculation landfill gas emission reductions.

Data Unit / Parameter:	Mass $_{CO2}$
Data unit:	Kg
Description:	Mass of CO_2 emitted as a process emissions
Source of data:	Measured or Estimated
Description of measurement methods and procedures to be applied:	This variable can be either measured or estimated. Measured process emissions would be conducted via a continuous monitoring system that records both the flow rate of the gas and the percent composition of CO_2. This would allow a mass to be accurately determined. If measurement is in place, calibration schedules and records must be provided in the project document. If estimation is used in absence of a continuous monitoring system, the details of the mass balance must be provided in the project document. The mass balance must include the justification around an average waste composition used in the mass balance.
Frequency of monitoring/recording:	Continuous measurement or hourly estimations
QA/QC procedures to be applied:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements or cross checking with other reported values.

Data Unit / Parameter:	Mass $_{N2O}$
Data unit:	Kg
Description:	Mass of N_2O emitted as a process emissions
Source of data:	Measured or Estimated
Description of measurement methods and procedures to be applied:	This variable can be either measured or estimated. Measured process emissions would be conducted via a continuous monitoring system that records both the flow rate of the gas and the percent composition of N_2O. This would allow a mass to be accurately determined. If measurement is in place, calibration schedules and records must be provided in the project document. If estimation is used in absence of a continuous monitoring system, the details of the mass balance must be provided in the project document. The mass balance must include the justification around an average waste composition used in the mass balance.
Frequency of monitoring/recording:	Continuous measurement or hourly estimations
QA/QC procedures to be applied:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements or cross checking with other reported values.

Data Unit / Parameter:	Mass $_{CH4}$
Data unit:	Kg
Description:	Mass of CH_4 emitted as a process emissions
Source of data:	Measured or Estimated
Description of measurement methods and procedures to be applied:	This variable can be either measured or estimated. Measured process emissions would be conducted via a continuous monitoring system that records both the flow rate of the gas and the percent composition of CH_4. This would allow a mass to be accurately determined. If measurement is in place, calibration schedules and records must be provided in the project document. If estimation is used in absence of a continuous monitoring system, the details of the mass balance must be provided in the project document. The mass balance must include the justification around an average waste composition used in the mass balance.
Frequency of monitoring/recording:	Continuous measurement or hourly estimations
QA/QC procedures to be applied:	If the measurement results differ significantly from previous measurements or other relevant data sources, conduct additional measurements or cross checking with other reported values.

8.3 Description of the Monitoring Plan

Data quality management must include sufficient data capture such that the mass and energy balances may be easily performed with the need for minimal assumptions and use of contingency procedures. The data shall be of sufficient quality to fulfill the quantification requirements and be substantiated by company records for the purpose of verification.

The project proponent shall establish and apply quality management procedures to manage data and information. Written procedures must be established for each measurement task outlining responsibility, timing and record location requirements. The greater the rigor of the management system for the data, the easier it will be to conduct an audit for the project.

In case of doubt regarding appropriateness of the proposed sample, the project proponent shall refer to the latest version of the CDM *General Guidelines for Sampling and Surveys for Small-Scale Project Activities and Programme of Activities (PoAs)*.

Record keeping practices shall include the following procedures:

- Electronic recording of values of logged primary parameters for each measurement interval;
- Offsite electronic back-up of all logged data;

- Written logs of operations and maintenance of the project system including notation of all shut-downs, start-ups and process adjustments; and
- Storage of all documents and records in a secure and retrievable manner for at least two years after the end of the project crediting period.

Quality assurance/Quality control (QA/QC) shall also be applied to add confidence that all measurements and calculations have been made correctly. These include, but are not limited to:

- Protecting monitoring equipment (sealed meters and data loggers);
- Protecting records of monitored data (hard copy and electronic storage);
- Checking data integrity on a regular and periodic basis (manual assessment, comparing redundant metered data, and detection of outstanding data/records);
- Comparing current estimates with previous estimates as a ‘reality check’;
- Provide sufficient training to operators to perform maintenance and calibration of monitoring devices;
- Establish minimum experience and requirements for operators in charge of project and monitoring; and
- Performing recalculations to make sure no mathematical errors have been made.

Requirements for sampling eligibility of a Territory within a Sustainable Community[6]:

- Project Units in the Territory, connected to the Sustainable Community and which apply all or part of the Sustainable Community activities (identified as ECM and/or waste diversion) are applicable for sampling as long the Sustainable Community data are collected and stored in the project proponent system.
- The project proponent’s data collection and storage shall be centrally controlled and administered.
- The project proponent shall demonstrate its capacity to identify project units with data that inappropriately[7] affects the confidence interval of the Sustainable Community; these project units shall either be audited or excluded from the Sustainable Community.

Confidence Interval requirements:

- The Confidence Interval shall be set to 95%.

---

[6] Sampling requirements follow guidance provided in *ANSI/ASQC Z1.4-2008* “Sampling Procedures and Tables for Inspection*” by Attributes* and *IAF MD 1:2007* “IAF Mandatory Document for the Certification of Multiple Sites Based on Sampling.”

[7] Inappropriate in this context means data collected which, when compared to regional conditions, are outside the acceptable range (defect).

Sampling size requirements:

- The sample shall be partly selective based on factors, such as importance of activities and GHG reduction volume, range of activities being conducted, exceptional performance (beyond Territory and sectoral performance).
- The sample shall be partly nonselective, with at least 20% of the sample being selected at random.
- The project proponent shall have a documented procedure for determining the sample to be taken when verifying project sites and submit to the validation/verification body.
- When necessary, stratified random sampling shall be conducted on homogeneous sub-populations. The criteria for sub-population grouping are based on appropriate economic sectors. The criteria are based on an official territory authority classification or an internationally recognized equivalent (examples include the North American Industry Classification System (NAICS) or Statistical Classification of Economic Activities in the European Community (NACE[8]).

For a Territory, there are three different levels of sampling:

- Normal: the size of the sample shall be the square root of the number of project units connected to the project proponent, rounded to the upper whole number.
- Reduced: the size of the sample shall be the square root of the number of project units connected to the project proponent reduced by a coefficient (max. 0.6) when the overall confidence interval of the Sustainable Community data exceeds the target value[9].
- Reinforced: the size of the sample shall be the square root of the number of project units connected to the project proponent increased by a coefficient (max. 1.3) when the overall confidence interval of the Sustainable Community data is below the target value.

Sample Defect requirements:

- The sample size shall be enlarged to a maximum of 160% of the initial size if the reported values for one or more GHG reduction activities is beyond the acceptable range (defect) and the number of defects exceeds the acceptable quality level.
- The sample size shall be reduced to a maximum of 60% of the initial size if all client facility reported values are within the acceptable range (no defects) for five consecutive samplings.

---

[8] The Statistical Classification of Economic Activities in the European Community (in French: *Nomenclature Statistique des Activités économiques dans la Communauté Européenne (NACE*)) is a pan-European classification system which groups organizations according to their business activities.

[9] The target value corresponds to a confidence interval of 95%.

Sectoral Scope 7

Fuel Switch from Gasoline to Ethanol in Flex-Fuel Vehicle Fleets

18 June 2012

Document Prepared by Keyassociados and Ecofrotas

Relationship to Approved or Pending Methodologies

There is no sectoral scope 7 methodology currently approved under the VCS. Also, none of the sectoral scope 7 methodologies under development in the VCS are focused on commercial fleet fossil fuel substitution, as further explained below:

Methodology for Determining GHG Emission Reductions Through Bicycle Sharing Projects – from sectoral scope 7, this methodology is applicable for project activities that reduce GHG emissions through the usage of public sharing-based bicycle projects which introduce an alternative mode of transportation to displace other, more carbon intensive modes.

Methodology for Efficiency Improvements HDV's and Mobile Machinery – from sectoral scope 7, this methodology aims to improve the efficiency of trucks and/or mobile machinery equipment. Measures to improve operating vehicle efficiency may include but are not limited to anti-idling devices, eco-drive, tire-rolling resistance improvement, air-conditioning system improvement, low viscosity oils, cab-heaters, aerodynamic drag reduction measures, transmission improvements, etc.

There is no approved or pending methodology in the UNFCCC, from sectoral scope 7, for which a revision could be requested to comprise the project activity of fossil fuel substitution in commercial fleets, as presented below:

AM0031 - Baseline methodology for bus rapid transit projects - focuses on the construction and operation of a new bus rapid transit system (BRT) for urban transport of passengers.

AM0090 - Modal shift in transportation of cargo from road transportation to water or rail transportation - focuses on the displacement of a more-carbon-intensive transportation mode.

ACM0016 - Baseline methodology for mass rapid transit projects - focuses on the establishment and operation of rail-based or bus-based mass rapid transit systems in urban or suburban regions for passenger transport by replacing a traditional urban bus-driven public transport system.

AMS-III.AA - Transportation energy efficiency activities using retrofit technologies - focuses on energy efficiency measures in transportation to reduce GHG emissions due to decreased fuel consumption.

AMS-III.AK - Biodiesel production and use for transport applications - focuses on the production of biodiesel that is used for transportation applications, where the biodiesel is produced from oilseed cultivated on dedicated plantations and from waste oil/fat.

AMS-III.AP - Transport energy efficiency activities using post-fit Idling Stop device - focuses on the demand side activities associated with the installation of post-fit type Idling Stop devices in passenger vehicles used for public transport, in order to reduce fossil fuel consumption and GHG emissions.

AMS-III.AQ - Introduction of Bio-CNG in transportation applications - focuses on the production of Biogenic Compressed Natural Gas (Bio-CNG) from renewable biomass including waste organic matters to be used in transportation applications. The crops from renewable biomass origin used for production of the Bio-CNG should be sourced from dedicated plantations.

AMS-III.AT - Transportation energy efficiency activities installing digital tachograph systems to commercial freight transport fleets - focuses on the installation of a digital tachograph system that reduces GHG emissions associated with fossil fuel combustion in freight transport by providing to the driver feedback against inefficient driving.

AMS-III.C - Emission reductions by electric and hybrid vehicles - comprises emission reductions from electric and hybrid vehicle use only.

AMS-III.S - Introduction of low-emission vehicles/technologies to commercial vehicle fleets - focuses on introducing low-greenhouse gas emitting vehicles for commercial passenger (including public transportation), material and freight transport, operating on a number of routes with comparable conditions. Retrofitting of existing vehicles is also included in the methodology.

AMS-III.T - Plant oil production and use for transport applications - covers project activities involving the cultivation of oilseeds, the production of plant oil and the use of plant oil for transportation applications.

AMS-III.U - Cable Cars for Mass Rapid Transit System (MRTS) - focuses on cable cars substituting traditional road based transport trips.

NM0360 - Use of lower energy-intensive intermodal transportation method to transport freight (use of pipeline rather than over-the-road truck) - assumes that switching from truck transportation to an alternative transport method of lower energy intensity will result in reduction of fossil fuel consumption.

NM0357 - Methodology for Rail Projects - applicable for rail projects investing in new infrastructure for passenger and cargo transport. Emission reductions are due to mode shift basically from road to rail.

SSC-NM074 - Emission Reductions through Improved Efficiency of Vehicle Fleets - for project activities that improve the efficiency of vehicle fleets through improvement of the operational efficiency, i.e. a reduction of fuel usage.

Among all assessed methodologies from sectoral scope 7, four have been considered more similar to the present one (AMS-III.T, AMS-III.AK, AMS-III.AQ and AM0090) and deserved a better evaluation regarding its applicability. In the case of AM0090, the present methodology does not involve a modal shift. Flex-fuel vehicles both in the baseline and project scenarios compose the commercial fleets, and it also does not refer to cargo transportation, it refers only to the choice between two types of fuel. The approved methodologies AMS-III.T, AMS-III.AK and AMS-III.AQ are related to the biofuel production, while the present methodology is focused on the option to consume fuels available in the market (ethanol instead of gasoline); and the present methodology refers to ethanol, not biodiesel or Bio-CNG.

As demonstrated for each UNFCCC sectoral scope 7 methodology presented above, none are applicable to the proposed project activity of commercial fleet fossil fuel substitution or presents the possibility of requesting a revision.

Regarding the Climate Action Reserve, there is no protocol from the sectoral scope of transport.

Table of Contents

1 SOURCES

This methodology is not based on any approved baseline and/or monitoring methodologies.

It refers to the latest approved versions of the following tools:

- *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion* (UNFCCC);
- *Combined tool to identify the baseline scenario and demonstrate additionality* (UNFCCC).

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology is applicable to project activities that aim at complete substitution of gasoline or gasoline blends by ethanol in commercial fleets of flex-fuel vehicles. The monitoring plan must guarantee exclusive consumption of ethanol by vehicles from the project boundary. This should be done using a fuel monitoring system (direct or indirect measurement) with continuous registration of place (gas station), date, type and quantity of fuel used in the project activity.

In order to calculate the baseline emissions, historical fuel consumption pattern shall be analysed and a factor that shows the ratio of gasoline to ethanol in the total consumption of fuel by commercial fleet shall be calculated. In cases where the project area is not homogenous in terms of availability and prices of fuels, it should be stratified into project regions. The fuel consumption pattern should be calculated for each project region. Historical fuel consumption pattern is based on historical data of the project proponent. In cases when no credible historical data is available or in the case of a Greenfield project activity instance, the historical average pattern of the same regional group shall be used.

Additionality shall be demonstrated by applying the latest version of CDM *Combined tool to identify the baseline scenario and demonstrate additionality*.

The baseline emissions are calculated by applying the determined fuel consumption pattern (ratio of gasoline to ethanol in the total fuel consumption during the historical reference period), corrected by a fuel conversion factor, to the total quantity of ethanol consumed in the year *y* of the project activity. The fuel conversion factor determines a quantity of ethanol needed to substitute one liter of gasoline in the type of vehicles used in the project activity.

Project emissions are calculated by applying the emission factor to the quantity of gasoline consumed in the project activity and monitored in liters.

The emissions reductions are calculated as the difference between the baseline emissions and the project emissions. No leakage emissions are attributed to this project type.

Additionality	Project Method
Crediting Baseline	Project Method

3 DEFINITIONS

For the purpose of this methodology, the following definitions apply:

Commercial fleet - 10 or more vehicles owned by a single company and used for business purposes.

Direct measurement – Direct measurement of fuel consumption in the project activity corresponds to a measurement that registers the data that will be utilized in the emission reduction calculation with no treatment (i.e., no statistical estimation or conversion can be used to find the fuel consumption in liters).

Emergency gasoline - gasoline consumed in cases of ethanol temporary unavailability in specific gas stations.

Ethanol - fuel produced from renewable biological resources such as plant biomass.

Flex-fuel vehicle - a flexible-fuel vehicle (FFV) is an automobile that can alternate between at least two sources of fuel, such as gasoline or ethanol blends in any proportion.

Fuel consumption pattern - proportion of gasoline to ethanol used in the flex-fuel vehicles of the project proponent commercial fleets in the baseline scenario.

Greenfield – any new project activity instance, corresponding to an existent flex-fuel vehicles fleet, with insufficient history under the monitoring conditions specified by the project activity.

I**ndirect measurement** – Indirect measurement of fuel consumption in the project activity corresponds to a measurement of a data registry that needs to be converted to the unit that will be used for the emission reduction calculation, or the measurement of a sample group that will be used to estimate the consumption of the whole fleet.

Lifecycle emissions - The aggregate quantity of greenhouse gas emissions (including direct and significant indirect emissions such as land use changes), related to the full fuel lifecycle, including all stages of fuel and feedstock production and distribution, from feedstock generation or extraction through the distribution, delivery and use of the finished fuel by the final consumer.[1]

Opportunity cost - The cost of an alternative that must be forgotten when the fleet owner decides to adhere the project activity (e.g., the benefits from the flexible alternative (the choice for the cheapest fuel type) that the fleet owner is giving up when opting for the exclusive consumption of ethanol).

Regional Grouping - is a multivariable method that aims at classifying a sample of subjects (or objects) on the basis of a set of measured variables.

Renewable materials - any natural resources of economic value that can be replaced or replenished fast enough so that the supply continues to be available in time. In the case of fuels, renewable materials are those whose source can be cultivated and/or replaced by human activity (e.g. wheat, corn, sugar beets, sugar cane and molasses).

[1] The definition of lifecycle emissions was adapted from the United States Energy Independence and Security Act of 2007 (EISA), retrieved from the United States Environmental Protection Agency (EPA), available at: http://www.epa.gov/oms/renewablefuels/420f10006.htm#footnotes

Start-up Gasoline - gasoline reserved for the ignition of ethanol engines at low temperatures in flex-fuel technologies, located in a separate reservoir of around 1 liter.

Vehicle owner - company responsible for the operational control of the vehicle.

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that aim at complete substitution of fossil fuels or blends of gasoline by ethanol in commercial fleets of the project proponent. The methodology is applicable under the following conditions:

- Project boundary contains commercial fleets that consist exclusively of flex-fuel vehicles (i.e. only flex-fuel vehicles are used both in baseline scenario and in the project activity);
- Only existent fleets of flex-fuel vehicles are eligible (i.e. flex-fuel vehicle acquisition is not acceptable under this methodology);
- In the baseline scenario, the vehicles use gasoline or blend of any proportion of ethanol and gasoline (0-99%);
- Fuel consumed in the project activity is exclusively ethanol (E100); up to 5% of total fuel consumed per fleet and per year can be gasoline, for emergency cases and for the start-up mechanism as required by the flex-fuel motor technology. Where a fleet consumes more than 5% of gasoline in a given year, it shall be permanently excluded from the project activity, with no possibility to be reinserted and no right to receive credits for the reductions achieved in that year and all subsequent ones;
- The project activity fuel (ethanol) is available at the same gas stations as the baseline fuel (gasoline or blend of ethanol and gasoline) for at least 50% of the gas stations available in the project region;
- Gasoline, ethanol and their blends comply with relevant regulations (national or regional market);
- Ethanol used in the project is produced from renewable resources[2];
- Ethanol used in the project shall have lower lifecycle emissions than the gasoline used in the baseline. The onus is upon the project proponent to clearly demonstrate this, failing which the project shall not be eligible for crediting.[3]

[2] In order to demonstrate that the ethanol used in the project activity is produced from renewable materials, the project proponent shall evaluate the production of the ethanol available in the project region and the Validation/Verification Body must evaluate such assessment and issue its favorable opinion on the renewable characteristic of ethanol for the project region.

[3] Several lifecycle analyses have concluded that ethanol can have lower lifecycle emissions than gasoline. Such studies have been performed by the U.S. EPA, UNEP and FAO. In order to demonstrate compliance with this applicability condition, project proponents may also reference other studies, as relevant to their project, available from a recognized, credible source, and reviewed for publication by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.

- The monitoring system is designed to allow measurement of the fuel consumption for each vehicle in each fleet within the project boundaries continuously (on each fueling operation), over the whole project crediting period and during the period to which the historical consumption pattern refers;

- The system of measurement (direct and indirect) shall guarantee that 95% of the fuel consumed per fleet and per year under the project activity is ethanol. When direct measurement is used, the Validation/Verification Body has the authority to decide when the measurement method adopted by the project activity is robust enough to ensure that the data (type and quantity of fuel consumed) obtained, processed and registered is reliable. When indirect measurement is used, the project activity must guarantee that the width of a 95% confidence interval does not exceed 30% of the estimated value, in order to ensure that the uncertainty range is not significant. If the data does not satisfy this criteria, it cannot be used in the project activity;

- No legal requirement exists to use exclusively ethanol fuel in commercial fleets in the relevant market (national or regional);

- Where the project proponent is not the owner of the commercial fleet vehicles (e.g., the project proponent is a fleet manager with many clients, each client being the owner of its respective commercial fleet vehicles), there shall exist a contract between the project proponent and each fleet owner to establish clear ownership of the emission reductions;

- As in the CDM baseline and monitoring methodologies related to the biofuel production (i.e., AMS.III-T, AMS.III-AK, and AMS.III-AQ discussed above), "*the retailer, the final users, and the producer are bound by a contract that states that the final consumers and retailers shall not claim emission reductions resulting from its consumption"*, the contract between the project proponent and the fleet owner shall include a clause stating that, to avoid double counting in the supply chain, the commercial fleet owner must not participate in any other emission reduction project associated with a biofuel producer or retailer. Only the commercial fleet owner or manager can claim emissions reductions under this methodology.

5 PROJECT BOUNDARY

The project boundary encompasses flex-fuel vehicles from the project commercial fleets. The project area includes all the gas stations used by the project commercial fleets as a part of the project activity.

The only emission source included in both the baseline and project scenario is the gasoline consumption by the commercial fleets within the project boundary[4]:

[4] This approach is the same used in AM0090.

Source		Gas	Included?	Justification/Explanation
Baseline	Gasoline Consumption	CO_2	Yes	Main emission source.
		CH_4	No	Excluded for simplification. This is conservative.
		N_2O	No	Excluded for simplification. This is conservative.
Project	Gasoline Consumption	CO_2	Yes	Main emission source.
		CH_4	No	Excluded for simplification. This is conservative.
		N_2O	No	Excluded for simplification. This is conservative.

Stratification of the project area into the project regions

In order to guarantee the accuracy and precision of the baseline emissions calculation, a stratification of the project region shall be carried out. Stratification is conducted *ex ante* and remains fixed for the whole project crediting period. It shall be based on publicly available data.

Stratification of the project area is conducted through a multivariable method that aims at classifying a sample of subjects (or objects) on the basis of a set of measured variables. The subjects are classified into a number of different groups in a way that similar subjects are placed in the same group. The obligatory variables that shall be included in the regional grouping of the project are fuel availability, prices and regulatory framework. Additional optional variables can be proposed by the project proponent and shall be justified.

The use of hierarchical methods (agglomerative or divisive) is suggested as the most suitable option for regional grouping of the project, considering the obligatory variables. Such methods include different approaches to define the distance that is used to establish the regional groups, such as Ward method (which minimizes the variance inside each group), single linkage (where the distance between two groups is the minimum of the distances of all pairs of patterns drawn from the two groups), complete linkage (where the distance between two groups is the maximum of all pairwise distances between patterns in the two groups), etc. Still, the project proponent can suggest application of non-hierarchical methods[5] (also known as k-means grouping methods) along with justification of the choice.

The project proponent shall select a distance measure (e.g., Euclidean distance) and justify why it is the most appropriate to determine similarity between regions in the project activity.

For both definition of the regional grouping method and distance measure to be applied by a project activity, the Validation/Verification Body has the authority to decide whether they are the most suitable and proper for the regional grouping process.

Therefore, a regional group is a subdivision of the project activity region, defined by its features of fuel availability, price, regulatory framework and other additional optional variables. The baseline and additionality assessments shall be conducted for each of the regional groups separately.

[5] In these methods the desired number of regional groups is specified in advance and the ’best’ solution is chosen.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

The project proponent shall apply the latest version of the CDM *Combined tool to identify the baseline scenario and demonstrate additionality* to identify the baseline scenario for every regional group and for every commercial fleet in the project boundary, including Greenfield instances.

When applying Step 1 of the CDM *Combined tool to identify the baseline scenario and demonstrate additionality*, the project proponent shall consider as alternative scenarios, at least the following alternatives:

S1: The proposed project activity undertaken without being registered as a VCS project activity;

S3: The continuation of the current situation, not requiring any investment or expenses to maintain the current situation.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Additionality shall be demonstrated for each regional group by applying the latest version of the CDM *Combined tool to identify the baseline scenario and demonstrate additionality*.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

The baseline emissions include exclusively the emissions from fossil fuel combustion by the commercial fleet that would have occurred in the baseline scenario.

The baseline emissions are calculated as follows:

$$BE_y = \sum_{i=x_1}^{x_n} BE_{FF,i,y} \quad (1)$$

Where:

BE_y	Baseline emissions in the year *y* (tCO_2);
$BE_{FF,i,y}$	Baseline emissions from gasoline combustion by commercial fleet *i* in year *y* (tCO_2e);
i	$x_1, x_2, \ldots, x_n$ commercial fleets in the project activity.

The baseline emissions from fossil fuel combustion by a commercial fleet are calculated as follows:

$$BE_{FF,i,y} = COEF_{gas,y} \bullet \sum_{R=r_1}^{r_m} FC_{gas,i,R,y} \quad (2)$$

Where:

$BE_{FF,i,y}$	Baseline emissions from gasoline combustion by commercial fleet *i* in year *y* (tCO_2e);

$FC_{gas,i,R,y}$	Gasoline consumption by the commercial fleet *i* in the baseline scenario, in regional group *R* in year *y* (L);
$COEF_{gas,y}$	CO_2 emission coefficient of gasoline in year *y* (tCO_2/L)
R	r_1, r_2, ... , r_m regional groups where a fleet *i* has fueled during the year *y*.

The gasoline consumption by fleets in the baseline scenario is calculated as follows:

$$FC_{gas,i,R,y} = FC_{ethanol,i,R,y} \bullet P_{i,R,BSL} \bullet T_{ff,y} \quad \textbf{(3)}$$

Where:

$FC_{gas,i,R,y}$	Gasoline consumption by the commercial fleet *i* in the baseline scenario, in regional group *R* in year *y* (L);
$FC_{ethanol,i,R,y}$	Ethanol consumption by the commercial fleet *i* in the project activity in regional group *R* in year *y* (L);
$P_{i,R,BSL}$	Baseline fuel consumption pattern of commercial fleet *i* in regional group *R* in the baseline scenario (adimensional);
$T_{ff,y}$	Conversion factor between gasoline and ethanol in year *y* (dimensionless);

8.1.1. Procedure to calculate the CO_2 emission coefficient ($COEF_{gas,y}$)

The CO_2 emission coefficient $COEF_{gas,y}$ is calculated through the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion*. It can be calculated using one of the following two options depending on the availability of data on gasoline as follows:

Option A: The CO_2 emission coefficient $COEF_{gas,y}$ is calculated based on the chemical composition of gasoline, using the following approach:

$$COEF_{gas,y} = w_{C,gas,y} \bullet \rho_{gas,y} \bullet 44/12 \quad \textbf{(4)}$$

Where:

$COEF_{gas,y}$	CO_2 emission coefficient of gasoline in year *y* (tCO_2/L);
$w_{C,gas,y}$	weighted average mass fraction of carbon in gasoline in year *y* (tC/mass unit);
$\rho_{gas,y}$	weighted average density of gasoline in year *y* (mass unit/L).

Option B: The CO_2 emission coefficient $COEF_{gas,y}$ is calculated based on net calorific value and CO_2 emission factor of gasoline, as follows:

$$COEF_{gas,y} = NCV_{gas,y} \bullet EF_{CO2,gas,y} \quad \textbf{(5)}$$

Where:

$COEF_{gas,y}$	CO_2 emission coefficient of gasoline in year *y* (tCO_2/L);
$NCV_{gas,y}$	weighted average net calorific value of gasoline in year *y* (GJ/L);
$EF_{CO2,gas,y}$	weighted average CO_2 emission factor of gasoline (tCO_2/GJ).

Option A is the preferred approach, if the necessary data is available.

8.1.2. Procedure to determine the baseline fuel consumption pattern of a commercial fleet ($P_{i,R,BSL}$)

Proportion between the use of gasoline and the use of ethanol in the annual fuel consumption in the baseline scenario in a regional group characterizes the baseline fuel consumption pattern of a fleet in this regional group. The historical values of the fuel consumption patterns of the project proponent's commercial fleets shall be adopted. For this purpose it is acceptable that a minimum reference period of three years and a maximum period that is consistent with the ethanol availability in the project region be used (i.e., it shall take into account national circumstances, including policies and market conditions). The Validation/Verification Body has the authority to decide whether the maximum historical period is suitable or not.

In the case of a Greenfield project activity instance, or if insufficient historical data is available, the historical average consumption pattern from the same regional group shall be adopted.

Baseline fuel consumption pattern in a regional group is determined as follows:

$$P_{i,R,BSL} = \frac{FC_{gas,i,R,BSL}}{FC_{gas,i,R,BSL} + FC_{ethanol,i,R,BSL}} \quad \textbf{(6)}$$

Where:

$P_{i,R,BSL}$	Baseline fuel consumption pattern of a commercial fleet *i* in regional group *R* in the baseline scenario (adimensional);
$FC_{gas,i,R,BSL}$	Total quantity of gasoline consumed by commercial fleet *i* in regional group *R* during the reference period (L);
$FC_{ethanol,i,R,BSL}$	Total quantity of ethanol consumed by commercial fleet *i* in regional group *R* during the reference period (L).

8.1.3. Procedure to determine the conversion factor between gasoline and ethanol ($T_{ff,y}$)

The conversion factor between gasoline and ethanol is calculated as a relationship between net calorific values (NCV) of these fuels. It shows the equivalent volume of ethanol necessary to substitute one liter of gasoline in the project activity.

The conversion factor between gasoline and ethanol is calculated as follows:

$$T_{ff,y} = \frac{NCV_{ethanol,y}}{NCV_{gas,y}} \quad \textbf{(7)}$$

Where:

$T_{ff,y}$	conversion factor between gasoline and ethanol in year *y*;
$NCV_{ethanol,y}$	weighted average net calorific value of ethanol in year *y* (GJ/L);
$NCV_{gas,y}$	weighted average net calorific value of gasoline in year *y* (GJ/L).

8.2 Project Emissions

Project emissions include start-up and emergency consumption of gasoline in the project activity, for which the sum shall not exceed 5% of the total fuel consumption under the project activity per each fleet per year. The project emissions from ethanol consumption that is renewable fuel are considered zero.

Project emissions are calculated as follows:

$$PE_y = \sum_{i=x_1}^{x_n} PE_{FC,i,y} \quad (8)$$

Where:

PE_y	Project emissions in year *y* (t CO_2/yr)
$PE_{FC,i,y}$	Project emissions from gasoline combustion by commercial fleet *i* in year *y* (t CO_2/yr)
i	x_1, x_2,..., x_n commercial fleets in the project activity.

Project emissions from gasoline combustion are calculated as follows:

$$PE_{FC,i,y} = FC_{gas,i,y} \bullet COEF_{gas,y} \quad (9)$$

Where:

$PE_{FC,i,y}$	Project emissions from gasoline combustion in year y (tCO_2);
$FC_{gas,i,y}$	Gasoline consumption by commercial fleet *i* in the project scenario in year *y* (L);
$COEF_{gas,y}$	CO_2 emission coefficient of gasoline in year *y* (tCO_2/L), according to Procedure 8.1.1.

8.3 Leakage

No leakage emissions are considered in this methodology.

8.4 Summary of GHG Emission Reduction and/or Removals

Emission reductions are calculated as follows:

$$ER_y = BE_y - PE_y - LE_y \quad (10)$$

Where:

ER_y	Emission reductions in year *y* (tCO_2e/yr)
BE_y	Baseline emissions in year *y* (tCO_2e/yr)
PE_y	Project emissions in year *y* (tCO_2/yr)
LE_y	Leakage emissions in year *y* (tCO_2/yr)

9 MONITORING

9.1 Data and Parameters Available at Validation

In addition to the parameters listed in the tables below, the provisions on data and parameters not monitored in the tools referred to in this methodology apply.

Data Unit / Parameter:	$P_{i,R,BSL}$
Data unit:	adimensional
Description:	Fuel consumption pattern of fleet *i* in project region *R*, in the baseline scenario
Source of data:	Calculated *ex ante*
Justification of choice of data or description of measurement methods and procedures applied:	Calculated according to Procedure 8.1.2.
Any comment:	

Data Unit / Parameter:	$FC_{gas,i,R,BSL}$
Data unit:	liters
Description:	Total quantity of gasoline consumed by commercial fleet *i* in project region *R* during the reference period before the start of the project activity
Source of data:	Historical values
Justification of choice of data or description of measurement methods and procedures applied:	The historical fuel consumption of the project proponent's commercial fleets, obtained through direct or indirect measurement of fuel quantity and type, shall be adopted. If direct measurement was used, the respective equipment shall have been regularly calibrated following the manufacture specification. If indirect measurement was used, the Validation/Verification Body has the authority to decide when the measure method adopted by the project activity is robust enough to ensure that the data (type and quantity of fuel consumed) obtained, processed and registered is reliable. In the case of a Greenfield project activity instance or if no sufficient historical data is available, the historical average consumption pattern from the same regional group shall be adopted.
Any comment:	

Data Unit / Parameter:	$FC_{ethanol,i,R,BSL}$
Data unit:	liters
Description:	Total quantity of ethanol consumed by commercial fleet *i* in

	project region *R* during the reference period before the start of the project activity
Source of data:	Historical values
Justification of choice of data or description of measurement methods and procedures applied:	The historical fuel consumption of the project proponent's commercial fleets, obtained through direct or indirect measurement of fuel quantity and type, shall be adopted. If direct measurement was used, the respective equipment shall have been regularly calibrated following the manufacture specification. If indirect measurement was used, the Validation/Verification Body has the authority to decide when the measure method adopted by the project activity is robust enough to ensure that the data (type and quantity of fuel consumed) obtained, processed and registered is reliable. In the case of a Greenfield project activity instance or if no sufficient historical data is available, the historical average consumption pattern from the same regional group shall be adopted.
Any comment:	

9.2 Data and Parameters Monitored

Data Unit / Parameter:	$NCV_{gas,y}$
Data unit:	GJ/L
Description:	Weighted average net calorific value of gasoline in year *y*
Source of data:	The following data sources may be used if the relevant conditions apply:

Data source	Conditions for using the data source
a) Values provided by the fuel supplier in invoices	This is the preferred source
b) Measurements by the project proponent	If a) is not available
c) Regional or national default values	If a) and b) are not available. These sources should be based on well documented, reliable sources (such as national energy balances)
d) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in Table 1.2 of Chapter 1 of Vol.2 (Energy) of the 2006 IPCC Guidelines on National	If a), b) and c) are not available

	GHG Inventories
Description of measurement methods and procedures to be applied:	For a) and b): Measurements should be undertaken in line with national or international fuel standards.
Frequency of monitoring/recording:	For a) and b): The NCV should be obtained for each fuel delivery, from which weighted average annual values should be calculated. For c): Review appropriateness of the values annually For d): Any future revision of the IPCC Guidelines should be taken into account
QA/QC procedures to be applied:	Verify if the values under a), b) and c) are within the uncertainty range of the IPCC default values as provided in Table 1.2, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements. The project proponent must justify the value according to such conditions and the Validation/Verification Body has the authority to decide when the justification is appropriate. The laboratories in a), b) or c) should have ISO 17025 accreditation or justify that they can comply with similar quality standards.
Any comment:	

Data Unit / Parameter:	$NCV_{ethanol,y}$
Data unit:	GJ/L
Description:	Weighted average net calorific value of ethanol in year *y*.
Source of data:	The following data sources may be used if the relevant conditions apply:

Data source	Conditions for using the data source
a) Values provided by the fuel supplier in invoices	This is the preferred source
b) Measurements by the project proponent	If a) is not available
c) Regional or national default values	If a) and b) are not available. These sources should be based on well documented, reliable sources (such as national energy balances)
d) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in Table 1.2 of Chapter 1 of Vol.2 (Energy) of the 2006 IPCC Guidelines on National	If a), b) and c) are not available

	GHG Inventories
Description of measurement methods and procedures to be applied:	For a) and b): Measurements should be undertaken in line with national or international fuel standards
Frequency of monitoring/recording:	For a) and b): The NCV should be obtained for each fuel delivery from which weighted average annual values should be calculated. For c): Review appropriateness of the values annually. For d): Any future revision of the IPCC Guidelines should be taken into account
QA/QC procedures to be applied:	Verify if the values under a), b) and c) are within the uncertainty range of the IPCC default values as provided in Table 1.2, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements. The project proponent must justify the value according to such conditions and the Validation/Verification Body has the authority to decide when the justification is appropriate. The laboratories in a), b) or c) should have ISO 17025 accreditation or justify that they can comply with similar quality standards.
Any comment:	

Data Unit / Parameter:	$FC_{ethanol,i,R,y}$
Data unit:	liters
Description:	Ethanol consumption by the commercial fleet *i* in the project scenario in project region *R* in year *y*
Source of data:	Refueling transactions database
Description of measurement methods and procedures to be applied:	Direct or indirect measurement of place (gas station), date, type and quantity of fuel used in the project activity.
Frequency of monitoring/recording:	Every transaction
QA/QC procedures to be applied:	If direct measurement is used, the respective equipment shall be regularly calibrated following the manufacture specification. If indirect measurement is used, the Validation/Verification Body has the authority to decide when the measure method adopted by the project activity is robust enough to ensure that the data (type and quantity of fuel consumed) obtained, processed and registered is reliable.
Any comment:	

Data Unit / Parameter:	$w_{C,gas,y}$
Data unit:	tC/mass unit of gasoline
Description:	Weighted average mass fraction of carbon in gasoline in year *y*.
Source of data:	The following data sources may be used if the relevant conditions apply: **Data source** — **Conditions for using the data source** a) Values provided by the fuel supplier in invoices — This is the preferred source b) Measurements by the project proponent — If a) is not available
Description of measurement methods and procedures to be applied:	Measurements should be undertaken in line with national or international fuel standards
Frequency of monitoring/recording:	The mass fraction of carbon should be obtained for each fuel delivery, from which weighted average annual values should be calculated.
QA/QC procedures to be applied:	Verify if the values under a) and b) are within the uncertainty range of the IPCC default values as provided in Table 1.3, Vol. 2 of the 2006 IPCC Guidelines. If the values fall below this range collect additional information from the testing laboratory to justify the outcome or conduct additional measurements. The project proponent must justify the value according to such conditions and the Validation/Verification Body has the authority to decide when the justification is appropriate. The laboratories in b) should have ISO 17025 accreditation or justify that they can comply with similar quality standards.
Any comment:	Applicable where Option A is used. Preferably the same data source should be used for $w_{C,gas,y}$ and $\rho_{gas,y}$.

Data Unit / Parameter:	$\rho_{gas,y}$
Data unit:	mass unit of gasoline/L
Description:	Weighted average density of gasoline in year *y* (mass unit/L)
Source of data:	The following data sources may be used if the relevant conditions apply: **Data source** — **Conditions for using the data source** a) Values provided by the fuel — This is the preferred source

	<table><tr><td>supplier in invoices</td><td></td></tr><tr><td>b) Measurements by the project proponent</td><td>If a) is not available</td></tr><tr><td>c) Regional or national default values</td><td>If a) and b) are not available. Data Unit / Parameter:	$FC_{gas,\ i,\ y}$
Data unit:	L
Description:	Gasoline consumption by commercial fleet *i* in the project scenario in year *y*
Source of data:	Refueling transactions database
Description of measurement methods and procedures to be applied:	Direct or indirect measurement of place (gas station), date, type and quantity of fuel used in the project activity.
Frequency of monitoring/recording:	Every transaction
QA/QC procedures to be applied:	If direct measurement is used, the respective equipment shall be regularly calibrated following the manufacture specification. If indirect measurement is used, the Validation/Verification Body has the authority to decide when the measure method adopted by the project activity is robust enough to ensure that the data (type and quantity of fuel consumed) obtained, processed and registered is reliable.
Any comment:	When the $FC_{gas,\ i,\ y}$ represents more than 5% of the sum of $FC_{ethanol,i,R,y}$ and $FC_{gas,\ i,\ y}$ for an individual fleet and year, the project activity instance corresponding to this fleet shall be definitely excluded from the project activity, with no possibility to be reinserted and no right to reduction credits derived from such transgression year.

9.3 Description of the Monitoring Plan

All data collected as a part of monitoring process should be archived electronically and be kept at least for 2 years after the end of the last project crediting period. 100% of the data should be monitored if not indicated otherwise in the tables above. All direct measurements should be conducted with calibrated measurement equipment according to relevant industry standards.

This methodology applies to project activities that are not broadly similar to an activity or measure covered by an existing approved or pending methodology.

None of the similar methodologies identified above could be revised without substantial changes to the section on project boundary.

None of the similar methodologies identified above could be revised without the addition of new procedures or scenarios to more than half of its sections.

Table of Contents

1 SOURCES

The VCS Methodology Template was used to develop this methodology.

This Methodology is based on elements of the following CDM methodologies:

- AMS-III.AA. "Transportation Energy Efficiency Activities using Retrofit Technologies" (Section 4)
- AMS-III.S. "Introduction of Low Emission Vehicles/Technologies to Commercial Vehicle Fleets" (Sections 4 and 8)
- ACM0017 "Production of Biodiesel for Use as Fuel" (Sections 6, 8.3, and 9.2)
- AM0090 "Modal Shift in Transportation of Cargo from Road Transportation to Water or Rail Transportation" (Sections 6 and 8)

This methodology refers to the latest approved version of the following CDM tool:

- *Combined tool to identify the baseline scenario and demonstrate additionality* (Section 6 Procedure for Determining the Baseline Scenario)[1]

This methodology refers to elements of the latest approved version of the following CDM tool:

- *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion* (Section 9.2 Data and Parameters Monitored, including: "Source of data", "Description of measurement methods and procedures to be applied", "QA/QC procedures to be applied")[2]

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

Pallets are flat, portable structures that support goods during handling, transportation and storage. This methodology outlines procedures to estimate the avoided net greenhouse gas (GHG) emissions resulting from project activities involving the use of pallets that are lighter in weight than their conventional alternatives for freight transport. Typical GHG reduction projects with lightweight pallets involve:

a) Replacing an existing fleet of conventional wood pallets with lightweight pallets, or
b) Setting up a new fleet of pallets using lightweight pallets.

In both cases, the baseline would be the same fleet of conventional pallets. Projects achieve GHG emission reductions through reducing the total weight of goods transported, hence reducing fuel consumption and associated GHG emissions.

This methodology provides procedures to select the baseline from amongst plausible scenarios and provides methods to transparently estimate the baseline GHG emissions. Project emissions are

[1] http://cdm.unfccc.int/methodologies/PAmethodologies/tools/am-tool-02-v4.0.0.pdf

[2] http://cdm.unfccc.int/methodologies/PAmethodologies/tools/am-tool-03-v2.pdf

quantified by monitoring the fuel consumption by captive truck fleets transporting freight using lightweight pallets.

Baseline emissions are quantified by assuming the same routes, vehicles, fuel, and driving behavior as the project, and modifying GHG emissions associated with fuel consumption to take account of increased weight transported.

Relevant GHG sources not included in the project boundary (ie, production of raw materials and pallet manufacturing) are considered as leakage.

Additionality	Project Method
Crediting Baseline	Project Method

3 DEFINITIONS

Captive Fleet: A collection of vehicles with clearly defined boundaries, typically owned or managed by one party.

Conventional pallet: A pallet composed mainly of either wood or plastic. Currently, wood pallets dominate the market, representing 90-95% of all pallets produced across the globe.[3]

Freight: Goods transported by commercial fleets.

Lightweight pallet: A pallet that is lighter in weight than its conventional alternative.

Pallet: A flat, portable structure that supports goods during handling, transport and storage.

Trip: A journey where the weight transported remains constant. A new trip begins each time there is a change in the transported weight.

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that reduce GHG emissions from the transportation of freight on truck fleets by reducing the weight of pallets transported, hence reducing fuel consumption. Emission reductions claimed under this methodology are only related to increased fuel efficiency due to the use of lightweight pallets.

[3] FP Innovations: PalletTrends 2009. http://www.valuetowood.ca/imports/pdf/en/market_profiles/2009/Palette-Trends2009.pdf

The following conditions apply to this methodology:

Pallet Performance Requirements

a) Lightweight pallets deployed in the project must offer the same or better technical performance compared to the baseline pallets. This must be demonstrated via certified conformance with ISO 8611-2.

Pallet Identification

a) Lightweight pallets deployed in the project must each have a unique ID (e.g., Radio-Frequency Identification (RFID) tags, Universal Product Code (UPC), etc.) to facilitate monitoring.

Fleet, Truck and Fuel Characteristics

a) Vehicles are part of a captive fleet.
b) If project proponent is not the captive fleet operator, a contract addressing ownership of emission reduction credits with the captive fleet operator is required.
c) When freight is transported, the freight must be transported on pallets in both the project and baseline scenarios.
d) If biofuel blends are used, the blending ratio in the project and baseline must be the same.

If any of these conditions are violated during a single trip, the trip must not be included in the project and no emission reduction credits can be claimed from the trip.

This methodology is not applicable to emission reductions from the following scenarios:

a) Introduction of low-emission vehicles (eg, compressed natural gas vehicles, electric vehicles, liquid petroleum gas vehicles, and hybrid vehicles with electrical and internal combustion motive systems);
b) Fuel switch in existing vehicles (eg, fossil fuel to plant oil use);
c) Retrofitting of existing vehicles (eg, switching from high greenhouse gas intensive to low greenhouse gas intensive fossil fuel);
d) Modal shift in transportation; and
e) Changes in truck freight capacity enabled by use of lightweight pallets.

5 PROJECT BOUNDARY

The project boundary encompasses truck fleets while carrying lightweight pallets as part of their cargo and consuming fossil fuel.

Emission sources are summarized in Table 1 below.

Source		Gas	Included?	Justification/Explanation
Baseline	Vehicles consuming fossil fuel	CO_2	Yes	Main emission source in the combustion of fossil fuel.
		CH_4	No	Excluded for simplification.
		N_2O	No	Excluded for simplification.
Project	Vehicles consuming fossil fuel	CO_2	Yes	Main emission source in the combustion of fossil fuel.
		CH_4	No	Excluded for simplification.
		N_2O	No	Excluded for simplification.

Project and baseline emissions from loading and unloading of trucks are excluded because they would not be significant.

Return trips (i.e., empty pallets only) can be included as a trip as part of the "Vehicles consuming fossil fuel" source if all requirements, including monitoring requirements, are met.

For simplification and conservativeness, production of raw materials used to manufacture conventional pallets and manufacturing of conventional pallets are not included in the baseline boundary.

Production of raw materials used to manufacture lightweight pallets and manufacturing of lightweight pallets are not included in the project boundary, but are included under leakage.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

Project participants must use the most recent version of the CDM's *Combined tool to identify the baseline scenario and demonstrate additionality* to identify alternative baseline scenarios and determine the most plausible scenario.

The following must be adhered to when applying each of the steps in the CDM tool:

Step 1: Identify all realistic and credible alternatives to using lightweight pallets

When applying Sub-step 1a of the tool, alternative scenarios for pallet types must include all realistic and credible alternatives to the project activity that are available in the relevant market.

The following likely scenarios for pallet types must be assessed, *inter alia*:

- Wood pallets, and
- Petroleum-based plastic pallets.

All considered scenarios must provide the same type and level of service, ie, they must be able to transport the same amount of freight as transported under the project activity.

Step 2: Barrier Analysis

Barrier analysis must be used to assess which of these alternatives is to be excluded from further consideration (i.e. alternatives where barriers are prohibitive or which are clearly economically unattractive) and Step 3 must be applied for all remaining alternatives.

Step 3: Investment Analysis

In applying Step 3, the following must be followed:

- The investment analysis must be carried out from the perspective of the project participants, i.e. the owner or operator of the truck fleet.
- At a minimum, project participants must take into account the following costs in the investment analysis:
    a. Costs of acquiring and maintaining pallets
    b. Fuel costs
    c. Costs of disposing of pallets at the end of their useful life

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Project participants must use the most recent version of the CDM's "Combined tool to identify the baseline scenario and demonstrate additionality" to demonstrate additionality. The additional procedures described above in Section 6 must be used when applying this tool.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

The first step to determine the baseline emissions is to calculate the fleet's project emission factor per tonne of freight carried 1 kilometer. The project emission factor is determined by dividing total fleet-wide, fuel consumption-related emissions for eligible trips during the project by the sum of freight weight and distance travelled for each vehicle and trip in the fleet. The weight transported must stay constant during each trip. Each time the weight changes, a trip must be declared and the project proponent monitors the weight of freight, distance travelled, and number of pallets for each trip. Only trips where there is complete substitution of the baseline pallets must be quantified using the following equations (i.e., no partial substitution at the trip level is allowed).

$$PEF_y = \sum_{j,k,y}\left(FC_{j,k,y} \times EF_{j,y}\right) \div \sum_{i,k,y}\left(W_{i,k,y} \times D_{i,k,y}\right) \qquad (1)$$

Where:

PEF_y Project emission factor in year y per weight-distance of freight (t CO_2/t km)
$FC_{j,k,y}$ Quantity of fuel type j combusted by the fleet for eligible trips k in year y (volume of fuel)
$EF_{j,y}$ GHG emission factor of fuel j in year y (t CO_2/unit volume of fuel consumed)
$W_{i,k,y}$ Weight of freight (including project pallets) transported by vehicle i for trip k in year y (metric tonnes)
$D_{i,k,y}$ Distance travelled by vehicle i for trip k in year y (km)

The total baseline emissions are then calculated using the project emission factor applied to the same fleet and distance travelled, assuming increased freight weight transported due to use of conventional pallets.

$$BE_y = PEF_y \times \sum_{i,k,y}\left(D_{i,k,y} \times \left(W_{i,k,y} + \left(P_B - P_P\right) \times N_{i,k,y}\right)\right) \qquad (2)$$

Where:

BE_y Total baseline emissions in year y (t CO_2/year)
PEF_y Project emission factor in year y per weight-distance of freight (t CO_2/t km)
$D_{i,k,y}$ Distance travelled by vehicle i for trip k in year y (km)
$W_{i,k,y}$ Weight of freight (including project pallets) transported by vehicle i for trip k in year y (metric tonnes)
P_B Weight of each baseline pallet (metric tonnes)
P_P Weight of each project pallet (metric tonnes)
$N_{i,k,y}$ Number of pallets carried by vehicle i for trip k in year y

8.1.1 Baseline Emissions (Alternative Approach)

This alternative approach can only be used if the data for the approach described in 8.1 is not available and must be used with the approach described in section 8.2.1. The approaches described in sections

8.1 and 8.2 are more accurate and preferred. If the data to determine the baseline emissions using the approach described in 8.1 is not available (eg, no fuel consumption or freight weight data), the following alternative approach using default emission factors from recognized sources is acceptable.

$$BE_y = DEF_{j,y} \times \sum_{i,k,y} \left(D_{i,k,y} \times \left(W_{i,k,y} + \left(P_B - P_P \right) \times N_{i,k,y} \right) \right) \quad (3)$$

Where:

BE_y Total baseline emissions in year y (t CO_2/year)
$DEF_{j,y}$ Default emission factor for fuel type j in year y per weight-distance of freight (t CO_2/t km)
$D_{i,k,y}$ Distance travelled by vehicle i for trip k in year y (km)
$W_{i,k,y}$ Weight of freight (including project pallets) transported by vehicle i for trip k in year y (metric tonnes)
P_B Weight of each baseline pallet (metric tonnes)
P_P Weight of each project pallet (metric tonnes)
$N_{i,k,y}$ Number of pallets carried by vehicle i for trip k in year y

8.2 Project Emissions

Project emissions are determined by monitoring the consumption of fuel for eligible trips (as defined above in section 8.1) for the entire fleet transporting freight using lightweight pallets, according to the following formula:

$$PE_y = \sum_{j,y} \left(FC_{j,k,y} \times EF_{j,y} \right) \quad (4)$$

Where:

PE_y Total project emissions in year y (t CO_2/year)
$FC_{j,k,y}$ Quantity of fuel type j combusted by the fleet for eligible trips k in year y (volume of fuel)
$EF_{j,y}$ GHG emission factor of fuel j in year y (t CO_2/unit volume of fuel consumed)

8.2.1 Project Emissions (Alternative Approach)

This alternative approach can only be used if the data for the approach described in 8.2 is not available and must be used with the approach described in section 8.1.1. The approaches described in sections 8.2 and 8.1 are more accurate and preferred. If the data to determine the project emissions using the approach described in 8.2 is not available (ie, no fuel consumption data), the following alternative approach using default emission factors from recognized sources is acceptable.

$$PE_y = DEF_{j,y} \times \sum_{i,k,y}(D_{i,k,y} \times W_{i,k,y}) \quad (5)$$

Where:

PE_y Total project emissions in year y (t CO_2/year)
$DEF_{j,y}$ Default emission factor for fuel type j in year y per weight-distance of freight (t CO_2/t km)
$D_{i,k,y}$ Distance travelled by vehicle i for trip k in year y (km)
$W_{i,k,y}$ Weight of freight (including project pallets) transported by vehicle i for trip k in year y (metric tonnes)

Note that using this alternative approach allows emission reductions to be calculated using a default emission factor, distance travelled, weight reduction per pallet, and the number of pallets carried. The total weight transported is the same in equations (3) and (5), and cancels out when project emissions are subtracted from baseline emissions. Baseline and project emissions can be quantified separately by using actual weight of freight transported data (if available), or by making reasonable assumptions about the weight of freight transported and justifying those assumptions. Any uncertainty in these assumptions will be eliminated when project emissions are subtracted from baseline emissions to quantify emission reductions.

8.3 Leakage

This methodology estimates the following sources of leakage:

- Production of raw materials used to manufacture lightweight pallets; and
- Manufacturing of lightweight pallets.

Positive leakage from baseline sources (e.g., production of raw materials used to manufacture conventional pallets, manufacturing of conventional pallets) is not included, which is conservative. Leakage associated with transportation of raw materials used to manufacture pallets, transportation of manufactured pallets (before first use) and end of life treatment for pallets is considered insignificant and is not included.

Leakage is calculated as follows:

$$LE_y = LE_{RM,y} + LE_{M,y} \quad (6)$$

Where:

LE_y Leakage emissions in year y (t CO_2)
$LE_{RM,y}$ Leakage emissions associated with production of raw materials used to manufacture lightweight pallets in year y (t CO_2)
$LE_{M,y}$ Leakage emissions associated with manufacturing of lightweight pallets

8.3.1 Production of raw materials used to manufacture lightweight pallets

Emissions from production of raw materials used to manufacture lightweight pallets are estimated by listing all raw materials that account for a total of at least 95% of the lightweight pallet mass, then estimating the upstream emissions for their production, as follows:

$$LE_{RM,y} = \Sigma_x (N \times M_x \times EF_x) \quad (7)$$

Where:

$LE_{RM,y}$	Leakage emissions associated with production of raw materials used to manufacture lightweight pallets in year y (t CO_2)
N	Number of pallets consumed per year
M_x	Mass of raw material x consumed per pallet manufactured (tonnes)
EF_x	Upstream emission factor for production of raw material x (t CO_2/t raw material x)

8.3.2 Manufacturing of lightweight pallets

Emissions from manufacturing of lightweight pallets are estimated by listing all GHG sources from manufacturing lightweight pallets, then estimating manufacturing emissions as follows:

$$LE_{M,y} = \Sigma_a(N \times A_a \times EF_a) \quad (8)$$

Where:

$LE_{M,y}$	Leakage emissions associated with manufacturing of lightweight pallets in year y (t CO_2)
N	Number of pallets consumed per year
A_a	Activity level from GHG source a per pallet manufactured (energy consumption or fuel volume units)
EF_a	Emission factor for GHG source a (t CO_2 /unit energy consumption or fuel volume)

If primary energy consumption data from manufacturing lightweight pallets is not available, the project proponent may use other primary or secondary data sources to estimate emissions from manufacturing of lightweight pallets. These sources of data must be justified (ie, alternative sources of data must be listed and the reasons for selecting the data used must be given) using criteria that include data source (recognized and authoritative sources are preferred); geographic, temporal and technology specificity; conservativeness (ie, does not overestimate emission reduction); and if the data is peer reviewed (preferred).

8.4 Summary of GHG Emission Reduction and/or Removals

Emission reductions are calculated as follows:

$$ER_y = BE_y - PE_y - LE_y \tag{9}$$

Where:

ER_Y Net GHG emissions reductions in year y
BE_Y Baseline emissions in year y
PE_y Project emissions in year y
LE_y Leakage in year y

9 MONITORING

9.1 Data and Parameters Available at Validation

Data Unit / Parameter:	P_B
Data unit:	Weight unit (e.g. metric tonnes)
Description:	Weight of each individual baseline pallet
Source of data:	Measurements using weight scales Manufacturer specifications
Justification of choice of data or description of measurement methods and procedures applied:	Obtain the weight of one baseline pallet by consulting with the specifications provided by the manufacturer. Cross check using properly calibrated weight scales and a statistically significant sample of baseline pallets.
Any comment:	-

Data Unit / Parameter:	$DEF_{j,y}$
Data unit:	t CO_2/t km
Description:	Default GHG emission factor for fuel type j per unit weight-distance of freight in year y
Source of data:	Statistics published by recognized sources such as US government or industry associations. For example, EPA Climate Leaders publication "Optional Emissions from Commuting, Business Travel & Product Transport, EPA43-R-08-006" or WRI/WBCSD GHG Protocol Mobile Combustion tool
Justification of choice of data or description of measurement methods and procedures applied:	The range of appropriate data must be documented and the chosen data must be justified, using criteria that include data source (recognized and authoritative sources); geographic, temporal and technology specificity; conservativeness (i.e., does not overestimate emission reduction); and if the data is peer reviewed (preferred).
Any comment:	The above justification is required to manage the uncertainty associated with this parameter.

9.2 Data and Parameters Monitored

Data Unit / Parameter:	$FC_{j,y}$
Data unit:	Volume units per year (e.g. gallons/year)
Description:	Quantity of fuel type *j* combusted by the fleet during the year *y*
Source of data:	Onsite and offsite sources a) Purchasing records b) Metering c) Logs
Description of measurement methods and procedures to be applied:	Purchasing records • For centralized purchases, use invoices from suppliers and adjust for inventory of fuel at beginning and end of year • For offsite purchases, use electronic records from cardlock or similar system Metering • Use fuel flow meters to measure volume of fuel transferred to vehicles at central facilities or offsite filling stations Logs • Record volume of fuel consumed per vehicle per refill in electronic or manual logs
Frequency of monitoring/recording:	Continuously
QA/QC procedures to be applied:	Purchasing records must be cross checked against metered fuel transferred to vehicles. Fuel flow meters must be calibrated according to current good practice (e.g., relevant industry standards). The consistency of metered fuel consumption quantities must be cross-checked by an annual reconciliation based on purchased quantities and stock changes. Metered fuel consumption quantities must also be cross-checked with available purchase invoices from financial records (e.g., cardlock system)
Any comment:	-

Data Unit / Parameter:	$EF_{j,y}$
Data unit:	t CO_2/unit volume of fuel consumed

Description:	GHG emission factor of fuel type *j* consumed by the fleet in year *y*
Source of data:	The following data sources may be used if the relevant conditions apply: **Data source** — **Conditions for using data source** a) Regional or national default values from recognized sources — These values must be based on well-documented, reliable sources (e.g., national energy balances, government publications, industry associations, WRI/WBCSD GHG Protocol) b) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in table 1.4 of Chapter 1 of Vol. 2 (Energy) of the 2006 IPCC Guidelines on National GHG Inventories — If a) is not available
Description of measurement methods and procedures to be applied:	If more than one recognized source is available, the most appropriate source must be selected, based on data quality indicators including technological appropriateness, regional specificity, and vintage of the data.
Frequency of monitoring/recording:	Review appropriateness of the values annually
QA/QC procedures to be applied:	Fuel type *j* must be recorded for each refill, transfer or other transaction, including the fraction of biofuel present (if applicable).
Any comment:	-

Nested table (Source of data):

Data source	Conditions for using data source
a) Regional or national default values from recognized sources	These values must be based on well-documented, reliable sources (e.g., national energy balances, government publications, industry associations, WRI/WBCSD GHG Protocol)
b) IPCC default values at the upper limit of the uncertainty at a 95% confidence interval as provided in table 1.4 of Chapter 1 of Vol. 2 (Energy) of the 2006 IPCC Guidelines on National GHG Inventories	If a) is not available

Data Unit / Parameter:	$W_{i,k,y}$
Data unit:	Weight unit (e.g. metric tonnes)

Description:	Weight of freight (including pallets) transported by vehicle *i* for trip *k* in year *y*
Source of data:	Onsite measurements by project participants, or Shipping records
Description of measurement methods and procedures to be applied:	The weight of freight transported under the VCS project by the project vehicles must be measured at the point of origin using weight scales. The amount must be cross-checked with the freight received at destination. If direct weight measurement is not feasible, shipping records must be used to estimate weight of freight transported.
Frequency of monitoring/recording:	Continuously
QA/QC procedures to be applied:	Weight scales must be calibrated according to current good practice (e.g., relevant industry standards). If measurements used, cross check measurements against shipping records. If shipping records used, cross check shipping records against billing or other information systems.
Any comment:	-

Data Unit / Parameter:	$D_{i,k,y}$
Data unit:	Distance unit (e.g. kilometers)
Description:	Total distance travelled by vehicle *i* for trip *k* in year *y* (kilometers)
Source of data:	a) Odometer readings; b) Tracking solution; and/or c) Electronic Data Interchange (EDI) / Advanced Shipping Notice (ASN) system
Description of measurement methods and procedures to be applied:	For a): Monitor odometer readings of all trucks in fleet at beginning and end of each trip. For b): Use a tracking solution (e.g. GPS vehicle tracking) to monitor routes and distances travelled by each vehicle. For c): Use transactional data from the fleet operator's EDI/ASN system, in conjunction with a tracking software solution to provide an audit trail of where the vehicles have travelled.
Frequency of monitoring/recording:	Continuously
QA/QC procedures to be applied:	Check consistency of distance records provided by the fleet operator by comparing recorded distances from odometer readings or tracking solution with information from other sources (e.g. driver logs and/or route maps).

Any comment:	-

Data Unit / Parameter:	P_P
Data unit:	Weight unit (e.g. metric tonnes)
Description:	Weight of each individual project pallet
Source of data:	Measurements using weight scales Manufacturer specifications
Description of measurement methods and procedures to be applied:	Obtain the weight of one project pallet by consulting with the specifications provided by the manufacturer.
Frequency of monitoring/recording:	Annually or more frequently if pallet specifications change.
QA/QC procedures to be applied:	Cross check using properly calibrated weight scales and a statistically significant sample of project pallets
Any comment:	-

Data Unit / Parameter:	$N_{i,k,y}$
Data unit:	Number
Description:	Number of pallets carried by vehicle *i* for trip *k*
Source of data:	Shipping records Unique ID for each pallet (e.g., Radio-Frequency Identification (RFID) tags, Universal Product Code (UPC), etc.)
Description of measurement methods and procedures to be applied:	EDI/ASN information system to make use of unique ID for each pallet so that the number of pallets carried by each vehicle for each trip is recorded automatically.
Frequency of monitoring/recording:	Continuously
QA/QC procedures to be applied:	Project participants must cross-check the total number of pallets recorded by the EDI/ASN information system with onsite shipping records. Cross check the average weight carried per pallet against pallet capacity for reasonableness and potential inconsistencies.
Any comment:	-

Leakage Data and Parameters

Data Unit / Parameter:	N
Data unit:	–
Description:	Number of pallets consumed by fleet operator per year
Source of data:	Average number of pallets in use and average lifetime of pallets
Description of measurement methods and procedures to be applied:	The number of pallets consumed per year is determined by monitoring the average number of pallets used by the fleet operator each year (e.g., average of beginning and ending inventory, or average of 12 monthly inventories), and dividing it by the average lifetime of each pallet. Average lifetime (i.e. number of years the average pallet lasts before its final disposal) is determined from internal records, manufacturer specifications and/or industry standard testing procedures.
Frequency of monitoring/recording:	Annually
QA/QC procedures to be applied:	Cross check against purchasing records for reasonableness. Note that annual purchases will vary depending on a number of factors, but will, over time, converge to the overall number of pallets consumed. The average lifetime from manufacturer specification or industry standards must be compared against internal records to account for project specific conditions.
Any comment:	-

Data Unit / Parameter:	M_x
Data unit:	Weight unit (e.g. metric tonnes)
Description:	Mass of raw material x consumed per pallet manufactured
Source of data:	Manufacturer specifications
Description of measurement methods and procedures to be applied:	The mass of each type of raw material consumed per pallet must be determined from manufacturer specifications and include the mass of raw material consumed as waste in the process.
Frequency of monitoring/recording:	Annually or more frequently if pallet specifications change

QA/QC procedures to be applied:	Cross check manufacturer specification against current version of pallet to ensure current pallet specifications are being used. Cross check against total weight of pallet to ensure at least 95% of the total pallet weight is accounted for.
Any comment:	-

Data Unit / Parameter:	EF_x
Data unit:	t CO_2 / t of raw material x
Description:	Upstream emission factor for production of raw materials for pallets
Source of data:	The following data sources may be used: a) Primary data from suppliers b) Industry data c) National Life Cycle Inventory (LCI) databases d) Commercial LCI databases
Description of measurement methods and procedures to be applied:	For secondary data, emission factors for each raw material must be determined from recognized sources for each raw material consumed. For raw materials with no secondary data available from a recognized source, proxy data must be used for a similar material that is likely to have a similar upstream emission factor. If more than one recognized source is available, the most appropriate source must be selected, based on data quality indicators including technological appropriateness, regional specificity, and vintage of the data.
Frequency of monitoring/recording:	Annually

QA/QC procedures to be applied:	For primary data from suppliers, request documentation of methodologies used and compare to good practices. Identify and correct any major deficiencies. For secondary data from publications or databases, compare multiple sources if available. The range of appropriate data must be documented and the chosen data must be justified, using criteria that include data source (recognized and authoritative sources are preferred); geographic, temporal and technology specificity; conservativeness (i.e., does not overestimate emission reduction); and if the data is peer reviewed (preferred).
Any comment:	The above justification is required to manage the uncertainty associated with this parameter.

Data Unit / Parameter:	A_a
Data unit:	Energy consumption or fuel volume units
Description:	Activity level from GHG source a per pallet during manufacturing of pallet
Source of data:	Manufacturer's records • Invoices from suppliers • Metered data
Description of measurement methods and procedures to be applied:	The activity level of each GHG emission source per pallet must be determined by monitoring the total amount of each energy consuming activity at the manufacturer's facility per year and dividing by the number of pallets produced by the manufacturer's facility per year. If more than one product is produced at the facility, allocation rules consistent with ISO 14040/44 must be applied.
Frequency of monitoring/recording:	Annually
QA/QC procedures to be applied:	-
Any comment:	-

Data Unit / Parameter:	EF_a
Data unit:	(t CO_2 /unit energy consumption or fuel volume units)
Description:	Emission factor for GHG source a

9.3 Description of the Monitoring Plan

The project proponent must establish, maintain and apply a monitoring plan and GHG information system that includes criteria and procedures for obtaining, recording, compiling and analyzing data, parameters and other information important for quantifying and reporting GHG emissions relevant for the project and baseline scenario. Monitoring procedures must address the following:

a) Types of data and information to be reported;
b) Units of measurement;
c) Origin of the data;
d) Monitoring methodologies (e.g., estimation, modeling, measurement, calculation);
e) Where options are provided in section 9 above, justification for the option selected;
f) Type of equipment used, if any;
g) Monitoring times and frequencies;
h) QA/QC procedures;
i) Monitoring roles and responsibilities, including experience and training requirements;
j) GHG information management systems, including the location, back up, and retention of stored data.

Where measurement and monitoring equipment is used, the project proponent must ensure the equipment is calibrated according to current good practice (eg, relevant industry standards).

All data collected as part of monitoring must be archived electronically and kept at least for 2 years after the end of the last project crediting period.

QA/QC procedures must include, but are not limited to:

Data Gathering, Input and Handling Measures

- Input data checked for typical errors, including inconsistent physical units, unit conversion errors, typographical errors caused by data transcription from one document to another; and missing data for specific time periods or physical units;
- Input time series data checked for large unexpected variations (eg, orders of magnitude) that could indicate input errors;
- All electronic files to use version control to ensure consistency;
- Physical protection of monitoring equipment (eg, sealed meters and data loggers); and
- Physical protection of records of monitored data (eg, hard copy and electronic records).

Data Documentation

- Input data units checked and documented;
- All sources of data, assumptions and emission factors documented;
- Changes to data, assumptions and emission factors documented; and
- Documented assumptions and algorithms validated based on best practices.

Calculations

- Units for input data and conversion factors documented;
- Units for all intermediate calculations and final results documented;

- Input data and calculated data clearly differentiated;
- Comparison to previous results to identify potential inconsistencies; and
- Results aggregated in various ways to identify potential inconsistencies.

Version 1.0, 16 November 2012
Sectoral Scope 14

Soil Carbon Quantification Methodology

Methodology developed by:

The Earth Partners LLC.

RELATIONSHIP TO APPROVED OR PENDING METHODOLOGIES

To date no similar methodologies have been approved under the VCS Program.

Four related methodologies are currently under development or approved under the VCS Program:

- *ALM Adoption of Sustainable Grassland Management through Adjustment of Fire and Grazing* (methodology under development)- This methodology is limited to activities on uncultivated grasslands where fire is a potential occurrence.
- *Agricultural Land Management – Improved Grassland Management* (methodology under development) – This methodology is dependent on the existence of applicable, tested soil models for determining soil carbon.
- *VM0017 Adoption of Sustainable Agricultural Land Management (SALM)* – This methodology focuses on a specific set of management practices
- *Methodology for Sustainable Grassland Management (SGM)* (methodology under development) – This methodology is specific to sustainable grassland management projects where ongoing degradation is occurring and is expected to continue
- *Calculating Emission Reductions in Rice Management Systems* (methodology under development) – This methodology is specific to reducing emissions from rice cultivation.

All of these existing proposed methodologies focus on specific elements of the ALM continuum. The use of soil carbon prediction models such as Century and DNDC are widely applied in these methodologies. This methodology is much more general, and is designed to be applicable to projects where a wide variety of activities may occur under the baseline or project scenario, such as timber harvesting, and fertilization. Soil carbon is measured in both the baseline and project scenarios and the DNDC model is used only for quantifying the methane and nitrous oxide emissions.

Table of Contents

1 SOURCES

This methodology and its modules have been developed on the accounting principles as set out in: IPCC 2003 Good Practice Guidance for Land Use, Land-Use Change and Forestry.

The modules used in this methodology are:

- *VMD0018 Methods to Determine Stratification*
- *VMD0019 Methods to Project Future Conditions*
- *VMD0020 Methods to Determine the Project Boundary*
- *VMD0021 Estimation of Stocks in the Soil Carbon Pool*
- *VMD0022 Estimation of Carbon Stocks in Living Plant Biomass*
- *VMD0023 Estimation of Carbon Stocks in the Litter Pool*
- *VMD0024 Estimation of Carbon Stocks in the Dead Wood Pool*
- *VMD0025 Estimation of Woody Biomass Harvesting and Utilization*
- *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool*
- *VMD0027 Estimation of Domesticated Animal Populations*
- *VMD0028 Estimation of Emissions from Domesticated Animals*
- *VMD0029 Estimation of Emissions of Non-CO_2 GHG from Soils*
- *VMD0030 Estimation of Emissions from Power Equipment*
- *VMD0031 Estimation of Emissions from Biomass Burning*
- *VMD0032 Estimation of Emissions from Activity Shifting Leakage*
- *VMD0033 Estimation of Emissions from Market Leakage*
- *VMD0034 Methods for Developing a Monitoring Plan*
- *VMD0035 Methods to Determine the Net Change in Atmospheric GHG Resulting from Project Activities*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology describes methods for quantifying and monitoring changes in carbon accrual in, and emissions from, soils, as well as from other GHG pools and sources which may be impacted by soil focused activities. The methodology is designed based on guidance provided in the IPCC 2003 Good Practice Guidance for Land Use, Land-Use Change and Forestry. This methodology has been designed to be applicable to conservation, ecosystem restoration and agricultural projects, as well as other projects where the management of soils directly, or management of hydrology, fertility and vegetation systems, can affect changes in soils and soil carbon. The methodology is applicable to a range of project activities designed to improve soils, including changes to agricultural practices, grassland and rangeland restorations, soil carbon protection and accrual benefits from reductions in erosion, grassland protection projects, and treatments designed to improve diversity and productivity of grassland and savanna plant communities.

The intention of the developers has been to create a methodology which includes sufficient detail on methods to allow a wide range of project proponents to use the methods during the development of soil carbon projects. However, accurately estimating and projecting the values of the various ecosystem carbon pools does require a significant level of technical ability on the part of the project proponent team. It is therefore expected that in many cases landowners and farmers may need to work with people with specific technical skills to complete the development of a soil carbon project description (PD) using this methodology.

This methodology provides methods for the quantification of soil carbon, as well as methods for quantifying changes in vegetation and litter pools which can be impacted by project activities, as compared with the baseline scenario.

This methodology does not address projects designed to enhance carbon sequestration in ancient soils (paleosols) that have been buried by more recent soil formations. While the same methods presented here are applicable to characterize the buried substrates, other methods (such as drilling rigs with a deeper boring capacity and split spoon sampling equipment) are beyond the scope of this methodology, which is focused on the extant active soil surfaces and active present day rooting zones soils.

This methodology is focused on addressing the following key variables:

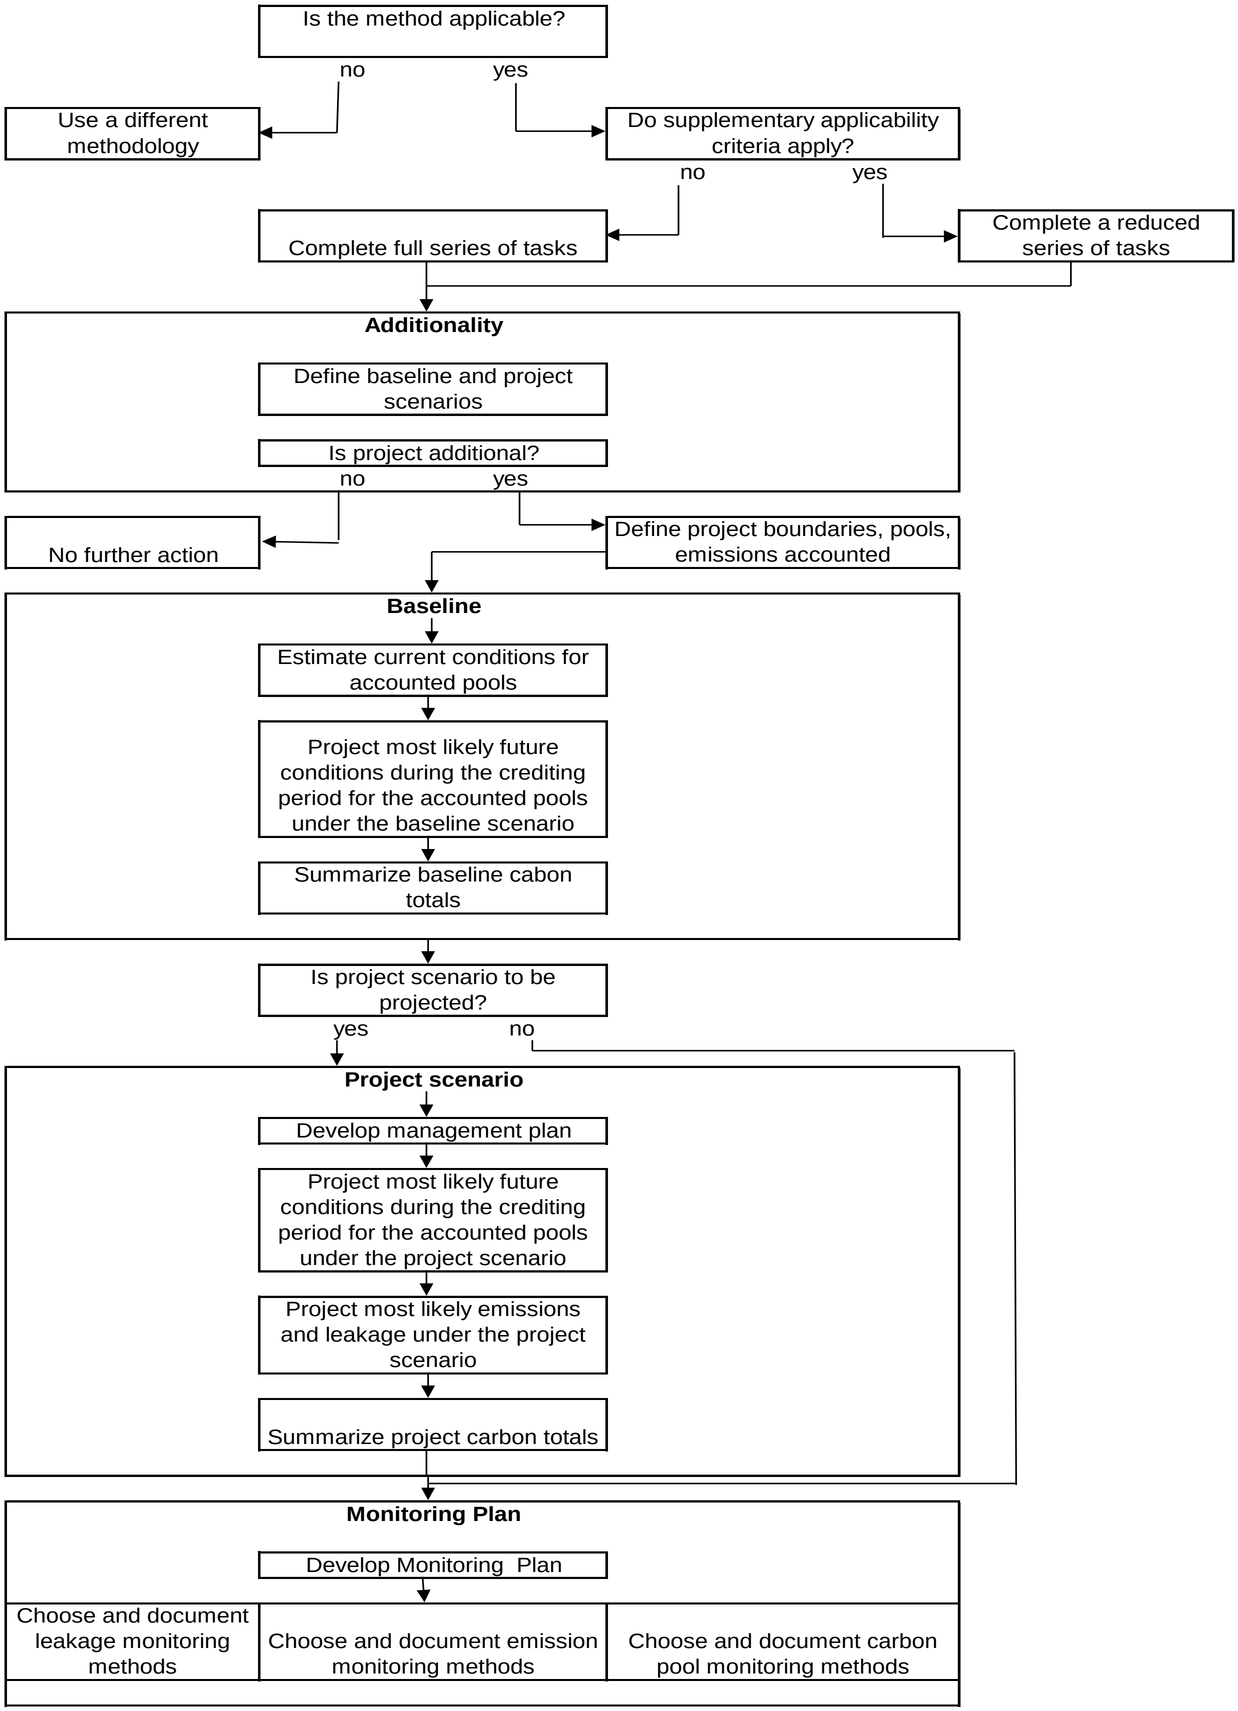
- Estimating the amount of carbon in the soil, litter, and living vegetation pools at the start of the project;
- Monitoring and documenting changes in soil carbon and the other carbon pools over time under the project scenario;
- Projecting changes in soil carbon and other pools under the baseline scenario;
- Estimating emissions of nitrous oxides and methane from soils, and,
- Estimating project leakage.

The methodology has been designed using a modular approach. This methodology document lays out the steps required to fulfill estimation, projection and quantification requirements for projects wishing to register credits under the VCS. The methodology calls on the associated modules for specific techniques and options for estimating or projecting the GHG impacts of changes in specific pools and emissions.

The methodology requires the completion of four main tasks, each of which is comprised of a number of sub-tasks:

1. Task 1: Identification of project boundary, demonstration of additionality and determination of the baseline scenario
2. Task 2: Ex-ante estimation and projection of carbon pools and emissions under the baseline scenario
3. Task 3: Ex-ante estimation and projection of carbon pools and emissions under the project scenario
4. Task 4: Development of a monitoring plan subsequent ex-post monitoring of pools and emissions under the project scenario as well as under the baseline scenario if a monitored baseline is used, and monitoring of leakage.

The overall process used by the methodology is shown in the following methodology map.



Is the method applicable?
no
yes
Use a different methodology
Do supplementary applicability criteria apply?
no
yes
Complete full series of tasks
Complete a reduced series of tasks
Additionality
Define baseline and project scenarios
Is project additional?
no
yes
No further action
Define project boundaries, pools, emissions accounted
Baseline
Estimate current conditions for accounted pools
Project most likely future conditions during the crediting period for the accounted pools under the baseline scenario
Summarize baseline cabon totals
Is project scenario to be projected?
yes
no
Project scenario
Develop management plan
Project most likely future conditions during the crediting period for the accounted pools under the project scenario
Project most likely emissions and leakage under the project scenario
Summarize project carbon totals
Monitoring Plan
Develop Monitoring Plan
Choose and document leakage monitoring methods
Choose and document emission monitoring methods
Choose and document carbon pool monitoring methods

3 DEFINITIONS

Activity Shifting Leakage: Activities that are moved by local actors from within the project area to outside due to the project, and which result in losses of carbon in pools outside the project area.

Agent: A person or organization undertaking actions which impact the management of carbon pools and emissions.

Baseline: The total amount of carbon within the project area in absence of the project.

Baseline Scenario: The most likely sequence of events and actions which would be expected to occur within the project area in the absence of the project.

Carbon Project: See *VCS Program Definitions* for project.

Conservative: Tending to err on the side of reduced creditable carbon in cases where uncertainty exists as to the correct value of variables, or relationships among variables.

Coarse Fragments: Pieces of rock or cemented soils > 2mm in diameter, and therefore too large to pass through the screen used in the laboratory prior to laboratory analyses.

Directly Attributable: The change or effect occurs as result of a chain of causal events linking the change or effect to an event, or to the actions of an agent. Each of the causal events or conditions in the chain must be primarily and directly caused by the previous event in the chain. Analysis of the linkages in the chain should show that for each one, the previous event is at least 75% responsible for the next event. For this reason, the relationship between an event, or the actions of an agent, and the directly attributable effect, typically consist of not more than a few causal linkages.

Ex-ante: Before the fact. Projection of values or conditions in the future.

Ex-post: After the fact. Estimation of values or conditions in the present or past.

Long Lived Wood Products: Products produced from harvested timber which is expected to persist and to sequester carbon for an extended period of time – typically 100 years, unless there is a specific reason for using a different time period.

Monitoring Event: The time at which monitoring of all of the relevant variables is undertaken, to determine the net change in atmospheric carbon attributable to the project.

Monitoring Period: The time period specified in a monitoring report during which GHG emission reduction or removals were generated by the project.

Monitoring Plan: Plan in which a monitoring schedule and methods will be documented.

Planned: Changes in the value of the variable are under the control of identified agents who are independent of the project proponent.

Project Area : The area or areas of land on which the project proponent will undertake the project activities.

Project Crediting Period: See *VCS Program Definitions.*

Project Scenario: The actions and events which are expected to occur as a result of implementing the project.

Significant: A pool or source is significant if it does not meet the criteria for being deemed de minimis. Specific carbon pools and GHG sources, including carbon pools and GHG sources that cause project and leakage emissions, may be deemed de minimis and do not have to be accounted for if together the omitted decrease in carbon stocks (in carbon pools) or increase in GHG emissions (from GHG sources) amounts to less than five percent of the total GHG benefit generated by the project.

Stratification: The division of an area into sub-units (strata) which are relatively homogenous for the value of the variable on which the stratification is based, which are repeatable in the landscape, and could reasonably be expected to be similarly identified and classified by different people.

Stratum (plural strata): An area of land within which the value of a variable, and the processes leading to change in that variable, are relatively homogenous.

Verification Date: A date, at which an independent verifier audits the results of monitoring.

Woody Biomass: Biomass which exists primarily in the form of lignified tissues, such as that of shrubs and trees. Typically accounting of woody biomass includes the non woody parts (leaves, etc.) of plants which contain woody biomass.

4 APPLICABILITY CONDITIONS

4.1 Mandatory Conditions

All projects using this methodology must meet the following conditions:

a. Projects must meet the most recent VCS requirements for one of the following three Agricultural Land Management activities:

- Improved Cropland Management (ICM)
- Improved Grassland Management (IGM)
- Cropland and Grassland Land-use Conversions (CGLC)

b. As of the project start date all of the project area consists of grasslands or croplands. Crops may include woody species grown for food products, fuel products or timber, providing that the densities of these crops do not meet the requirements for definition of these lands as forest lands. The project area must not consist of forest, wetlands, or peatlands, as such terms are defined under the VCS.

c. The only baseline activities that could be displaced by the project activities are grazing and fodder production, crop production and timber production.

d. Project activities must not include changes in surface and shallow (<1m) soil water regimes through flood irrigation, drainage or other significant anthropogenic changes in the ground water table.

e. The project activity must not cause a significant change in termite populations, as compared with the baseline scenario.

4.2 Optional Conditions

The following conditions do not need to be met to utilize the methodology. However, each of these conditions allows the simplification of the methodology through the elimination of the requirement for the completion of specific tasks.

a. The activities and agents which have caused the degradation of the croplands, grasslands or rangelands are expected to continue to impact the area in the absence of the project activity. On that basis, it can be demonstrated that the total carbon content of the soil organic and inorganic carbon pools within the project area is highly unlikely to increase under the baseline scenario during the project crediting period.

   Consequence if met: Project proponent may conservatively assume that soil carbon content for all future dates under the baseline scenario shall be accounted as equal to the current soil carbon content, subject to re-assessment at year 10, as required under the VCS rules.

b. Changes in above and below ground living biomass pools within the project area can be shown to be insignificant under either the baseline or project scenarios.

   Consequence if met: Project proponent is not required to complete Tasks 2.4, 2.5, 2.6, 3.3, 3.4, 4.3 and 4.4 of this document.

c. Woody biomass is found within the project area, but amounts of current and projected wood harvest under the baseline and project scenarios are not significant.

   Consequence if met: Project proponent is not required to complete Tasks 2.7, 2.8, 2.9, 3.5, 3.6, 4.5, and 4.6 of this document.

d. GHG emissions from populations of domesticated animals are expected to remain the same or decline under the project scenario as compared with the baseline scenario.

Consequence if met: Project proponent is not required to complete Tasks 2.12, 2.13, 2.14, 3.8, 3.9, 4.8, and 4.9 of this document.

e. No significant change is expected to occur in the amounts or locations of any of the following conditions or activities between the baseline scenario and the project scenario:

- Amount or location of application of organic or inorganic fertilizers.
- Amount or location of domesticated animal grazing and deposition of manure or urine.
- Amount or location of areas subject to flooding, and duration of flooding.
- Amount or location of nitrogen fixing species.

Consequence if met: Project proponent is not required to complete Tasks 2.15, 2.16, 3.10, and 4.12 of this document.

5 PROJECT BOUNDARY

Task 1: Identification of project boundary, demonstration of additionality and determination of the baseline scenario

Task 1.1 Project boundary determination
Requirement: For all projects
Goal: To determine the project boundary for baseline scenario and additionality purposes.
Method: Determine the project boundary using the module *VMD0020 Methods to Determine Project Boundary*

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

Task 1: Identification of project boundary, demonstration of additionality and determination of the baseline scenario (continued)

Task 1.2 Baseline scenario determination

Requirement: Required for all projects.

Goal: To determine the most plausible baseline scenario.

Method: Determine the baseline scenario(s) for the project area using the latest version of the CDM *Combined tool to identify the baseline scenario and demonstrate additionality for A/R CDM project activities.*

The tool has been designed for A/R CDM project activities, but is used for the purposes of this methodology in an ALM context. As such, the following applies:

- Where the tool refers to A/R it must be understood as referring to ALM activities.

- Where the tool refers to forestation, it must be understood as referring to the project agricultural land management activities, and where the tool refers to forest, it must be understood as referring to agricultural land.
- Where the tool refers to CDM, it must be understood as referring to VCS.
- Where the tool refers to tCERs or lCERs, it must be understood as referring to VCUs.
- In case there is a conflict between the CDM tool requirements and the VCS rules, then the VCS rules must be followed.
- Where the tool makes reference to events occurring before or after December 31 1989, it must be understood as referring to events occurring before or after 10 years prior to the project start date.

Use of the tool is subject to the following:

- Applicability conditions: The tool is applicable for all VCS ALM project types that comply with the VCS eligibility rules as set out by AFOLU Requirements v3.2 section 4.2.2, or updated version
- Step 0: Start Date: Must follow most up to date VCS rules.
- Step 1 Point 9: Identify the alternative land management scenario in absence of the VCS ALM project

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Task 1: Identification of project boundary, demonstration of additionality and determination of the baseline scenario (continued)

Task 1.3 Demonstration of additionality

Requirement: Required for all projects

Goal: to determine the additionality of the project.

Method: The project proponent must demonstrate whether or not the proposed project activity is additional using the latest version of the CDM *Combined tool to identify the baseline scenario and demonstrate additionality for A/R CDM project activities*, following the same guidance given in section 6 above, or use the latest version of the VCS *Tool for Demonstration and Assessment of Additionality in VCS AFOLU Project Activities*.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

Estimation of the carbon content of current pools, and projection of carbon pools and emissions under the baseline scenario is undertaken using the following the steps:

Task 2: Ex-ante estimation and projection of carbon pools and emissions under the baseline scenario

Task 2.1 Project area stratification for soil carbon

Requirement: Required for all projects.

Goal: To divide the project area into one or more strata within which the existing soil carbon pools and soil carbon dynamics are relatively uniform.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with soil carbon as the relevant variable *X.*

Task 2.2 Estimation of the current carbon content of the soil carbon pool per unit of area, for each stratum

Requirement: Required for all projects.

Goal: To sample the organic and inorganic soil carbon content in each stratum with a sampling intensity sufficient to estimate, at the required levels of statistical precision and accuracy, the amount of soil carbon per unit area.

Methods: Use module *VMD0022 Estimation of Stocks in the Soil Carbon Pool*.

Task 2.3 Projection of the future carbon content of the soil carbon pool per unit of area, for each stratum

Requirement: Required for all projects.

Goal: To project the future organic and inorganic soil carbon content per unit area in each stratum for each projected verification date within the project crediting period under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, and *VMD0021 Estimation of Stocks in the Soil Carbon Pool*, unless optional applicability condition (a) (See Section 4) is met.

Task Notes: If optional applicability condition (a) of this methodology is met, soils within the project area are demonstrated to be subject to continued degradation. Therefore, gains in soil carbon under the baseline scenario do not need to be projected. If this applicability condition is met, the methodology allows the project proponent to conservatively assume that the current carbon content of the soils will continue to be the carbon content of the soils throughout the project crediting period under the baseline scenario. In this case, no further work need be done on this task. This approach follows the simplifying precedent set in *CDM AR-AM0001*, now part of the consolidated methodology *CDM AR-ACM0002*.

Task 2.4 Project area stratification for biomass

Requirement: Required for all projects where the difference in total above and below ground biomass carbon between the project scenario and the baseline scenario at any time after the project start date is expected to be significant. Optional for all other projects.

Goal: To divide the project area into one or more strata within which the existing vegetation carbon pools and vegetation dynamics are relatively uniform.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with above and below ground biomass stocks per unit area as the relevant variable *X*.

Task 2.5 Estimation of the carbon content of current aboveground woody and non-woody biomass and below ground living biomass pools

Requirement: Same criteria as Task 2.4.

Goal: To sample the aboveground biomass pools and derive the belowground biomass pool in each stratum with a sampling intensity sufficient to estimate, at the required levels of statistical precision and accuracy, the amount of biomass carbon per unit area.

Methods: Use module *VMD0022 Estimation of Carbon Stocks in Living Plant Biomass*.

Task 2.6 Projection of future biomass pools under the baseline scenario

Requirement: Same criteria as Task 2.4.

Goal: To determine the most likely future changes in total biomass within the project area under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with biomass pools as the relevant variable *X*.

Task 2.7 Estimation of the amount of current wood harvest from within the project area used for production of long lived wood products

Requirement: Required where the harvest of significant amounts of woody biomass currently occurs within the project area, or is expected to occur in the future under the baseline scenario, and some or all of that woody biomass is used for the production of long lived wood products. Optional and not recommended in all other cases.

Goal: To estimate the current amount of woody biomass harvesting taking place within the project area.

Methods: Use module *VMD0025 Estimation of Woody Biomass Harvesting and Utilization*.

Task 2.8 Projection of future wood harvest outputs

Requirement: Same criteria as Task 2.7.

Goal: To project the most probable amount of woody biomass harvesting, and utilization of that harvest for the production of long lived wood products, that is expected to occur under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with wood harvest and utilization for long lived wood products as the relevant variable *X*.

Task 2.9 Long Lived Wood Products

Requirement: Same criteria as Task 2.7.

Goal: To project the amount of carbon which will be sequestered in long lived wood products under the baseline scenario.

Methods: Use module *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool*, with the outputs from Tasks 2.7 and 2.8 as the inputs.

Task 2.10 Estimation of current dead wood pools within the project area

Requirement: Required where there are significant amounts of dead wood in the project area at the project start date, and removals of dead wood through utilization, reduced inputs or accelerated burning as part of a management activity are expected to occur under the project scenario. Optional under all other circumstances.

Goal: To estimate the current amount of biomass contained in dead wood pools.

Methods: Use module *VMD0024 Estimation of Carbon Stocks in the Dead Wood Pool*.

Task 2.11 Projection of future dead wood pools within the project area

Requirement: Same as Task 2.10.

Goal: To project the amount of biomass which will be contained in dead wood pools under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with dead wood pools as the relevant variable *X*.

Task 2.12 Estimation of current average domesticated animal populations within the project area

Requirement: Required where GHG emissions from domesticated animal populations within the project area are expected to be significantly greater under the project scenario as compared with the baseline scenario at any time during the project crediting period. Optional under all other circumstances

Goal: To estimate the average current populations of domesticated animals within the project area.

Methods: Use the module *VMD0027 Estimation of Emissions from Domesticated Animals*.

Task 2.13 Projection of future domesticated animal populations under the baseline scenario

Requirement: Same as Task 2.12.

Goal: To project the future populations of domesticated animals under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with domesticated animal populations as the relevant variable *X.*

Task Notes: If at any time within the project crediting period the populations of domesticated animals under the baseline scenario are projected to be greater than those found at the project start date, populations at that time must be accounted as being equal to current levels. Conservatively, this methodology does not account for projected increases in animal populations and resulting emissions under the baseline scenario.

Task 2.14 Estimation of emissions of GHGs from domesticated animals within the project area under the baseline scenario

Requirement: Same as Task 2.11.

Goal: To estimate GHG emissions from current and projected future domesticated animal populations under the baseline scenario.

Methods: Use module *VMD0028 Estimation of Emissions from Domesticated Animals*, with the outputs from Tasks 2.9 and 2.10 as the inputs.

Task 2.15 Estimation of current soil emissions of N_2O or CH_4 from within the project area

Requirement: Required where emissions of N_2O or CH_4 from the soils within the project area are expected to be significantly greater under the project scenario as compared with the baseline scenario at any time within the project crediting period. Optional under all other circumstances.

Goal: To estimate the current emissions of N_2O or CH_4 from within the project area.

Methods: Use module *VMD0029 Emissions of Non-CO_2 GHGs from Soils*.

Task 2.16 Projection of future emissions of N_2O or CH_4 from the soils within the project area

Requirement: Required if at any time within the project crediting period the emissions of N_2O or CH_4 from the soils within the project area under the baseline scenario are projected to be greater than those found under the project scenario. Optional under all other circumstances.

Goal: To project future emissions from soils under the baseline scenario, in the case that these emissions are expected to decline.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with relevant input variable(s) from the module *VMD0029 Estimation of Emissions of Non CO2 GHG from Soils*, as the relevant variable(s) *X.* Then, based on the outputs from this module, use the module *VMD0029 Estimation of Emissions of Non-*CO_2 *GHG from Soils* to estimate the projected future emissions.

Task 2.17 Projected emissions from use of power equipment

Requirement: Required for all projects where emissions from power equipment directly attributable to activities within the project area are expected to be significantly greater under the project scenario as compared with the baseline scenario. Not to be used in all other circumstances. Conservatively, this methodology does not account for emission reductions arising from reductions in the use of power equipment under the project scenario as compared with the baseline scenario.

Goal: To project GHG emissions for the monitoring period from the use of power equipment under the baseline scenario. Note that in this methodology emissions of GHGs due to the use of power equipment directly attributable to activities within the project area are all accounted as baseline or project emissions, whether or not the actual emissions occur within the project area.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with fuel uses in power equipment as the relevant variable(s) *X.* Then, based on the outputs from this module, use the module *VMD0030 Estimation of Emissions from Power Equipment* to estimate the projected future emissions.

Task 2.18 Estimation of current litter pools.

Requirement: Required where significant decreases in litter pools within the project area are expected under the project scenario as compared with the baseline scenario at any time within the project crediting period. Optional under all other circumstances.

Goal: To estimate the carbon content of the litter pool within the project area.

Methods: Use module *VMD0023 Estimation of Carbon Stocks in the Litter Pool.*

Task 2.19 Projection of future litter pools

Requirement: Same as Task 2.18.

Goal: To project emissions from future litter pools under the baseline scenario where these emissions are expected to decline under the baseline scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with relevant input variable(s) from the module *VMD0023 Estimation of Carbon Stocks in the Litter Pool*, as the relevant variable(s) *X.*

Task Notes: If at any time in the project crediting period the litter pools within the project area under the baseline scenario are projected to be less than those at the project start date, litter pools for that time period must be accounted as being equal to levels at the project start date. Conservatively, this methodology does not account for projected decreases in litter pools under the baseline scenario.

Task 2.20 Summation of estimates and projections under the baseline scenario

Requirement: Required for all projects.

Goal: To sum current and future carbon sequestration and emissions under the baseline scenario.

Methods: Use module: *VMD0035 Methods to Determine the Net Change in Atmospheric GHG Resulting from Project Activities*.

8.2 Project Emissions

Task 3: (A) Ex-Ante Projection of GHG Pools and Emissions In the Project Scenario (Project Emissions)

Estimation of the carbon content of current pools and projection of carbon pools and emissions under the project scenario is undertaken using the following the steps:

Task 3.1 Ex-ante soil restratification

Requirement: Required for all projects.

Goal: To divide the project area into one or more strata within which the projected soil carbon pools and soil carbon dynamics are expected to be relatively uniform under the project scenario, given the stratification determined in Task 2.1, and the proposed treatment under the project scenario.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with soil carbon as the relevant variable *X.*

Task 3.2 Projection of treatment impacts per stratum, and effects on soil C pools

Requirement: Required for all projects.

Goal: To project, for the time within the project crediting period, the changes in soil carbon pools which are expected to occur in each stratum within the project area, given the planned treatments for the stratum.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with soil carbon as the relevant variable *X*, and module *VMD0021 Estimation of Stocks in the Soil Carbon Pool.*

Task 3.3 Ex-ante biomass re-stratification

Requirement: Required for all projects where significant decreases in living biomass pools are expected to occur under the project scenario, as compared with the baseline scenario. Optional in all other circumstances.

Goal: To divide the project area into one or more strata within which treatments are expected to result in living vegetation carbon pools and living vegetation dynamics which are relatively uniform for the full project crediting period.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with living biomass as the relevant variable *X.*

Task 3.4 Projection of future aboveground woody and non-woody and below ground living biomass pools under the project scenario

Requirement: Same as Task 3.3.

Goal: To project for the monitoring period the aboveground woody and non-woody biomass and belowground living biomass pools in each stratum based on expected treatment regimes, and to estimate the amount of living biomass carbon per unit area based on those projections.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with live biomass as the relevant variable *X* and the module *VMD0022 Estimation of Carbon Stocks in Living Plant Biomass*.

Task 3.5 Projection of future wood harvest outputs under the project scenario

Requirement: Required for all projects where the harvest of woody biomass within the project area is expected to be significantly lower under the project scenario as compared with the baseline scenario at any time within the project crediting period and some or all of that woody biomass is used for the production of long lived wood products. Optional but recommended in the case that harvests of woody biomass under the project scenario are expected to be significantly greater than those under the baseline scenario. Optional, but not recommended, where no significant wood harvest takes place under either the baseline or project scenario, or where no significant change in levels of wood harvest are expected under the project scenario as compared with the baseline scenario.

Goal: To project for the monitoring period the amount of woody biomass harvesting which is expected to take place within the project area under the project scenario, and the percentage of that harvest which is expected to be used for the production of long lived wood products.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with wood harvest and wood utilization as the relevant variable *X.*

Task 3.6 Projection of C sequestration in long lived wood products

Requirement: Same as Task 3.5.

Goal: To estimate the amount of carbon which will be sequestered in long lived wood products under the project scenario, based on the projections prepared in Task 3.5.

Methods: Use module *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool*, with the outputs from Task 3.5 as the inputs.

Task 3.7 Projection of future dead wood pools within the project area under the project scenario

Requirement: Required where significant amounts of dead wood are found on the site at the project start date, and removals of dead wood through utilization, reduced inputs, or accelerated burning as part of a management activity, are expected to occur under the project scenario. Optional in all other circumstances.

Goal: To estimate the amount of biomass which will be sequestered in dead wood pools under the project scenario.

Methods: Use the module *VMD0019 Methods to Project Future Conditions*, with dead wood pools as the relevant variable *X*.

Task 3.8 Projection of future domesticated animal populations under the project scenario

Requirement: Required where increases in the emissions of GHGs from domesticated animal populations are expected under the project scenario as compared with the baseline scenario. Not to be used in all other circumstances. Conservatively, this methodology does not account for projected decreases in emissions from domesticated animals under the project scenario as compared with the baseline scenario.

Goal: To project the future populations of domesticated animals for the monitoring period under the project scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with domesticated animal populations as the relevant variable *X.*

Task 3.9 Estimation of emissions of GHGs from domesticated animals within the project area under the project scenario

Requirement: Same as Task 2.10.

Goal: To estimate the emissions of GHGs from the current and projected future populations of domesticated animals under the project scenario the monitoring period based on the projections prepared in Task 3.7.

Methods: Use module *VMD0027 Estimation of Emissions From Domesticated Animals*, with the outputs from Task 3.7 as the inputs.

Task 3.10 Projection of future emissions of N_2O or CH_4 from the soils within the project area

Requirement: Required where significant increases in the emissions of N_2O or CH_4 from the soils within the project area are expected under the project scenario as compared with the baseline scenario. Optional under all other circumstances.

Goal: To estimate future emissions from soils under the project scenario, in the case that these emissions are expected to increase.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with relevant input variable(s) from the module *VMD0029 Estimation of Emissions of Non CO2 GHG From Soils*, as the relevant variable(s) *X.* Then, based on the outputs from this module, use the module *VMD0029 Estimation of Emissions of Non* CO_2 *GHG from Soils*, to estimate the projected future emissions.

Task 3.11 Projected emissions from use of power equipment

Requirement: Required for all projects where emissions from power equipment directly attributable to activities within the project area are expected to be *significantly* greater under the project scenario as compared with the baseline scenario. Not for use in all other circumstances. Conservatively, this methodology does not account for emission reductions arising from reductions in the use of power equipment under the project scenario as compared with the baseline scenario.

Goal: To estimate GHG emissions for the monitoring period from the use of power equipment under the project scenario. Note that in this methodology emissions of GHGs due to the use of power equipment directly attributable to the project are all accounted for as a project emissions, whether or not they occur within the project boundary.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with fuel use in power equipment as the relevant variable(s) *X.* Then, based on the outputs from this module, use the module *VMD0030 Estimation of Emissions from Power Equipment*, to estimate the projected future emissions.

Task 3.12 Projection of future litter pools

Requirement: Required where *significant* decreases in the carbon content of the litter carbon pool are expected under the project scenario as compared with the baseline scenario. Optional under all other circumstances.

Goal: To estimate future litter pools under the project scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with litter carbon pools as the relevant variable *X.*

Task 3.13 Projection of biomass consumption by fire

Requirement: Required where *significant* burning is expected to be used for management of the project area under the project scenario. Optional but not recommended otherwise.

Goal: To project the future amounts of biomass consumed by fire during the project crediting period under the project scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with biomass consumed by fire as the relevant variable *X.*

Task Notes: This step shall be done twice if biomass burning is to be done both within the project area, and outside of the project area as a consequence of displacement leakage. In that case, the results will be used for separate calculations during Task 3.16.

Task 3.14 Projection of non CO_2 emissions from burning

Requirement: Same as Task 3.13.

Goal: To estimate emissions of non CO2 GHGs from burning of biomass.

Methods: Use module *VMD0029 Estimation of Emissions of Non CO2 GHG from Soils.*

Task Notes: This step shall be done twice if biomass burning is done both within the project area, and outside of the project area as a consequence of activity shifting leakage. In that case, the results will be reported and accounted separately during Task 3.13 above.

Task 3.15 Summation of ex-ante estimates and projections under the project scenario

Requirement: Required for all projects.

Goal: To sum current and future carbon sequestration and emissions under the project scenario.

Methods: Use module *VMD0035 Methods to Determine the Net Change in Atmospheric GHG Resulting from Project Activities*, setting leakage variables to 0, as these will be accounted for in section 8.3 below.

Task 4: (A) Ex-Post Accounting of GHG Pools and Emissions (Project Emissions)

Ex-post accounting of GHG pools and emissions must be undertaken prior to each verification event, and at least once every 5 years during the project crediting period. Note that where leakage mitigation measures include tree planting, agricultural intensification, fertilization, fodder production, and/or other measures to enhance cropland and/or grazing land areas, then any significant increase in GHG emissions associated with these activities must be accounted for using the relevant module, whether or not they occur within the project area, unless they are deemed not significant, or can otherwise be conservatively excluded.

Task 4.1 Ex-post soil re-stratification

Requirement: Required for all projects.

Goal: To divide the project area into one or more strata within which the soil carbon pools and soil carbon dynamics are relatively uniform at the time of sampling.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with soil carbon as the relevant variable *X.*

Task 4.2 Estimation of the carbon content of current soil carbon pools per unit of area, for each stratum

Requirement: Required for all projects.

Goal: To sample the organic and inorganic soil carbon content in each stratum with a sampling intensity sufficient to allow estimation, at the required levels of statistical precision and accuracy, of the amount of soil carbon per unit area.

Methods: Use module *VMD0021 Estimation of Stocks in the Soil Carbon Pool.*

Task 4.3 Ex-post living biomass re-stratification

Requirement: Required for all projects where the aboveground woody and non-woody biomass and belowground living biomass carbon under the project scenario is found to be significantly less than that projected under the baseline scenarios at any time after the project start date. Optional under all other circumstances. Typically completion of this task will be required where the project area before the project start date contains more than scattered woody vegetation, and where the project activities include clearance, site preparation, burning or other activities likely to eliminate woody vegetation, or alternatively to enhance the recruitment of woody vegetation.

Goal: To divide the project area into one or more strata within which the vegetation carbon pools at the end of the project crediting period are relatively uniform.

Methods: Use module *VMD0018 Methods to Determine Stratification*, with above- and belowground living biomass stocks per unit area as the relevant variable *X.*

Task 4.4 Estimation of the carbon content of aboveground woody and non-woody and below ground living biomass pools

Requirement: Same as Task 4.3.

Goal: To sample the aboveground woody and non-woody biomass and below ground living biomass pools in each stratum to a sampling intensity sufficient to allow estimation to the required levels of statistical precision and accuracy of the amount of living biomass carbon per unit area.

Methods: Use module *VMD0022 Estimation of Carbon Stocks in Living Plant Biomass.*

Task 4.5 Estimation of the amount of wood harvest from within the project area used for production of long lived wood products

Requirement: Required for all projects where the harvest of woody biomass within the project area is expected to be *significantly* lower under the project scenario as compared with the baseline scenario at any time within the project crediting period, and some or all of that woody biomass is used for the production of long lived wood products. Optional but recommended in the case that harvests of woody biomass under the project scenario are expected to be significantly greater than those under the baseline scenario. Optional but not recommended in the case where no significant wood harvest takes place under either the baseline or project scenario, or where no significant change in levels of wood harvest are expected under the project scenario, as compared with the baseline scenario.

Goal: To estimate the amount of woody biomass harvesting taking place within the project area during a monitoring period.

Methods: Use module *VMD0025 Estimation of Woody Biomass Harvesting and Utilization*.

Task 4.6 Long Lived Wood Products

Requirement: Same criteria as Task 4.5.

Goal: To project amount of carbon which will be sequestered in long lived wood products derived from harvesting from within the project area during the monitoring period.

Methods: Use module *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool*, with the outputs from Task 4.5 as the inputs.

Task 4.7 Estimation of dead wood pools within the project area

Requirement: Required where dead wood is found on the site at the project start date, and *significant* removals of dead wood through utilization, reduced inputs, or accelerated burning as part of a management activity, are expected to occur under the project scenario. Optional under all other circumstances.

Goal: To estimate the current amount of biomass contained in dead wood pools.

Methods: Use module *VMD0024 Estimation of Carbon Stocks in the Dead Wood Pool*.

Task 4.8 Estimation of current average domesticated animal populations within the project area

Requirement: Required where increases in emissions from domesticated animals within the project area could occur in the project scenario as compared with the baseline scenario, due either to increases in populations or changes in feeding practices., Optional under all other circumstances.

Goal: To estimate the average current populations of domesticated animals within the project area during the monitoring period.

Methods: Use module *VMD0028 Estimation of Emissions from Domesticated Animals*.

Task 4.9 Estimation of emissions of GHGs from domesticated animals within the project area

Requirement: Required where increases in emissions from domesticated animals within the project area could occur in the project scenario as compared with the baselines scenario, due either to increases in populations or changes in feeding practices. Not for use under all other circumstances, to conservatively ensure that crediting for reductions in emissions from domesticated animals does not occur.

Goal: To estimate the emissions of GHGs from the current populations of domesticated animals during the monitoring period.

Methods: Use module *VMD0028 Estimation of Emissions from Domesticated Animals*, with the outputs from Task 4.8 as inputs.

Task 4.10 Estimation of emissions from use of power equipment

Requirement: Required for all projects where emissions from power equipment directly attributable to activities within the project area could be *significantly* greater under the project scenario as compared with the baseline scenario. Not for use in all other circumstances. Conservatively, this methodology does not account for emission reductions arising from reductions in the use of power equipment under the project scenario as compared with the baseline scenario.

Goal: To estimate GHG emissions from the use of power equipment under the project scenario during the monitoring period.

Methods: Use module *VMD0030 Estimation of Emissions from Power Equipment*.

Task notes: Under this methodology emissions of GHGs due to the use of power equipment directly attributable to the project are all accounted as a project emission, whether or not they occur within the project boundary.

Task 4.11 Estimation of non CO_2 emissions from burning

Requirement: Required where *significant* burning has been used for management of the project area under the project scenario. Optional but not recommended under all other circumstances.

Goal: To estimate emissions of non CO_2 GHGs from burning of biomass.

Methods: Use module *VMD0031 Estimation of Emissions from Biomass Burning*.

Task notes: This step must be done twice if biomass burning is done both within the project area and outside of the project area as a consequence of displacement leakage. In that case, the results will be reported and accounted separately during Task 4.15 and/or Task 4.16.

Task 4.12 Monitoring and estimation of soil emissions of N_2O or CH_4 from within the project area

Requirement: Required where *significant* increases in the emissions of N_2O or CH_4 from the soils within the project area are expected under the project scenario as compared with the baseline scenario. Optional under all other circumstances.

Goal: To estimate the emissions of N_2O or CH_4 from within the project area.

Methods: Use module *VMD0029 Estimation of Emissions of Non CO_2 GHG from Soils*.

Task notes: These estimations are expected to be based on the same models as those used during the ex-ante project study, unless improvements in models have occurred in the interim. In either case, values of variables used in the models must be updated to reflect actual conditions which have occurred during the monitoring period. If an updated model is used, and if modeling of baseline emissions was done as part of the baseline study, that modeling must be redone using the improved models.

Task 4.13 Estimation of current litter pools.

Requirement: Required where *significant* decreases in the carbon content of the litter pool are expected under the project scenario as compared with the baseline scenario. Optional under all other circumstances.

Goal: To estimate the carbon content of the litter pool within the project area.

Methods: Use module *VMD0023 Estimation of Carbon Stocks in the Litter Pool*.

Task 4.14 Summation of estimates of GHG fluxes under the project scenario

Requirement: Required for all projects.

Goal: To sum carbon sequestration and emission impacts directly attributable to the project activity based on the monitoring undertaken during the monitoring period.

Methods: Use module *VMD0035 Methods to Determine the Net Change in Atmospheric GHG Resulting from Project Activities*, setting leakage variables to 0, as these will be accounted in section 8.3 below.

8.3 Leakage

Under the VCS rules GHG pools and emissions affected by leakage are projected both ex-ante and accounted ex-post. Note that projects must not account for positive leakage (ie, where GHG emissions decrease, or removals increase, outside the project area due to project activities).

Task 3: (B) Ex-Ante Projection of GHG Pools and Emissions in the Project Scenario (Leakage)

Task 3.16 Projection of leakage due to displacement of grazing, fodder and agricultural production

Requirement: Required for projects where domesticated animal grazing or fodder or agricultural production occurred within the project area at the project start date, and where these activities are projected to decline within the project area due to project activities.

Goal: To project of future emissions from agricultural production, domesticated animals or fodder production displaced under the project scenario.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with displacement of domesticated animals or agricultural production as the relevant variable(s) *X.* Then, based on the outputs from this module, use module *VMD0032 Estimation of Emissions from Activity Shifting Leakage*, to estimate the impacts. Depending on the results from the module *VMD0032 Estimation of Emissions From Activity Shifting Leakage*, calculations of emissions may require the use of other modules.

Task 3.17 Projection of leakage due to displacement of wood harvesting

Requirement: Required for projects where displacement of wood harvest to areas outside of the project boundary is projected to occur.

Goal: To project future emissions from wood harvest displaced under the project scenario. Projection includes the reductions in emissions from these displaced wood harvest activities where they are expected to result in the production of long lived wood products.

Methods: Use module *VMD0019 Methods to Project Future Conditions*, with displacement of wood harvest as the relevant variable(s) *X*. Then, based on the outputs from this module, use module *VMD0032 Estimation of Emissions from Activity Shifting Leakage*, to estimate the impacts. Depending on the results from module *VMD0032 Estimation of Emissions from Activity Shifting Leakage*, calculations of emissions may require the use of other modules.

Task notes: Where wood harvesting occurs outside of the project boundary as a result of activity shifting leakage, and where that wood harvesting results in the production of long lived wood products, module *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool* must be used to estimate the amounts of carbon stored in wood products resulting from the wood harvesting.

Task 3.18 Projection of market leakage

Requirement: Required for projects where reductions in the production of wood, animals or agricultural products within the project area are expected under the project scenario as compared with the baseline scenario, and where Tasks 3.16 and 3.17 do not find that direct displacement of these activities to identifiable areas outside the project area fully replaces the production lost within the project area.

Goal: To project leakage caused by increases in prices or demand for products resulting from reduced production of these products within the project area under the project scenario.

Methods: Use module *VMD0033 Estimation of Emissions from Market Leakage*.

Task 4: (B) Ex-Post Accounting of Leakage from GHG Pools and Emissions (Leakage)

Task 4.15 Monitoring and estimation of emissions from grazing, fodder and agricultural production displacement

Requirement: Required for projects where domesticated animal grazing or fodder or agricultural production occurred within the project area at the project start date, and where these activities have declined within the project area due to project activities.

Goal: Estimation of emissions from domesticated animals or fodder production displaced as a result of project activities during the crediting period.

Methods: Use module *VMD0032 Estimation of Emissions from Activity Shifting Leakage*, to estimate the impacts. Depending on the results from the module, calculations of emissions may require the use of other modules.

Task 4.16 Monitoring and estimation of emissions from wood harvest displacement

Requirement: Required for projects where wood harvest occurred within the project area at the project start date, and where total wood harvest from the project area over the monitoring period will decline as compared with that projected under the baseline scenario.

Goal: Estimation of emissions from wood harvesting displaced as a result of project activities during the crediting period.

Methods: Use module *VMD0032 Estimation of Emissions from Activity Shifting Leakage*, to estimate the impacts. Depending on the results from the, calculations of emissions may require the use of other modules. Where displaced wood harvesting results in the production of long lived wood products, module *VMD0026 Estimation of Carbon Stocks in the Long Lived Wood Products Pool*, must also be used.

Task 4.17 Estimation of market leakage

Requirement: Required for projects where reductions in the production of wood, animals, or agricultural products within the project area have occurred under the project scenario, as compared with the baseline scenario, and where Tasks 4.15 and 4.16 do not find that direct displacement of these activities to identifiable areas outside the project area fully replaces the production lost within the project area.

Goal: To estimate leakage caused by increases in prices or demand for products resulting from reduced production of these products within the project area under the project scenario.

Methods: Use module *VMD0033 Estimation of Emissions from Market Leakage*.

Task notes: If market leakage has been projected in Task 3, and if the input conditions remain the same ex-post as those predicted ex-ante, the projections completed in Task 3.14 may be used to satisfy the requirements of this task.

8.4 Summary of GHG Emission Reduction and/or Removals

Task 4: Ex-Post Accounting of GHG Pools and Emissions (Net Emissions Reductions and/or Removals)

Task 4.18* Calculation *of GHG emission reductions and/or removals

Requirement: Required for all projects.

Goal: To summarize net greenhouse gas benefit of project activity.

Methods: Use module *VMD0035 Methods to Determine the Net Change in Atmospheric GHG Resulting from Project Activities*.

Task notes: Net changes in atmospheric GHG at t=z can only be calculated ex-post.

9 MONITORING

9.1 Data and Parameters Available at Validation

Data and parameters available at validation are given in the modules associated with this methodology.

9.2 Data and Parameters Monitored

Data and parameters available at validation are given in the modules associated with this methodology.

9.3 Description of the Monitoring Plan

The monitoring plan must be prepared using module *VMD0034 Methods for Developing a Monitoring Plan*. This module includes specifications on quality assurance and quality control that must be followed during development of the project description and other project documents.

Quantifying N_2O Emissions Reductions in Agricultural Crops through Nitrogen Fertilizer Rate Reduction

Methodology prepared by:

MICHIGAN STATE UNIVERSITY   EPRI | ELECTRIC POWER RESEARCH INSTITUTE

Acknowledgements

The VCS Methodology VM0022*, Quantifying N_2O Emissions Reductions in Agricultural Crops through Nitrogen Fertilizer Rate Reduction*, was developed by Michigan State University (MSU) with support from the Electric Power Research Institute (EPRI).

Principal authors are Neville Millar, G. Philip Robertson, and Adam Diamant with collaborators Ronald J. Gehl, Peter R. Grace, and John P. Hoben.

The authors thank Suzanne Sippel and Iurii Shcherbak for help with specific analyses, and many reviewers both public and anonymous for helpful suggestions for improvement. Financial support was provided by EPRI, the US National Science Foundation's Longterm Ecological Research Program, and MSU AgBioResearch.

Limitation of Liability

The methodology is licensed "as is." The methodology developer disclaims any and all responsibilities or warranties of any kind or nature, whether express or implied, in relation to merchantability or fitness for a particular purpose by any other person or entity of the methodology or any derivative works.

Project proponents, end users and any other relevant persons or entities assume the entire risk and responsibility for the safety, efficacy, performance, design, marketability, title and quality of the methodology or any derivative works prepared by or used by them.

The methodology developer assumes no liability in respect of any infringement of any rights of third parties due to the activities of project proponent, end user or any other person or entity, under the methodology or any derivative works. In no event shall methodology developer or its affiliates, including its trustees, directors, officers, faculty, staff, students, employees, consultants and agents, be responsible or liable for any direct, indirect, special, punitive, incidental or consequential damages or lost profits arising out of project proponent, end user or any other person or entity's use of the methodology.

None of the methodology developer, any of its affiliates, or any of its respective agents shall have any liability or responsibility whatsoever to project proponent, end user or any other person or entity for or on account of (and project proponent agrees and covenants, and agrees to cause each of its affiliate, end user or any other person or entity to agree and covenant, not to sue the methodology developer, any of its affiliates, or any of its respective agents in connection with) any injury, loss, or damage of any kind or nature, sustained by, or any damage assessed or asserted against, or any other liability incurred by or imposed upon, project proponents, end users or any other person or entity, whether direct, indirect, special, punitive, incidental, consequential or otherwise arising under any legal theory (and further without limitation any existing or anticipated profits or opportunities for profits lost by project proponents, end users or any other person or entity), arising out of or in connection with or resulting from (i) the reproduction, use, display, performance, license or sale of the methodology or derivative works by project proponents, end users or any other person or entity, (ii) the use of any copyrights by project proponent, end user or any other person or entity, (iii) any advertising or other promotional activities with respect to either of the foregoing, or (iv) the production, use or sale of any product identified, characterized or otherwise developed by project proponent, end user or any other person or entity with the aid of the copyrights.

2006 IPCC Guidelines for National Greenhouse Gas Inventories

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology quantifies emissions reductions of nitrous oxide (N_2O) from agriculture in the United States (US), as brought about by reductions in the rate of nitrogen (N) fertilizer (synthetic and organic) applied to cropland. The methodology encourages the application of economically optimum N fertilizer rates that do not harm productivity, and requires the use of verifiable best management practices for N timing, placement, and type. Depending on the US state where a project is implemented, the methodology uses either a generally accepted IPCC Tier 1 emission factor or an empirically derived Tier 2 regional emission factor (applicable in the 12 state North Central Region) to aid in calculating N_2O emissions reductions. The approach is straightforward and transparent and is a practical solution to help reduce N_2O emissions and other reactive N pollutants from agriculture. The field research that underpins the methodology is publicly available in the peer-reviewed literature.

Nitrous oxide production in agricultural soil occurs predominantly through the microbial transformations of inorganic N (Robertson and Groffman 2007). The potential to produce and emit N_2O increases with the increasing availability of N (Bouwman et al. 1993). Due to the strong influence of available soil N on N_2O emissions, some emissions of N_2O are an unavoidable consequence of maintaining highly productive cropland (Mosier 2002). However, any activity or process that acts to keep available soil N low will lead to lower N_2O emissions. Anthropogenic activities that lower the input of N into cropland agriculture help to reduce emissions of N_2O (Robertson and Vitousek 2009).

To date the vast majority of evidence supports N input as the most robust and reliable default proxy for calculating N_2O emissions. It is consistent and straightforward to quantify as a metric and its use is substantiated by the IPCC, which uses annual N rate as the default method for calculating N_2O emissions from managed land in national greenhouse gas inventories. Moreover, its alteration is readily accessible to management intervention.

Table 1: Additionality and Crediting Baseline Methods

Additionality	Performance Method
Crediting Baseline	Performance Method

3 DEFINITIONS

Synthetic nitrogen fertilizer: Any synthetic fertilizer (solid, liquid, gaseous) containing nitrogen (N). This may be a single nutrient fertilizer product (only including N), or any other synthetic fertilizer containing N, such as multi–nutrient fertilizers (e.g., N–P–K fertilizers) and ‘enhanced–efficiency’ N fertilizers (e.g., slow release, controlled release and stabilized N fertilizers).

Organic nitrogen fertilizer: Any organic material containing N, including animal manure, compost and sewage sludge.

Direct N_2O emissions: Those emitted directly from the site to which fertilizer N has been applied.

Indirect N_2O emissions: Those emitted beyond the site to which fertilizer N has been applied, but as a result of the fertilizer N applied at the site

North Central Region: The North Central Region (NCR) of the USA encompasses the 12 Midwestern states of Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota and Wisconsin.

4 APPLICABILITY CONDITIONS

4.1 The methodology applies to Agricultural Land Management (ALM) project activities) that reduce net nitrous oxide (N_2O) emissions from agricultural cropping systems by reducing the nitrogen (N) fertilizer application rate compared to the business as usual (BAU) scenario.

4.2 Implementation of project activities under this methodology must not lead to violation of any applicable law even if the law is not enforced.

4.3 Projects must not be at sites that have not be cleared of native ecosystems and where eligible cropping systems have been grown for at least ten years prior to project implementation. Eligible cropping systems are defined in the applicability condition 4.8.

4.4 The following conditions with respect to fertilizer nitrogen sources must be met:

Sources of fertilizer N eligible under this methodology must be a sub–set of those detailed in the 2006 IPCC Guidelines for National Greenhouse Gas Inventories and can include:

- Synthetic N fertilizers; and
- Organic N fertilizers.

All other N input sources (e.g., crop residue N, atmospheric N deposition (other than as an indirect N_2O emissions pathway) and soil N mineralization associated with soil management practices do not qualify for consideration.

All eligible N inputs on a mass basis are considered equal irrespective of their source.

4.5 The following conditions with respect to fertilizer nitrogen management must be met:

- Fertilizer N additions to the soil during a whole crop cycle are eligible for determination of the yearly fertilizer N rate irrespective of when N is applied during the calendar year or whether N application is split between calendar years for a single crop.

- During the project crediting period, adherence to 'Best Management Practices' (BMPs) as they relate to the application of synthetic and organic N fertilizer at the project site is required. These BMPs are related to N fertilizer formulation (or N content of organic additions) and dates and methods of application. Details of fertilizer BMPs are readily available for each US state via state departments of agriculture and from federal agencies such as the Natural Resources Conservation Service (NRCS) and the USDA Farm Service Agency. More generally these BMPs are described in the Global 4R Nutrient (Fertilizer) Stewardship Framework (Right Source–Rate–Time–Place), published by the International Plant Nutrition Institute (IPNI).

- The project proponent must demonstrate that during each cropping season included in the project crediting period the total N rate to be applied to the project area is sufficient to generate expected annual yield similar to the average annual yield of the same crop(s) grown during the baseline period. Documentation required to demonstrate that this applicability condition has been met is described in Section 9.2.

4.6 Both direct and indirect pathways of N_2O emissions as outlined by the 2006 IPCC Guidelines for National Greenhouse Gas Inventories are eligible under this methodology. Indirect N_2O emissions can occur in the following scenarios

- Following the volatilization of the gases NH_3 and NOx produced as a result of the N input to the project site and the subsequent re–deposition of these gases and their products NH_4^+ and NO_3^- to soils and waters beyond the project site;

- After leaching and runoff of N (mainly as NO_3-) applied to the project site enters receiving waters or soils beyond the project site (only applicable to regions where leaching and runoff is considered to occur – see Appendix A).

4.7 Projects must be implemented in the US only.

4.8 The following conditions with respect to cropping systems must be met:

- Projects located in the US including all fertilized agricultural crops where the product is harvested for food, livestock fodder or for another economic purpose must use Method 1 (described in section 8) to calculate direct N_2O emissions.

- Projects located in the NCR of the US that involve corn in row–crop systems such as continuous corn and rotations of corn–soybean or corn-soybean-wheat must use Method 2 (described in section 8) to calculate direct N_2O emissions.

- Projects located in the NCR that involve crops other than corn including crops in rotation with corn must use Method 1 to calculate direct N_2O emissions.

Projects must also state and justify ex-ante in the Project Document whether they will apply Method 1 or Method 2 as determined by their geographic location and cropping system. The same method must be applied to the calculation of direct N_2O emissions in the baseline and project case and used for the demonstration of additionality.

4.9 The project crop area must be the same as or less than the baseline crop area in order to ensure that the same land area is used in emission reduction calculations.

4.10 Projects must not be on sites with 'organic' soils or Histosols, as defined by the US Soil Taxonomy. The unique properties of Histosols are a very high content of organic matter (OM) in the upper 80 cm (32 in) of the soils and no permafrost. The amount of organic matter is at least 20 to 30 percent by mass (200-300 g OM kg dry soil-1) in more than half of this thickness, or the horizon that is rich in organic matter rests on rock or rock rubble. Most Histosols are peats or mucks, which consist of more or less decomposed plant remains that accumulated in water, but some formed from forest litter or moss, or both, and are freely drained. USDA NRCS soils maps for individual fields can be used to determine whether a field is underlain by a soil series in the Histosol Order.

5 PROJECT BOUNDARY

Spatial boundary

The spatial boundary of the project encompasses both direct and indirect emissions of N_2O, and includes the project site where fertilizer N is directly applied as well as any additional soils and waters where byproducts of the fertilizer N input (such as the gases NH_3 and NOx, and their products NH_4^+ and NO_3^-) are re-deposited.

The project proponent must define the project site where fertilizer N is directly applied in the Project Document, but is not required to define the specific areas where byproducts may be re-deposited beyond the project site.

Temporal boundary

The project crediting period must follow the requirements for ALM projects focusing exclusively on emissions reductions of N_2O as set out in the most recent version of the VCS Standard.

Greenhouse gases

Table 1 summarizes the greenhouse gases accounted for in the calculations of baseline emissions and project emissions.

Table 1. Greenhouse gases and their sources

Source		Gas	Included?	Justification/Explanation
Baseline	Direct emissions synthetic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
		CO_2	No	Not significant - de minimis

Source		Gas	Included?	Justification/Explanation
	Indirect emissions synthetic fertilizer	CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
	Direct emissions organic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from fertilizer N addition
	Indirect emissions organic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
Project	Direct emissions synthetic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
	Indirect emissions synthetic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
	Direct emissions organic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer
	Indirect emissions organic fertilizer	CO_2	No	Not significant - de minimis
		CH_4	No	Not significant - de minimis
		N_2O	Yes	N_2O is the major emissions source from N fertilizer

Carbon pools

Table 2 summarizes the carbon pools included in projects using this methodology.

Soil carbon is the primary pool of concern for ALM methodologies. In accordance with VCS AFOLU requirements v3.3, methodologies targeting N_2O emission reductions need to account for any significant reductions in soil C stocks.

In this methodology reductions in N fertilizer rate resulting from project implementation will not result in significant (> 5% of the total CO_2e benefits from reduction in N_2O emissions) decreases in soil C stock. Evidence presented in Appendix B in the form of peer reviewed literature details how the soil C pool is deemed de minimis. Appendix B can be used for projects using this methodology as a criterion to exclude the soil C pool.

Table 2. Carbon pools considered in the methodology

Carbon Pool	Included?	Justification/Explanation
Above ground woody biomass	No	Not relevant or subject to significant change – de minimis

Carbon Pool	Included?	Justification/Explanation
Above ground non woody biomass	No	Not relevant or subject to significant change – de minimis
Below ground biomass	No	Not relevant or subject to significant change – de minimis
Litter	No	Not relevant or subject to significant change – de minimis
Dead wood	No	Not relevant or subject to significant change – de minimis
Soil	Yes	Change is nil or positive or (reduction is de minimis)
Wood products	No	Not relevant or subject to significant change – de minimis

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

The baseline scenario is the continuation of the historical cropping practices where, in the absence of the project activity, N fertilizer rate is applied in a business as usual (BAU) manner, resulting in higher emissions of N_2O from the soil when compared to a situation where the project is implemented and the application of lower N fertilizer rate results in lower emissions of N_2O.

The baseline emissions are the amount of N_2O that would have been emitted to the atmosphere during the project crediting period under the N rate practice that would have been in place had the project not been implemented.

The determination of baseline N_2O emissions is carried out using one of two Approaches. Both Approaches use a yield-goal calculation method to generate a baseline fertilizer N application rate, from which emissions of N_2O are calculated. Approach 1 derives the baseline N rate from producer-specific N fertilizer management records, and Approach 2 derives the baseline N rate from county-level records aggregated by the USDA National Agricultural Statistics Service: USDA crop yield data in conjunction with standard state-specific University-recommended yield-goal based equations for calculating N rates from these yields for the period in question.

Due to its finer spatial resolution (site specificity), project proponents must use Approach 1 if data is available. Approach 2 (county scale data) can be used if relevant site-specific records are not available or verifiable for Approach 1. The same Approach must be applied to synthetic N fertilizer and organic N fertilizer if both kinds of fertilizers have been applied during the baseline period.

Approach 1

The baseline N fertilizer rate is determined from the project proponents' management records for at least the previous five years (monoculture) or six years (e.g., three cycles of a two crop rotation, or two cycles of a three crop rotation) prior to the proposed project implementation year.

Management records from which baseline fertilizer N rate can be directly determined is required under this Approach. Examples of these include synthetic fertilizer purchase and application rate records, as well as manure application rate and manure N content data.

Determination of the baseline N_2O emissions must be based on an average of the previous N rate applications for the specific crop(s). A worked example of a baseline N rate calculation using Approach 1 is given in Appendix C.

Approach 2

If the baseline fertilizer N rate for the specific crop(s) cannot be established from project proponent records (Approach 1), then Approach 2 can be used. With Approach 2, the baseline fertilizer N rate is calculated from crop yield data at the county level (available from the United States Department of Agriculture – National Agricultural Statistics Service (USDA – NASS)) and equations for determining fertilizer N rate recommendations based on yield goal estimates (found in e.g., state department of agriculture and university agricultural extension documents).

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

Additionality is assessed through the performance method. The performance method requires projects to meet with requirements on regulatory surplus and exceed the performance benchmark specified below.

Regulatory Surplus

Project proponents meet the requirements for regulatory surplus if:

There is no mandatory law, statute or other regulatory framework in place at the local, state, or federal level, requiring producers to reduce fertilizer N input rate below that of a BAU scenario.

Appendix D provides more information and presents a list of regulations at Federal and State level that deal with practices relating to synthetic and organic N fertilizer management in the agricultural sector. Project developers must consider and evaluate the applicability of all such regulations in the context of the proposed project in order to satisfy the regulatory surplus requirements.

Performance Benchmark

Projects proponents must exceed a performance benchmark threshold that represents BAU. The BAU value is identical to the baseline value for N fertilizer application rate. The baseline value for N fertilizer rate is equivalent to the widespread and general practice of producers to apply N fertilizer rates based upon recommendations derived from yield goal calculations known to overestimate crop needs.

Reductions in N fertilizer rate and therefore N_2O emissions below the BAU site specific value (Approach 1) or below the BAU value in the county where the project is to be conducted (Approach 2) will result in a project exceeding the performance benchmark. The benchmark is defined in terms of N_2O emissions (Mg CO_2e ha^{-1}). Detailed examples using Approach 1 and Approach 2 to determine the benchmark are shown in Appendix C. Evidence for the wide-scale, historic, and continued adoption of the yield-goal approach, and therefore its legitimacy as a performance benchmark for demonstrating additionality in US crop-based agriculture is given in Appendix E.

Further discussion on why Approach 2 is conservative and the trade-offs between false positives (the crediting of activities that are not additional) and false negatives (the exclusion of activities that are additional) is also presented in Appendix E.

The procedures described below are the requirements for determining the benchmark for a crop grown in a single project site using Approach 2.

- Identify project site
- Identify project crop
- Identify years in which crop has been harvested in project site.
- Gather data on crop yield from these years in relevant US county from USDA-NASS
- Use equation C2 (Appendix C) or other relevant equation to calculate predicted crop yield (YG_t)
- Incorporate YG_t into relevant 'yield goal' equation for calculating N rate (e.g., equation C1 in Appendix C)
- Calculate annual N rates based upon field rotation and management (e.g., incorporating N credits)
- Calculate average annual N rate (i.e., baseline N rate) from all annual N rates
- Reduce N rate below the baseline N rate during project crediting period
- Record and maintain project N rate records

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

All emissions of N_2O (baseline and project, direct and indirect) are reported in units of Megagram of carbon dioxide equivalents (Mg CO_2e). One (1) Mg is equivalent to 1×10^6g or one (1) metric Ton or one (1) tonne.

Emissions for baseline and project period are calculated on a per hectare (ha) of land basis.

In the calculations below, year t is the 12-month period following the first input of N fertilizer dedicated to a particular crop, or the period of time following this input prior to an N input dedicated to a separate and subsequent crop at the same project site,

The subscripts B (e.g., $F_{B\ SN,\ t}$) and P (e.g., $F_{P\ SN,\ t}$) are added to distinguish the terms for baseline and project emission factors, respectively. All other factors without these subscripts will be applicable for use in both project and baseline emission calculations.

In calculating direct and indirect emissions of N_2O, the methodology utilizes terminology and scientific rationale presented in the most recent 2006 IPCC Guidelines for National Greenhouse Gas Inventories.

8.1 Baseline Emissions

Baseline emissions can be calculated by the following equation:

$$N_2O_{B\ total,\ t} = N_2O_{B\ direct,\ t} + N_2O_{B\ indirect,\ t} \quad (1)$$

Where:

$N_2O_{B\ total,\ t}$ Total baseline N_2O emissions, Mg CO_2e ha^{-1} in year t;

$N_2O_{B\ direct,\ t}$	Direct baseline N_2O emissions from the project site, Mg CO_2e ha^{-1} in year t;
$N_2O_{B\ indirect,\ t}$	Indirect baseline N_2O emissions beyond the project site, Mg CO_2e ha^{-1} in year t.

Direct emissions

Method 1

The direct baseline nitrous oxide emissions from nitrogen fertilization for Method 1 can be calculated using the following equations:

$$N_2O_{B\ direct,\ t} = (F_{B\ SN,\ t} + F_{B\ ON,\ t}) * EF_{BDM1} * N_2O_{MW} * N_2O_{GWP} \quad (2)$$

$$F_{B\ SN,\ t} = M_{B\ SF,\ t} * NC_{B\ SF} \quad (3)$$

$$F_{B\ ON,\ t} = M_{B\ OF,\ t} * NC_{B\ OF} \quad (4)$$

Where:

$F_{B\ SN,\ t}$	Baseline synthetic N fertilizer applied, Mg N ha^{-1} in year t;
$F_{B\ ON,\ t}$	Baseline organic N fertilizer applied, Mg N ha^{-1} in year t;
$M_{B\ SF,\ t}$	Mass of baseline N containing synthetic fertilizer applied, Mg ha^{-1} in year t;
$M_{B\ OF,\ t}$	Mass of baseline N containing organic fertilizer applied, Mg ha^{-1} in year t;
$NC_{B\ SF}$	N content of baseline synthetic fertilizer applied, g N $(100g\ fertilizer)^{-1}$;
$NC_{B\ OF}$	N content of baseline organic fertilizer applied g N $(100g\ fertilizer)^{-1}$;
EF_{BDM1}	Emission factor for baseline direct N_2O emissions from N inputs Mg N_2O–N $(Mg\ N\ input)^{-1}$ (IPCC default Tier 1 = 0.01. See Appendix F);
N_2O_{MW}	Ratio of molecular weights of N_2O to N (44/28), Mg N_2O $(Mg\ N)^{-1}$;
N_2O_{GWP}	Global Warming Potential for N_2O, Mg CO_2e $(Mg\ N_2O)^{-1}$ (IPCC default = 310. See Appendix F).

Method 2

Direct emissions of N_2O will be calculated using a NCR derived (IPCC Tier 2) equation for baseline and project emissions. See Appendix G. The direct baseline nitrous oxide emissions from nitrogen fertilization for Method 2 can be calculated using the following equations:

$$N_2O_{B\ direct,\ t} = (F_{B\ SN,\ t} + F_{B\ ON,\ t}) * EF_{BDM2} * N_2O_{MW} * N_2O_{GWP} \quad (5)$$

$$F_{B\ SN,\ t} = M_{B\ SF,\ t} * NC_{B\ SF} \quad (3)$$

$$F_{B\ ON,\ t} = M_{B\ OF,\ t} * NC_{B\ OF} \quad (4)$$

$$EF_{BDM2} = 6.7 * 10^{-4} * (\exp (6.7 * [F_{B\ SN,\ t} + F_{B\ ON,\ t}]) – 1) / (F_{B\ SN,\ t} + F_{B\ ON,\ t}) \quad (6)$$

Where:

EF_{BDM2} — Emission factor for baseline direct N_2O emissions from N inputs Mg N_2O–N (Mg N input)$^{-1}$. See Appendix G for details of emission factor calculation.

All other terms are as for Method 1.

For Method 1 and Method 2, the amounts of applied mineral nitrogen fertilizers ($F_{B\ SN,\ t}$) and of applied organic nitrogen fertilizers ($F_{B\ ON,\ t}$) are not adjusted for the amounts of NH_3 and NO_x volatilization after application to soil. Reasons for the removal are given in 2006 IPCC Guidelines for National Greenhouse Gas Inventories (Volume 4, Chapter 11, Note 11).

The baseline fertilizer N rate value calculated using Approach 2 represents the product of the mass and the N content of the synthetic N containing fertilizer, i.e., $M_{B\ SF,\ t} * NC_{B\ SF}$, and as such can be used directly as the value of $F_{B\ SN,\ t}$. Approach 2 is not applicable for the calculation of the baseline organic fertilizer N rate, therefore the value of $F_{B\ ON,\ t} = 0$.

Indirect emissions

The indirect baseline nitrous oxide emissions from nitrogen fertilization can be calculated using the following equations:

$$N_2O_{B\ indirect,\ t} = N_2O_{B\ volat,\ t} + N_2O_{B\ leach,\ t} \quad (7)$$

$$N_2O_{B\ volat,\ t} = [(F_{B\ SN,\ t} * Frac_{GASF}) + (F_{B\ ON,\ t} * Frac_{GASM})] * EF_{BIV} * N_2O_{MW} * N_2O_{GWP} \quad (8)$$

$$N_2O_{B\ leach,\ t} = (F_{B\ SN,\ t} + F_{B\ ON,\ t}) * Frac_{LEACH} * EF_{BIL} * N_2O_{MW} * N_2O_{GWP} \quad (9)$$

Where:

$N_2O_{B\ indirect,\ t}$ — Indirect baseline N_2O emissions beyond the project site, Mg CO_2e ha^{-1} in year t;

$N_2O_{B\ volat,\ t}$ — Indirect baseline N_2O emissions produced from atmospheric deposition of N volatilized as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;

$N_2O_{B\ leach,\ t}$ — Indirect baseline N_2O emissions produced from leaching and runoff of N in regions where leaching and runoff occurs, as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;

$F_{B\ SN,\ t}$ — Baseline synthetic N fertilizer applied, Mg N ha^{-1} in year t;

$F_{B\ ON,\ t}$ — Baseline organic N fertilizer applied, Mg N ha^{-1} in year t;

$Frac_{GASF}$ — Fraction of all synthetic N added to baseline soils that volatilizes as NH_3 and NO_x, dimensionless (IPCC default Tier 1 = 0.10. See Appendix F);

$Frac_{GASM}$ — Fraction of all organic N added to baseline soils that volatilizes as NH_3 and NO_x, dimensionless (IPCC default Tier 1 = 0.20. See Appendix F);

$Frac_{LEACH}$ — Fraction of N added (synthetic or organic) to baseline soils that is lost through leaching and runoff, in regions where leaching and runoff occurs, dimensionless (IPCC default Tier 1 = 0.30. See Appendix A and F);

EF_{BIV} Emission factor for baseline N_2O emissions from atmospheric deposition of N on soils and water surfaces, [Mg N_2O–N (Mg NH_3–N + NO_x–N volatilized)$^{-1}$] (IPCC default Tier 1 = 0.01. See Appendix F);

EF_{BIL} Emission factor for baseline N_2O emissions from N leaching and runoff, Mg N_2O–N (Mg N leached and runoff)$^{-1}$ (IPCC default Tier 1 = 0.0075. See Appendix F);

N_2O_{MW} Ratio of molecular weights of N_2O to N (44/28), Mg N_2O (Mg N)$^{-1}$;

N_2O_{GWP} Global Warming Potential for N_2O, Mg CO_2e (Mg N_2O)$^{-1}$ (IPCC default = 310. See Appendix F).

At project sites where leaching and runoff do not occur (see Appendix A), indirect N_2O emissions are calculated by removing the factor $N_2O_{B\ leach,\ t}$ from equation 7.

8.2 Project Emissions

Project emissions can be calculated by the following equation:

$$N_2O_{P\ total,\ t} = N_2O_{P\ direct,\ t} + N_2O_{P\ indirect,\ t} \quad (10)$$

Where:

$N_2O_{P\ total,\ t}$ Total project N_2O emissions, Mg CO_2e ha^{-1} in year t;

$N_2O_{P\ direct,\ t}$ Direct project N_2O emissions from the project site, Mg CO_2e ha^{-1} in year t;

$N_2O_{P\ indirect,\ t}$ Indirect project N_2O emissions beyond the project site, Mg CO_2e ha^{-1} in year t.

Direct emissions

Method 1

The project direct nitrous oxide emissions from nitrogen fertilization can be calculated using equations as follows:

$$N_2O_{P\ direct,\ t} = (F_{P\ SN,\ t} + F_{P\ ON,\ t}) * EF_{PDM1} * N_2O_{MW} * N_2O_{GWP} \quad (11)$$

$$F_{P\ SN,\ t} = M_{P\ SF,\ t} * NC_{P\ SF} \quad (12)$$

$$F_{P\ ON,\ t} = M_{P\ OF,\ t} * NC_{P\ OF} \quad (13)$$

Where:

$F_{P\ SN,\ t}$ Project synthetic N fertilizer applied, Mg N ha^{-1} in year t;

$F_{P\ ON,\ t}$ Project organic N fertilizer applied, Mg N ha^{-1} in year t;

$M_{P\ SF,\ t}$ Mass of project N containing synthetic fertilizer applied, Mg ha^{-1} in year t;

$M_{P\ OF,\ t}$ Mass of project N containing organic fertilizer applied, Mg ha^{-1} in year t;

$NC_{P\ SF}$ N content of project synthetic fertilizer applied g N (100g fertilizer)$^{-1}$;

$NC_{P\ OF}$ N content of project organic fertilizer applied g N (100g fertilizer)$^{-1}$;

EF_{PDM1}	Emission factor for project N_2O emissions from N inputs, Mg N_2O–N (Mg N input)$^{-1}$ (IPCC default = 0.01. See Appendix F);
N_2O_{MW}	Ratio of molecular weights of N_2O to N (44/28), Mg N_2O (Mg N)$^{-1}$;
N_2O_{GWP}	Global Warming Potential for N_2O, Mg CO_2e (Mg N_2O)$^{-1}$ (IPCC default = 310. See Appendix F).

Method 2

The direct project nitrous oxide emissions from nitrogen fertilization for Method 2 can be calculated using the following equations:

$$N_2O_{P\ direct,\ t} = (F_{P\ SN,\ t} + F_{P\ ON,\ t}) * EF_{PDM2} * N_2O_{MW} * N_2O_{GWP} \quad (14)$$

$$F_{P\ SN,\ t} = M_{P\ SF,\ t} * NC_{P\ SF} \quad (12)$$

$$F_{P\ ON,\ t} = M_{P\ OF,\ t} * NC_{P\ OF} \quad (13)$$

$$EF_{PDM2} = 6.7 * 10^{-4} * (\exp(6.7 * [F_{P\ SN,\ t} + F_{P\ ON,\ t}]) – 1) / (F_{P\ SN,\ t} + F_{P\ ON,\ t}) \quad (15)$$

Where:

EF_{PDM2}	Emission factor for project direct N_2O emissions from N inputs Mg N_2O–N (Mg N input)$^{-1}$. See Appendix **G** for details of emission factor calculation.

All other terms are as for Method 1.

For Method 1 and Method 2, the amounts of applied mineral nitrogen fertilizers ($F_{B\ SN,\ t}$) and of applied organic nitrogen fertilizers ($F_{B\ ON,\ t}$) are not adjusted for the amounts of NH_3 and NO_x volatilization after application to soil. Reasons for the removal are given in 2006 IPCC Guidelines for National Greenhouse Gas Inventories (Volume 4, Chapter 11, Note 11).

Indirect emissions

The indirect project nitrous oxide emissions from nitrogen fertilization can be calculated using the following equations:

$$N_2O_{P\ indirect,\ t} = N_2O_{P\ volat,\ t} + N_2O_{P\ leach,\ t} \quad (16)$$

$$N_2O_{P\ volat,\ t} = [(F_{P\ SN,\ t} * Frac_{GASF}) + (F_{P\ ON,\ t} * Frac_{GASM})] * EF_{PIV} * N_2O_{MW} * N_2O_{GWP} \quad (17)$$

$$N_2O_{P\ leach,\ t} = (F_{P\ SN,\ t} + F_{P\ ON,\ t}) * Frac_{LEACH} * EF_{PIL} * N_2O_{MW} * N_2O_{GWP} \quad (18)$$

Where:

$N_2O_{P\ indirect,\ t}$	Indirect project N_2O emissions beyond the project site, Mg CO_2e ha^{-1} in year t;
$N_2O_{P\ volat,\ t}$	Indirect project N_2O emissions produced from atmospheric deposition of N volatilized as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;

$N_2O_{P\ leach,\ t}$	Indirect project N_2O emissions produced from leaching and runoff of N in regions where leaching and runoff occurs, as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;
$F_{P\ SN,\ t}$	Project synthetic N fertilizer applied adjusted for volatilization as NH_3 and NO_x, and leaching and runoff where applicable, Mg N ha^{-1} in year t;
$F_{P\ ON,\ t}$	Project organic N fertilizer applied adjusted for volatilization as NH_3 and NO_x, and leaching and runoff where applicable, Mg N ha^{-1} in year t;
$Frac_{GASF}$	Fraction of all synthetic N added to project soils that volatilizes as NH_3 and NO_x, dimensionless (IPCC default Tier 1 = 0.10. See Appendix F);
$Frac_{GASM}$	Fraction of all organic N added to project soils that volatilizes as NH_3 and NO_x, dimensionless (IPCC default Tier 1 = 0.20. See Appendix F);
$Frac_{LEACH}$	Fraction of N added (synthetic or organic) to project soils that is lost through leaching and runoff, in regions where leaching and runoff occurs, dimensionless (IPCC default Tier 1 = 0.30. See Appendix A and F);
EF_{PIV}	Emission factor for project N_2O emissions from atmospheric deposition of N on soils and water surfaces, [Mg N_2O–N (Mg NH_3–N + NO_x–N volatilized)$^{-1}$] (IPCC default Tier 1 = 0.01. See Appendix F);
EF_{PIL}	Emission factor for project N_2O emissions from N leaching and runoff, Mg N_2O–N (Mg N leached and runoff)$^{-1}$ (IPCC default Tier 1 = 0.0075. See Appendix F);
N_2O_{MW}	Ratio of molecular weights of N_2O to N (44/28), Mg N_2O (Mg N)$^{-1}$;
N_2O_{GWP}	Global Warming Potential for N_2O, Mg CO_2e (Mg N_2O)$^{-1}$ (IPCC default = 310. See Appendix F).

At project sites where leaching and runoff do not occur (see Appendix A), project indirect N_2O emissions are calculated by removing the factor $N_2O_{P\ leach,\ t}$ from equation 16.

8.3 Leakage

Leakage risks from increased N_2O emissions and other greenhouse gas emissions, and decreased C pools outside the ALM project boundary are not relevant and are not included in emissions calculations due to the reasons described below:

Leakage risks are negligible for ALM projects involving cropland management activities because the land in the project scenario remains maintained for commodity production. Therefore, no production activities outside the project boundary are required to compensate for a productivity decline.

Crop producers are highly risk averse and will not intentionally suffer reduced crop yields. Reducing N rates and the adoption of N rates based on economic optimization will not result in a reduction in crop yield. Extensive historical and current data from Midwestern states at typical crop-to-fertilizer price ratios indicate that there will be no significant change in crop yield as a result of lowering N fertilizer rate from current rates to the economic optimum (ISU 2004, Sawyer et al. 2006, Hoben et al. 2011). Consequently, with no reduction in productivity at the project site there will be no associated incentive for a shift of activity or increased production outside of the project site, which might in turn result in increased N fertilizer use and N_2O emissions. With no yield reduction there will also be no decrease in soil C input and therefore no change in soil C sequestration due to project activities (see section 5 and Appendix B). The leakage potential is therefore negligible.

Moreover, although accounting for ‘positive leakage’ is not eligible, less available N in the soil will result in a reduction in other gaseous and hydrologic N pollutants (e.g., NH_3, NO_x, and NO_3^-).

8.4 Summary of GHG Emission Reduction and/or Removals

The uncertainty associated with a reduction in N_2O emissions brought about by a reduction in N rate between the baseline period and the project period is calculated as:

N_2O Emissions $_{(RED\ UNC)}$ $[1 – \{0.63 * \exp(-40 * [N_{Proj}]^2)\}] * 100$ (19)

Where:

N_2O Emissions $_{(RED\ UNC)}$ Uncertainty in N_2O emissions reductions associated with a reduction in N rate, %;

N_{Proj} = $F_{P\ SN,\ t} + F_{P\ ON,\ t}$ project N input, Mg N ha^{-1} yr^{-1}.

Equation (19) is applicable to projects that determine their baseline N rate (and therefore baseline N_2O emissions) using either Approach 1 or Approach 2 (section 6). Further details of how emissions uncertainty is derived are given in Appendix G.

Project proponents will use equation (19) to calculate emissions reductions uncertainties (%) for a project. Confidence deductions as a result of uncertainty will be applied using the conservative factors specified in the CDM Meth Panel guidance on addressing uncertainty in its Thirty Second Meeting Report, Appendix 14 (Table 3 below).

Table 3: Conservativeness factors for emissions reductions based upon uncertainty at 95% confidence level.

Uncertainty range at 95% confidence level of project emissions reductions§	Conservativeness factor	Uncertainty deduction*
< ± 15%	1.000	0.000
> ± 15% ≤ ± 30%	0.943	0.057
> ± 30% ≤ ± 50%	0.893	0.107
> ± 50% ≤ ± 100%	0.836	0.164

§ Uncertainty in emissions reductions does not exceed 100% (see Appendix G).
* Where uncertainty in emissions reductions is < ± 15%, no deductions will be applied.
Uncertainty deduction (UNC) = (1 – Conservativeness factor). See equation (20).

Emissions reductions and calculations of VCUs

Equation (20) calculates the N_2O emission reductions brought about by project implementation:

$N_2O_{PR,\ t}$ = $[(N_2O_{B\ total,\ t} - N_2O_{P\ total,\ t}) * A_P] * (1 - LK) * (1 - UNC)$ (20)

Where:

$N_2O_{PR,\,t}$	Reduction in total N_2O emissions brought about by project implementation, Mg CO_2e in year t;
$N_2O_{B\ total,\,t}$	Total baseline N_2O emissions within the project spatial boundary as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;
$N_2O_{P\ total,\,t}$	Total project N_2O emissions within the project spatial boundary as a result of N application at the project site, Mg CO_2e ha^{-1} in year t;
A_P	Project area, ha;
LK	Leakage deduction (set as 0 in this methodology, as described in section 8.3);
UNC	Uncertainty deduction (set as in Table 3 [this section] in this methodology).

Equation (21) calculates the amount of VCUs issued:

$$VCU_t = N_2O_{PR,\,t} * (1 - BUF) \quad (21)$$

Where:

VCU_t	Verified Carbon Units (VCUs) at time t, Mg CO_2e;
BUF	Buffer deduction (set as 0 in this methodology).

9 MONITORING

9.1 Data and Parameters Available at Validation

Data Unit / Parameter:	$M_{B\ SF,\,t}$
Data unit:	Mg ha^{-1} yr^{-1}
Description:	Baseline synthetic N containing fertilizer applied
Source of data:	Project proponent records (Approach 1)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	Approach 2 calculates baseline fertilizer N rate = ($M_{B\ SF,\,t}$ * $NC_{B\ SF}$), and is substituted into equation 3 to calculate $F_{B\ SN,\,t}$.

Data Unit / Parameter:	$M_{B\ OF,\,t}$
Data unit:	Mg ha^{-1} yr^{-1}

Description:	Baseline organic N containing fertilizer applied
Source of data:	Project proponent records (Approach 1)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	Approach 2 is not applicable for the calculation of $M_{B\ OF,\ t}$.

Data Unit / Parameter:	$NC_{B\ SF}$
Data unit:	g N $(100g\ fertilizer)^{-1}$
Description:	Nitrogen content of baseline synthetic fertilizer applied
Source of data:	Project proponent records (Approach 1)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	Approach 2 calculates baseline fertilizer N rate = ($M_{B\ SF,\ t}$ * $NC_{B\ SF}$), and is substituted into equation 3 to calculate $F_{B\ SN,\ t}$.

Data Unit / Parameter:	$NC_{B\ OF}$
Data unit:	g N $(100g\ fertilizer)^{-1}$
Description:	Nitrogen content of baseline organic fertilizer applied
Source of data:	Project proponent records (Approach 1)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	Approach 2 is not applicable for the calculation of $NC_{B\ OF}$.

Data Unit / Parameter:	Baseline Crop yield
Data unit:	Mg $ha^{-1}\ yr^{-1}$

Description:	Crop yield (standard reporting method for particular crop, e.g., dry grain yield)
Source of data:	Project proponent records (Approach 1) or county level data (Approach 2)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	Baseline Crop area
Data unit:	Hectare (ha)
Description:	Area of crop(s) planted, from which baseline fertilizer N rate determined
Source of data:	Project proponent records (Approach 1 and 2)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	The baseline crop area must encompass the project crop area in order to ensure that the same land area is used in emission reduction calculations.

Data Unit / Parameter:	$Frac_{GASF}$
Data unit:	Dimensionless
Description:	Fraction of all synthetic N added to project soils that volatilizes as NH_3 and NO_x
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.10)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	$Frac_{GASM}$
Data unit:	Dimensionless

Description:	Fraction of all organic N added to project soils that volatilizes as NH_3 and NO_x,
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.20)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	$Frac_{LEACH}$
Data unit:	Dimensionless
Description:	Fraction of N added (synthetic or organic) to project soils that is lost through leaching and runoff, in regions where leaching and runoff occurs
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.30)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	EF_{BDM1}
Data unit:	Mg N_2O–N (Mg N input)$^{-1}$
Description:	Emission factor for baseline direct N_2O emissions from N inputs (Method 1)
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.01)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	EF_{BDM2}
Data unit:	Mg N_2O–N (Mg N input)$^{-1}$

Description:	Emission factor for baseline direct N_2O emissions from N inputs (Method 2)
Source of data:	Empirical research on producer fields throughout Michigan
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	Parameter only valid in North Central Region of the US (Appendix G; Hoben et al. 2011).

Data Unit / Parameter:	EF_{BIV}
Data unit:	Mg N_2O–N (Mg NH_3–N + NO_x–N volatilized)$^{-1}$
Description:	Emission factor for baseline N_2O emissions from atmospheric deposition of N on soils and water surfaces
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.01)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	EF_{BIL}
Data unit:	Mg N_2O–N (Mg N leached and runoff)$^{-1}$
Description:	Emission factor for baseline N_2O emissions from N leaching and runoff,
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.0075)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	EF_{PDM1}
Data unit:	Mg N_2O–N (Mg N input)$^{-1}$

Description:	Emission factor for project direct N_2O emissions from N inputs (Method 1)
Source of data:	2006 IPCC Guidelines for National Greenhouse Gas Inventories (default Tier 1 = 0.01)
Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

Data Unit / Parameter:	EF_{PDM2}
Data unit:	Mg N_2O–N (Mg N input)$^{-1}$
Description:	Emission factor for project direct N_2O emissions from N inputs (Method 2)

Justification of choice of data or description of measurement methods and procedures applied:	
Any comment:	

9.2 Data and Parameters Monitored

Data Unit / Parameter:	$M_{P\ SF,\ t}$
Data unit:	Mg N yr^{-1}
Description:	Mass of project synthetic N containing fertilizer applied
Source of data:	Project proponent records
Description of measurement methods and procedures to be applied:	Generally accepted field application methods using calibrated applicators of known capacity for fertilizer mass or volume determination
Frequency of monitoring/recording:	Annual
QA/QC procedures to be applied:	Verify calibration and capacity of applicators
Any comment:	

Data Unit / Parameter:	$M_{P\ OF,\ t}$
Data unit:	Mg N yr^{-1}
Description:	Mass of project organic N containing fertilizer applied
Source of data:	Project proponent records
Description of measurement methods and procedures to be applied:	Generally accepted methods using calibrated applicators of known weight/volume for liquid and solid organic material application
Frequency of monitoring/recording:	Annual
QA/QC procedures to be applied:	Verify calibration and capacity of applicators and number of loads applied

Any comment:	

Data Unit / Parameter:	$NC_{P\ SF}$
Data unit:	g N (100g fertilizer)$^{-1}$
Description:	Nitrogen content of project synthetic fertilizer applied
Source of data:	Project proponent records
Description of measurement methods and procedures to be applied:	Generally accepted procedures for sampling, handling and analysis of bulk fertilizer
Frequency of monitoring/recording:	Annual
QA/QC procedures to be applied:	Verify fertilizer is from accredited source*
Any comment:	

Data Unit / Parameter:	$NC_{P\ OF}$
Data unit:	g N (100g fertilizer)$^{-1}$
Description:	Nitrogen content of project organic fertilizer applied
Source of data:	Project proponent records
Description of measurement methods and procedures to be applied:	Generally accepted sampling and handling procedures for organic materials. Laboratory analysis for total N using total Kjeldahl Nitrogen [TKN] or total N by combustion)
Frequency of monitoring/recording:	Annual
QA/QC procedures to be applied:	Verify N content from laboratory analysis documentation
Any comment:	

Data Unit / Parameter:	Project Crop area
Data unit:	Hectare (ha)
Description:	Area of crop(s) planted, from which project fertilizer N rate determined
Source of data:	Project proponent records

Description of measurement methods and procedures to be applied:	As per requirements of VCS version 3 “Project location for AFOLU projects must be specified using geodetic polygons to delineate the geographic area of each AFOLU project activity and provided in a KML file.
Frequency of monitoring/recording:	Each project crediting period
QA/QC procedures to be applied:	Verify file(s) coincide with project field(s) geographic boundary
Any comment:	

*The formulation of the synthetic N containing fertilizer must also be verified. From this the N content (% of mass) can be determined. Farmers’ records must be cross-checked with records from synthetic and organic N fertilizer suppliers. In case of discrepancies between the records of the farmers and those from suppliers of synthetic and organic N containing fertilizers, the most conservative value(s) must be taken.

To demonstrate the total amount of N to be applied to the project area during a cropping season is sufficient to generate expected annual yield similar to the average annual yield of the same crop(s) during the baseline period as required in Section 4 (Fertilizer Nitrogen Management), the project proponent is required to provide one of the following two forms of evidence (1 or 2 below).

1. Demonstrate consistency with the most recent state or regional N rate recommendations provided by the University Agriculture Extension Service, state department of agriculture, or a federal agency such as the USDA Natural Resources Conservation Service (NRCS) or Farm Service Agency (FSA). In this context, “consistency” means that the total amount of N to be applied to the project area during a cropping season must be equal to or greater than 80% of the lowest estimate of N rate range recommended for the relevant crop(s) in the region in which they are grown. This can be demonstrated using one of the two approaches below (a or b below):

    a. Consistent with the total N rate recommended in official publications from these organizations, such as extension bulletins or soil test lab reports.

    b. Consistent with data output from approved N rate calculators. Examples of approved N rate calculators include the Iowa State University corn nitrogen rate calculator (http://extension.agron.iastate.edu/soilfertility/nrate.aspx) for multiple Midwest states, and the University of Wisconsin corn N rate calculator (http://ipcm.wisc.edu/iPhone/tabid/120/Default.aspx) for Wisconsin, both of which calculate the profitable N rate range for corn around the maximum return to nitrogen (MRTN) rate. Other N rate calculators can be used provided they have been made available to the public by a University Agriculture Extension Service, state department of agriculture, or a federal agency, such as the USDA NRCS or FSA. A worked example demonstrating the use of the Iowa State University corn nitrogen calculator is shown in Appendix H.

2. Written certification provided by a professional crop advisor (see below) stating that total amount of N to be applied to the project area during a cropping season is sufficient to generate expected annual yield similar to the average annual yield of the same crop(s) grown during the baseline period.

The professional crop advisor must be: (a) a Certified Crop Advisor (CCA) certified by the American Society of Agronomy (ASA); (b) a Certified Professional Crop Consultant (CPCC) certified by the Soil and

Water Conservation Society (SWCS); (c) a professional staff member of a University Agricultural Extension Service; (c) a professional staff member of the USDA NRCS or FSA; (d) a professional staff member of a state agriculture agency in the state in which the project is located; or (e) an equivalent professional crop advisor as demonstrated by similar professional qualifications.

9.3 Description of the Monitoring Plan

The data and parameters required for baseline validation and during the project period are detailed in sections 9.1 and 9.2, respectively.

Information on accepted methods for sampling and handling, and measuring mass and N content of fertilizer can be found in state university agricultural extension documents.

Data for monitored parameters are derived from farmer records that are used for compliance with a myriad of farm-related programs, including state and federal BMPs. These farmer records also are consistent with project documents required for verification during the project period.

10 APPENDICES

APPENDIX A - Equations for determining if leaching and runoff occur at project site

The approach presented here uses default (Tier 1) values for leaching and run-off from the 2006 IPCC Guidelines for National Greenhouse Gas Inventories, and the ratio of growing season values of precipitation to potential evapotranspiration.

A project site is considered to have a $Frac_{LEACH}$ default value of 0.30 kg N (kg N additions)$^{-1}$) when:

$$Precip_{GS} / PET_{GS} \geq 1.00 \quad \text{(A1)}$$

A project site is considered to have a $Frac_{LEACH}$ default value of 0.00 kg N (kg N additions)$^{-1}$) when:

$$Precip_{GS} / PET_{GS} < 1.00 \quad \text{(A2)}$$

Where:

$Precip_{GS}$	=	Precipitation during the growing season, mm;
PET_{GS}	=	Potential evapotranspiration during the growing season, mm.

The growing season is considered to occur from May – September inclusive, unless otherwise verifiable. Planting and harvesting or frost records can be used to verify that the growing season is other than May – September. While this period is appropriate for corn over most of the NCR, in southern parts of the US corn can be planted a number of weeks prior to the beginning of May. Also, for example, if winter annual crops such as winter wheat and fall canola are grown, the appropriate growing season may be October – July.

Where crop irrigation is employed, irrigation water is considered equivalent to rainfall, and as such, project proponents will add irrigation water input to precipitation data to calculate total precipitation during the growing season or annually as required. Water from drip irrigation is excluded.

Average values for precipitation and irrigation water and potential evapotranspiration for baseline determination are calculated from the same time period used to determine baseline fertilizer N rate, i.e., consistent with project proponents' records (Approach 1) or county level data (Approach 2).

Information sources for determining if leaching and runoff occur at project site

If site specific data for precipitation and potential evapotranspiration are not readily available, data from local meteorological stations can be used. A centralized information source to identify these stations in the US can be found at the National Oceanic and Atmospheric Administration's (NOAA) National Weather Service (NWS) station information webpage: http://www.weather.gov/tg/siteloc.shtml. Archived data for all US meteorological sites can be found at the National Climatic Data Center (NCDC): http://lwf.ncdc.noaa.gov/oa/climate/stationlocator.html.

Individual US states may also have meteorological data available through academic or other institutions. In Michigan for example, annual precipitation and potential evapotranspiration data can be obtained from the Michigan Automated Weather Network (MAWN): http://www.agweather.geo.msu.edu/mawn.

Potential Evapotranspiration (PET) at project sites may also be calculated using the FAO Penman–Monteith equation. More information can be found in Allen et al. (1998).

APPENDIX B - Evidence relating to exclusion of soil C in methodology accounting

Appendix B can be used for projects using this methodology as a criterion to exclude the soil C pool.

Soil carbon is the primary pool of concern for ALM methodologies. In accordance with VCS AFOLU requirements v3.0, methodologies targeting N_2O emission reductions need to account for any significant reductions in soil C stocks.

In this methodology reductions in N fertilizer rate resulting from project implementation will not result in significant (> 5% of the total CO_2e benefits from reduction in N_2O emissions) decreases in soil C stock. Peer reviewed literature details how the soil C pool is deemed de minimis.

N fertilizer can increase soil C stocks by increasing crop growth and associated rates of crop residue production. Because this methodology will not result in significant crop growth (yield) declines and therefore no declines in residue inputs, there can be no associated decline in soil C stocks. In fact available evidence suggests that excess N can speed decomposition (Parton et al. 2007) and thereby lower (Khan et al. 2007) or maintain (Russell et al. 2009) C stocks that might otherwise increase, suggesting that this methodology may, if anything, promote soil C sequestration. We nevertheless make no such claim.

Therefore, the soil C pool is deemed de minimis and is excluded from methodology accounting.

APPENDIX C – Calculating baseline N fertilizer rate

Approach 1

The baseline fertilizer N rate is determined from the project proponents management records for at least the previous five years (monoculture) or six years (e.g., three cycles of a two crop rotation, or two cycles of a three crop rotation) prior to the proposed project implementation year.

Management records from which baseline fertilizer N rate can be directly determined are required. Examples of these include synthetic fertilizer purchase and application rate records, as well as manure application rate and manure N content history.

Determination of the baseline N_2O emissions are based on an average of the previous N rate applications for the specific crop(s).

Worked example - Calculating baseline fertilizer N rate for corn in a corn–soybean rotation

For a proposed project beginning in 2011, a producer (project proponent) has applied the following fertilizer N rates to a corn–soybean rotation in the previous 6 years (3 rotations, Table C1).

Table C1. Fertilizer N rates applied to a corn–soybean rotation (2005 – 2010).

Year	Crop/Rotation	Synthetic Fertilizer N rate (kg N ha^{-1} yr^{-1})	Organic Fertilizer N rate (kg N ha^{-1} yr^{-1})	Total Fertilizer N rate (kg N ha^{-1} yr^{-1})
2005	Corn	180	20	200
2006	Soybean	0	10	10
2007	Corn	160	30	190
2008	Soybean	20	0	20
2009	Corn	190	20	210
2010	Soybean	0	0	0
2005–2010 Average	Soybean	= (0+20+0)/3 =6.7	= (10+0+0)/3 = 3.3	= (10+20+0)/3 = 10
2005–2010 Average	Corn	= (180+160+190)/3 ≈ 177	= (20+30+20)/3 ≈ 23	= (200+190+210)/3 = 200
2005–2010 Average	Corn–Soybean	= (180+0+160+20+190+0)/6 ≈ 92	= (20+10+30+0+20+0)/6 ≈ 13	= (200+10+190+20+210+0)/6 = 105

The baseline fertilizer N rate for a corn crop in the proposed project to be planted in 2011 is calculated from the average of the total fertilizer N rate applied to the previous 3 corn crops during the previous 6 years, i.e., = (200 + 190 + 210)/3 = 200 kg N ha^{-1} yr^{-1}. Reductions from this baseline 'common practice' rate are considered additional and are credited.

N.B. The baseline synthetic and organic fertilizer N rate (Table C1) in each year (t), are calculated from:

($M_{B\ SF,\ t}$ * $NC_{B\ SF}$) and ($M_{B\ OF,\ t}$ * $NC_{B\ OF}$), respectively,

Where:

$M_{B\ SF,\ t}$	Baseline N containing synthetic fertilizer applied, Mg ha^{-1} in year t;
$M_{B\ OF,\ t}$	Baseline N containing organic fertilizer applied, Mg ha^{-1} in year t;
$NC_{B\ SF}$	Nitrogen content of baseline synthetic fertilizer applied g N $(100g\ fertilizer)^{-1}$;
$NC_{B\ OF}$	Nitrogen content of baseline organic fertilizer applied g N $(100g\ fertilizer)^{-1}$;

Approach 2

If the baseline fertilizer N rate cannot be determined from project proponent records (Approach 1), then Approach 2 is used. With Approach 2, the baseline fertilizer N rate is calculated from crop yield data at the county level (available from the United States Department of Agriculture – National Agricultural Statistics Service (USDA – NASS)) and equations for determining fertilizer N rate recommendations based on yield goal estimates (found in e.g., state department of agriculture and university agricultural extension documents). The baseline fertilizer N rate value calculated using Approach 2 represents the product of the mass and the N content of the synthetic N containing fertilizer, i.e., $M_{B\ SF,\ t}$ * $NC_{B\ SF}$. Approach 2 is not applicable for the calculation of the baseline organic fertilizer N rate, therefore the value of $F_{B\ ON,\ t} = 0$.

Worked example - Calculating baseline fertilizer N rate for corn in a corn–soybean rotation in Tuscola County, Michigan

From the methodology "During the project crediting period, adherence to 'Best Management Practices' (BMPs) for the management of synthetic and organic N fertilizer at the project site is required.

For a project developer based in Michigan, the Michigan Department of Agriculture publication Generally Accepted Agricultural Management Practices (GAAMP) for Nutrient Utilization, (2013, or most recent version) is consulted (Michigan Department of Agriculture 2013). This publication recommends the Michigan State University (MSU) Extension Bulletin E–2904 – Nutrient Recommendations for Field Crops in Michigan (Warncke et al. 2004), for selecting the appropriate rate of N fertilizer for corn.

From Extension Bulletin E–2904 the equation for calculating the N rate (lb N $acre^{-1}$) recommendation for a corn (grain) crop planted in rotation with soybean in mineral soil is given by:

$$N\ rate = (1.36 * YG_t) - 27 - NC \quad (C1)$$

Where:

YG_t	Yield goal of crop in year t, to which recommended N rate will be applied, bushel $acre^{-1}$;
NC	Nitrogen credit from previous soybean crop, lb N $acre^{-1}$.

In Extension Bulletin E–2904 soybean is given an N credit of 30 lb N acre^{-1}.

To calculate the predicted future corn yield the following equation is used:

$$YG_t = 1.05 * [(Y_{t-2} + Y_{t-4} + Y_{t-6}) / 3] \quad (C2)$$

Where:

Y_t = Project start date (year)

Y_{t-n} = Average county yield of crop in years 2, 4, and 6 prior to project adoption.

The approach of taking previous year's yield data and multiplying by 105% (1.05) in order to calculate the yield goal for the forthcoming crop is a common and conservative practice for producers. The approach is consistent with typical recommendations from university extension and agronomic organizations. Documentation outlining this approach is found for example in Fertilizer Suggestions for Corn – G174, University of Nebraska, Lincoln (Shapiro et al. 2003), and The Illinois Council on Best Management Practices (2001).

For Approach 2, the previous years yield data is determined from interrogation of the USDA – NASS web pages (Figures C1 and C2, http://www.nass.usda.gov).

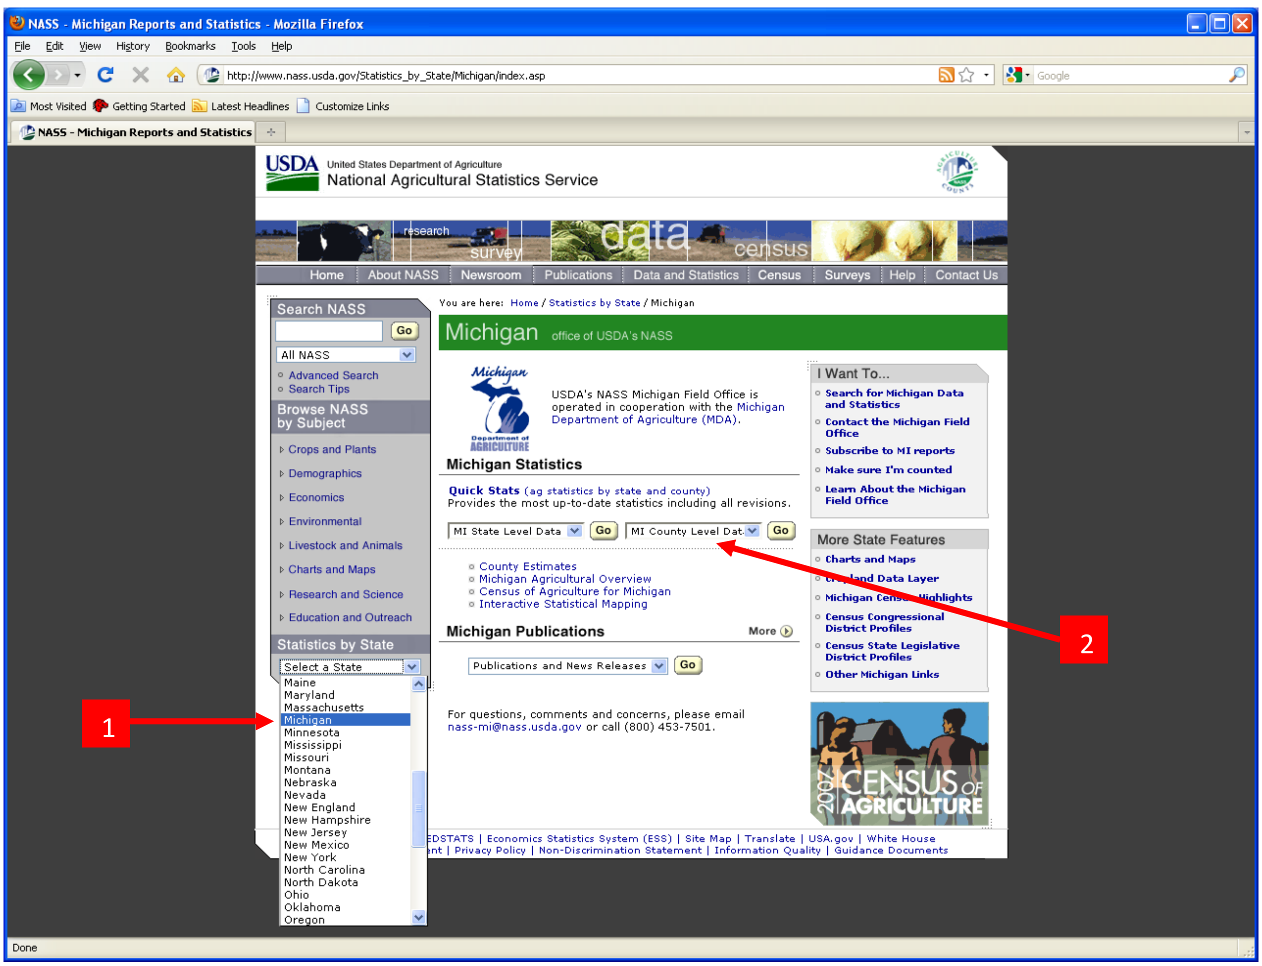

Figure C1. USDA – NASS screen shot showing selection menus for State (1), and County (2) level data inquiry.

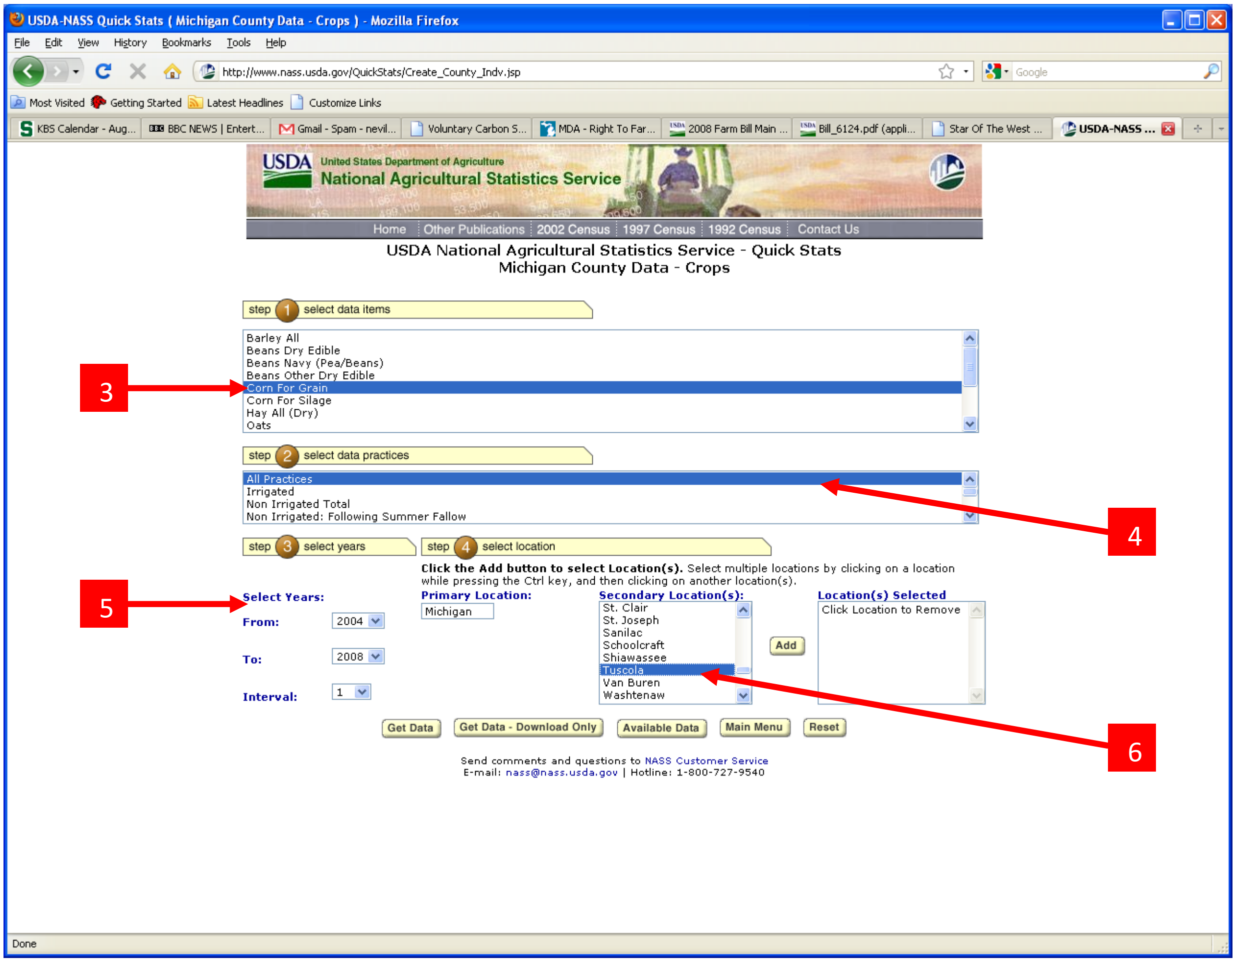

Figure C2. USDA – NASS screen shot showing selection menus for crop (3), practice (4), years (5) and County (6).

Data is downloaded as .csv files from which average yield data can be calculated (Table C2).

Table C2. Area planted, area harvested, yield data and total county production for corn (grain) in Tuscola county Michigan, for years 2005 through 2010.

	2005	2006	2007	2008	2009	2010
Yield (bushel acre^{-1})	148	154	134	174	164	148

The use of crop yield data from USDA – NASS must be consistent with the crop rotation history of the proposed project site(s). In this example a project field has had corn grown in rotation with soybean for at least the last six years (2005 – 2010, starting with corn). The calculation therefore must use USDA – NASS data for corn yield from 2005, 2007 and 2009 for a project start date of 2011. Using equation C2, we can calculate the yield goal for corn in 2011 (year t) as follows:

YG t = 1.05 * [(148 + 134 + 164) / (3)]

= 156.1 bushel $acre^{-1}$

From equation C1 the fertilizer N rate recommendation for corn (grain) in Michigan:

= (1.36 * 156.1) - 27 - 30

= 155.3 lb N $acre^{-1}$

For conversion from non SI (lb N acre-1) to SI (kg N ha-1) units, the value is multiplied by 1.12 (a conversion factor accepted by the American Society of Agronomy (ASA), the Crop Science Society of America (CSSA), and the Soil Science Society of America (SSSA).

http://www.soils.org/files/publications/journals-sitable-coversions.pdf.

The fertilizer N rate recommendation for corn (grain) is then:

= 174.0 kg N ha^{-1}

This value is considered the baseline fertilizer N rate for corn (grain) in a corn–soybean rotation for any proposed project site situated in the county of Tuscola, Michigan that had a project start date in 2011.

Depending on the proposed project details, similar equations for crops in other states can be utilized.

Note, as with Approach 1 the BAU baseline N fertilizer rate initially calculated remains fixed for the crediting period.

Information on the use of nitrogen credits from organic N fertilizer (manure) when Approach 2 is used is given in Appendix E.

APPENDIX D – Regulatory Surplus

To demonstrate additionality a project will need to pass a regulatory surplus test.

Project developers will pass this test if 'there is no mandatory law, statute or other regulatory framework in place at the local, state, or federal level, requiring producers to reduce fertilizer N input rate below that of a business–as–usual, i.e., common–practice scenario.'

The following paragraphs present some information and examples of regulations that deal with fertilizers and their application. The following is not meant to be an exhaustive list of regulations. Project developers must conduct a complete evaluation of federal, state and local regulations applicable to fertilizer use in the selected project location as part of the additionality assessment.

There is no Federal fertilizer statute and fertilizers are regulated under the individual States' authority. The Federal government does not regulate fertilizer directly however, there are regulations concerning the production, use and disposal of hazardous materials, drinking and surface water contamination and air pollution that are indirectly relevant to the use of hazardous materials in fertilizers and the application of fertilizers to land.

Below is a list of regulations at the Federal and State (Michigan) level that deal in some part with practices relating to synthetic and organic N fertilizer management in the agricultural sector.

Federal Regulations

The Food, Conservation, and Energy Act (2008)

The Military Munitions Rule (1997)

The Water Quality Amendment Act (1987)

The Superfund Amendments and Reauthorization Act (SARA) (1986)

Resource Conservation and Recovery Act of 1976 (RCRA) Statute - Solid Waste Disposal, Title 42, Chap. 82, Subchapter III - Hazardous Waste Management

The Federal Water Pollution Control Act (1972)

Hazardous Waste Regulation, 40 CFR, Part 503, Standards for the Use or Disposal of Sewage Sludge

The Occupational Safety and Health Administration (OSHA) Hazard Communication Standard (29 CFR 1910.1200)

State Regulations

Each state in the US has its own fertilizer regulatory program. State regulations for fertilizers are generally developed and administered by State agriculture departments. Such regulations primarily address efficacy claims and composition statements of the active ingredients displayed on fertilizer labels. Most States have fertilizer regulations similar to that of the Association of American Plant Food Control Officials (AAPFCO) model Uniform State Fertilizer Bill.

The Uniform State Fertilizer Bill is a model bill providing the legal authority to regulate the registration, packaging, labeling, sale, storage, distribution, use and application of fertilizer and fertilizer materials. There are specific requirements for the accurate and meaningful labeling of fertilizers, including terms and definitions, and regulations for the storage requirements for bulk fluid and dry fertilizers.

Other AAPFCO Uniform Bills which may relate to fertilizer N application include the Uniform Soil Amendment Bill, the Model Agricultural Liming Materials Bill, the Model Chemigation Bill and the Uniform State Ammonia Bill.

Example: Michigan State Regulations

Below are state level regulations indirectly relating to fertilizer N management as outlined in the Michigan Department of Agriculture Generally Accepted Agricultural and Management Practices (GAAMP) for Nutrient Utilization publication (Michigan Department of Agriculture, 2013).

These regulations apply to ‘a person applying, distributing, and storing fertilizer or organic materials in Michigan’ who ‘must comply with the relevant state and federal laws and regulations promulgated under these statutes, including but not limited to’:

Public Act 451: Natural Resources and Environmental Protection Act of 1994

Public Act 346: Commercial Drivers' License Law of 1988

Public Act 368: Michigan Public Health Code of 1978

Public Act 399: State of Michigan Safe Drinking Water Act of 1976

Public Act 154: Michigan Occupational Safety and Health Act (MIOSHA) of 1974

Public Act 162: Michigan Liming Materials Law of 1955

Further useful information regarding fertilizer regulations can be found at the Safe Fertilizer Information Institute (http://saffii.com/uslaw.aspx).

APPENDIX E – Business as Usual (BAU) practice for N fertilizer application and justification for Approach 2

In using this methodology, project proponents must exceed a performance benchmark. Project proponents exceed the performance benchmark by reducing their N fertilizer rate below the BAU rate, which is also the baseline value for N fertilizer rate for the proposed project. This baseline scenario equates the N fertilizer application with the widespread and general practice of producers to apply N fertilizer rates based upon recommendations derived from yield goal estimates. Reductions in N fertilizer rate below the baseline site specific value (Approach 1) or below the baseline value in the county where the project is to be conducted (Approach 2) will result in a project exceeding the performance benchmark. Both Approach 1 and 2, used to establish the project baseline, operate on the principle that a reduction in N fertilizer rate below the baseline results in a predictable, concomitant reduction in N_2O emissions. Project additionality is achieved through a reduction in N rate below the baseline scenario, such that 'new' N_2O emissions are prevented from entering the atmosphere. These avoided emissions occur immediately, are irreversible, and are permanent.

Evidence for the wide-scale historic, continued, and extensive use of the yield goal approach as the baseline (BAU) scenario, and therefore its legitimacy as a performance benchmark for testing additionality in crop-based agriculture, is given below.

Justification of the yield goal approach as a BAU baseline scenario

Since the 1970s it has been common practice throughout the NCR and the conterminous US in general for producers to apply rates of N fertilizer based on recommendations derived from yield goal estimates (e.g., Fixen, 2006; Shapiro et al. 2003; Warncke et al. 2004). The agricultural departments of land grant universities, state and federal agricultural organizations continue to endorse yield-goal N fertilizer rate recommendations (e.g., Michigan Department of Agriculture, 2013, USDA – NRCS, 2011; 2012). For example, the recently updated (July 2012) USDA – NRCS Conservation Effects Assessment Project (CEAP) states:

"Nutrient management systems have four basic criteria for application of commercial fertilizers and manure. 1. *Apply nutrients at the appropriate rate based on soil and plant tissue analyses and realistic yield goals.*"

All these organizations represent a common source of external information that provides advice directly or indirectly to producers. This network serves as the foundation for producer BAU practice in the NCR and beyond, constituting a sector-wide approach for calculating baseline N fertilizer rates and, by extension, emissions of N_2O.

Despite this, very few studies have quantitatively examined the numerous factors and their complex interactions and impact on a farmers' decision of how much N fertilizer to apply to a crop. Those that have done so indicate that the majority of farmers rely heavily on their own experience, as well as on advice from fertilizer dealers. For example, using USDA data Ribaudo et al. (2011) found that 72% of growers base their N fertilizer application decision on 'routine practice', and from a recent survey sent to 1000 farmers in SW Michigan, Stuart et al. (2012) found that almost all respondents receive information from fertilizer and seed dealers on how to determine their N fertilizer application rates; for 55% this represents the most important source of information; only 18% used university recommendations as their most important source.

Important though these data are, they do not report the dealers' rationale or calculations for the advice given. This data is scarce. However, university recommendations are based on yield goal calculations, and in the MI survey, Stuart et al. (2012) found that 72% of commercial corn farmers use a simple yield-goal calculation to derive their N rate. This value is identical to the percentage of growers who base their N fertilizer application decision on routine practice (Ribaudo et al. 2011). The remaining 28% appear to use some combination of other farmers, private consultants, magazine articles, and other informal sources unlikely to be as conservative (Stuart et al. 2012).

From the MI survey, of the farmers who fertilized using simple N-to-yield-goal ratios (lbs N per bushel of corn) the percentages who reported a particular ratio were 5 (>1.3), 21 (1.1 to 1.3), 55 (0.8 to 1), and 19 (<0.8).

If we use the five year average corn grain yield for MI between 2007 and 2011 of 143 bushels per acre, we can estimate N rate applications (kg N ha^{-1}) for these groups as >208, 176 to 208, 128 to 160, and <128, respectively. Extrapolating these trends nationally where average corn grain yield between 2007 and 2011 was 154 bushels per acre, we get >224, 190 to 224, 138 to 172, and <138, respectively.

It is not known whether respondents to the MI survey took into account N contributions (N credits) from other sources such as prior leguminous crops or manure. If not (as is likely), then on average there would be an increased percentage of respondents placed in the higher ratios (1.1 to 1.3, and > 1.3). In the survey, nearly half of the respondents used both commercial synthetic N fertilizers and manure on their crops (none used manure N only – consistent with national data, e.g., Ribaudo et al. 2011). However, nearly 60% never tested their manure for N content and 64% never kept any records if they did. This suggests that the N rates were under-reported, and therefore the respondent's N-to-yield-goal ratio underestimated. Under-reporting of N rate application has been reported elsewhere. For example, data from California across a wide range of crops indicate that on average producers apply approximately 38 lbs N per acre (~42 kg N per hectare) more than they report (Rosenstock et al. 2013). Data from Ribaudo et al. (2011) indicates that when farmers use both manure and commercial fertilizer, they apply on average 28% higher N rates to their crops, when compared to farmers who apply only synthetic N fertilizers. This is despite the recommendation to farmers who use both N sources to apply 10% less N than to those who use only synthetic N.

Despite decades-old concerns and quantitative evidence that yield goal-based recommendations are inaccurate (e.g., Lory and Scharf 2003) and too liberal for recommending N fertilizer rate, the practice is still widely recommended and followed. This inevitably leads to applications of N fertilizer in excess of crop requirements, principally as a result of unrealistic yield goal estimates (e.g., Vanotti and Bundy 1994). Furthermore, to maintain viable operations, farmers may manage temporal variability in weather and soil N by over-applying N to protect against downside risk (i.e., use an 'insurance' N application rate) (Sheriff, 2005; Babcock, 1992; Babcock and Blackmer, 1992). Additionally, farmers may take a 'safety net' approach to maximize economic returns by setting an optimistic yield goal for a given field based on an optimum weather year to ensure that the needed amount of N for maximum yields is available (Schepers et al., 1986; Bock and Hergert, 1991). Thus, during the years in which weather is not optimal for maximizing yields, N will be over-applied from an agronomic standpoint. By definition, optimal conditions are infrequent, so farmers over-fertilize crops in most years. It is therefore safe to conclude that reductions in N rate below those determined by yield-goal based calculations (i.e., the BAU baseline scenario) can be implemented to reduce the amount of excess N in cropland agriculture, thereby decreasing its N_2O burden without reducing crop productivity.

A regional approach to optimize crop yield has recently been developed that utilizes historical and current N fertilizer rate research data from field trials to determine economically profitable N inputs, expressed as a range of N rates around a maximum return to N (MRTN) at different N fertilizer and crop prices (Iowa State University Agronomy Extension 2004). The US Midwest states currently providing data for this approach are Iowa, Illinois, Indiana, Michigan, Minnesota, Ohio, and Wisconsin. Producers with relevant cropping systems in these states (and other states that may subsequently become involved) may wish to adopt a N fertilizer rate for the project within the economically profitable N rate range calculated, using this approach (Millar et al. 2010). Use of MRTN to reduce N rate use is not required, however – other methods may be used to reduce rates to better match crop needs, including the use of improved fertilizer application timing, fertilizer formulations, cover-crop N capture, or any of a number of other practices known to better match N fertilizer input to crop N needs than BAU approaches (Robertson and Vitousek 2009).

Justification for Approach 2 for determining the baseline scenario

If the baseline fertilizer N rate for a specific crop cannot be established from project proponent records (Approach 1), then Approach 2 can be used. With Approach 2, baseline N fertilizer rate is calculated from crop yield data at the county level, available from United States Department of Agriculture – National Agricultural Statistics Service (USDA – NASS), and equations for determining N fertilizer rate recommendations based on yield goal estimates (e.g., found in state department of agriculture and land grant university agriculture department documents).

The use of crop yield data from USDA – NASS must be consistent with the crop rotation history of the proposed project site. For example, a project field in which corn has been grown in alternate years with soybean for the last six years (2006 – 2011; starting with corn) must use USDA – NASS data for corn yield for the relevant county from 2006, 2008 and 2010 for a project start date of 2012. This requirement reduces the uncertainty in baseline calculation, as county crop yield records for an individual year reflect the prevailing environmental and economic conditions at that time. This requirement also reduces the potential for 'gaming' as project proponents cannot select historical data that might have the effect of artificially increasing the baseline.

The rationale for why Approach 2 is conservative, and discussion on the trade-offs between false positives (the crediting of activities that are not additional) and false negatives (the exclusion of activities that are additional) in relation to Approach 2 calculations are presented below.

The use of Approach 2 will typically underestimate baseline N inputs due to two major factors: 1. the use of county level crop yield data sets that include non-commercial and small-scale farming operations that tend to have lower productivity than large scale operations; and, 2. the compulsory inclusion of N credits from organic fertilizer (manure) applications in yield goal equations as an artificial means to lower baseline N rate recommendations, and therefore baseline N_2O emissions. Overall, this underestimation will bias the award of offset credits towards a false negative outcome (the exclusion of activities that are additional).

The use of county level crop yield data

The county level crop yield data from USDA – NASS required to back-calculate baseline N fertilizer rates using Approach 2 includes data collected through the annual County Agricultural Production Survey (CAPS) and the Census of Agriculture (COA) conducted every five years.

The CAPS provides data needed to estimate production of crops at the county level for state and federal programs, and is conducted in 44 states with all counties in these states represented in the sampling. The target population is all farms and ranches in each state, with each state developing its own data collection strategy, typically a mail survey with second mailings or a telephone follow-up to ensure adequate coverage for each county. The average, annual county yield data therefore inherently covers crops to which only synthetic N fertilizer and both synthetic and organic N fertilizers have been applied.

As defined by the CAPS and COA, a farm is any place from which $1,000 or more of agricultural products are normally produced and sold during the surveyed year. Between 2002 and 2007 (latest available) the COA found that the number of farms with sales of less than $1,000 increased by 118,000, with most of the growth in US farm numbers coming from small operations. In 2007, 60% of total US agricultural sales came from farms where annual sales were less than $10,000. Small farms account for 91% of all farms in the US with a large percentage of these farms specializing in grain production.

Data linking farm size to crop yields is limited, but a specially conducted USDA ARMS survey on the cost of production of corn in 1996 found that part-time farmers and small farm operations tended to have lower production efficiency, higher corn production costs per bushel and lower than average yields (Foreman, 2001). Therefore the link between lower yields and small farm size and the continuing trend for increasing numbers of part-time farmers and small farm operations in the US provides evidence that the average county yield reported will tend to underestimate the yields obtainable from larger, more efficient operators who will most likely constitute the majority of project developers, at least in the short-term. This will result in lower county-level yields' biasing the fertilizer N estimate for the larger growers towards lower N application rates (a lower county-level yield will result in a lower predicted baseline N rate for those farmers with higher yields).

The compulsory inclusion of N credits from manure applications

The most common form of organic N applied to cropland in the US is animal manure. Most of the US cropland (~ 70%) receiving manure is used to grow corn (Ribaudo et al. 2011). Nationwide, about 14% of all N fertilized corn acres (~10% for all crops) are treated with both commercial synthetic N and manure N. Nationally, this amounts to approximately 13 million acres of corn based upon 2012 planting data (USDA – NASS). USDA ARMS data provides evidence that when used; manure is associated with over application of N. For example, with farmers who used a soil or tissue test as a means to estimate their N need, the average N application rate by those who used both synthetic and manure N was 175 lbs N per acre, compared to 136 lbs N per acre for growers who used synthetic N only. As noted earlier, this was despite a 10% lower recommendation for fields receiving both N sources compared to those receiving only a commercial synthetic N source (Ribaudo et al. 2011).

When using Approach 2, project proponents will include a nitrogen credit from organic N fertilizer (manure). The inclusion of an N credit for organic N fertilizer in some or all of the baseline years for which an estimate of the N fertilizer rate is required will, in effect, act to reduce the calculated average baseline N rate and therefore baseline N_2O emissions. Irrespective of the actual use of organic N fertilizers during the baseline period, and whether this is verifiable in part or not, this procedure will act to lower the baseline N_2O emissions of the project field when compared to a scenario when no N credit for organic N fertilizer is applied. This approach is conservative.

Seven hypothetical scenarios (some more likely than others) relating to document and data availability are presented below, along with the rationale for the required N credit associated with them:

1. No records are available to verify the timing (i.e., the year or growing season), amount, or N content of the organic N fertilizer;

2. Records are available that verify the timing, but not the amount or N content of the organic N fertilizer

3. Records are available that verify the timing, and amount, but not the N content of the organic N fertilizer

4. Records are available that verify the amount, but not the timing and N content of the organic N fertilizer

5. Records are available that verify the amount and timing, but not the N content of the organic N fertilizer.

6. Records are available that verify the N content, but not the amount or timing of the organic N fertilizer

7. Records are available that verify the amount and N content, but not the timing of the organic N fertilizer

In six of these seven cases, at least one of the three requirements is available to determine the organic N fertilizer applied during the entire baseline period. In three of these cases, two of the three requirements are available. If all three requirements regarding data were met then the project would use Approach 1 for calculation of the baseline N rate for organic fertilizer.

The rationale behind the approach matches an increased availability of records with a decreased N credit for organic N fertilizer, and therefore an increased baseline N rate, and baseline N_2O emissions. In effect the approach 'rewards' more comprehensive record keeping, as an increased baseline N rate will potentially allow for larger decreases in N rate during the project period and therefore greater financial payback through the award of offset credits. Note that all individual requirements are weighted equally.

There is therefore no incentive (financial or otherwise) to deliberately withhold documentary evidence establishing the application of organic (or indeed synthetic) N fertilizer during the baseline period. Doing so would act to artificially reduce the value of the baseline N rate (and therefore baseline N_2O emissions), thereby reducing: 1) the likelihood that an N rate reduction could take place at all; and 2) the magnitude of that reduction, without a producer's incurring a yield penalty or substantially increasing the risk of doing so.

Note that if records of the timing of organic fertilizer application (i.e., the year or growing season [but not necessarily the exact date]) are absent, but the amount and / or N content are available then it will be assumed that organic fertilizer has been applied in all relevant cropping cycles previous to the project crop in the project field during the baseline period.

Scenario crediting

The quantitative basis for applying the specific N credit for organic fertilizer (manure) is derived from the recent USDA ERS report "Nitrogen in Agricultural Systems: Implications for Conservation Policy" (Ribaudo et al. 2011). Using national Agricultural Resource Management Survey (ARMS) data, the report found that farmers who used both synthetic fertilizer and manure (all sources), applied on average 90 lbs N per acre from the manure.

So:

For scenario 1 where none of the three data requirements are available, the nitrogen credit from organic fertilizer will be:

$$90 * 1.5 = 145 \text{ lbs N per acre}$$

$$= 162 \text{ kg N ha}^{-1}$$

For scenarios where one of the three requirements is available (scenarios 2, 4, and 6), the nitrogen credit from organic fertilizer will be:

90 * 1.2	=	108 lbs N per acre
	=	121 kg N ha^{-1}

For scenarios where two of the three requirements are available (scenarios 3, 5, and 7, the nitrogen credit from organic fertilizer will be:

90 * 1.0	=	90 lbs N per acre
	=	101 kg N ha^{-1}

Using the worked example given for Approach 2 in Appendix C, where the N rate (lb N $acre^{-1}$) is calculated as:

$$N\ rate = (1.36 * YG_t) - 27 - NC \quad (E1)$$

Where:

YG_t = 156.1 bushel $acre^{-1}$

If we assume that two of the three data requirements are available from records, the N credit equals the sum of the N credit from the previous soybean crop (30 lbs N per acre) and the previous manure applications (90 lbs N per acre).

Therefore:

N rate	=	(1.36 * 156.1) - 27 - (30 + 90)
	=	65 lb N $acre^{-1}$
	=	73 kg N ha^{-1}

APPENDIX F - Default factors

The default (Tier 1) values used in the methodology for calculating direct and indirect emissions of N_2O from the baseline and project scenarios are taken from the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (Volume 4, Chapter 11).

The terminology of the factors used in this methodology differs from that used in the IPCC guidelines, but the factors are equivalent in value and usage.

The IPCC uncertainty ranges for each factor or fraction can be considered conservative with respect to their application to agricultural soils, as their use in IPCC Guidelines is applicable to a wider environmental coverage, i.e., managed soils, including forests and grasslands as well as agriculture.

Table F1. Default factors used to estimate direct and indirect emissions of N_2O in the methodology.

N_2O Emissions	Methodology factor	IPCC factor	Default value	Uncertainty range
Direct	EF_{BDM1}, EF_{PDM1}	EF_1	0.010	0.003 - 0.03
Indirect	EF_{BIV}, EF_{PIV}	EF_4	0.010	0.002 - 0.05
Indirect	EF_{BIL}, EF_{PIL}	EF_5	0.0075	0.0005 - .025
Direct/Indirect	$Frac_{GASF}$	$Frac_{GASF}$	0.10	0.03 - 0.3
Direct/Indirect	$Frac_{GASM}$	$Frac_{GASM}$	0.20	0.05 - 0.5
Direct/Indirect	$Frac_{LEACH}$	$Frac_{LEACH}$	0.30	0.1 - 0.8

Conversion of N_2O–N to N_2O

Conversion of N_2O–N (the mass of the nitrogen component of the nitrous oxide molecule emitted) to N_2O for reporting emission reductions in units of CO_2e is performed by multiplication of the ratio of the molecular weight of N_2O to the atomic weight of the two N atoms in the N_2O molecule:

$$N_2O = N_2O\text{–}N * 44/28$$

Global Warming Potential of N_2O

The GWP value of 310 for N_2O used in the methodology is the 100-year value proposed in the Intergovernmental Panel on Climate Change Second Assessment Report (SAR).

The value of 310 is the direct GWP for one molecule of N_2O on a mass basis for a 100 year time horizon, relative to one molecule of CO_2, which is ascribed a value of 1 by convention. This means that a molecule of contemporary N_2O released to the atmosphere will have 310 times the radiative impact of a molecule of CO_2 released at the same time. The conversion can be represented as:

$$N_2O_{GWP} = 310, \text{Mg } CO_2e \text{ (Mg } N_2O)^{-1}$$

APPENDIX G – Background research on Method 2 for estimating emissions

In the North Central Region (NCR), direct emissions of N_2O for baseline and project scenarios in corn-based, row-crop rotations can be calculated using Method 2. Method 2 uses an emissions factor determined from multi–year field studies conducted in Michigan. This emissions factor is consistent with IPCC Tier 2 methodological guidelines and in this methodology assigned the terms EF_{BDM2} and EF_{PDM2} for baseline and project emission calculations, respectively.

Full details of study sites, sampling, data analysis, results, and other information are in Hoben et al. (2011), and at http://onlinelibrary.wiley.com/doi/10.1111/j.1365-2486.2010.02349.x/suppinfo.

The uncertainty assessment for emissions reductions, including the derivation of the Tier 2 emissions factor are detailed below.

Overview

Previous research conducted by McSwiney and Robertson (2005), and more recently by Hoben et al. (2011) and Millar et al. (2013) show that N_2O emissions can increase exponentially with increasing N fertilizer rate, particularly at high rates that exceed the crop N uptake capacity.

These unique field studies in the North Central Region (NCR) specifically investigated long–term N_2O emission responses to a large number of N fertilizer rate treatments in row–crop agriculture. The large number of N rates and the small increments between them allow better resolution of the shape of the relationship between N rate and N_2O emissions.

The producer sites used in the development of the Tier 2 approach (Hoben et al. 2011) encompassed a wide range of soil type, texture, and grain yield that were comparable and broadly representative of commercial corn crop rotations and conditions throughout the NCR. During the study years, the sites experienced a wide range of environmental conditions throughout the growing season. In years with normal precipitation, crop yields at these sites are typical of the NCR as a whole (Smith et al. 2007). The N rates employed in Hoben et al. (2011) also are within the range commonly required for optimum corn-grain production and recommended for the US Midwest (Sawyer et al., 2006; Vitosh et al., 1995).

The non–linearity of N_2O emissions has significant consequences when comparing N_2O emissions reductions with the IPCC Tier 1 approach. An identical N fertilizer rate reduction will result in a significantly smaller reduction in N_2O emissions when the Tier 1 emission factor is used in calculations, when compared to the Tier 2 emission factor. The increasing divergence of N_2O emissions between Tier 1 and Tier 2 approaches, particularly at higher N rates, helps incentivize the reduction in N rate. Millar et al (2010) show an example of this.

Uncertainty assessment

Methodologies and procedures adopted to calculate emissions of N_2O have been refined over many years, and are conservative in nature. Here we outline assumptions, parameters and procedures that relate to uncertainty in N_2O emissions in the methodology. We focus on the derivation of the regional NCR emissions factor used in equation (6) and (15) in sections 8.1 and 8.2, respectively. More detailed information on field-sampling and laboratory analytical techniques is given in Hoben et al. (2011).

Appendix F (Table FI) provides information on uncertainty ranges for IPCC Tier 1 emissions factors for direct and indirect N_2O emissions and other factors used in the methodology. Use of these IPCC emissions factors is universally accepted as a mechanism for calculating N_2O emissions – they are science driven and used in many currently accepted AFOLU methodologies for calculating N_2O emissions. Further details on these factors, their derivation and their robustness for use in N_2O emissions calculations can also be found in the 2006 IPCC Guidelines for National Greenhouse Gas Inventories, Revision Nov. 2008 - Chapter 11: N_2O Emissions from Managed Soils, and CO_2 Emissions from Lime and Urea Application.

Application of N fertilizer

The methodology monitors five parameters during the project period. Four of these relate directly to the calculation of N rate applied at the project site. These are detailed along with their measurement and QA/QC procedures, in section 9.2 of the methodology.

All of these parameters are assumed to have negligible uncertainty.

Derivation of regional (NCR) emissions factor

Daily N_2O emissions

Values for daily N_2O emissions have negligible uncertainty; field and laboratory sampling and analytical techniques have been refined over many years to standardize methodologies and minimize analytical uncertainty. We used standard methods to measure daily emissions as described in Hoben et al. (2011).

Annual N_2O emissions

We determined total annual emissions by interpolating daily emissions between sampling days. This was carried out using linear interpolation – a broadly accepted mechanism in the scientific peer reviewed literature. In brief, the sum of the rate of N_2O emissions on two successive sampling days was divided by two (averaged), and this average rate was multiplied by the period (in days) between the two measurements, then added to the previous cumulative emissions total. This can be represented by:

$$C_B = C_A + [(D_A + D_B) / 2] * (B-A) \quad (G1)$$

Where:

C_B	=	Cumulative N_2O emission as of day B (g N_2O-N ha^{-1});
C_A	=	Cumulative N_2O emission as of day A (g N_2O-N ha^{-1});
D_A	=	Daily gas flux on day A (g N_2O-N ha^{-1} d^{-1});
D_B	=	Daily gas flux on day B (g N_2O-N ha^{-1} d^{-1});
B	=	Day of latest emissions measurement (day of year);
A	=	Day of previous emissions measurement (day of year).

Annual emissions (g N_2O-N ha^{-1} yr^{-1}) of N_2O for each field replicate were calculated from daily N_2O emissions (g N_2O-N ha^{-1} d^{-1}) measured in each block (4) at each N rate (6, including zero) at each site during the year for all site years (8), to give a total of 192 cumulative annual N_2O emissions data points (4 * 8 * 6). These individual cumulative annual emissions, calculated directly from daily N_2O emissions with negligible uncertainty, are also assumed to have negligible uncertainty.

The best-fit line that defines the mathematical relationship between N rate (kg N ha^{-1} yr^{-1}) and N_2O emissions (g N_2O-N ha^{-1} yr^{-1}) for all 192 data points is:

$$N_2O \text{ emissions} = 670 * \exp(0.0067 * N \text{ rate}) \quad (G2)$$

Where, N rate is the equivalent of $F_{B\,SN,t} + F_{B\,ON,t}$ for baseline N input (equation [2]) and $F_{P\,SN,t} + F_{P\,ON,t}$ for project N input (equation [11]).

The standard error (SE) associated with N_2O emissions, is:

N_2O emissions $_{(SE)}$ = 58 * exp (0.010 * N rate) (G3)

Figure G1 shows this relationship.

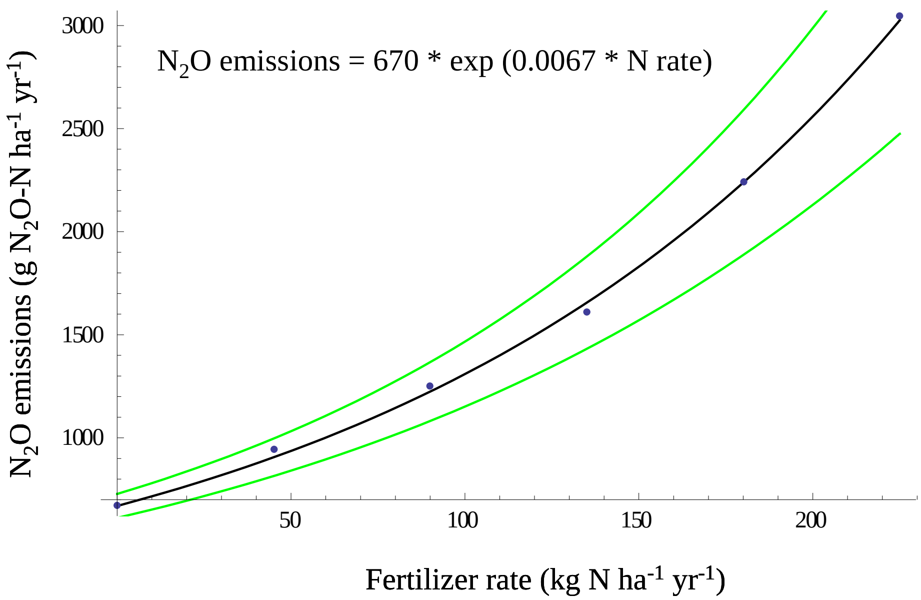

Figure G1. Relationship between N_2O emissions (g N_2O-N ha^{-1} yr^{-1}) and N fertilizer rate (kg N ha^{-1} yr^{-1}) for baseline and project N fertilizer rates (black line). Standard errors (± 58 * exp [0.010 * N rate]) are also shown (green lines). Calculated using Mathematica (v. 8, Wolfram Research Inc., 2011).

N_2O emissions reductions

Raw N_2O emissions reduction values were obtained by subtracting cumulative annual emissions of lower N application rates from cumulative annual emissions of higher N application rates (i.e., 0, 45, 90, 135, 180, and 225 kg N ha^{-1} yr^{-1}) within the same block, site, and year. This emissions difference was then divided by the difference in rate between the N rate pairs. Thus, we obtained 32 values (4 blocks * 8 site years) for the emission reductions for each of the 15 pairs (e.g., 45 → 0, 90→ 0, 90 → 45, etc.).

To best define the interpolation of the empirical data for emissions reductions - N_2O emissions $_{(RED)}$ - many types of function were tested, including linear and exponential functions with various parameter combinations. The function below (Equation [G4]) derived from equation [G2] above) was also tested.

N_2O emissions $_{(RED)}$ = 0.67 * {exp (6.7 * N_{Base}) - exp (6.7 * N_{Proj})} / (N_{Base} - N_{Proj}) (G4)

Where:

N_2O emissions $_{(RED)}$ = N_2O emissions reductions, g N_2O-N ha^{-1} yr^{-1};

N_{Base} = $F_{B\ SN,\ t}$ + $F_{B\ ON,\ t}$ baseline N input, Mg N ha^{-1} yr^{-1};

N_{Proj} = $F_{P\ SN,\ t}$ + $F_{P\ ON,\ t}$ project N input, Mg N ha^{-1} yr^{-1}.

Equation (G4) outperformed all linear functions and works as effectively as more complex exponential functions.

Emissions factors

The emissions factor for N_2O is defined as the fraction of N applied that is released as nitrogen in N_2O (N_2O-N) at a non-zero N rate minus the N_2O-N emitted at zero N rate.

The emissions factors for baseline and project calculations were obtained by dividing the reduction function (equation G4) by 1 * 10^6 (to convert g N_2O-N / Mg N rate to Mg N_2O-N / Mg N rate). We then formatted the equation to compare baseline and project N rates to zero N rate. Therefore we have:

$$EF_{Base} = 6.7 * 10^{-4} * (\exp[6.7 * N_{Base}] - 1) / N_{Base} \quad (G5)$$

$$EF_{Proj} = 6.7 * 10^{-4} * (\exp[6.7 * N_{Proj}] - 1) / N_{Proj} \quad (G6)$$

Where:

EF_{Base} and EF_{Proj} are equivalent to EF_{BDM2} (Equation [6]) and EF_{PDM2} (equation [15]), respectively.

Emissions reduction uncertainty

The standard error equation (G3) is useful for describing uncertainty in annual emissions but cannot be used to accurately describe uncertainty for emissions reductions in the range of smaller N rate reductions (10 – 20 kg N ha^{-1} yr^{-1}).

Instead the 32 values (4 blocks * 8 site years) for the emission reductions for each of the 15 pairs (e.g., 45 → 0, 90→ 0, 90 → 45, etc.) were used to obtain variability of the mean using the Bootstrap method (Monte Carlo algorithm with case re-sampling, Mathematica – v. 8, Wolfram Research Inc., 2011).

For each pair of N fertilizer rate reductions a random sample of 32 baseline values was taken and replaced with a random sample of 32 project values to compute a mean reduction. This process was repeated 100,000 times and the overall standard error of the means were calculated.

The standard error of the means was then multiplied by 1.645 (the critical value of normal one-sided test at 95% confidence) and divided by the average emissions reduction to give the fraction of the average that is within the 95% confidence interval. These values plotted against N rate are represented by Equation (G7), which calculates the uncertainty associated with a reduction in N rate during the project period:

$$N_2O\ Emissions_{(RED\ UNC)} \quad [1 - \{0.63 * \exp(-40 * [N_{Proj}]^2)\}] * 100 \quad (G7)$$

Where:

N_2O Emissions $_{(RED\ UNC)}$		Uncertainty in N_2O emissions reductions associated with a reduction in N rate, %;
N_{Proj}	=	$F_{P\ SN,\ t} + F_{P\ ON,\ t}$ project N input, Mg N ha^{-1} yr^{-1}.

Equation (G7) is identical to equation 19 in section 8.4 of this methodology.

Within the empirical N rate data range (0 – 225 kg N ha^{-1} yr^{-1}) the highest uncertainty was ~90%. There is no evidence to suggest that higher N rates would generate uncertainties above 100%, therefore the Gaussian function was used to constrain uncertainty below 100%.

Project proponents will use equation (G7) to calculate emissions reductions uncertainties (%) for a project. Confidence deductions as a result of uncertainty will be applied using the conservative factors specified in the CDM Meth Panel guidance on addressing uncertainty in its Thirty Second Meeting Report, Appendix 14 (Table G1).

Table G1: Conservativeness factors for emissions reductions based upon uncertainty at 95% confidence level.

Uncertainty range at 95% confidence level of project emissions reductions§	**Conservativeness factor**	**Uncertainty deduction***
< ± 15%	1.000	0.000
> ± 15% ≤ ± 30%	0.943	0.057
> ± 30% ≤ ± 50%	0.893	0.107
> ± 50% ≤ ± 100%	0.836	0.164

§ Uncertainty in emissions reductions does not exceed 100%. * Where uncertainty in emissions reductions is < ± 15%, no deductions will be applied. Uncertainty deduction (UNC) = (1 – Conservativeness factor).

APPENDIX H – Calculations to determine sufficiency of project N rate using N rate calculator

Below is a worked example demonstrating how the proposed N rate for a project area can be shown to be consistent with data output from an approved N rate calculator. In this example the Iowa State University corn nitrogen calculator is used (http://extension.agron.iastate.edu/soilfertility/nrate.aspx).

The Iowa State University corn nitrogen calculator calculates the profitable N rate range around the maximum return to nitrogen (MRTN) rate in continuous corn and corn-soybean rotations in seven states in the U.S. Midwest.

To show consistency, the total amount of N to be applied to the project area during a corn cropping season must be equal to or greater than 80% of the lowest estimate of the N rate range recommended for corn in the region in which it is grown.

Worked example for a proposed project in Michigan in a corn-soybean rotation

Calculating baseline fertilizer N rate for corn in a corn–soybean rotation
In the project area where corn will be grown, the farmer has previously applied N fertilizer to corn in rotation with soybean during 3 of the previous 6 years (Table H1). In this example the source of the N fertilizer is synthetic N but it could also have been organic N such as manure – the calculation would be the same.

Table H1. N fertilizer rates applied to corn in a corn–soybean rotation (2006 – 2011)

Year	Crop	Fertilizer N rate (kg N ha^{-1} yr^{-1})
2006	Corn	140
2007	Soybean	0
2008	Corn	160
2009	Soybean	0
2010	Corn	150
2011	Soybean	0
2006–2011 Average	Corn	= (140+160+150)/3 = 150

The baseline fertilizer N rate for the corn crop in the proposed project to be planted in 2012 is calculated from the average of the total N fertilizer applied to the previous 3 corn crops during the previous 6 years, i.e. 150 kg N ha^{-1} yr^{-1}. Reductions from this baseline rate are considered additional and are credited.

The proposed project N rate for the corn crop to be planted in 2012 is 125 kg N ha^{-1}.

Demonstrating consistency with Iowa State University corn nitrogen calculator

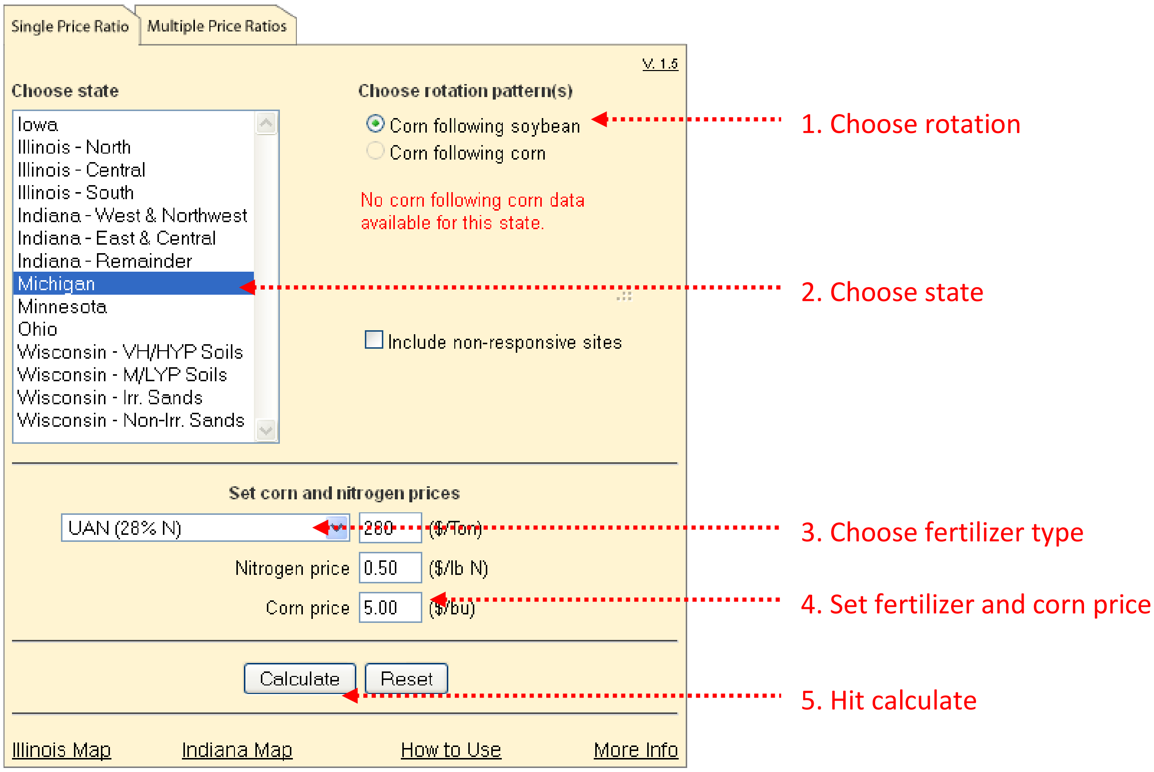

Figure H1. Screen shot of Iowa State University corn nitrogen calculator, showing selection menus for 1) rotation, 2) state, 3) N fertilizer type, and 4) N fertilizer and corn price.

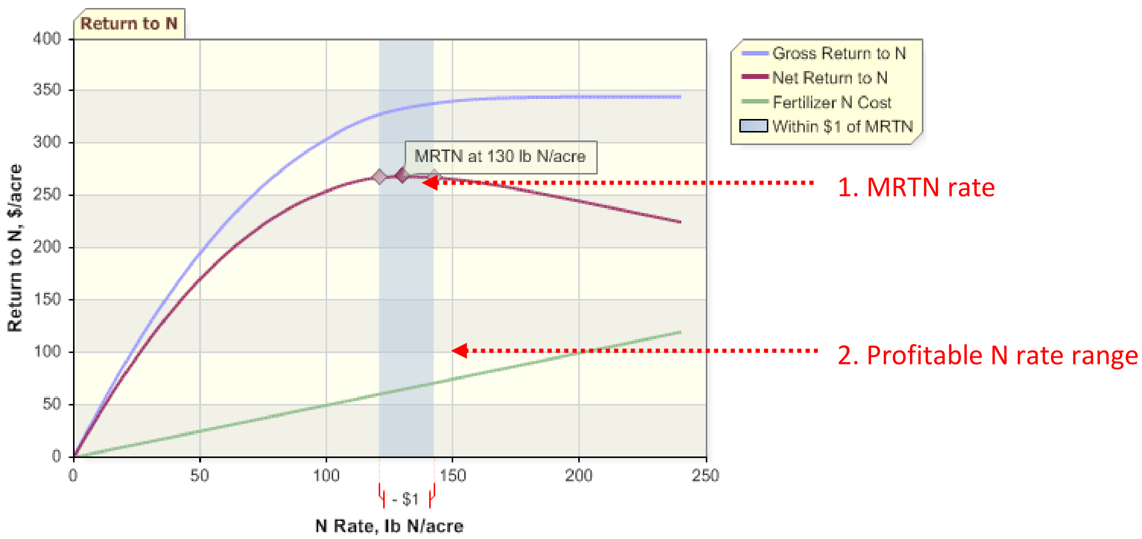

Figure H2. Screen shot of Iowa State University corn nitrogen calculator, showing 1) maximum return to nitrogen (MRTN) rate, and 2) profitable N rate range (blue shaded column; within $1.00 per acre of MRTN) for the project area specifications.

For the project conditions, the MRTN rate is 130 lb N acre^{-1}, with a profitable N rate range of 121 to 142 lb N acre^{-1}. For conversion from imperial units (lb N acre^{-1}) to metric (kg N ha^{-1}), the imperial value is multiplied by 1.12 (a conversion factor accepted by the American Society of Agronomy at http://www.soils.org/files/publications/journals-sitable-coversions.pdf). Therefore, in metric units the MRTN rate is 146 kg N ha^{-1}, with a profitable N rate range of 136 to 159 kg N ha^{-1}. 80% of the lowest recommended N rate is 109 kg N ha^{-1} (0.8 x 136 = 109); the proposed project N rate of 125 kg N ha^{-1} is higher than this so is consistent and eligible for use in the project area.

CDM *Tool to determine the baseline efficiency of thermal or electric energy generation systems*

CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology quantifies the GHG emission reductions resulting from the use of Hydrogen Peroxide-based Propylene Oxide (HPPO) technology, which requires less GHG-intensive reagents and requires less energy for the production of Propylene Oxide (PO) compared to other production processes.

This methodology is based on the project being developed by MTP HPPO Manufacturing Co., Ltd, a joint venture between The Siam Cement Public Co., Ltd and The Dow Chemical Company. The project involves the construction of a PO production facility that will use HPPO technology instead of the conventional Chlorohydrin (CHPO)-chlor-alkali process.

PO is an organic compound with the molecular formula CH_3CHCH_2O. This colorless volatile liquid is produced on a large scale industrially. PO is a very common chemical building block used to produce commercial and industrial products including polyether polyols, propylene glycols and propylene glycol ethers. It is among the most diffused chemical intermediates in the world and its production continues to grow.

There are many processes (or chemical routes) that are used in the industry to synthesize PO. Industrial production of PO generally starts from propylene. Two general approaches are then employed, one involving hydrochlorination and the other involving oxidation. The hydrochlorination route, which uses chlorohydrin technology, is the traditional route and proceeds via the conversion of propylene to PO. There are also other possible routes to produce PO based on co-oxidation of the organic chemicals isobutene or ethylbenzene. However, these alternative routes are characterized by substantial production of co-products, such as *t*-butyl alcohol or styrene, respectively.

This methodology is not designed to address all types of PO production processes. Its application is limited to projects wherein PO is the only output expected (ie, no co-products are produced in the process). The methodology is applicable only to greenfield projects where the project activity is the implementation of the HPPO process and where implementation of the CHPO-chlor-alkali process is identified as the baseline scenario.

In this methodology, the GHG emissions produced by different chemical manufacturing processes using different reagents are being compared. Comparing two processes that do not use the same input materials not only entails a comparison of emissions that occur in the PO production facility but requires a broader approach, similar to a life cycle assessment where emissions due to reagent production are also taken into account. The methodology therefore distinguishes (for both baseline and project processes) between two classes of emissions:

- **Upstream emissions**: includes emission sources linked to the reagents being used in the PO production process.

- **Process emissions**: includes emission sources located within the PO production facility and include emissions associated with the synthesis of the PO as well as emissions associated with by-product and waste treatment.

Since the product is the same in both the baseline and project scenarios, downstream emissions would be the same and have therefore not been considered. The emissions associated with the construction of the PO production facility are also ignored as they are not expected to be significantly different in the baseline and project scenarios. As such, this methodology considers only upstream and process emissions.

The methodology quantifies emission reductions from a more energy efficient PO production process, which has significant capital and recurring costs estimated to be over US$1,500 per tonne of PO. As a result, the methodology does not create any incentives for producing PO for the sole purpose of earning carbon credits.

The key elements of this methodology are as follows:

- **Applicability conditions:** The methodology is applicable to greenfield projects where PO is the only expected output (ie, no co-products are produced in the production process). Nevertheless, in practice, due to selectivity of the catalysts, by-products may be produced in the production process. Such by-products must not be more than 10% (in mass terms) relative to the PO output. As a consequence, the methodology is applicable only to projects where the project activity is the implementation of the HPPO process and where implementation of the CHPO-chlor-alkali process is identified as the baseline scenario.

- **Project boundary:** The project boundary includes upstream emissions from reagent production and process emissions from the synthesis of PO and from by-product and waste treatment.

- **Baseline scenario:** The baseline scenario is determined through an evaluation of the likely alternatives, accounting for local/national regulations and laws, investment analyses and/or barriers. A list of pre-defined alternatives is included in this methodology; this list is non-exhaustive and additional alternatives may be proposed by project proponents.

- **Additionality:** Additionality must be demonstrated through the application of the latest version of the CDM *Tool for the demonstration and assessment of additionality*.

- **Baseline emissions:** Baseline emissions include upstream emissions and process emissions.

  Upstream emissions include emissions associated with the baseline reagents. For simplification, and as a conservative approach, the following upstream emission sources are excluded:

  - Emissions associated with raw materials that are in an unprocessed or minimally processed state;
  - Raw material extraction;
  - Catalysts;
  - Transportation; and
  - Reagents common in quantity and quality to the project activity.

  Process emissions include emissions resulting from energy usage (eg, heat and electricity) for transforming the reagents into the final product and also for waste and by-product treatment. For simplification, and as a conservative approach, emissions linked to waste and by-products may be neglected if credible data to estimate same is not available. Process emissions due to energy usage are calculated based upon the specific energy required per tonne of PO production, and the associated emission factor for the thermal/electrical energy generation, respectively.

- **Project emissions:** Project emissions include upstream emissions and process emissions.

  Upstream emissions include emissions associated with the project reagents. For simplification, and as a conservative approach, the same upstream emission sources as under the baseline scenario are excluded for the project scenario.

  Process emissions include emissions resulting from energy usage (eg, heat and electricity) for transforming the reagents into the final product and also for waste and by-product treatment.

  Emissions linked to energy, electricity and steam are calculated using the latest versions of the CDM *Tool to calculate baseline, project and/or leakage emissions from electricity consumption* and the CDM *Tool to calculate project or leakage CO2 emissions from fossil fuel combustion,* respectively.

  Apart from waste contained in wastewater streams, most of the waste generated on-site is usually incinerated. Emissions from the incineration of such waste streams must be estimated by considering the carbon content of the waste stream (based on their chemical formula). By-products that can be recovered from the process and used for other processes within the project boundary are considered as carbon neutral since all emissions linked to their treatment are included in the project boundary and are already taken into account. Incineration of waste streams often involves co-firing of fossil fuels. Emissions from fossil fuel consumption are also considered.

- **Leakage:** Leakage is not considered an issue under this methodology.
- **Emission reductions:** The emission reductions are calculated as baseline emissions minus project emissions.
- **Monitoring:** As all parameters are related to the production process, monitoring must follow standard industrial practice.

Additionality	Project Method
Crediting Baseline	Project Method

3 DEFINITIONS

For the purposes of this methodology, the following definitions apply:

By-Products: Incidental (ie, undesired) products deriving from chemical processes. Water is not considered to be a by-product.

Chlorohydrin Process (CHPO Process): Process whereby propylene is combined with hypochlorous acid to form a chlorohydrin intermediate, which is subsequently dechlorohydronated to PO. This process leads to the formation of salts.

CHPO-Chlor-Alkali Process: A specific CHPO process where caustic soda facilitates a dechlorohydronation reaction, leading to large quantities of NaCl brine.

CHPO-Lime Process: A specific CHPO process where lime is used as a chlorine absorber. Quick-lime (CaO) is mixed with water to form calcium hydroxide which is mixed with a chlorohydrin solution. This process leads to large quantities of effluent with $CaCl_2$ loads.

Co-Oxidation: PO production process that co-produces styrene (POSM) and t-butyl (POTBA).

Co-Products: Products deriving from the chemical process which is not the primary product. Water is not considered to be a co-product.

Cumene Hydroperoxide Process (CHP Process): Process where CHP is used for the epoxidation of propylene[1]. This route produces DMBA as a co-product which may be further recycled to cumene.

Hydrogen Peroxide-Based PO Process (HPPO Process): Process consisting of the production of PO from propylene and hydrogen peroxide[2].

Oxidation: PO production process that does not lead to co-products.

Propylene Oxide Styrene Monomer Process (POSM Process): Hydroperoxidation production route to PO that co-produces styrene monomer. This process involves the co-oxidation of ethylbenzene and styrene, and produces PO and styrene.

Propylene Oxide Tertiary Butyl Alcohol Process (POTBA Process): Hydroperoxidation production route to PO that co-produces t-butyl. This process involves the co-oxidation of isobutene and styrene, and produces PO and t-butyl.

Propylene Oxide (PO): An organic compound with the molecular formula CH_3CHCH_2O. This colourless volatile liquid is produced on a large scale industrially, its major application being its use in the production of polyether polyols, which are used for making polyurethane plastics.

Waste: Material generated by the production process which is not sold or re-used in other processes on-site. Waste streams may be incinerated on-site, treated within the project boundary (eg, wastewater) or disposed of (eg, at solid disposal site).

4 APPLICABILITY CONDITIONS

This methodology is applicable under the following conditions:

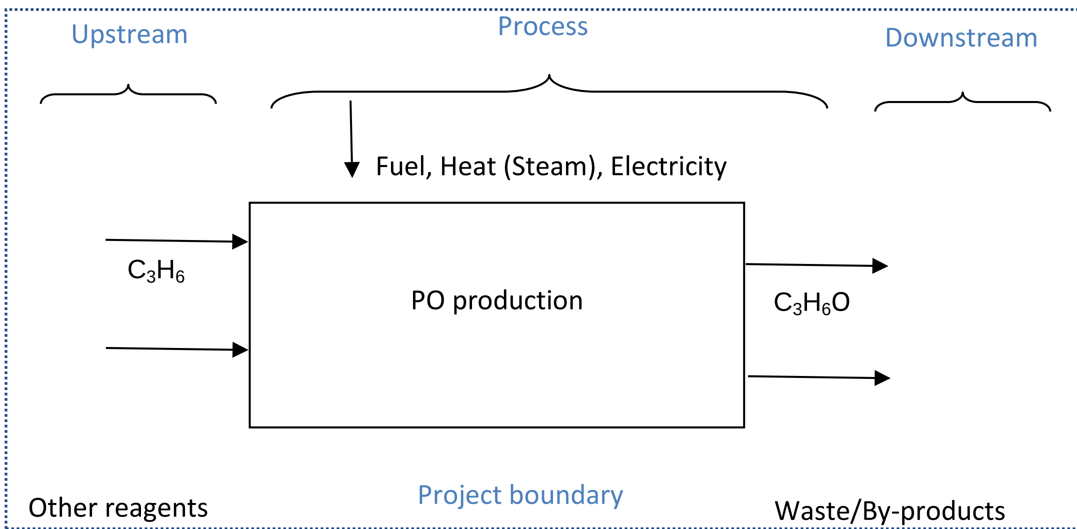
- The methodology is limited to greenfield projects (ie, new PO production facilities) wherein PO is the only output.
- The PO production process must not produce any co-products. There may be by-products produced in the PO production process, due to the selectivity of catalysts.
- The PO production process must not create more than 10% (in mass terms) by-product, relative to PO output.
- The methodology is applicable only to projects where the project activity is the implementation of the HPPO process and where implementation of the CHPO-chlor-alkali process is identified as the baseline scenario.

[1] Patented by Sumitomo (World patent 01/05778 A1).
[2] There are two patents linked to this process. One is owned by DOW (US patent 7,138,534), and the other by Degussa (6,878,836).

- The project may be located in any geographic region of the world.
- The applicability conditions of the tools referenced in this methodology also apply.

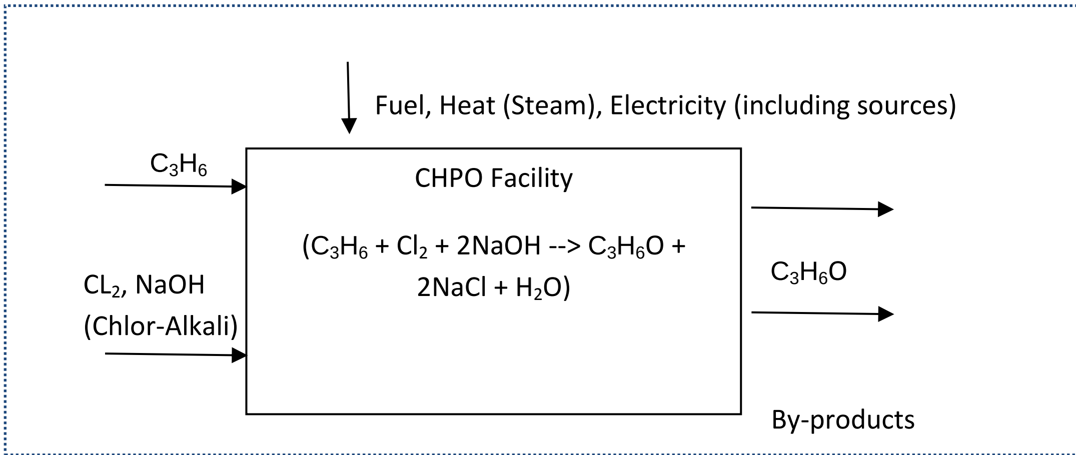
5 PROJECT BOUNDARY

The spatial extent of the project boundary encompasses (1) the upstream emissions from reagent production and (2) the emissions from the PO production facility (ie, the cumulative emissions beginning from reagents admission and synthesis of PO through to the treatment of by-products and waste from the production process).

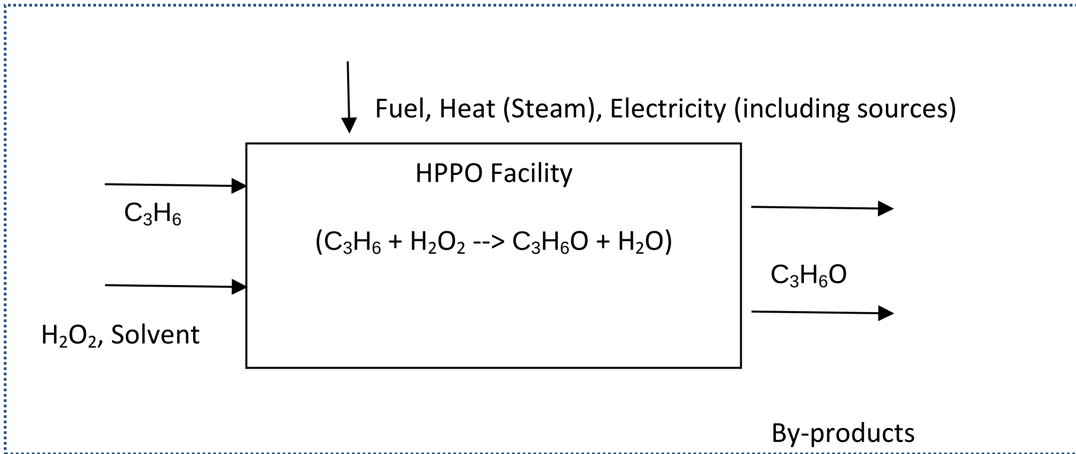


The project boundary also encompasses the project's electricity system(s) and the heat/steam generation system that the PO production facility is connected to. The spatial extent of the project electricity system consists of the power plants that are physically connected through transmission and distribution lines to the project activity and that can be dispatched without significant transmission constraints. The spatial extent for the heat (steam) system is similar, including the heat/steam generating systems that are physically connected to the project activity and that can be displaced without significant constraints.

For the CHPO-chlor-alkali process (baseline scenario), the spatial extent of the project boundary is defined as follows:



For the HPPO process (project activity), the spatial extent of the project boundary is defined as follows:



The greenhouse gases included in, or excluded from, the project boundary are shown in the table below:

Source		Gas	Included?	Justification/Explanation
Baseline	Emissions associated with the production of baseline reagents	CO_2	Yes	The emissions associated with Cl_2 and NaOH (chlor-alkali) production are accounted for as these are generally not found naturally and are produced in an industrial facility. The emissions associated with C_3H_6 have, however, not been accounted for as its usage would be essentially the same as in the project activity.
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.
	Emissions associated with steam and electricity requirements of the production process	CO_2	Yes	Emissions could arise from the combustion of fossil fuels for providing steam and/or electricity to the PO production facility.
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.
	Emissions associated with treatment of waste produced by the production process	CO_2	Yes	Emissions could arise from the incineration of waste.
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.

Source		Gas	Included?	Justification/Explanation
Project	Emissions associated with the production of project reagents	CO_2	Yes	The emissions associated with H_2O_2 production and methanol as a solvent (make-up) have been accounted for as these reagents are generally not found naturally and are produced in an industrial facility. The emissions associated with C_3H_6 have, however, not been accounted for as its usage would be essentially the same as in the baseline activity.
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.
	Emissions associated with steam and electricity requirements of the production process	CO_2	Yes	Emissions could arise from the combustion of fossil fuels for providing steam and/or electricity to the PO production facility
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.
	Emissions associated with treatment of waste produced by the production process	CO_2	Yes	Emissions could arise from the incineration of waste (eg, low boils, waste gas, etc.).
		CH_4	No	Excluded for simplification, this is conservative.
		N_2O	No	Excluded for simplification, this is conservative.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

Project proponents must apply the following steps to identify the baseline scenario:

Step 1: Identification of plausible alternative scenarios

This step serves to identify all alternative scenarios to the project activity which could qualify as the baseline scenario. Alternatives must be able to deliver outputs or services[3] that are equivalent to what has been implemented previously, or is currently being implemented in the relevant country/region. Given that the only output intended from production is PO (ie, no co-products), identified alternatives must therefore consist of all commercially available PO technologies. The list of alternatives must therefore consist of at least (but not limited to):

P1: The project activity without carbon revenues;

P2: A PO production facility with comparable capacity using a CHPO process (CHPO-lime or CHPO-chlor-alkali processes);

P3: A PO production facility with comparable capacity using any other commercially available technology.

Step 2: Consistency with mandatory applicable laws and regulations

This step serves to eliminate alternatives that are not in compliance with all applicable mandatory legal and regulatory requirements.

Step 3: Barrier analysis

This step serves to identify barriers and to assess which alternative scenarios are prevented by these barriers. Scenarios that face prohibitive barriers must be eliminated by applying Step 3 of the latest version of the CDM *Tool for demonstration and assessment of additionality*.

If only one alternative remains, this must be considered the baseline scenario. If more than one alternative remains, proceed to Step 4.

Step 4: Economic analysis

This step serves to compare the economic or financial attractiveness of all alternatives that are remaining and identify the scenario that is the most economically and/or financially attractive. The economic analysis must be completed by applying Step 2 of the latest approved version of the CDM *Tool for the demonstration and assessment of additionality*.

[3] The processes wherein co-products are produced (eg, CHP, POSM and POTBA processes) are not considered as likely alternatives.

This methodology is only applicable if implementation of the CHPO-chlor-alkali process is identified as the baseline scenario.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

The additionality of the project activity must be demonstrated and assessed using the latest version of the CDM *Tool for the demonstration and assessment of additionality*. While demonstrating the additionality of the project activity, the project proponent must consider the different baseline alternatives described in the section above.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

Baseline emissions are calculated as follows:

$$BE_y = BE_{Upstream,y} + BE_{Process,y} \tag{1}$$

Where:

BE_y	Baseline emission in year y (tCO_2)
$BE_{Upstream,y}$	Emissions associated with the baseline reagents required for the production of PO in year y (tCO_2)
$BE_{Process,y}$	Emissions due to energy usage (heat and electricity) for transforming the baseline reagents into the final product (PO) and also for waste and by-product treatment in year y (tCO_2)

Upstream emissions (**$BE_{Upstream,y}$**):

The upstream emissions are based on the various reagents used in the process. The reagents used in the baseline (CHPO-chlor-alkali process) are C_3H_6, Cl_2 and NaOH. The emissions associated with C_3H_6, however, are not accounted for as usage would be essentially the same as in the project activity. The emissions associated with Cl_2 and NaOH (chlor-alkali) production have been included as these are generally not found naturally and are be produced in an industrial facility.

The emissions associated with chlor-alkali production are calculated as follows:

$$BE_{Upstream,y} = be_{Chlor-Alkali,y} \times PO_y \tag{2}$$

Where:

$be_{Chlor\text{-}Alkali,\,y}$	Quantity of CO_2 emitted from chlor-alkali production per unit of PO in year y (tonnes)
PO_y	Quantity of PO produced in year y (tonnes)

The chlor-alkali production process involves the electrolysis of aqueous sodium chloride (brine) in a membrane cell. The CO_2 emissions associated with chlor-alkali production are calculated as follows[4]:

$$be_{Chlor-Alkali,y} = \left(\frac{71}{58}\right) \times ec_{Chlor-Alkali,y} \times EF_{EL,y} \qquad \textbf{(3)}$$

Where:

$ec_{Chlor\text{-}Alkali,\,y}$	Energy consumption per tonne of Cl_2 production in year y (MWh/tCl_2)
$EF_{EL,y}$	Emission factor for electricity generation in year y (tCO_2/MWh)
71/58	Ratio between the molecular weights of Cl_2 and C_3H_6O (mass units/mass units)

Process emissions (**$BE_{Process,y}$**):

The process emissions arise due to energy usage (eg, heat and electricity) for transforming the reagents into the final product and also from waste treatment.

The emissions associated with energy usage are calculated as follows:

$$BE_{Process,y} = BE_{Heat,y} + BE_{Elec,y} + BE_{Waste,y} \qquad \textbf{(4)}$$

Where:

$BE_{Heat,y}$	Emissions due to thermal energy (heat/steam) for transforming the baseline reagents into the final product (PO) and also for waste treatment in year y (tCO_2)
$BE_{Elec,y}$	Emissions due to electrical energy for transforming the baseline reagents into the final product (PO) and also for waste treatment in year y (tCO_2)
$BE_{Waste,y}$	Emissions due to treatment of waste in year y (tCO_2)

[4] The equation has been presented in terms of chlorine and PO, and so the energy consumption is also linked to chlorine.

The CO_2 emissions from thermal energy (heat/steam) are calculated as follows:

$$BE_{Heat,y} = SSC_{CHPO} \times PO_y \times EF_{Steam,y} \quad (5)$$

Where:

SSC_{CHPO}	Specific thermal energy consumption ratio in PO production through the CHPO-chlor-alkali process (TJ/tonne of PO)
$EF_{Steam,y}$	Emission factor for thermal energy generation in year y (tCO_2/TJ)

The emission factor for thermal energy generation is calculated as follows:

$$EF_{Steam,y} = EF_{CO2,i,y} / \eta_{Boiler,y} \quad (6)$$

Where:

$EF_{CO2,\,I,\,y}$	Weighted average CO_2 emission factor of fuel type i in year y (tCO_2/TJ)
$\eta_{Boiler,y}$	Efficiency of the steam generating system in year y

The CO_2 emissions from electrical energy are calculated as follows:

$$BE_{Elec,y} = SEC_{CHPO} \times PO_y \times EF_{El,y} \quad (7)$$

Where:

SEC_{CHPO}	Specific electrical energy consumption ratio in PO production through the CHPO-chlor-alkali process (MWh/tonne of PO)
$EF_{El,y}$	Emission factor for electricity generation in year y (tCO_2/MWh)

For the specific thermal energy consumption ratio in PO production through the CHPO-chlor-alkali process, data must be derived from an independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.

The CO_2 emissions from waste treatment are calculated as follows:

$$BE_{Waste,y} = \left(\frac{44}{12}\right) \times \left(CA_{Waste,Baseline}\right) + FC_{i,Baseline} \times COEF_i \quad \textbf{(8)}$$

Where:

$CA_{Waste, Baseline}$	Carbon amount in the waste stream derived from the carbon amount in the propylene feed, PO and by-products in the baseline (tonnes)
44/12	Ratio between the molecular weights of CO_2 and carbon (mass units/mass units)
$FC_{i,Baseline}$	Quantity of fuel type i combusted in the incinerator in the baseline (mass or volume unit/year)
$COEF_i$	CO_2 emission coefficient of fuel type i (tCO_2/mass or volume unit)

The carbon amount in the waste stream derived from the carbon amount in the propylene feed, PO and by-products in the baseline must be determined by applying equations 17 and 18.

The CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion* must be used to calculate the CO_2 emission coefficient.

The carbon amount in the waste stream and fuel combusted in the incinerator must be presented in terms of PO output.

For simplification, and as a conservative approach, the emissions linked to waste and by-products may be neglected if data from an independent third party report from a recognized, credible source (reviewed by an appropriately qualified, independent organization or appropriate peer review group) or published by a government agency, to estimate same is not available.

8.2 Project Emissions

Project emissions are calculated as follows:

$$PE_y = PE_{Upstream,y} + PE_{Process,y} \quad \textbf{(9)}$$

Where:

PE_y	Project emissions in year y (tCO_2)
$PE_{Upstream,y}$	Emissions associated with the project reagents for the production of PO in year y (tCO_2)
$PE_{Process,y}$	Emissions due to energy usage (heat and electricity) for transforming the

project reagents into the final product (PO) and also for waste treatment in year y (tCO_2)

Upstream emissions ($PE_{Upstream,y}$ ***):***

The upstream emissions are based on the various reagents used in the PO production process. The reagents used in the project scenario (HPPO process) are C_3H_6 and H_2O_2. However, the emissions associated with C_3H_6 are not accounted for as its usage would be essentially the same as in the baseline activity. The emissions associated with H_2O_2 production have been included as this compound is generally not found naturally and is produced in an industrial facility. Further, since the reaction is carried out in solvents[5], the emissions associated with the make-up solvent (in this case methanol) are considered as well.

The upstream emissions are calculated as follows:

$$PE_{Upstream,y} = PE_{Upstream,H2O2,y} + PE_{Upstream,Solvent,y} \quad \textbf{(10)}$$

The emissions associated with H_2O_2 production are calculated as follows:

$$PE_{Upstream,H2O2,y} = \left(\frac{34}{58}\right) \times pe_{HP} \times PO_y \quad \textbf{(11)}$$

Where:

pe_{HP}	Quantity of CO_2 that would be emitted per tonne of H_2O_2 (tCO_2/tH_2O_2)[6]
PO_y	Quantity of PO produced in year y (tonnes)
34/58	Ratio between the molecular weights of H_2O_2 and C_3H_6O (mass units/mass units)

The emissions associated with make-up methanol are calculated as follows:

$$PE_{Upstream,Solvent,y} = pe_{Sol} \times sol_y \times PO_y \quad \textbf{(12)}$$

Where:

pe_{Sol}	Quantity of CO_2 that is emitted per tonne of solvent (tCO_2/tonne of solvent)

[5] Typically solvents of polar nature are used, such as alcohols, ketones, ethers, etc.

sol_y	Quantity of solvent required per tonne of PO in year y (tonnes)
PO_y	Quantity of PO produced in year y (tonnes)

Note that sol_y, as found in equation 12 above, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "sol_y x PO_y" is represented by Sol_y in equation 12 above, the value of which is monitored in accordance with the procedures described in Section 9.2.

Process emissions (**$PE_{Process,y}$**):

The process emissions arise from the energy usage (eg, heat and electricity) required for transforming the reagents into the final product, and for by-product and waste treatment.

The process emissions are calculated as follows:

$$PE_{Process,y} = PE_{Heat,y} + PE_{Elec,y} + PE_{Waste,y} \quad \textbf{(13)}$$

Where:

$PE_{Heat,y}$	Emissions due to thermal energy (heat/steam) for transforming the project reagents into the final product in year y (tCO_2)
$PE_{Elec,y}$	Emissions due to electrical energy for transforming the project reagents into the final product in year y (tCO_2)
$PE_{Waste,y}$	Emissions due to treatment of waste products in year y (tCO_2)

The CO_2 emissions from thermal energy (heat/steam) are calculated as follows:

$$PE_{Heat,y} = SSC_{HPPO,y} \times PO_y \times EF_{Steam,y} \quad \textbf{(14)}$$

Where:

$SSC_{HPPO,\, y}$	Specific thermal energy consumption ratio in PO production through the HPPO process in year y (TJ/tonne of PO)
$EF_{Steam,y}$	Emission factor for thermal energy generation in year y (tCO_2/TJ)

Note that SSC_{HPPO}, as found in equation 14 above, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "$SSC_{HPPO,y}$ x PO_y" is represented by SC_{HPPO} in equation 14 above, the value of which is monitored in accordance with the procedures described in Section 9.2.

The emission factor for thermal energy generation is the same as calculated for the baseline emissions.

The CO_2 emissions from electrical energy are calculated as follows:

$$PE_{El,y} = SEC_{HPPO,y} \times PO_y \times EF_{El,y} \quad \textbf{(15)}$$

Where:

$SEC_{HPPO,y}$	Specific electrical energy consumption ratio in PO production through the HPPO process in year y (MWh/tonne of PO)
$EF_{El,y}$	Emission factor for electricity generation in year y (tCO_2/MWh)

Note that SEC_{HPPO}, as found in equation 15 above, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "SEC_{HPPO} x PO_y" is represented by EC_{HPPO} in equation 15 above, the value of which is monitored in accordance with the procedures described in Section 9.2.

The emission factor for electricity generation is the same as calculated for the baseline emissions.

The CO_2 emissions from waste treatment are calculated as follows:

$$PE_{Waste,y} = \left(\frac{44}{12}\right) \times \left(CA_{Waste,y}\right) + FC_{i,y} \times COEF_{i,y} \quad \textbf{(16)}$$

Where:

$CA_{Waste,y}$	Carbon amount in the waste stream derived from the carbon amount in the propylene feed, solvent, PO and by-products in year y (tonnes)
44/12	Ratio between the molecular weights of CO_2 and carbon (mass units/mass units)
$FC_{i,y}$	Quantity of fuel type i combusted in the incinerator in year y (mass or volume unit/year)
$COEF_{i,y}$	CO_2 emission coefficient of fuel type i in year y (tCO_2/mass or volume unit)

The CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion* must be used to calculate the CO_2 emission coefficient.

The carbon amount in the waste stream must be calculated as follows:

$$CA_{Waste,y} = CA_{Propylene,y} + CA_{Solvent,y} - \left(CA_{PO,y} + CA_{Byproducts,y}\right) \quad \textbf{(17)}$$

Where:

$CA_{Propylene,\ y}$	Carbon amount in the propylene feed in year y (tonnes)
$CA_{Solvent,\ y}$	Carbon amount in the solvent used in year y (tonnes)
$CA_{PO,\ y}$	Carbon amount in PO produced in year y (tonnes)
$CA_{Byproducts,\ y}$	Carbon amount in the by-products in year y (tonnes)

The total amount of carbon in a particular product is a function of the respective carbon fraction and the quantity of the product, expressed as follows:

$$CA_{x,y} = ca_{x,y} \times Q_{x,y} \quad \textbf{(18)}$$

Where:

$CA_{x,\ y}$	Carbon amount in the product x in year y (tonnes)
$ca_{x,\ y}$	Carbon fraction in the product x in year y (mass units/mass units)
$Q_{x,\ y}$	Quantity of the product x in year y (tonnes)
x	propylene, solvent, PO, by-product, waste

For example, where methanol is being used as a solvent, which gives the by-product monopropyleneglycol ($C_3H_8O_2$), equation 17 is represented as follows:

$$CA_{Waste,y} = \left(\frac{36}{42}\right) \times Q_{Propylene,y} + \left(\frac{12}{32}\right) \times Sol_y - \left(\frac{36}{58}\right) \times PO_y - \left(\frac{36}{76}\right) \times Q_{Byproduct,y} \quad \textbf{(19)}$$

Where:

36/42	Carbon fraction in propylene (mass units/mass units)
12/32	Carbon fraction in methanol (mass units/mass units)
36/58	Carbon fraction in PO (mass units/mass units)
36/76	Carbon fraction in monopropyleneglycol (mass units/mass units)
$Q_{Propylene,\ y}$	Quantity of propylene used in year y (tonnes)

Sol_y	Quantity of make-up methanol used in year y (tonnes)
PO_y	Quantity of PO produced in year y (tonnes)
$Q_{Byproduct, y}$	Quantity of monopropyleneglycol produced in year y (tonnes)

8.3 Leakage

Leakage is not considered an issue under this methodology. The main emissions potentially giving rise to leakage in the context of the project are emissions arising due to construction of the PO production facility and transportation of reagents. These emissions sources are excluded as these would be higher in the baseline scenario as compared to project scenario.

8.4 Summary of GHG Emission Reduction and/or Removals

Emission reductions are calculated as follows:

$$ER_y = BE_y - PE_y - LE_y \quad (20)$$

Where:

ER_y	Emission reductions in year *y* (tCO_2e/yr)
BE_y	Baseline emissions in year *y* (tCO_2/yr)
PE_y	Project emissions in year *y* (tCO_2e/yr)
LE_y	Leakage emissions in year y (tCO_2e/yr)

9 MONITORING

9.1 Data and Parameters Available at Validation

Data Unit / Parameter:	$ec_{Chlor\text{-}Alkali, y}$
Data unit:	MWh/tCl_2
Description:	Energy consumption per tonne of Cl_2 production in year y.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description	The membrane cell process is the preferred

of measurement methods and procedures applied:	process for new PO production facilities. Thus, it is assumed that production of chlor-alkali in the baseline PO production facility is through the membrane cell process[7].
Any comment:	-

Data Unit / Parameter:	SSC_{CHPO}
Data unit:	TJ/tonne of PO
Description:	Specific thermal energy consumption ratio in PO production through the CHPO-chlor-alkali process.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	Steam consumption is converted conservatively into energy terms using enthalpy values and accounting for any condensate return.
Any comment:	-

Data Unit / Parameter:	SEC_{CHPO}
Data unit:	MWh/tonne of PO
Description:	Specific electrical energy consumption ratio in PO production through the CHPO-chlor-alkali process.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	-
Any comment:	-

[7] http://www.miga.org/documents/ChlorAlkali.pdf

Data Unit / Parameter:	pe_{HP}
Data unit:	tCO_2/tH_2O_2
Description:	Quantity of CO_2 emitted per tonne of H_2O_2.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	-
Any comment:	-

Data Unit / Parameter:	pe_{Sol}
Data unit:	tCO_2/tonne of methanol solvent
Description:	Quantity of CO_2 emitted per tonne of methanol.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	-
Any comment:	-

Data Unit / Parameter:	$ca_{Waste, Baseline}$
Data unit:	tC/tonne of PO
Description:	Carbon amount in the waste stream combusted in the incinerator in the baseline per tonne of PO.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	-
Any comment:	-

Data Unit / Parameter:	$fc_{i,Baseline}$
Data unit:	Mass or volume unit in baseline per tonne of PO
Description:	Quantity of fuel type i combusted in the incinerator in the baseline per tonne of PO.
Source of data:	Independent third party report from a recognized, credible source which must be reviewed by an appropriately qualified, independent organization or appropriate peer review group, or be published by a government agency.
Justification of choice of data or description of measurement methods and procedures applied:	-
Any comment:	-

9.2 Data and Parameters Monitored

Data Unit / Parameter:	PO_y
Data unit:	Tonnes
Description:	Final quantity of PO produced in year y.
Source of data:	PO production facility records.
Description of measurement methods and procedures to be applied:	Flow-rate meters, mass meters, cross-check with stock verification records.
Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly.
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines or national standards, and cross-checked with production stock inventory.
Any comment:	-

Data Unit / Parameter:	Sol_y
Data unit:	Tonnes
Description:	Quantity of make-up methanol solvent used in year y.
Source of data:	PO production facility records.
Description of measurement methods and procedures to be applied:	Flow-rate meters, mass meters, cross-check with stock verification records.

Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly.
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines or national standards, and cross-checked with stock inventory.
Any comment:	Note that sol_y, as found in equation 12, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "sol_y x PO_y" is represented by Sol_y in equation 12, the value of which is monitored in accordance with the procedures described above.

Data Unit / Parameter:	$EF_{EL,y}$
Data unit:	tCO_2/MWh
Description:	Emission factor for electricity generation in year y.
Source of data:	Calculate the emission factor using the procedures in the latest approved version of the CDM *Tool to calculate the emission factor for an electricity system*.
Description of measurement methods and procedures to be applied:	As per the CDM *Tool to calculate the emission factor for an electricity system.*
Frequency of monitoring/recording:	As per the CDM *Tool to calculate the emission factor for an electricity system.*
QA/QC procedures to be applied:	As per the CDM *Tool to calculate the emission factor for an electricity system.*
Any comment:	-

Data Unit / Parameter:	$EF_{CO2, I, y}$
Data unit:	tCO_2/TJ
Description:	Weighted average CO_2 emission factor of fuel type i in year y.
Source of data:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Description of measurement methods and procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Frequency of monitoring/recording:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel*

	combustion.
QA/QC procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Any comment:	-

Data Unit / Parameter:	$\eta_{Boiler,y}$
Data unit:	-
Description:	Efficiency of the steam generating system in year y.
Source of data:	As per the CDM *Tool to determine the baseline efficiency of thermal or electric energy generation systems.*
Description of measurement methods and procedures to be applied:	As per the CDM *Tool to determine the baseline efficiency of thermal or electric energy generation systems.*
Frequency of monitoring/recording:	As per the CDM *Tool to determine the baseline efficiency of thermal or electric energy generation systems.*
QA/QC procedures to be applied:	As per the CDM T*ool to determine the baseline efficiency of thermal or electric energy generation systems.*
Any comment:	-

Data Unit / Parameter:	$SC_{HPPO,\ y}$
Data unit:	TJ
Description:	Thermal energy consumption in PO production through the HPPO process in year y.
Source of data:	PO production facility records.
Description of measurement methods and procedures to be applied:	This parameter must be determined as the difference of the enthalpy of the process heat (steam) supplied to PO production process in the project method, minus the enthalpy of the feed-water, the boiler blow-down and any condensate return. The respective enthalpies are determined based on the mass (or volume) flows, the temperatures and, in case of superheated steam, the pressure. Steam tables or appropriate thermodynamic equations may be used to calculate the enthalpy as a function of

	temperature and pressure.
Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly.
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines, and cross-checked with other PO production facility records.
Any comment:	Note that SSC_{HPPO}, as found in equation 14, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "$SSC_{HPPO,y}$ x PO_y" is represented by SC_{HPPO} in equation 14, the value of which is monitored in accordance with the procedures described above.

Data Unit / Parameter:	$EC_{HPPO, y}$
Data unit:	MWh
Description:	Electrical energy consumption in PO production through the HPPO process in year y.
Source of data:	PO production facility records.
Description of measurement methods and procedures to be applied:	Electrical consumption is monitored continuously and the average specific electrical energy consumption is calculated based on PO production.
Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly.
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines or national standards.
Any comment:	Note that SEC_{HPPO}, as found in equation 15, is used only for ex-ante estimations, and its value must be estimated based upon the design details of the project. For ex-post calculations, "SEC_{HPPO} x PO_y" is represented by EC_{HPPO} in equation 15, the value of which is monitored in accordance with the procedures described above.

Data Unit / Parameter:	$Q_{Propylene,y}$
Data unit:	Tonnes
Description:	Quantity of propylene used in year y.

Source of data:	PO production facility records
Description of measurement methods and procedures to be applied:	Flow-rate meters, mass meters, cross-check with stock verification records.
Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines or national standards, and cross-checked with stock inventory.
Any comment:	-

Data Unit / Parameter:	$Q_{By\text{-}product,y}$
Data unit:	Tonnes
Description:	Quantity of by-product produced in year y.
Source of data:	PO production facility records
Description of measurement methods and procedures to be applied:	Flow-rate meters, mass meters, cross-check with stock verification records.
Frequency of monitoring/recording:	Data monitoring is continuous and aggregate recording must be performed at least monthly
QA/QC procedures to be applied:	Meters must be calibrated regularly according to manufacturer's guidelines or national standards, and cross-checked with stock inventory.
Any comment:	-

Data Unit / Parameter:	$FC_{i,y}$
Data unit:	Mass or volume unit/year
Description:	Quantity of fuel type i combusted in the incinerator in year y.
Source of data:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Description of measurement methods and procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Frequency of monitoring/recording:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
QA/QC procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*

Any comment:	-

Data Unit / Parameter:	$COEF_{i,y}$
Data unit:	tCO_2/mass or volume unit
Description:	CO_2 emission coefficient of fuel type i in year y.
Source of data:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Description of measurement methods and procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Frequency of monitoring/recording:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
QA/QC procedures to be applied:	As per the CDM *Tool to calculate project or leakage CO_2 emissions from fossil fuel combustion.*
Any comment:	-

9.3 Description of the Monitoring Plan

The project proponent must establish, maintain and apply a monitoring plan and GHG information system that includes criteria and procedures for obtaining, recording, compiling and analyzing data, parameters and other information important for quantifying and reporting GHG emissions relevant for the project and baseline scenario. Monitoring procedures must address the following:

a) Types of data and information to be reported;

b) Units of measurement;

c) Origin of the data;

d) Monitoring methodologies (eg, estimation, measurement, calculation);

e) Type of equipment used, if any;

f) Monitoring times and frequencies;

g) QA/QC procedures;

h) Monitoring roles and responsibilities; and

i) GHG information management systems, including the location, back up, and retention of stored data.

Where measurement and monitoring equipment is used, the project proponent must ensure the equipment is calibrated according to current good practice (eg, relevant industry standards). All data collected as part of monitoring must be archived electronically and kept at least for two years after the end of the last project crediting period.

QA/QC procedures include, but are not limited to:

Data Gathering, Input and Handling Measures

- Input data checked for typical errors, including inconsistent physical units, unit conversion errors, typographical errors caused by data transcription from one document to another and missing data for specific time periods or physical units.
- Input time series data checked for large unexpected variations (eg, orders of magnitude) that could indicate input errors.
- All electronic files use version control to ensure consistency.
- Physical protection of monitoring equipment (eg, sealed meters and data loggers).
- Physical protection of records of monitored data (eg, hard copy and electronic records).

Data Documentation

- Input data units checked and documented.
- All sources of data, assumptions and emission factors documented.
- Changes to data, assumptions and emission factors documented.
- Documented assumptions and algorithms validated based on best practices.

Calculations

- Units for input data and conversion factors documented.
- Units for all intermediate calculations and final results documented.
- Input data and calculated data clearly differentiated.
- Comparison to previous results to identify potential inconsistencies.
- Results aggregated in various ways to identify potential inconsistencies.

Methodology for Coastal Wetland Creation

Methodology developed by:

Louisiana Coastal Protection and Restoration Authority

Methodology prepared by:

CH2M Hill

EcoPartners

Table of Contents

1 SOURCES

This methodology was developed based on the requirements in the following documents:

- *VCS Standard, v3.3*
- *AFOLU Requirements, v3.3*
- *Program Definitions, v3.4*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

Additionality and Crediting Method	
Additionality	Activity Method
Crediting Baseline	Project Method

This methodology quantifies the greenhouse gas benefits of wetland creation activities. The scope of this methodology includes two primary project activities – substrate establishment and vegetation establishment – typically implemented in combination in order to create new wetlands (ie, to restore wetlands that have degraded to open water.) The methodology also allows for implementation of either project activity individually.

The methodology also addresses the potential for the establishment of woody vegetation. As such, this methodology is categorized as a Restoring Wetland Ecosystems (RWE) + Afforestation, Reforestation and Revegetation (ARR) methodology.

This methodology is only applicable to projects located in the United States of America, as set out further in the applicability conditions.

2.1 Project Activities

Wetland creation projects must be designed such that the wetland, over time, will support the ecological processes and functions of a mature wetland habitat. If retention dikes are part of the design, natural degradation and manual breaches must be planned in order to allow for regular tidal exchange or hydrologic connectivity to the surrounding area. The created wetland must support wetland vegetation species capable of contributing to soil carbon accumulation.

The project proponent must include a plan for the establishment and maintenance of a permanent wetland plant community after project construction. The plan must provide evidence that the project area will meet the definition of a wetland upon completion of project activities (but a formal wetland delineation survey is not required). This plan may include natural colonization or manual planting or seeding of the project area. The plan also must demonstrate how the project will be maintained over the project crediting period. Maintenance requirements and activities will vary geographically due to different ecological and physical processes which may influence the project area (eg, elevation deficit vs. shoreline erosion).

Active maintenance may not be required if the created wetland is designed and constructed to offset local processes – including impaired hydrological connectivity – which may have led to the initial deterioration of the historic wetland. For instance, projects created in more protected areas may not be as susceptible to shoreline erosion forces. In addition, other non-related restoration projects near the project area may help alleviate historic issues such as nutrient and sediment source deficits. In Louisiana, for example, future planned diversions of Mississippi River water are designed to supply fresh water, nutrients, and sediment to surrounding wetlands and may influence and sustain the project area depending on proximity to and configuration with the diversion.

The project proponent must demonstrate that the project engineering and design takes into account local water level elevation, tidal range, geotechnical characteristics, sea level rise projections, and the range of plant growth within those constraints.

Monitoring Requirements: Project Activities
The monitoring report must include the following whenever substrate is established: **MRR.1** Plan for establishment of a permanent wetland plant community after project construction. Plan must include long-term monitoring of emergent vegetation and plans for continued maintenance should it become necessary. This documentation must demonstrate that the project activity results in the accumulation or maintenance of soil carbon stock and that, upon completion of the project activities, the project area must meet the definition of a wetland. **MRR.2** Evidence that the project engineering and design takes into account local water level elevation, tidal range, geotechnical characteristics, sea level rise projections, and the range of plant growth within those constraints.

2.1.1 Substrate Establishment

Wetland creation projects are formed with materials including, but not limited to, excavated or dredged sediments from waterways such as rivers, channels, canals, and embayments. Excavated sediments must be placed in open water areas to create tidal wetlands that support emergent plant establishment and growth.

The project activity of creating a wetland from open water first requires the project proponent to select a proper site location that is adjacent to a sediment source which contains a sufficient volume and is within the technical capabilities of delivering the required sediment to the project site to meet design criteria. It is common, but not required, to construct a temporary retention dike around the project area to contain the sediment material and allow for dewatering and compaction in the initial years after project construction. The temporary dike is typically constructed by machinery such as an excavator. Once complete, the project area is filled with sediment via hydraulic or mechanical dredge, pipelines, or other mechanical methods to the proper elevation as determined in the engineering and design documents based on water levels (current and projected), sediment characteristics and geotechnical analyses. The retention dikes may be designed to naturally subside to elevations which will allow for tidal exchange and hydrologic connectivity but may require manual breaches or removal after the project area sediment has consolidated to target levels.

The project proponent must provide documentation of the substrate establishment activities to demonstrate the expected post-construction conditions in the project area.

Monitoring Requirements: Substrate Establishment
The monitoring report must include the following whenever substrate is established: **MRR.3** Post-construction report, including an as-built drawing showing plan view and cross section of the project area along with an estimate of post-construction sediment elevation relative to a geodetic or tidal datum. **MRR.4** Aerial image of the project area within three years prior to construction and an aerial image within one year post-construction.

2.1.2 Vegetation Establishment

The project proponent may use natural colonization, seeding or transplantation to accomplish vegetation coverage. Depending on the time of year when the project construction is complete or the time required for substrate settlement, planting or seeding may need to occur at a future time. When seeding or transplantation occurs, the project proponent may provide a description or design drawing of post-planting or seeding, indicating the species, quantity, and photographs of the operation.

The project proponent must provide documentation of the vegetation establishment activities to demonstrate that the activities result in the accumulation or maintenance of soil carbon stock.

When the activity includes the establishment of woody vegetation, ARR+RWE requirements and methods apply to the project. Such ARR+RWE establishment activities must not include nitrogen fertilization, active peatland drainage, or lowering of the water table depth (eg, draining or construction of channels in order to harvest). Projects with an ARR+RWE component must not include commercial harvest of woody biomass; the extent of ARR requirements is limited to vegetation establishment with no management as reflected by applicability condition 6 in Section 4.

Monitoring Requirements: Vegetation Establishment
The monitoring report must include the following whenever vegetation is established: **MRR.5** A description of the quantity, species, date and location of vegetation establishment, and photographs of the operation. **MRR.6** Aerial image of the project area indicating where species were established.

2.2 Application Overview

If the project meets the applicability conditions of this methodology (see Section 4), the project proponent must follow five steps to ensure that the design of the project activities and monitoring methods meet the requirements of this methodology. Upon completion of the final step, emissions reductions and/or removals are quantified.

2.2.1 Step One: Define the Project

The first step is to identify the boundary of the project area in accordance with Section 5, following the current VCS requirements for RWE project activities. Selecting GHG sources may require an *ex-ante* analysis of expected emissions reductions and/or removals from project activities to determine *de minimis* sources (see Section 8.4.3). The project area is the location where project activities will be implemented, defined in Section 5.3.

2.2.2 Step Two: Characterize Baseline

In this step, the project proponent uses Section 6 to demonstrate that the project area would have remained as open water (see applicability condition 3) and whether dredging would have occurred in the baseline scenario. It is possible that dredging would not have occurred in the baseline scenario, which is allowed by this methodology. In the case where dredging would have occurred in the baseline scenario, emissions from energy consumption must be quantified (see Section 8.1.1).

2.2.3 Step Three: Plan Project and Monitoring Activities

Project activities must adhere to the requirements established in Section 2.1. Monitoring activities must be designed in accordance with Section 9 and are documented in a monitoring plan. Methods for monitoring are described in Appendices A, B, C, D and E. The use of any different methods must be justified by the project proponent as a methodology deviation, in accordance with the VCS rules.

The project proponent determines which sources are *de minimis*, if any, prior to validation (see Sections 8.4.3.1 and 8.4.3.2).

2.2.4 Step Four: Implement Project Activities

The project must be implemented in accordance with the validated project description. If the project is a grouped project, project activities may be implemented as separate project activity instances rather than as a single project activity instance (see Section 9.5).

2.2.5 Step Five: Monitor and Report

During and after the implementation of project activities, the project proponent must use the monitoring plan as the basis for determining emissions reductions and/or removals (see Section 9). For carbon stocks, all plots must be measured prior to the first verification event. The data from monitoring are used in Section 8.

For grouped projects, there are additional monitoring requirements (see Section 9.5). New project activity instances may require modifications to the monitoring plan.

2.3 Notation

The notation used in this methodology is meant to communicate the variables and mathematical processes used to quantify carbon stock, gas fluxes, and greenhouse gas emission reductions over time.

2.3.1 Equations

Equations in this methodology are bracketed (eg, [G.1] in-text) and the full equations are located in Appendix G. Equations in Appendix G contain additional information including citations, literature sources and comments.

At times, similar operations are performed in multiple places on different variables. Rather than repeating nearly identical equations, a single, generic equation with the placeholder x or y is given. To estimate each pool or GHG source, the relevant variable or equation may be substituted for x as indicated within the methodology.

2.3.2 Variables

Variables in this methodology and their units are enumerated in the list of variables in Appendix J. For most of these variables, their units are in tonnes of carbon dioxide equivalents. The variables x and y (with and without subscripts) are sometimes used as placeholder variables — they may stand in for another variable or the results of an equation as indicated by the methodology text.

2.3.2.1 Variable, Subscript and Superscript Designations

Some variables are noted with special designations that allow the reader to immediately identify important information about the variable. The absence of designations also implies information about the variable.

The types of designations are given in Table 1, with examples of the use of these designations given in Section 2.2.3.2. Designations are only provided for variables in Sections 8 and 9.

Table 1: Variable designations and designation descriptions

Designation	Description
Quantity	The type of quantity that the variable represents (see Sections 2.3.6, 2.3.9, 2.3.10, 2.3.11, 2.3.12 and 2.3.15).
Accounting Level	The type of accounting level implies that the variable is part of monitoring.
Change	If the Δ symbol is designated, then the quantity represents a change over a monitoring period rather than cumulative since the project start date. The absence of a change designation implies that the quantity is cumulative since the project start date or that the quantity is part of monitoring which may not be cumulative or over the monitoring period.
Source	The type of source is specified as an acronym in Section 3.1. The absence of source implies that the variable is part of monitoring or that the variable is from multiple sources.
Period	The reference to a monitoring period (see Section 2.3.7).
Index	The reference to a unit.

2.3.2.2 Designation Examples

Tables 2, 3, 4, 5 and 6 provide example variables with designations and designation descriptions.

Table 2: Example variables with designations and designation descriptions

$E_{B\,\Delta\,EC}^{[m]}$		
Component	Designation	Description
E	Quantity	This indicates an emission or an emission reduction and/or removal (see Section 2.3.14). Uppercase means the unit is a total for the project area.
B	Accounting Level	Indicates the emission or an emission reduction and/or removal occurred in the baseline scenario (see definition for P).
Δ	Change	The emission or emission reduction and/or removal is for a period of time.
EC	Source	The emission or emission reduction and/or removal is from energy consumption.
$[m]$	Period	This emission or emission reduction and/or removal is from the monitoring period.

Table 3: Example variables with designations and designation descriptions

$F_{P\,\Delta\,CH4}^{[m-1]}$		
Component	Designation	Description
F	Quantity	This indicates a flux (see Section 2.3.11). Uppercase means the unit is a total for the project area.
P	Accounting Level	Indicates the flux is as a result of the project.
Δ	Change	The flux is for a period of time.
$CH4$	Source	The flux is for methane.
$[m-1]$	Period	This flux is for the prior monitoring period.

Table 4: Example variables with designations and designation descriptions*

$E_{GER\,\Delta}^{[m=1]}$		
Component	Designation	Description
E	Quantity	This indicates an emission or an emission reduction and/or removal (see Section 2.3.14). Uppercase means the unit is a total for the project area.
GER	Accounting Level	The emission or an emission reduction and/or removal constitutes the Gross Emission Reductions (see definition for GERs).
Δ	Change	The emission or emission reduction and/or removal is for a period of time.
$[m=1]$	Period	The emission or emission reduction and/or removal is for the first monitoring period.

*Note that the absence of a P, B or L in the example given in Table 4 above indicates the emission or emission reduction and/or removal is not specific to the project, baseline or leakage.

Table 5: Example variables with designations and designation descriptions*

$E_{NER}^{[m]}$		
Component	Designation	Description
E	Quantity	This indicates an emission or emission reduction and/or removal (see Section 2.3.14). Uppercase means the unit is a total for the project area.
NER	Accounting Level	The emission or emission reduction and/or removal is constitutes the Net Emission Reductions (see definition for NERs).
$[m]$	Period	This emission or emission reduction and/or removal is for the monitoring period.

*Note that the absence of a P, B or L indicates the emission or emission reduction and/or removal is not specific to the project, baseline or leakage. The absence of a Δ indicates the emission or emission reduction and/or removal is not over a period of time, but rather cumulative since the project start date.

Table 6: Example variables with designations and designation descriptions*

$g_{B\,(ty)}^{[m]}$		
Component	Designation	Description
g	Quantity	This indicates a unit of energy (see Section 2.3.12). Lower-case means the unit is per metric tonne of sediment.
B	Accounting Level	Indicates the unit of energy would have resulted in the baseline (see definition for P)
(ty)	Index	The unit of energy is for type ty. The parentheses indicate that ty is an index rather than a designation (such as *P* for project scenario).
$[m]$	Period	This unit of energy is for the monitoring period.

*Note that the absence of a Δ indicates the unit of energy is not over a period of time, but rather cumulative since the project start date.

2.3.3 Summations

Summations use set notation. Sets of variables are indicated using script notation, which reduces the number of variables used as well as the complexity of summations.

2.3.4 Standard Deviations and Variances

Standard deviation is indicated by the σ symbol, with subscripts used to indicate the quantity for which it is estimated. Variance is indicated by the σ^2 symbol and is the square of standard deviation. Standard deviations may not necessarily be in units of tCO_2e.

2.3.5 Standard Errors

Estimated standard error is indicated by the U symbol, with additional subscripts used to indicate the quantity for which the uncertainty is estimated. Standard errors are always in units of tCO_2e.

2.3.6 Theoretical Parameters and Parameterized Models

Parameters to model are denoted by variables, such as the surface friction velocity parameter u_*. When such parameters have a "hat" on them – such as the parameter $\hat{p}_{B\ (ty)}$– they refer to an estimated value rather than a known quantity.

2.3.7 Monitoring Periods

Monitoring periods are notated using bracketed superscripts $[m]$. The first monitoring period is denoted by $[m = 1]$, the second monitoring period $[m = 2]$, and so forth. These superscripts should not be confused with references to equations numbers, as equation numbers are never in superscript. Also see the definition for monitoring period. A verification event is the reporting and verification of NERs claimed for a monitoring period. A monitoring period that is $[m = 0]$ denotes "prior to the project start date."

2.3.8 Baseline, Project and Leakage Estimates

Estimates related to baseline, project and leakage emissions reductions and/or removals and carbon stocks are specifically denoted with B, P and L in the subscripts of variables, respectively.

2.3.9 Averages for Stocks

Average carbon (measured in tCO_2e/ha) to which accounting is applied is denoted by a lower-case c, with subscripts to differentiate between carbon pools as indicated in the list of variables. For example, $c_{P\ SOC}^{[m]}$ indicates the average carbon stock in soil organic carbon in the project area in monitoring period $[m]$. Subscripts from carbon pools are acronyms listed in Section 3.1.

2.3.10 Totals for Stocks

Total carbon (measured by tCO_2e) to which accounting is applied is denoted by a capital C, with subscripts to differentiate between carbon pools as indicated in the list of variables. Subscripts from carbon pools are acronyms listed in Section 3.1.

2.3.11 Fluxes for Methane and Nitrous Oxide

Fluxes are expressed in units of tCO_2e per day by the variable F with subscripts to differentiate between GHG sources as indicated in the list of variables. Fluxes always contain a Δ in the subscript when the flux emissions are over the monitoring period. For example, $F^{[m]}_{P\,\Delta\,CH4}$ indicates the methane flux in the project area in monitoring period $[m]$. Subscripts from GHG sources are acronyms listed in Section 3.1. Some equations in Appendices B and C use a lower-case f, signifying that the units are tCO_2e per acre per day. It is important to note that although the units for fluxes are in tCO_2e per day, this does not imply that monitored fluxes have a daily resolution. Monitoring may be periodic or seasonal, as per Section 9.2.2.4.1.

2.3.12 Units of Energy or Fuel

Energy or fuel consumption is expressed as a total or per different units as specified in Table 10, denoted by a capital G for a total and a lower-case g per unit (which may be metric tonne of sediment). For example, $G^{[m]}_{P\,\Delta\,FC\,(ty)}$ indicates the total project energy consumption for energy type (ty) during monitoring period $[m]$.

2.3.13 Masses of Sediment

Sediment transport is used to estimate energy consumption in Section 8.1.1, denoted over a monitoring period as a total with an uppercase M. For example, $M^{[m]}_{P\,\Delta}$ indicates the total sediment transport as a result of project activities during monitoring period $[m]$. Masses of sediment are always quantified as metric tonnes.

2.3.14 Emissions Reductions and/or Removals

Total emissions reductions and/or removals (measured as tCO_2e) from accounting are denoted by a capital E, with subscripts to differentiate between carbon pools as indicated in the list of variables. For example, $E^{[m]}_{P\,\Delta}$ indicates the project emissions reductions and/or removals during monitoring period $[m]$. Subscripts from carbon pools and GHG sources are acronyms listed in Section 3.1.

Emissions are represented by negative E values, while emissions removals are represented by positive E values.

2.3.15 Quantified Uncertainties

Uncertainties in major carbon pools or fluxes are expressed as standard error of a total (measured by tCO_2e or tCO_2e/day, respectively) and are denoted using a capital letter U. For example, $U^{[m]}_{P\,\Delta\,CS}$ is used to indicate the uncertainty in estimated carbon stocks at monitoring period $[m]$. Because this methodology's gas flux measurement methods (described in Appendix B and Appendix C) are inherently conservative, no uncertainty is calculated for methane and nitrous oxide gas fluxes. Thus, uncertainties are calculated for carbon stock estimates only.

2.4 Documentation Requirements

2.4.1 Project Description Requirements

To ensure the project meets the requirements set out in the methodology, this methodology includes Project Description Requirements (PDRs). The project proponent must provide evidence and documentation for each PDR. PDRs are listed in each section of this methodology and in Appendix K.

Project proponents must note that in addition to the PDRs set out in this methodology, the project must adhere to all VCS rules when applying this methodology (ie, the PDRs cover all the requirements of the methodology, but they do not necessarily cover each and every VCS requirement relevant to the project).

2.4.2 Monitoring Report Requirements

To ensure the project's compliance with the methodology, this methodology includes Monitoring Report Requirements (MRRs). The project proponent must provide evidence and documentation for each MRR. MRRs are listed in each section of this methodology and in Appendix L.

2.5 Units versus Resolution of Emissions Reductions and/or Removals Accounting

The methodology accounts for emission reductions and/or removals using daily units in Section 8. Accounting is specified by day to facilitate intra-annual monitoring events and the verification of monitoring periods that may span more or less than exactly a single year.

Although emissions reductions and/or removals are calculated on a daily basis, they may not be measured or monitored on a daily basis. The requirements in Section 9 and in Appendices B, C, D and E specify that measurements are taken periodically throughout the monitoring period, and the duration or interval of those measurements does not need to be daily.

3 DEFINITIONS

In addition to the definitions set out in VCS document *Program Definitions*, the following definitions apply to this methodology:

Accretion Depth
Vertical measurement of accumulated soil material from $t^{[m-1]}$ to $t^{[m]}$

Baseline Emissions
For any monitoring period, baseline emissions $E_{B\,\Delta}^{[m]}$ are a sum of estimated emissions over selected carbon pools during the time between two verification events

Baseline Reevaluation
Revision of the baseline scenario which occurs every 10 years

Buffer Release
A periodic release of buffer credits from the AFOLU pooled buffer account

Chamber Sampling Type
A type of temporal sample using static chambers that is either peak, seasonal, or monthly (see Section 9.2.2.4.1)

Coarse Root
A root greater than or equal to 2 mm in diameter

Covariate
A variable possibly predictive of the outcome under study. Synonymous with the term *proxy*, as defined in VCS document *Program Definitions*

de minimis
Considered a negligible source of emissions (<5% of total GHG benefit generated by the project) and therefore not accounted for (see Section 8.4.3)

Degraded Wetland
Area that previously met the definition of a wetland, but now no longer meets that definition due to disruptions in normal hydrological and ecological processes and linkages (ie, the wetland converted to open water, or similar degraded state, in response to impaired sediment supply, sea level rise, impaired water quality, or similar reason). A degraded wetland may include areas of open water.

Direct Measurement
A method used to quantify energy consumption by measuring the volume of fuel consumed (see Section 9.2.4.1)

Dredging
The removal or excavation of bottom sediments from an aquatic environment for the creation or maintenance of waterways

Ebullition
The sudden release to the atmosphere of bubbles of gas (usually methane) from submerged sediment

Eddy Covariance Sampling Type
A type of temporal sample using eddy covariance that is either peak periodic, peak cumulative, seasonal, or monthly (see Section 9.2.2.4.2)

Eddy Covariance
A micrometeorological technique to estimate flux of heat, water, atmospheric trace gases and pollutants that relies on turbulence to calculate fluxes

Energy Type
A type of energy listed in Table 10

Estuarine
A tidal water body or wetland with mixing of fresh and (ocean-derived) salt water, where salinity is greater than or equal to 0.5 ppt (parts per thousand) during the period of average annual low flow

Fixed Soil Sample Depth
At the time of project validation, a fixed depth for soil sampling of the original project soil is defined by the project proponent, which cannot exceed 100 cm. The only time when the fixed sample depth may be exceeded is when accretion depth is measured from $t^{[m-1]}$ to $t^{[m]}$. For any monitoring event, a total sample depth (for carbon stock) cannot exceed the pre-defined fixed soil sample depth and the accretion depth from the current and previous monitoring event.

Flux
A flow of gas into the atmosphere expressed as a rate of mass per unit time and area (accounted for in terms of tCO_2e/ac/day)

Gross GHG Emission Reductions and Removals (GERs)
Tonnes of carbon dioxide equivalent (tCO_2e) emissions that are reduced or removed from the atmosphere due to project activities, given as the difference between baseline and project emissions or emissions reductions and/or removals, minus emissions from leakage (see Sections 8.1, 8.2 and 8.3)

Herbaceous Marsh
Wetland that is periodically flooded and generally characterized by a growth of grasses, sedges, cattails and rushes

Hydrologically Connected Areas
Two or more areas which may share matter, energy, and organisms as a result of water movement

Monitoring Period
An interval of time following the project start date and designated for systematically verifying project claims of GHG emissions reductions and/or removals. Specifically, an interval of time from $t^{[m-1]}$ to $t^{[m]}$ where $t^{[m-1]} \geq 0$ (the project crediting period start date) and $t^{[m-1]} < t^{[m]}$. The length of the monitoring period is $t^{[m]} - t^{[m-1]}$ where m denotes the number of any single monitoring period and t the number of days after the project crediting period start date that is the end of the monitoring period. A monitoring period that is $[m = 0]$ denotes "prior to the project start date."

Net GHG Emission Reductions and/or Removals (NERs)
Tonnes of carbon dioxide equivalent (tCO_2e) emissions that are reduced or removed from the atmosphere due to project activities, given as GERs adjusted for certain deductions and additions (see Sections 8.4.1, 8.4.2.1 and 8.4.2.3)

Non-Tree
Vegetation such as shrubs, grasses, sedges and other herbaceous plants which does not meet the definition of a tree

Open Water
Water with 90% of its area having a depth that does not support emergent vegetation, and no more than 10% sparse vegetation. Water with dense vegetation is not considered open water.

Original Project Soil
Soil resulting from the emplacement of sediments at the project start date

Permanent Plot
A plot with fixed area and location used to repeatedly measure change in carbon stocks over time

Programmatic Dredging Project
Routine, ongoing dredging often associated with maintaining navigability

Project Area
The geographic area controlled by the project proponent where project activities are implemented

Project Emissions or Emissions Reductions and/or Removals
Project emissions or emissions reductions and/or removals for any monitoring period $[m]$ as estimated by the events of accretion, flux and energy consumption

Project Performance
A comparison of ex-post credit generation to ex-ante estimates over time

Reference Area
An area delineated by the project proponent used to estimate emissions from methane ebullition in the baseline

Sampling Period
The period of months for static chamber or eddy covariance measurement of methane flux corresponding to a sample type (see Section 9.2.2.4.2)

Single Event Dredging Project
A dredging event associated with a discrete planned project

Soil
Unconsolidated mineral or organic material on the immediate surface of the Earth that serves as a natural medium for the growth of land plants

Soil Organic Matter
The organic matter that may be found in soil, not including coarse roots

Substrate Establishment
Adding sediment to an area devoid of sediment, or to add sediment in an open water system to raise the land elevation such that emergent plants can colonize

Tree
A perennial plant containing secondary wood and that is at least three meters tall at maturity

Tidal
A water body or wetland exposed to vertical water level fluctuations corresponding to lunar-solar gravitational cycles. The area may have freshwater or saltwater characteristics (eg, freshwater riverine and lacustrine systems may experience tidal influence without ocean-derived salts).

Vegetation Establishment
The process of seeding or transplanting vegetation to the soil, or providing adequate conditions for natural plant colonization

Verification Event
The reporting and verification of NERs claimed for a monitoring period

Water Impoundment
A body of water created or stored by impoundment structures, such as dams, dikes and levees

Water Table
The surface where water pressure in the soil is equal to the atmospheric pressure

3.1 Acronyms

AG	Above ground
AGNT	Above ground non-tree
AGT	Above ground tree
ARR	Afforestation, reforestation, and revegetation
AS	Activity-shifting
B	Baseline scenario
BA	AFOLU pooled buffer account

BG	Below ground
BGNT	Below ground non-tree
BGT	Below ground tree
BR	Buffer release
CF	Carbon fraction
CH_4	Methane
CO_2	Carbon dioxide
CO_2e	Carbon dioxide equivalent
CS	Carbon stock
CWA	Clean Water Act
EC	Energy consumption
GERs	Gross GHG Emissions Reductions and/or Removals
GHG	Greenhouse gas
GIS	Geographic Information System
GPS	Global Positioning System
L	Leakage
LQD	Liquid
ME	Market-effects
MRR	Monitoring Report Requirement
NERs	Net GHG Emission Reductions and/or Removals
NOAA	National Oceanic and Atmospheric Administration
NPDES	National Pollutant Discharge Elimination System
N_2O	Nitrous oxide
P	Project scenario
PAI	Project Activity Instance
PAIA	Project Activity Instance Area
PD	Project Description
PDR	Project Description requirement
PM	Proxy method for energy consumption
SE	Standard error

SLD	Solid
SPC	Species
U	Uncertainty
USACE	U.S. Army Corps of Engineers
USEPA	U.S. Environmental Protection Agency
USFWS	U.S. Fish and Wildlife Service
VCS	Verified Carbon Standard
VCUs	Verified Carbon Units
VVB	Validation/Verification Body
WR	Wetland restoration

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that create tidal or estuarine wetlands through substrate establishment and/or vegetation establishment.

This methodology is applicable under the following conditions:

1. Project activities must include activities intended to create new wetlands in coastal ecosystems through substrate establishment, vegetation establishment, or both.
2. Project activities must not actively lower the water table depth.
3. The project area must meet the definitions of tidal or estuarine, open water, and degraded wetland before project activities are implemented and would have remained open water in the absence of the project activities (see Section 6.1).
4. The project area must be entirely within tidal or estuarine areas within the coastal zone boundary,[1] and must meet the definition of Waters of the United States,[2] excluding the Great Lakes.[3]

[1] Areas within the coastal zone boundary, as defined by each state of the US. Refer to NOAA's Ocean and Coastal Resource websites or individual coastal zone management maps: http://coastalmanagement.noaa.gov/mystate/welcome.html and http://coastalmanagement.noaa.gov/mystate/docs/StateCZBoundaries.pdf.

[2] For definition of Waters of the United States, refer to: http://www.epa.gov/region6/6en/w/watersus.htm.

[3] Great Lakes: The geographic scope does not include portions of Minnesota, Wisconsin, Michigan, Illinois, Indiana, Ohio, Pennsylvania and New York which are hydrologically connected to the Great Lakes.

6 When ARR+RWE project activities are implemented and include the establishment of woody vegetation, there must not be commercial harvest activities, nitrogen fertilization or active peatland drainage (see Section 2.1.2).

7 The project proponent must have obtained the necessary permits to demonstrate that the project will not have a significant negative impact on hydrologically connected areas (see Section 8.3.3). This applicability condition must be satisfied at validation or at the first verification event.

PD Requirements: Applicability Conditions
The project description must include the following: **PDR.1** For each applicability condition, credible evidence in the form of analysis, documentation or third-party reports to satisfy the condition.

5 PROJECT BOUNDARY

5.1 Selecting GHG Sources

The greenhouse gases included in, and excluded from, the project boundary are set out in Table 7 below.

Table 7: GHG sources

	Source	Gas	Included?	Justification/Explanation	Affected by Project?
Baseline	Dredging, transport and re-handling for navigability or maintenance	CO_2	Yes	Emitted by fuel combustion regardless of fuel type.	No
		CH_4	Yes		
		N_2O	Yes		
		Other	None		
	Methane ebullition	CO_2	No	Methane bubbling may occur in open water; the quantity thereof may be included and monitored if desired.	No
		CH_4	Optional		
		N_2O	No		
		Other	None		
Project	Dredging, transport and placement for project activities	CO_2	Yes	Emitted by fuel combustion regardless of fuel type.	Yes
		CH_4	Yes		
		N_2O	Yes		
		Other	None		
	Habitat regeneration	CO_2	Yes	Major pool considered.	Yes
		CH_4	Yes	Wetland creation may result in an increase in CH_4 emissions in comparison to the open water baseline scenario.	
		N_2O	Yes, if significant	Wetland creation may result in an increase in N_2O emissions in comparison to the open water baseline scenario.	
		Other	None		

PD Requirements: GHG Sources
The project description must include the following: **PDR.2** A list of the included and excluded GHG sources.

5.2 Selecting Carbon Pools

The carbon pools included in or excluded from the project boundary are shown in Table 8 below.

Table 8: Carbon pools

Pool	Included?	Relevant to:	Justification/Comments
Above ground tree biomass	Included	Project	Major carbon pool required by VCS *AFOLU Requirements*.
Above ground non tree biomass	Optional	Project	May be conservatively excluded.
Below ground biomass	Optional	Project	May be conservatively excluded, but recommended when applicable root-shoot ratios are available. Only applicable in forested or woody habitats, not herbaceous ones.
Litter	Excluded	-	Conservatively excluded.
Dead wood	Excluded	-	Conservatively excluded.
Soil organic carbon	Included	Project	Major carbon pool expected to increase due to project activities.
Wood products	Excluded	-	Conservatively excluded. Not expected to be a significant pool.

Optional pools may always be conservatively excluded. The baseline scenario allows for up to 10% vegetation cover (see definition of open water in Section 3), but it is conservative to exclude the CO_2 emissions that occur from the likely loss of wetlands, CH_4 emissions from ongoing biogeochemical activity in the remaining vegetation or methane ebullition that would be expected to occur in the baseline scenario. The set of selected carbon pools is denoted by $\mathcal{C}$.

PD Requirements: Carbon Pools
The project description must include the following: **PDR.3** A list of the selected and excluded carbon pools.

5.2.1 Allochthonous Carbon in Soil Organic Carbon Pool

Autochthonous carbon sequestration, resulting from the growth of vegetation in the project area, must be estimated separately from allochthonous carbon, where there is reasonable evidence that the mass of carbon that is imported to the site exceeds that which is exported. The fate of transported organic matter must be conservatively assessed, where relevant. The opposite condition also may exist, where the mass of exported carbon from the growth of vegetation as a result of project activities is greater than the mass of carbon that would be washed out to sea under baseline conditions.

5.2.1.1 Criteria for Projects Located Within Louisiana

For projects located within Louisiana, and not within the direct influence of a river diversion or river mouth, project proponents are not required to account for allochthonous carbon import because such import has been demonstrated to be negligible (see Appendix I).

Where river diversions are implemented to enhance growth and maintenance of created wetlands, and where such river diversions are designed to import substantial quantities of mineral-associated carbon, the project proponent must justify the exclusion of allochthonous carbon using the criteria listed in Section 5.2.1.2, or must quantify the carbon import per the procedures described in Section 9.2.6.

Where there exists an artificial water impoundment which affects the hydrological regime of the project area, the project proponent must justify the exclusion of allochthonous carbon using the criteria listed in Section 5.2.1.2, or must quantify the carbon import per the procedures described in Section 9.2.6.

5.2.1.2 Criteria for Projects Located Outside Louisiana

For projects located outside Louisiana, the project proponent may conservatively exclude allochthonous carbon by using publicly available regional case studies, peer-reviewed literature or regional models to justify that the import of organic matter will not cause carbon accretion estimates to be significantly overestimated. The justification and evidence must be commensurate with the justification provided in Appendix I for projects located within Louisiana. The justification must include the following evidence which must be applicable to the geomorphology of the project area:

- Description of the dominant sources of sediments with respect to external (ie, fluvial) inputs or internal (within estuary or tidal freshwater wetland) recycling.
- Proximity of the project area with respect to direct fluvial inputs or near-shore sediment sources.
- An annual mass estimate of the total carbon imported or exported from the estuary or tidal freshwater wetland where the project area is located.
- Description of the project area/region with respect to tidal energy (such as flood- or ebb-dominated) or tidal dispersive flux. Under ebb-dominated conditions, ‘outwelling’ or transfer of carbon from the tidal wetland to the ocean would be reasonably expected.

If the project proponent cannot demonstrate that allochthonous carbon sedimentation in the project area can be conservatively excluded, monitoring of allochthonous carbon must follow the methods in Section 9.2.6, where marker horizons are used to differentiate between carbon accreted in the project area as a result of project activities and allochthonous carbon imported into the project area.

PD Requirements: Allochthonous Carbon in Soil Organic Carbon Pool
For projects located outside Louisiana, the project description must include the following in order to demonstrate that allochthonous carbon import can be conservatively ignored: **PDR.4** Narrative justification that the import of organic matter will not cause carbon accretion estimates to be significantly overestimated including citations to case studies, literature or models. **PDR.5** Description of the dominant sources of sediments with respect to external (ie, fluvial) inputs or internal (within estuary or tidal freshwater wetland) recycling. **PDR.6** Proximity of the project area with respect to direct fluvial inputs or near-shore sediment sources. **PDR.7** An annual mass estimate of the total carbon imported or exported from the estuary or tidal freshwater wetland where the project is located. **PDR.8** Description of the project area with respect to tidal energy (such as flood- or ebb-dominated) or tidal dispersive flux.

5.3 Delineating Spatial Boundaries of Project Area

The spatial boundaries of the project must be delineated using GIS techniques. The project area may consist of multiple project activity instances. That is, the project area need not be spatially contiguous and may comprise one parcel or multiple adjacent or non-adjacent parcels. The project proponent must demonstrate control of the project area as described in the most recent version of the VCS *AFOLU Requirements*.

At the project start date, the entire project area must meet the definition of open water (see Section 3 for definition). The project proponent also must demonstrate that the project area meets the definition of tidal or estuarine open water wetlands which once supported emergent wetland vegetation – such as freshwater or saltwater herbaceous marsh, scrub-shrub or forest (eg, mangrove, cypress-tupelo swamp) – but which are degraded (prior to the implementation of project activities) to a flooded or subtidal condition. In order to demonstrate that the project area is located in a tidal or estuarine system, the project proponent must provide one of the following:

- Federal or state agency supporting documentation describing the project's tidal or salinity designation. For example, the National Wetland Inventory *Wetlands Mapper* provides both tidal and salinity descriptors or modifiers for the coastal areas of the United States, or

- Peer-reviewed literature showing the proximity of the project area to study areas and the evidence of tidal influence or presence of salinity greater than 0.5 ppt (parts per thousand), or
- The location of the tide gage adjacent to the project area and data which show either a discernible diurnal, semi-diurnal or mixed-tide signal; salinity greater than 0.5 ppt (parts per thousand) during the year; or evidence of a tidal datum designation (MLLW, MSL, MHHW, etc.).

Further, the project proponent must demonstrate compliance with the most current version of the VCS *AFOLU Requirements* regarding the clearing of native ecosystems.

Additionally, the project proponent must assess the hydrological connectivity of the project area to surrounding areas using the procedures described in Section 8.3.1 and demonstrate that there are no negative impacts to hydrologically connected areas and that any adjacent hydrologically connected areas are not likely to affect the GHG emissions of the project area.

Sea level rise may affect the project area by converting wetlands into shallow open water if the rate of sea level rise exceeds the rate of soil elevation gain. Because the project boundaries are fixed throughout the lifetime of the project, any lateral movement of wetlands in the project area caused by sea level rise is inherently captured by monitoring activities (see Section 9). However, given the significant potential impact of sea level rise on constructed wetlands in the coastal zone, the proponent must demonstrate that the project's spatial boundaries and wetland establishment activities have taken into account projections of future sea level rise. In particular, the project proponent must review current technical scientific literature relevant to the area (considering sources such as the most recent IPCC assessment report and peer-reviewed literature), document expected sea level rise in the vicinity of the project area, and demonstrate that wetland construction activities have been designed to withstand expected sea level rise.

In addition, the project description must include the following:

- A description of the existing natural or constructed measures for ensuring resilience to sea level rise (eg, how existing landforms or constructed features offer physical protection of the project area).
- A description of the post-construction soil surface elevation relative to mean sea level, taking into account estimated accretion, subsidence and sea level rise parameters within the project area.

After project activities commence, it is possible that one or more tidal channels will develop within the project area. Such areas must remain part of the project area and must not be excluded.

PD Requirements: Delineating Spatial Boundaries
The project description must include the following: **PDR.9** GIS-based maps of the project area with, at a minimum, the features listed in Section 5.3 above. **PDR.10** Documentation that the entire project area is/was open water at the project start date. **PDR.11** Evidence that the project area meets the definition of tidal or estuarine open water wetlands which once supported emergent wetland vegetation. **PDR.12** Evidence that the project area is compliant with the most current version of the VCS *AFOLU Requirements* regarding the clearing of native ecosystems. **PDR.13** If methane emissions are included in the baseline scenario, an estimate of the average water depth in the project area prior to the implementation of project activities (see Section 6.3). **PDR.14** Documentation that the project proponent has control over the project area, in accordance with the most recent version of the VCS *AFOLU Requirements*. **PDR.15** Documentation of the assessment of effects to hydrologically connected areas as further described in Section 8.3.1. **PDR.16** Documentation of projected sea level rise in the vicinity of the project area, evidence that existing landforms or constructed features are expected to withstand project sea level rise, and a description of the post-construction soil surface elevation relative to mean sea level.

5.4 Defining Temporal Project Boundaries

Temporal project boundaries define the period of time when the project area was under the control of the project proponent and are used to determine the dates at which project activities, monitoring activities, and baseline reevaluation must occur. The following temporal project boundaries must be defined:

- The project start date.
- The length of the project crediting period.
- The dates and periodicity of baseline reevaluation and monitoring periods. A baseline reevaluation after the project start date and monitoring must conform to the VCS rules.

Within six months of the project crediting period start date and prior to the first verification event, the monitoring equipment must be installed per Sections 9.2.1.1 and 9.2.2.4. Upon the project start date, records of energy consumption must be maintained per the requirements of Section 9.2.4.

For the project duration, the project proponent must reevaluate the baseline in accordance with the VCS rules (see Section 6.4).

The project proponent must document the planned duration of monitoring periods and corresponding frequency of verification events.

PD Requirements: Temporal Project Boundaries
The project description must include the following: **PDR.17** The project start date. **PDR.18** The project crediting period start date and length. **PDR.19** The date by which mandatory baseline reassessment must occur after the project start date. **PDR.20** A timeline including the first anticipated monitoring period showing when project activities will be implemented. **PDR.21** A timeline for anticipated subsequent monitoring periods.

Monitoring Requirements: Temporal Project Boundaries
The monitoring report must include the following: **MRR.7** The project start date. **MRR.8** The project crediting period start date and length. **MRR.9** Evidence of the start of monitoring per the frequency requirements described in Sections 5.4, 9.2.1.1, 9.2.2.4, and 9.2.3.4.

5.5 Grouped Projects

In addition to the requirements for grouped projects set out in the *VCS Standard*, the project proponent must establish criteria at the time of project validation that include the following:

- Landscape configuration: All project activity instances must be similar with respect to biogeochemical processes, which are affected principally by such factors as vegetation type, salinity, and presence or absence of external nitrate loading.
- Monitoring methods: In order to facilitate the consistent accounting of all project activity instances within a single project, all project activity instances must employ the same methods to monitor emissions reductions and removals (eg, direct measurement, models from literature, or proxy model) for each included GHG source. Similarly, all project activity instances must employ the same modeling assumptions and sampling protocols for the selected monitoring methods.

Additional monitoring requirements must also be followed for grouped projects, per Section 9.5.

The set of all project activity instances is denoted by $\mathcal{G}$.

PD Requirements: Grouped Projects
If grouped projects are developed, the project description must include the following, as per the requirements set out in the *VCS Standard*: **PDR.22** A list and descriptions of all enrolled project activity instances in the group at the time of validation. **PDR.23** A map of the designated geographic area within which all project activity instances in the group may be located, indicating that all instances are in the same region. **PDR.24** A list of eligibility criteria for project activity instances.

Monitoring Requirements: Grouped Projects
If grouped projects are developed, the monitoring report must include the following, as per the requirements set out in the *VCS Standard*: **MRR.10** A list and description of all project activity instances in the project. **MRR.11** A map of the boundaries of all project activity instances in the project demonstrating that all instances are in the designated geographic region.

6 PROCEDURE FOR DETERMINING THE BASELINE SCENARIO

6.1 Demonstrating the Most Plausible Baseline Scenario

The project proponent must consider a range of alternative land uses when determining the baseline scenario for both RWE and ARR+RWE projects. Possible baseline scenarios may include a continuation of open water, additional wetland loss in accordance with long-term trends, natural reestablishment of the wetland or alternative wetland reestablishment activities not associated with carbon finance. The project description must include a comparative assessment of the implementation barriers and net benefits faced by the project and its alternatives.

As per the applicability conditions, this methodology is only applicable where the following baseline scenario is identified:

> The project area must meet the definitions of tidal or estuarine, open water, and degraded wetland before project activities are implemented and would have remained open water in the absence of the project activities.

The project proponent must use one of the analysis methods described in Section 6.1.1 or 6.1.2 to demonstrate the baseline scenario.

To demonstrate that this applicability condition has been met, it is recommended that the project proponent acquire data from USGS data sets (ie, Couvillion 2012) or the U.S. Fish & Wildlife Service's National Wetlands Inventory to show that the project area historically met the definition of a wetland and thus the definition of degraded wetland. If the applicability condition is met as required under the methodology, the only possible baseline scenario is open water. To support the chosen analysis method, the project proponent also must provide evidence of long-term water level changes in the project area with minimum record length of 20 years of hydrological data (eg, water table, water level, sea level). The evidence must demonstrate the long-term nature of the documented pattern of wetland loss.

The project proponent must also demonstrate that wetland creation is unlikely to occur in the project area based upon historical evidence of land accretion and loss.

PD Requirements: Baseline Scenario
The project description must include the following: **PDR.25** Results of a comparative assessment of the implementation barriers and net benefits faced by the project and its alternatives, and justification for the most plausible baseline scenario. **PDR.26** Documentation to demonstrate that the project area previously met the definition of a wetland before converting to open water. Documentation must include hydrological data to show evidence of long-term patterns of wetland loss. **PDR.27** The selected method for demonstrating the baseline scenario in the project area (regional land use change or spatial analysis).

6.1.1 Using a Published Regional Land Use Change Analysis

The baseline scenario may be demonstrated through documentation regarding land loss rates in the hydrologic basin in which the project area is located. Documentation must be based on Landsat or other satellite or aerial imagery that shows a trend of continued land loss or static condition in the basin for a period of at least 10 years prior to the project start date or the date of baseline reevaluation (see Section 6.4). Examples include the US Geologic Survey publication 'Land Area Change in Coastal Louisiana from 1932 to 2010', or the US Fish & Wildlife Service, National Wetlands Inventory, 'Wetlands Status and Trends' report series. The documentation must be from peer-reviewed literature, government publication or third party publication and must be publicly available.

The project proponent must also identify the boundary of the project area and its proximity to any existing and/or future water management activities (eg, river diversions) which could influence the project area. If water management activities are identified (either existing or planned over the next 10 years), the project proponent must address the potential for land-building based on significant deposition of sediment in the project area in the absence of project activities. An updated figure of water management activities must also be identified in the baseline reassessment.

PD Requirements: Regional Land Use Change for Baseline Scenario
The project description must include the following: **PDR.28** A reference to the document providing evidence of continued land loss or static condition in the basin for a period of 10 years prior to the project start date. **PDR.29** A summary of the referenced document indicating where in the document the evidence is provided. **PDR.30** Documentation of water management activities (eg, river diversions) that could influence the baseline scenario.

6.1.2 Conducting a Spatial Analysis

The baseline scenario may be demonstrated using high-resolution satellite or aerial imagery that demonstrates that the area of open water (ie, non-wetland) has not decreased over time in the region surrounding the project area. Sections 6.1.2.1 and 6.1.2.2 provide guidance on conducting the analysis. For such analysis, the following requirements must be met:

- The analysis must be conducted using data from two points in time (image dates) at least ten years apart, one of which is within two years prior to the project start date or date of baseline reevaluation (see Section 6.4).
- The two image dates must be within the same three-month period of their respective years to prevent seasonal variability.
- The study region must be at least three times the size of the project area.
- The study region must be located in an area near the project area, with similar climatic and edaphic conditions.
- Cloud cover must not exceed 20% of the study region for either image date.
- Accuracy determined by error checking or ground-truthing must be at least 90%.
- The analysis must infer that the area of open water in the study region has not decreased over time via natural processes.

The region of analysis may or may not include the project area.

PD Requirements: Spatial Analysis for Baseline Scenario	
The project description must include the following:	
PDR.31	A report describing how the analysis was conducted, including data sources and dates, demonstration of conformance with the requirements listed in Section 6.1.2, and justification for the selection of the region in which the analysis was conducted.
PDR.32	A map of the region in which the analysis was conducted.
PDR.33	The quantified change in water area.

6.1.2.1 Selecting Image Type

Aerial or satellite imagery must be high-resolution or multispectral in order to accurately delineate wetland vs. open water. Multiple images from each image date may be used to increase cloud-free coverage of the study region. The analysis must consider varying water levels on land areas at the time of the imagery, and the potential impact on interpretation of imagery. Proper pre-processing techniques must be observed, such as geometric and radiometric corrections, cloud and shadow removal and reduction of haze, as needed.

6.1.2.2 Classifying and Post-Processing

Change detection analysis may be used to determine the change in water area over time. Post-processing must include error checking and ground-truthing as needed to ensure accurate land cover assessment. For further information, see the detailed maps included with the US Geologic Survey publication 'Land Area Change in Coastal Louisiana from 1932 to 2010,' as well as Klemas (2011) for a detailed description regarding remote sensing techniques to monitor changes in wetlands.

6.2 Determining Dredging in Baseline Scenario

In the baseline scenario, dredging may or may not occur for navigation or maintenance purposes. Dredging may include hydraulic and mechanical machinery and the methods of sediment removal and disposal may be classified as permanent or temporary (see dredging activities described in Table 9). If dredging is included in the baseline scenario, this must be clearly identified in the project description.

In large rivers or near-shore coastal environments, navigation dredging may include a combination of temporary displacement (thalweg or current disposal) and temporary open water disposal that occurs within the banks of the river or within an embayment. In the case of temporary displacement/disposal, sediments may be re-handled multiple times before permanent removal occurs. The project proponent may account for sediment re-handling. Permanent sediment removal also may occur with dredging, transportation, and disposal at open water sites or confined disposal areas (facilities).

For the baseline scenario, the process of dredging must be described based on a single event (planned project) or routine programmatic dredging. The baseline dredging must contain a description of equipment types, method of dredging/transport/disposal/re-handling, sediment volume, and energy type and energy quantity used. The documentation of dredging activities also must include a description of the likely fate of dredged sediments in the baseline, thus indicating that the sediments would not be used for wetland creation activities in the baseline scenario.

Acceptable documents for describing single event dredging projects or programmatic dredging projects may include but are not limited to a Section 10 permit (River and Harbors Act 1899), Dredge Material Management Plan (USACE) and interagency project documents that provide descriptions or authorization for project-specific or routine operations (eg, Beneficial Use of Dredge Material, BUDMAT).

Table 9: Types of dredging activities and alternative sediment fates (permanent or temporary)

	Sediment Fate	Typical Equipment	Description
Baseline	Temporary displacement	Dustpan dredge; cutterhead suction dredge; mechanical excavator	Sediments are dredged and displaced in the river/nearshore current, subject to subsequent downstream removal from the waterway. The process of temporary sediment displacement is also described as *agitation* or *thalweg disposal*.
	Temporary removal and disposal	Hopper dredge; barge; mechanical excavator	Sediments are dredged, then transported in a confined vessel and disposed of in a temporary area, subject to subsequent downstream removal from the waterway.
	Permanent disposal	Cutterhead suction dredge; hopper dredge; mechanical excavator	Permanent sediment disposal may include confined upland disposal, non-wetland beneficial use, ocean dredge material dump site.

PD Requirements: Determination of Dredging
The project description must include the following: **PDR.34** Statement regarding whether dredging is included in the baseline scenario. **PDR.35** If dredging is included in the baseline scenario, a description of the single event or programmatic dredging projects, including the likely fate of dredged sediments in the baseline scenario.

6.2.1 Determining Navigability of Dredge Site Waterway

The project proponent must demonstrate whether navigation or maintenance dredging would have occurred in the baseline. Acceptable documents for demonstrating dredging would have occurred may include but are not limited to a Section 10 permit (River and Harbors Act 1899) or Dredge Material Management Plan (USACE) or interagency project documents that provide descriptions or authorization for project-specific or routine operations (eg, Beneficial Use of Dredge Material, BUDMAT).

If navigation or maintenance dredging in the baseline cannot be demonstrated, then baseline emissions from energy consumption must be zero per Section 8.1.1.

PD Requirements: Demonstration of Navigability
The project description must include the following if navigation or maintenance dredging can be demonstrated in the baseline scenario: **PDR.36** Map of dredging activities, including justification for planned dredging locations. **PDR.37** Documents that demonstrate dredging would have occurred.

6.2.2 Determining Energy Consumption for Dredging

When dredging occurs in the baseline scenario for navigation or maintenance, the project proponent must estimate the energy types and quantities used for dredging. For each energy type in Table 10, the project proponent must estimate the unit of energy consumed per metric tonne of sediment removed from the sediment source in the baseline scenario. These estimates must be based on private industry or federal cost-engineering procedures or data. These estimates may include energy consumption from dredging, transport, disposal and re-handling of sediment. The assumptions of equipment type(s), sediment production rates, duration of operations, and conveyance distances must be used to justify these estimates.

The project proponent must use conservative assumptions when determining these estimates. In the baseline scenario, low estimates of energy consumption for dredging are more conservative than high estimates.

The set of all energy types in the baseline scenario is denoted $\mathcal{T}_{B\ EC}$ and the unit of energy consumed per metric tonne of sediment removed from the sediment source for energy type (ty) is denoted by $g_{B\ EC\ (ty)}$ (see Section 8.1.1).

PD Requirements: Determination of Baseline Energy Consumption
The project description must include the following: **PDR.38** For each energy type in Table 10, the estimate of the unit of energy consumed per metric tonne of sediment dredged. **PDR.39** Description of equipment types and method or process of sediment dredging, transport, disposal, re-handling, sediment production rates, duration of operations and conveyance distances. **PDR.40** Estimates of cumulative sediment quantity excavated and re-handled, including temporary disposal and displacement activities, if applicable. **PDR.41** Source of procedures or data on which these estimates are based.

6.3 Determining Methane Emissions in Baseline Scenario

Methane ebullition, or bubbling from sediments, sometimes occurs in open water and may increase the GHG emissions associated with the baseline scenario in which the project area remains open water. It is optional to include emissions from methane ebullition in the baseline scenario. If baseline emissions from methane ebullition are included, the project proponent must monitor such emissions in an area of open water – referred to as a reference area – located near the project area and with environmental conditions similar to those found in the project area prior to the start of wetland creation activities (see Section 6.3.1). Methane emissions must then be monitored in the reference area (see Section 9.2.7).

6.3.1 Delineating Reference Area Boundaries

If emissions from methane ebullition are included in the baseline scenario, the project proponent must define a reference area in which emissions flux from ebullition is measured and demonstrate that the reference area is similar to the project area with respect to the following criteria:

a. Hydrologically and biogeochemically similar to the project area:

   i. Must meet the definition of open water, with no soil exposed during normal tidal cycle,

ii. Must be devoid or mostly devoid of vegetation,

iii. Must exhibit similar salinity and presence or absence of tidal influence, and

iv. Must be similar with respect to presence or absence of external nitrate loading (see Section 9.2.3.1).

b. Similar landscape configuration with respect to proximity to river delta(s), specifically if the project area is not within a delta, the reference area must not be located within a delta.

c. Soil type of similar substrate to the project area as of the project start date, specifically the soils must be classified as the same *Soil Series* as reported by the USDA NRCS Soil Survey; or if the *Soil Series* is different, then the percent organic matter of the upper 30cm of soil must occur within a common range.

d. Constrained to a minimum water depth no less than the minimum depth in the project area.

Furthermore, water depth must be recorded at each sample point. The average depth of these measurements must be at least as deep as the average depth measured in the project area as of the project start date.

Measurements in the reference area are described in Section 9.2.7.

PD Requirements: Determination of Baseline Methane Emissions
The project description must include the following: **PDR.42** Description and justification for the selected reference area.

6.4 Reevaluating the Baseline Scenario

The baseline scenario must be reevaluated every ten years in accordance with the VCS rules. The baseline reevaluation must meet the requirements in Section 6.1. If new project activity instances have been added in the case of a grouped project, the reevaluation must meet the requirements in Section 6.2.

7 PROCEDURE FOR DEMONSTRATING ADDITIONALITY

This methodology uses an activity method for the demonstration of additionality. Project activities that meet the applicability conditions of this methodology (see Section 4) and demonstrate regulatory surplus are deemed as additional.

7.1 Regulatory Surplus

Project proponents must demonstrate regulatory surplus in accordance with the rules and requirements regarding regulatory surplus set out in the latest version of the *VCS Standard*.

PD Requirements: Demonstration of Project Additionality
The project description must include the following: **PDR.43** Demonstration that pertinent laws and regulations have been reviewed and that none mandate the project activities.

7.2 Positive List

The applicability conditions of this methodology represent the positive list. The project must demonstrate that it meets all of the applicability conditions, and in so doing, it is deemed as complying with the positive list.

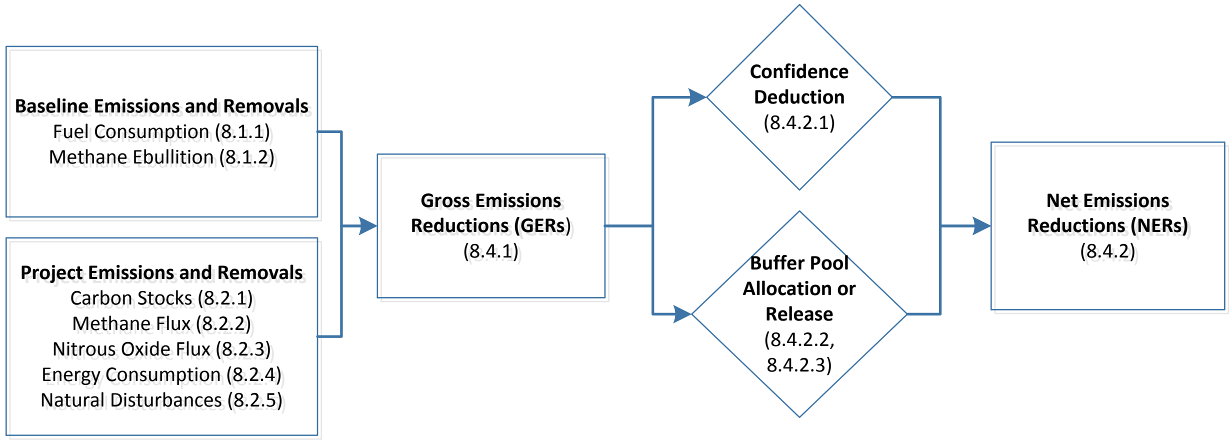
The positive list was established using the activity penetration option (Option A in the *VCS Standard*). Demonstration of additionality following this approach is set out in Appendix H – Supporting Information on Development of Positive List.

PD Requirements: Demonstration of Project Additionality
The project description must include the following: **PDR.44** Evidence that project activities comply with all applicability conditions set out under Section 4 above.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

The project proponent must calculate gross emissions reductions and/or removals (GERs) in each monitoring period. GERs are calculated by subtracting project emissions or emissions reductions and/or removals from baseline emissions. The project proponent must then calculate net emissions reductions and/or removals (NERs) by taking into account a confidence deduction (if any) and buffer pool allocation.

Cumulative GERs and NERs are quantified as those since the project crediting period start date up to the end of the monitoring period. Current GERs and NERs are quantified as those since the end of the previous monitoring period to the end of the monitoring period.



When quantifying GHG emissions reductions and removals, the project proponent must note the difference between units and resolution of monitoring data described in Section 2.5.

8.1 Baseline Emissions

Baseline emissions $E_{B\,\Delta}^{[m]}$ for the monitoring period are given by equation [G.6], equal to the sum of baseline emissions from energy consumption and emissions from methane ebullition for the monitoring period. Note that $E_{B\,\Delta}^{[m]}$ is always less than or equal to zero.

Monitoring Requirements: Baseline Emissions
The monitoring report must include the following: **MRR.12** Calculations of current baseline emissions $E_{\mathrm{B}\,\Delta}^{[m]}$ for the (current) monitoring period. **MRR.13** Calculations of baseline emissions $E_{\mathrm{B}\,\Delta}^{[m-1]}$ for prior monitoring periods.

8.1.1 Calculating Emissions from Energy Consumption

Baseline emissions from energy consumption are given by equation [G.3] where $g_{B\,(ty)}^{[m]}$ is the energy consumed per metric tonne of sediment dredged in the baseline using energy type (ty), and $M_{P\,\Delta}^{[m]}$ is the mass of sediment dredged from the sediment source as a result of project activities during the monitoring period. Note that, since $E_{B\,\Delta\,EC}^{[m]}$ is an emission, its value is always less than or equal to zero.

The energy consumed per metric tonne of sediment dredged in the baseline is determined in Section 6.2.2. The mass of sediment dredged from the sediment source is determined each monitoring period using Section 9.2.5.

The emissions coefficients $e_{(ty)}$ for each energy type are given in Table 10. Energy emissions coefficients for fuels are defined by the EPA Final Mandatory Reporting of Greenhouse Gases Rule, while electricity emissions are determined using the most recent U.S. EPA eGRID database. For both, it is important to note that these factors are updated periodically and that the factor which is applicable for the year in which the emissions occurred must be used. Refer to Appendix M for documentation and sources of the emission coefficients listed in Table 10.

Table 10: Emissions coefficients (including CO_2, CH_4, N_2O) for energy types

Energy Type (ty)	Project Proponent Reports As:	Emission Coefficient $\boldsymbol{e_{(ty)}}$
Diesel	Gal	0.010241 tCO_2e / gal
Motor gasoline	Gal	0.008809 tCO_2e / gal
Biodiesel	Gal	0.009459 tCO_2e / gal
Compressed natural gas	Scf	0.000055 tCO_2e / scf
Electric grid	kWh	eGRID regional emission factor (tCO_2e/kWh)

Monitoring Requirements: Emissions Coefficients
The monitoring report must include the following if an emission coefficient is used for the electric grid: **MRR.14** Source and date of the emission coefficient. **MRR.15** Reference to the exact page number or worksheet cell in the source.

8.1.2 Calculating Emissions from Methane Ebullition

If baseline emissions from open water methane ebullition are included in the project accounting, these emissions $\boldsymbol{E_{B\,\Delta\,CH4}^{[m]}}$ are calculated using equation [G.5] and are expressed in units of tCO_2e. These emissions are the product of the daily flux and the number of days in the monitoring period. Note that, since $E_{B\,\Delta\,CH4}^{[m]}$ is an emission, its value is always less than or equal to zero.

8.2 Project Emissions or Emission Reductions and/or Removals

Project emissions or emission reductions and/or removals $E_{P\,\Delta}^{[m]}$ for the monitoring period are given by equation [G.15], equal to emissions or emission reductions and/or removals from change in carbon stocks, nitrous oxide, methane and energy consumption resulting from the implementation of project activities.

Project emissions will occur if the flux emissions and emissions from energy consumption are greater than carbon accretion for the monitoring period, in which case $E_{P\,\Delta}^{[m]}$ will be negative. Likewise, project emission removals will occur if carbon accretion is greater than flux emissions and emissions from energy consumption, in which case $E_{P\,\Delta}^{[m]}$ will be positive.

Monitoring Requirements: Project Emissions or Emission Reductions and/or Removals
The monitoring report must include the following: **MRR.16** Calculations of current project emissions or emissions reductions and/or removals $E_{P\,\Delta}^{[m]}$ as of the monitoring period. **MRR.17** Calculations of project emissions or emissions reductions and/or removals $E_{P\,\Delta}^{[m-1]}$ from prior monitoring periods.

8.2.1 Calculating Emission Removals in Carbon Stocks

Carbon stocks must be monitored during the project crediting period to calculate the GHG emissions or removals that occur as a result of project activities. Current emissions or emissions reductions and/or removals from carbon stocks $E_{P\,\Delta\,CS}^{[m]}$ are defined as the difference between carbon stocks from the prior monitoring period and carbon stocks from the monitoring period as given in equation [G.8] for a project that is not grouped and equation [G.9] for a grouped project; carbon stock estimates are derived from methods described in Section 9.2.1. Note that $E_{P\,\Delta\,CS}^{[m]}$ is positive if vegetation growth has occurred and carbon stocks have not been reduced by disturbances.

8.2.2 Calculating Emissions from Methane

Project emissions from methane $E_{P\,\Delta\,CH4}^{[m]}$ are calculated using equation [G.11] and are expressed in units tCO_2e. These emissions are the product of the daily flux and the number of days in the monitoring period. Note that, since $E_{P\,\Delta\,CH4}^{[m]}$ is an emission, its value is less than or equal to zero.

8.2.3 Calculating Emissions from Nitrous Oxide

Project emissions from nitrous oxide $E_{P\,\Delta\,N2O}^{[m]}$ are calculated using equation [G.13] and are expressed in units tCO_2e. These emissions are the product of the daily flux and the number of days in the monitoring period, as described in Section 9.2.2. Note that, since $E_{P\,\Delta\,N2O}^{[m]}$ is an emission, its value is less than or equal to zero.

8.2.4 Calculating Emissions from Energy Consumption

Project emissions from energy consumption are given by equation [G.14], the total energy consumed as a result of project activities. Energy use and type must be monitored per Section 9.2.4. The emissions coefficients $e_{(ty)}$ for each energy type are given in Table 10 found in Section 8.1.1. Note that, since $E_{P\,\Delta\,EC}^{[m]}$ is an emission, its value is less than or equal to zero.

8.2.5 Calculating Emissions from Disturbances

Emissions from natural disturbances and other events within the project area are inherently captured by the monitoring of carbon stocks (see Section 9.2.1). The project area must be monitored regularly for evidence of significant disturbance. The following disturbance events may be significant:

- Hurricanes
- Fires
- Marsh dieback

For guidance on how to define a significant disturbance, project proponents should refer to the definition of *loss event* in the current version of the *VCS Program Definitions.*

In the event that a significant disturbance is apparent, the project proponent must document the nature and extent of the disturbance and, if necessary, re-measure existing plots or install new plots in the disturbed area. In order to estimate these carbon stocks, the project area may need to be re-stratified per Appendix A as part of monitoring (see Section 9). If the disturbance is likely to qualify as a loss event, the loss event must be reported in accordance with VCS rules.

If re-stratification is necessary, the new strata must be effective as of the date of the disturbance, thus ensuring that the stratification accurately represents conditions in the project area.

PD Requirements: Emissions or Emissions Reductions and/or Removals Events in Project Area
The project description must include the following: **PDR.45** The selected definition of a significant disturbance.

Monitoring Requirements: Emissions or Emissions Reductions and/or Removals Events in Project Area
The monitoring report must include the following: **MRR.18** The selected definition of a significant disturbance. **MRR.19** A map of the boundaries of any significant disturbance in the project area during the monitoring period. **MRR.20** Evidence that plots were installed into these disturbed areas and were measured per Section 9.2.1.

8.3 Leakage

8.3.1 Determining Activity-Shifting Leakage

Activity-shifting leakage is zero because the project area continues to be open water in the baseline scenario, and wetland creation does not materially change the land use activities outside of the project area. Thus, leakage from shifting livestock, agricultural activities or communities cannot occur. Further, dredging emissions occur in both the baseline and project scenarios and as such are not considered as leakage emissions from machinery.

8.3.2 Determining Market-Effects Leakage

Market-effects leakage is zero as there is no commercial value to the baseline scenario of open water. As a result, no change in supply and demand can exist, nor can shift in production exist elsewhere outside of the project area.

8.3.3 Demonstrating No Ecological Leakage

As a result of adding sediment to the project area during wetland creation, the watershed-scale hydrology could be affected. These effects could cause displacement of water (either standing or flowing) to areas not inundated prior to the project start date. The project proponent must demonstrate that the project will not have a significant negative impact on hydrologically connected areas, and therefore, that there will be no ecological leakage.

In order to demonstrate that the project will not have a significant negative impact on hydrologically connected areas, the project proponent must demonstrate compliance with Section 404 of the Clean Water Act by providing an individual or general permit issued by the USACE, prior to the completion of the first verification event. Where applicable, compliance with Section 10 of the Clean Water Act (River and Harbors Act) must also be demonstrated. Likewise, any NEPA analyses and decision documents must be provided (ie, a Finding of No Significant Impact [FONSI] for an Environmental Assessment or a Record of Decision [ROD] for an Environmental Impact Statement), where applicable.

Where the project proponent demonstrates that the project will not have a significant negative impact on hydrologically connected areas in accordance with the requirements above, ecological leakage is considered to be zero.

PD Requirements: Hydrologic Effects
The project description must include the following: **PDR.46** Where possible at validation, demonstration that the project will not have a significant negative impact on hydrologically connected areas, in accordance with the requirements of Section 8.3.3.

Monitoring Requirements: Hydrologic Effects
The monitoring report must include the following: **MRR.21** Demonstration that the project will not have a significant negative impact on hydrologically connected areas, in accordance with the requirements of Section 8.3.3, where same has not already been demonstrated at validation.

8.4 Summary of GHG Emission Reduction and/or Removals

The GHG emissions reductions resulting from the project activities are quantified in two steps: Gross Emissions Reductions (GERs) and Net Emissions Reductions (NERs), Sections 8.4.1 and 8.4.2, respectively. The quantity of NERs are those that are available for retirement or sale, and are GERs minus a confidence deduction (Section 8.4.2.1) and allocation to the AFOLU pooled buffer account (Section 8.4.2.2), plus a buffer release (Section 8.4.2.3). The quantity of GERs is the difference between baseline and project emissions or emissions reductions and/or removals.

8.4.1 Quantifying Gross Emission Reductions and/or Removals

Gross Emissions Reductions (GERs) for a monitoring period $[m]$ are quantified using equation [G.16] and are equal to the total baseline emissions over the monitoring period minus the total project emissions or emissions reductions and/or removals over the monitoring period.

Monitoring Requirements: Quantification of GERs	
The monitoring report must include the following:	
MRR.22	Quantified GERs for the monitoring period including references to calculations.
MRR.23	Quantified GERs for the prior monitoring period.
MRR.24	A graph of GERs by monitoring period for all monitoring periods to date.

8.4.1.1 Handling Reversals Resulting from Energy Consumption

In the event that quantified GERs are negative – indicating that project emissions or emissions reductions and/or removals are greater than baseline emissions – and that the cause of this event is the consumption of energy by project activities, the project must not generate NERs until cumulative GERs $E_{GER}^{[m]}$ are greater than zero per equation [G.17]. Note that although cumulative GERs may be greater than zero, a reversal may still occur.

8.4.2 Quantifying Net Emissions Reduction and/or Removals

Net Emissions Reductions (NERs) are equivalent to quantified GERs less a confidence deduction (if any) and AFOLU pooled buffer account allocation. NERs generated during a monitoring period $[m]$ are determined using equation [G.21]. Quantified NERs should be rounded down to the nearest whole number.

Monitoring Requirements: Quantification of NERs	
The monitoring report must include the following:	
MRR.25	Quantified NERs for the monitoring period including references to calculations.
MRR.26	Quantified NERs for the prior monitoring period.
MRR.27	A graph of NERs by monitoring period for all monitoring periods to date.

8.4.2.1 Calculating the Confidence Deduction

The confidence deduction $E_{U\,\Delta}^{[m]}$ is given by equation [G.19] where uncertainty in the estimate of the total carbon stock is given by equation [G.18], the sum of squared-uncertainty in all selected carbon pools $\mathcal{C}$. If the monitoring plan specifies a different sampling design, equations for uncertainty will differ for biomass and soil (see Section 9).

Uncertainty is calculated solely on the basis of the carbon stock estimate and does not include uncertainty in the measurements of methane and nitrous oxide. Although estimates of methane and nitrous oxide flux are uncertain, the flux measurement methods set out in in this methodology (Sections 9.2.2 and 9.2.3) are designed to provide conservative (ie, high) estimates of project emissions or emissions reductions and/or removals from these GHG sources. Thus, the uncertainty associated with an unbiased estimate of these fluxes is expected to be negligible when compared to the intentional difference between these estimates and the true (but unknown) fluxes. Therefore, the confidence deduction does not include uncertainty from methane or nitrous oxide estimates.

The confidence deduction must be greater than or equal to zero. If the result from equation [G.19] is less than zero, the confidence deduction must be set to zero.

Monitoring Requirements: Confidence Deduction	
The monitoring report must include the following:	
MRR.28	The calculated confidence deduction and supporting calculations.
MRR.29	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.

8.4.2.2 Determining Allocation to AFOLU pooled buffer account

The project proponent must undertake an assessment of non-permanence risks that apply to the project. This assessment must conform to current VCS requirements and must be used to determine the allocation of GERs to the AFOLU pooled buffer account. GERs allocated to the AFOLU pooled buffer account are denoted by $E_{BA\,\Delta}^{[m]}$ as given in equation [G.20] and must be based on the change in carbon stocks for the monitoring period as described in Section 8.2.1. GERs allocated to the AFOLU pooled buffer account must be rounded up to the nearest whole number.

Monitoring Requirements: AFOLU pooled buffer account	
The monitoring report must include the following:	
MRR.30	Reference to the VCS requirements used to determine the AFOLU pooled buffer account allocation.
MRR.31	Reference to calculations used to determine the AFOLU pooled buffer account allocation.

8.4.2.3 Determining Release from AFOLU pooled buffer account

Periodically, the project may be eligible for a release of credits from the AFOLU pooled buffer account. The buffer release $E_{BR\,\Delta}^{[m]}$ must be determined in accordance with VCS requirements.

Monitoring Requirements: Buffer Release	
The monitoring report must include the following:	
MRR.32	Reference to the VCS requirements used to determine the release from the AFOLU pooled buffer account.
MRR.33	Reference to calculations used to determine the buffer release.

8.4.2.4 Quantifying Vintages over a Monitoring Period

When the monitoring period spans more than one calendar year, NERs must be allocated by year, proportional to the number of calendar days in each year relative to the total number of days in the monitoring period. Quantified NERs should be rounded to the nearest whole number for each vintage year such that the sum of vintages in each monitoring period is equal to the NERs for that monitoring period.

Monitoring Requirements: Vintages
The monitoring report must include the following: **MRR.34** Quantified NERs by vintage year for the monitoring period including references to calculations.

8.4.3 Estimating Ex-Ante GHG Emission Reductions and/or Removals

To calculate ex-ante estimates of greenhouse gas reductions and removals, use the steps outlined in Section 8, substituting estimates of parameters that require monitoring with conservative estimates of those parameters derived from scientific literature or preliminary sampling as applicable. The following table lists the parameters required and provides guidance for estimating ex-ante project benefits in a conservative fashion. Note that derived quantities are not shown in this table.

Data / Parameter	Unit	Description	Ex-Ante Source of Data	Guidance for Conservative Estimation
$b^{[m]}$	Unit-less	Buffer withholding percentage calculated as required by the VCS AFOLU Non-Permanence Risk Tool	VCS AFOLU Non-Permanence Risk Tool	The non-permanence risk tool is to be applied at validation, therefore the value of $b^{[m]}$ should be known.
$C_{P\ CS}^{[m]}$	tCO_2e	Cumulative carbon stocks in project area for monitoring period	Scientific literature or preliminary sampling in areas of past wetland creation	It is conservative to underestimate carbon stocks.
$E_{P\ \Delta\ N2O}^{[m]}$	tCO_2e	Total emissions for nitrous oxide in project area over monitoring period	Select appropriate estimates from the tables given in Section 8.4.3.2	NA
$E_{P\ \Delta\ CH4}^{[m]}$, $E_{B\ \Delta\ CH4}^{[m]}$	tCO_2e	Total methane emissions in project area over monitoring period	Scientific literature or preliminary sampling	It is conservative to overestimate methane emissions in the project scenario.
$E_{BR\ \Delta}^{[m]}$	tCO_2e	Buffer release	See current VCS requirements	
$e_{(ty)}$	tCO_2e/gal	Emissions coefficient from Table 10 in Section 8.1.1 for energy type ty	Apply coefficients as given in Table 10	NA
$p_{B\ (ty)}$	unitless	Proportion of energy for energy type ty consumed in the baseline scenario	Records of past energy use for similar activities	It is conservative to assume that energy types with lower emission factors would have been used predominantly in the baseline scenario.
$p_{P\ (ty)}$	unitless	Proportion of energy for energy type ty consumed in the project scenario	Records of past energy use for similar activities	It is conservative to assume that energy types with higher emission factors would have been used predominantly in the project scenario.

Data / Parameter	Unit	Description	Ex-Ante Source of Data	Guidance for Conservative Estimation
U_s	tCO_2e	Standard error for a set of strata	Guidance from Appendix A may be used to plan sampling that is likely to meet a targeted precision level	See Appendix A

8.4.3.1 Determining Whether Emissions from Methane are *de minimis*

In systems with high salinity (>18 ppt), methane emissions may be *de minimis*. Such emissions are considered *de minimis* if, together with any other sources which may be *de minimis*, they account for less than 5% of the total GHG benefit generated by the project. The project proponent may choose one of the following methods to demonstrate that methane emissions are *de minimis*:

1. Models from literature (see Section 9.2.2.1)
2. Proxy models (see Section 9.2.2.2)
3. Direct measurements (see Section 9.2.2.3)

8.4.3.2 Determining Whether Emissions from Nitrous Oxide are *de minimis*

In systems without nitrate loading, nitrous oxide emissions may be *de minimis*. Such emissions are considered *de minimis* if, together with any other sources which may be *de minimis*, they account for less than 5% of the total GHG benefit generated by the project. The project proponent may choose one of the following methods to demonstrate that nitrous oxide emissions are *de minimis*:

1. Default factors (see Section 9.2.3.1)
2. Proxy models (see Section 9.2.3.2)
3. Direct measurements (see Section 9.2.3.3)

8.4.4 Evaluating Project Performance

Project performance must be evaluated each verification event and deviations from *ex-ante* NERs must be described. Differences in credit generation from *ex-ante* estimates may result from changes in the quality of data (literature estimates versus carbon stock estimates), changes in measurement approaches, occurrences of disturbance events or baseline re-evaluation.

Monitoring Requirements: Project Performance
The monitoring report must include the following: **MRR.35** Comparison of NERs presented for verification relative to those from *ex-ante* estimates. **MRR.36** Description of the cause and effect of differences from *ex-ante* estimates.

9 MONITORING

Project proponents must monitor the applicable GHG sources and selected carbon pools identified for the project (see Section 5.1 and Section

5.2). Table 11 provides a step-by-step summary of the monitoring program. Given that multiple GHG sources must be monitored across multiple carbon pools, it is likely that stratification of the project area will improve sampling efficiency and overall monitoring costs (see Section 9.1). Thus, stratification is performed prior to any field measurements.

The project proponent must then develop a monitoring plan to guide monitoring activities. The methods for measuring and estimating carbon stocks and gas fluxes described in the monitoring plan must adhere to the requirements provided in Section 9.2. The monitoring plan must be implemented in the first monitoring period and must guide ongoing monitoring for the duration of the project crediting period.

Using the monitoring plan as a guide, the values of data and parameters identified in Sections 9.3 and 9.4 must be reported in the project description (PD) or monitoring report (MR). When monitoring carbon stocks and fluxes, the project proponent must note the difference between accounting units (typically tCO_2e/day) and the frequency and interval monitoring activities (see Section 2.5).

Finally, grouped projects must report additional information in the Monitoring Report per Section 9.5.

Table 11: Stages of the monitoring program

Development Task	Selection of GHG sources and carbon pools →	Stratification →	Monitoring plan →	Monitoring activities
Key Activities	Identify applicable GHG sources. Select carbon pools for measurement and accounting. Determine which sources are *de minimis*, if any	Stratify project area to focus monitoring effort and reduce costs.	Develop sampling methods and procedures. Schedule dates and locations of monitoring events. Develop methods for storing, auditing and reporting monitoring data.	Perform monitoring activities. Synthesize and report monitoring data. In the event of a significant disturbance, re-stratify per Section 8.2.5 as described in Sections 9.1 and 9.2.1.2.
Section of Methodology	5.1 and 5.2	9.1 and 9.2.1.2	9.2	9.2, 9.3 and 9.4

In the case of a methodology deviation, alternative criteria and procedures relating to monitoring and measurement must still meet the requirements of Section 9.2.

9.1 Stratification

Stratification is recommended for the direct measurement of carbon stocks, and is required for the direct measurement of methane and nitrous oxide fluxes. Appendix A provides general guidelines for stratifying the project area, including guidance on allocating sampling and measurement units within strata. Different stratification systems may be used for estimating different emissions or emissions reductions and/or removals from different GHG sources.

In the case of direct measurement of carbon stocks, stratification may be used to improve sampling efficiency and thereby reduce the effort and costs associated with monitoring. In particular, stratification is likely to reduce the uncertainty of population estimates within each stratum, which often will reduce the number of plot measurements needed to meet VCS precision requirements.

For methane and nitrous oxide fluxes, stratification is used to identify the stratum that is likely to yield the greatest flux of each gas on an annual basis. The project proponent must measure the identified stratum for each gas. If desired, other strata may be measured as well.

In order to further streamline monitoring activities, in cases where the project proponent encounters a very small stratum (eg, a tidal channel that becomes established naturally within the project area), it is permissible to combine the stratum with another stratum with higher estimated emissions flux per unit of area. In the event that the very small stratum is combined with another stratum with lower estimated emissions flux per unit area, the project proponent must show that the difference in emissions is expected to be *de minimis*.

9.1.1 Multiple Flux Monitoring Methods in Strata

The project proponent may select one method for monitoring methane or nitrous oxide emissions fluxes across all strata (as described in Sections 9.2.2 and 9.2.3). Alternatively, the project proponent may choose to apply different methods to different strata.

For example, the project proponent may choose to use a well-accepted model to predict methane flux in a stratum that is well-vegetated (provided the project proponent can demonstrate the requirements of Section 9.2.2.1) and chamber measurements to directly measure methane flux elsewhere. Per Sections 9.2.1.2 and 9.2.1.3, the project proponent then allocates the chambers to the stratum and locations within the stratum that will likely yield the greatest methane flux over the course of the year.

The project proponent must clearly indicate in the monitoring plan the methods that are to be used and to which stratum each is to be applied (see Section 9.2).

The project proponent must use a stratum-area weighted average to calculate emissions fluxes for the purpose of accounting in Section 8.

9.2 Description of the Monitoring Plan

The project proponent must develop a monitoring plan to guide monitoring activities. The monitoring plan must include a description of measurement methods and procedures and an approximate schedule indicating when the project proponent will perform each monitoring activity throughout the entire project crediting period. The monitoring plan must include the following:

1. The purpose of monitoring;
2. Sampling procedures for carbon stocks and fluxes;
3. Anticipated dates and locations for sampling over a five-year period;
4. Organizational structure, responsibilities and competencies of individuals and organizations responsible for monitoring;
5. Methods for generating, recording, storing, aggregating, collating and reporting data per Sections 9.2.1, 9.2.2 and 9.2.3; and
6. Methods for internal auditing and handling of any identified non-conformities to the monitoring plan.

The schedule for monitoring activities must be based upon the guidance provided in this methodology for the frequency of measurement for the applicable GHG sources.

Table 12: Approximate schedule of monitoring activities by GHG source

<table>
<tr><th colspan="2"></th><th>First verification</th><th>Years 1-10 after first verification</th><th>Years 11 + after first verification</th></tr>
<tr><td colspan="2">Carbon stocks (9.2.1.4)</td><td>All plots measured.</td><td>All plots measured at least once. May ‘cycle’ through a portion of plots each year.</td><td>All plots measured at least once every 5 years. May ‘cycle’ through a portion of plots each year.</td></tr>
<tr><td rowspan="2">Methane</td><td>Project (9.2.2.4)</td><td>Flux measured regardless of monitoring method.</td><td colspan="2">Model from literature: No direct measurements. Assess applicability of methods at each verification event.

Direct measurement: Flux measured every year. (Chamber method: at least 2 measurement events per year; eddy covariance method: at least 21 days of measurements per year)</td></tr>
<tr><td>Baseline (9.2.7)</td><td>Flux measured regardless of monitoring method.</td><td colspan="2">(same as above)</td></tr>
<tr><td colspan="2">Nitrous oxide (9.2.3.4)</td><td>Flux measured regardless of monitoring method.</td><td colspan="2">Model from literature: No direct measurements. Assess applicability of methods at each verification event.
Proxy model: Direct measurement of covariates every monitoring period.
Direct measurement: Flux measured every year. (at least 12 measurement events; see Section 9.2.3.4)</td></tr>
</table>

PD Requirements: Monitoring Plan
The project description must include the following: **PDR.47** A summary of carbon stock sampling procedures for the project area, with a copy of a sampling protocol used by field personnel to carry out measurements. **PDR.48** A summary of flux measurement procedures for the project area, with a copy of a flux measurement protocol used by field personnel to carry out measurements. **PDR.49** A reference to the monitoring plan. **PDR.50** Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.

Monitoring Requirements: Monitoring Plan	
The monitoring report must include the following:	
MRR.37	Documentation of training for field measurement crews.
MRR.38	Documentation of data quality assessment.
MRR.39	References to plot allocation for carbon stock measurement.
MRR.40	List of plot geodetic coordinates for plots and flux measurement devices.
MRR.41	Description and diagram of flux measurements devices for methane and/or nitrous oxide.
MRR.42	The estimated carbon stock, standard error of the total for each stock, and the sample size for each stratum in the project area.
MRR.43	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.
MRR.44	Frequency of monitoring for each plot and flux measurement location – all carbon stock plots must be measured for the first verification.

9.2.1 Monitoring Project Carbon Stocks

Carbon stocks must be monitored prior to the first verification, at least once within 10 years after the first verification, and at least once every 5 years thereafter, and not necessarily at every verification event. Total carbon stock for the selected carbon pools is calculated using equation [G.7].

9.2.1.1 Requirements for First Verification

At the first verification, carbon stocks prior to the project start date must be estimated, denoted as $C_P^{[m=0]}$, using equation [G.7]. If plots were not installed prior to the project start date, stratification from aerial imagery may be required to estimate $C_P^{[m=0]}$ (see Section 9.2.1.2).

All plots must be measured at the first verification.

9.2.1.2 Requirements for Stratification

Stratification may be used to improve sampling efficiency, and may be required to estimate carbon stocks prior to the first monitoring period (see Section 9.2.1.1). Appendix A provides general guidelines for stratifying the project area, including guidance on allocating measurement units within strata. For measurements of carbon stocks, some strata may not be measured if these areas can conservatively be assumed not to accumulate soil or biomass carbon stock. For example, an aerial photo may be used to delineate unproductive areas in which minimal above ground biomass has accumulated in a given monitoring period. Rather than allocating sample units to these strata, the project proponent may conservatively assume that these areas have a stock of zero, focusing sampling efforts on areas that have more substantial biomass accumulation.

Strata boundaries may change over time to improve carbon stock estimates.

PD Requirements: Stratification
The project description must include the following if stratification is not elected for either biomass or SOC: **PDR.51** Justification for not stratifying carbon stocks.

9.2.1.2.1 Stratification for SOC

When estimating soil carbon stocks, the project proponent may stratify the project area according to factors such as water depth, elevation or relative terrain position, soil type maps, or vegetation cover. A map of all identified strata and their areas must be reported as well as the allocation of plots within each stratum.

PD Requirements: Stratification for SOC
The project description must include the following if the project area is stratified: **PDR.52** Description for how the strata were delineated. **PDR.53** Map(s) of the initial strata boundaries.

Monitoring Requirements: Stratification for SOC
The monitoring report must include the following if the project area is stratified: **MRR.45** Map(s) of the current strata boundaries. **MRR.46** A description of changes to the strata boundaries (if applicable).

9.2.1.2.2 Stratification for Biomass

When estimating biomass carbon stocks, the project proponent may stratify the project area according to factors such as vegetation type; age, stocking, or vegetation density; site quality; elevation or relative terrain position. A map of all identified strata and their areas must be reported as well as the allocation of plots within each stratum.

PD Requirements: Stratification for Biomass
The project description must include the following if the project area is stratified: **PDR.54** Description for how the strata were delineated. **PDR.55** Map(s) of the initial strata boundaries.

Monitoring Requirements: Stratification for Biomass
The monitoring report must include the following if the project area is stratified: **MRR.47** Map(s) of the current strata boundaries. **MRR.48** A description of changes to the strata boundaries (if applicable)

9.2.1.3 Direct Measurement for Stock Change

The project proponent must take direct measurements of biomass and SOC. The project proponent must use the protocols prescribed in Appendix D and Appendix E as the basis for carbon stock measurement in the monitoring plan.

The project proponent must describe the methods for allocating plots to strata and within strata.

PD Requirements: Measuring Carbon Stocks
The project description must include the following: **PDR.56** Method for allocating plots to stratum. **PDR.57** Description of plot sizes and layout (such as the use of nests and their sizes) for each carbon pool.

Monitoring Requirements: Measuring Carbon Stocks
The monitoring report must include the following: **MRR.49** Method for allocating plots to stratum. **MRR.50** Map of the location of plots within strata. **MRR.51** Description of plot sizes and layout (such as the use of nests and their sizes) for each carbon pool.

9.2.1.3.1 Soil Plot Design

Permanent plots must be randomly allocated in the project area. Artificial marker horizons (feldspar or other technique) may be used to define the original project soil surface after the implementation of project activities. The project proponent must specify the maximum soil sample depth, which will be fixed for the life of the project.

PD Requirements: Soil Plot Design
The project description must include the following: **PDR.58** Diagram of a soil plot showing the locations of artificial marker horizons and core samples within the plot over time. **PDR.59** Description of the fixed soil sample depth.

Monitoring Requirements: Soil Plot Design
The monitoring report must include the following: **MRR.52** For each measured soil plot, a diagram showing the location of installed artificial marker horizons and sampled cores. **MRR.53** Field report describing soil sample depths (accretion depth and fixed soil sample depth) and coring devices used to collect samples. The report must also include number of soil samples and their identification in a chain of custody form submitted to the laboratory.

9.2.1.4 Frequency of Measurement

All plots must be measured at the first verification. For the remainder of the project crediting period, carbon stocks must be monitored at least once within the next 10 years and at least once every five years thereafter, and not necessarily at every verification event. The project proponent may choose to 'cycle' through a portion of measurement plots over the five-year period.

PD Requirements: Frequency of Carbon Stock Measurements	
The project description must include the following:	
PDR.60	The anticipated frequency of monitoring for each plot and flux measurement location – all carbon stock plots should be measured for the first verification.

Monitoring Requirements: Frequency of Carbon Stock Measurements	
The monitoring report must include the following:	
MRR.54	List of plots measured during the monitoring period – all carbon stock plots should be measured for the first verification.

9.2.2 Monitoring Project Methane Flux

In the project case, methane flux $F^{[m]}_{P\,\Delta\,CH4}$ must be monitored using one of three approaches: models taken from peer reviewed scientific literature (Section 9.2.2.1), proxy methods developed by the project proponent (Section 9.2.2.2) or direct measurement of flux from the project area (Section 9.2.2.3). All three approaches result in an estimate of flux in units of tCO_2e/day, which is then used in equation [G.11] to predict emissions as a result of project activities (see Section 8.2.2). Specific field methods for measuring methane flux are described in Appendices B and C.

In deciding which monitoring approach to use, keep in mind that direct measurement is usually the most demanding in terms of time and cost. If the project proponent is able to identify a model that meets the requirements herein, it will likely be the most efficient method.

Once an approach is selected, it cannot be changed after the first verification event unless it is being changed to direct measurement.

PD Requirements: Monitoring Methane
The project description must include the following: **PDR.61** The selected approach for monitoring methane.

9.2.2.1 Models from Literature

Methane flux may be predicted using a process model or proxy model selected from peer-reviewed scientific literature but only after the model has been demonstrated to be applicable to the project area. In selecting a model and demonstrating that it is applicable to the project area, the project proponent must do the following:

1. Provide a description of the model that includes references to key technical papers and justifies why the selected model is appropriate for predicting methane flux in the project area.

2. Enumerate the assumptions (or applicability conditions) of the model, explain how each of those assumptions is satisfied in the application of the model to the project area.

3. List all parameters of the model, providing the values applied, the source of those parameters, and providing a justification for why the selected value is appropriate to the project area. If parameters are selected by the user to calibrate the model, the project proponent must justify the values selected for these parameters conservatively predicts emissions. Modeling conducted in support of credit generation activities must use parameter values that are specific to the project area where it is possible to do so (ie, the model must be calibrated based on measurements made at the project site, not applied with default settings).

4. List any forcing variables or covariates (for example, meteorological or hydrological measureable variables available at each time step for which the model is run) that drive the model and provide a plan to obtain project area-specific values for those parameters.

At the initial project verification and at baseline reevaluation, the model's applicability must be assessed by comparison to direct field measurements of methane flux. The project proponent must do all of the following to determine if the model is applicable to the project area:

1. Directly measure methane flux for one season as described in Appendix B. The measurements must meet all assumptions outlined in Appendix B. Appendix B is designed to provide conservative (high) estimates of methane flux.

2. Use the selected and calibrated model to predict the measured methane flux independent of any data used to calibrate the model.

3. Estimate the model error as the sum of the differences between predicted and measured fluxes, divided by the number of measurements.

4. The mean error must demonstrate that the model conservatively over-predicts emissions fluxes compared to direct measurement of methane flux.

Predicted emissions fluxes by the selected model from literature must be converted to units of tCO_2e/day, such that they can be used directly in equation [G.11] as described in Section 8.2.2 (for the distinction between units and resolution, see Section 2.5).

If a model(s) from literature is selected, it must be justified at the time of validation and its applicability determined at the first verification event and subsequent baseline reevaluations.

PD Requirements: Methane Models from Literature
The project description must include the following if a model from literature is used to estimate methane flux: **PDR.62** Justification of methane flux model from the literature, per the requirements of Section 9.2.2.1.

Monitoring Requirements: Methane Models from Literature
The monitoring report must include the following if a model from literature is used to estimate methane flux: **MRR.55** Demonstration that the selected model is applicable to the project area per the requirements of Section 9.2.2.1. **MRR.56** Description of how model predictions are converted to tCO_2e/day.

9.2.2.2 Proxy Modeling

Project proponents may develop new proxy models to predict methane flux from wetland ecosystems. In building such a predictive model, the project proponent must measure or collect published data on response variables (methane flux) using the guidance in Appendix B as well as possible covariates, consider a range of alternative models and select a model using statistically sound procedures, and apply the model at each verification event to predict methane flux. Use Sections 9.2.2.2.1, 9.2.2.2.2, 9.2.2.2.3 and 9.2.2.2.4 to develop new proxy models.

Although the possible covariates to methane flux must be reported at the time of validation, the selected model and data used to fit the model must be reported at the time of the first verification event.

Such models must comply with requirements for models set out in the *VCS Standard*.

9.2.2.2.1 Considering Covariates

In developing a statistical model, project proponents should first develop a list of possible covariates and list sources of potential data for those covariates, which may include direct field measurement, remote sensing, peer-reviewed scientific literature, and technical reports completed by government agencies. Covariates to be considered may include but are not limited to soil salinity, water salinity, soil temperature, water temperature, air temperature, flooding, spectral reflectance, elevation, flooding frequency, flooding depth, soil organic carbon, and sulfate concentrations. From the initially considered covariates, identify those whose data availability and expected relationship with methane flux are most relevant to the project needs.

Possible and selected covariates and sources for covariates must be validated.

PD Requirements: Covariates for Proxy Methane Models
The project description must include the following if a proxy model is used to estimate methane flux: **PDR.63** A list of possible covariates and the sources of data available for each. **PDR.64** A list of selected covariates to be used for model fitting.

9.2.2.2.2 Collecting Data for Model Fitting and Response Variables

Data for model fitting may be collected from a combination of direct field measurements (see Appendix B), peer-reviewed scientific literature and/or technical reports issued by government agencies. Field data must be collected to cover the entire range of methane emissions flux potentially expected by the project, as well as the values of covariates that correspond to that range. Additional guidance is provided in Section 4.1.7 of the *VCS Standard v3.3*.

When data are collected directly by the project proponent in the field, a data collection plan (or protocol) must be prepared, detailing the data collection methods and referencing appropriate technical source documents.

Monitoring Requirements: Data Collection for Proxy Methane Model
The first monitoring report must include the following if an proxy model is used to estimate methane flux: **MRR.57** Complete references to the source of any data collected from literature or reports. **MRR.58** Data collection procedures, plans or protocols for any data collected directly from the project area.

9.2.2.2.3 Model Fitting, Selection, and Goodness of Fit

This methodology is not prescriptive with regard to model form and fitting procedures, as various types of models may be appropriate depending on the observed relationship between covariates and response variables. However, the model must be fit using sound and well documented statistical methods. The model must predict methane flux in tCO_2e/day (or units that can be converted appropriately) from some combination of measurable covariates. The project proponents must consider a variety of model forms and data transformations as appropriate to the data collected. During model fitting, attention should be paid to outliers and overly influential data points. Residual plots should be analyzed to confirm that model fitting assumptions have been met. Model selection and goodness of fit must be evaluated as described in Appendix F.

Monitoring Requirements: Model Fit for Methane
The first monitoring report must include the following if a proxy model is used to estimate methane flux: **MRR.59** The form of the selected model. **MRR.60** Summary statistics of the model fit as appropriate to the fitting of the model. **MRR.61** The estimated model parameters. **MRR.62** A description of the range of covariate data with which the model was fit.

9.2.2.2.4 Predicting Methane Flux

When a proxy model is used, measurement of the selected covariates replaces direct measurement of methane flux at each verification event. Covariates must be measured according to the procedures outlined by the project proponent in Section 9.2.2.2.1 and their actual values reported. Use the measured values as inputs to the statistical model. In the case that there is uncertainty about the value of a covariate model input, choose the value that results in the most conservative (ie, largest) estimate of methane emissions flux. Models must not be extrapolated more than 10% (that is, no independent variables that exceed the range from which the model was fit by more than 10% must be input into the model).

Monitoring Requirements: Model Prediction for Methane
The first monitoring report must include the following if an proxy model is used to estimate methane flux: **MRR.63** The values of any measured covariates. **MRR.64** The predicted methane flux.

9.2.2.3 Direct Measurement

Either chamber measurements (Section 9.2.2.3.2), eddy covariance measurements (Section 9.2.2.3.3), or other substantive equivalent techniques must be used. The project proponent must select the measurement method at the time of validation.

Monitoring of gas fluxes is inherently uncertain when aggregated over space and time. This methodology addresses this uncertainty by providing requirements that ensure the fluxes are overestimated, rather than underestimated, using conservativeness as a mediator to accuracy. These requirements include guidelines for stratification, a requirement for making measurements in the stratum expected to have the highest emissions, and guidelines for the points in time during which measurements are made.

To convert monitoring data from flux per acre per day to flux per day as required in Section 8.2.2, use equation [G.10].

Monitoring Requirements: Processed Chamber and Eddy Covariance Flux Data
The monitoring report must include the following: **MRR.65** A table of chamber flux or eddy covariance emission summary statistics of the mean (±1SEM) and number of samples for each mean in tCO_2e/ac/day for each sample location within a stratum.

9.2.2.3.1 Stratification

Stratification must be used to determine the stratum that is likely to yield the greatest methane emissions flux over the course of a year. Appendix A, Section A.1, provides general guidelines for stratifying the project area. Direct measurements must be conducted in the stratum that is likely to yield the greatest methane emissions flux, and may optionally be conducted in other strata as well, using appropriate area weighted stratification estimators as provided in appendix A.

The following factors predominantly affect methane emissions flux:

1. Carbon source: Methane emissions are associated with productive emergent plants that supply labile organic matter for methane producing bacteria. Areas with stressed plants or low plant productivity may have limited emissions over an annual period.

2. Soil saturation or reduction-oxidation potential: Persistent soil saturation or inundation above the wetland surface indicates reduced conditions and a likelihood of enhanced methane emissions. Methane production occurs when the reduction-oxidation potential is less than < 200mV. Optimal methane production occurs when redox is below -200mV.

3. Sulfate (salinity): The absence of sulfate favors methane production. The regular replenishment of sulfate with seawater from tidal action can suppress methane production. Methane production can occur when sulfate is less than 4mM umol (or typically when salinity < 18ppt).

4. Plant traits: 'Shunt' plant species are capable of conducting methane from the soil to atmosphere. A comprehensive list of species is not known, however, candidate genera that contain substantial aerenhymatous roots and shoots includes: *Typha*, *Sagittaria*, *Peltandra*, *Nuphar*, *Nymphaea*, *Phragmites*, and *Cladium* (see Couwenberg 2009).

5. Electron acceptors: In the absence of sulfate and other electron acceptors, such as nitrate and iron, methane production may be enhanced.

These factors must be considered when determining the stratum that is likely to yield the greatest methane emissions flux. The project proponent must justify the selected strata for direct measurement, including time considerations related to cyclical changes in the tidal frame.

Strata boundaries may change over time. If this occurs, the project proponent must ensure that the stratum likely to yield the greatest methane flux is always measured.

PD Requirements: Stratification for Methane Emissions
The project description must include the following if direct measurement is used to estimate methane flux: **PDR.65** Description for how the strata were delineated. **PDR.66** Map(s) of the initial strata boundaries indicating which stratum is likely to yield the greatest methane emissions flux. **PDR.67** Justification per the criteria in Section 9.2.2.3.1 for the stratum that is likely to yield the greatest methane emissions flux.

Monitoring Requirements: Stratification for Methane Emissions
The monitoring report must include the following if direct measurement is used to estimate methane flux: **MRR.66** Map(s) of the current strata boundaries. **MRR.67** A description of changes to the strata boundaries (if applicable).

9.2.2.3.2 Chamber Measurements

If the chamber measurement method is selected, the project proponent must take direct measurements of methane flux using chambers. The project proponent may use the protocols prescribed in Appendix B as the basis for flux measurement in the monitoring plan.

Within stratum, chambers must be located in areas that are likely to yield the greatest methane emissions flux over the course of a year (see factors in Section 9.2.2.3.1).

PD Requirements: Instrumentation for Chambers
The project description must include the following: **PDR.68** Diagram of chamber design.

Monitoring Requirements: Instrumentation for Chambers
The monitoring report must include the following: **MRR.68** Diagram of chamber design. **MRR.69** Map showing the location of chambers in the project area.

9.2.2.3.3 Eddy Covariance Measurements

The project proponent may take direct measurements of methane flux using eddy covariance. The project proponent may use the protocols prescribed in Appendix C as the basis for flux measurement in the monitoring plan.

The footprint of the eddy covariance tower must be more than half in the stratum determined to yield the greatest methane emissions flux over the course of a year (see factors in Section 9.2.2.3.1). The tower must be located in the stratum determined to yield the greatest methane emissions flux over the course of a year. The footprint of the tower must be defined using a published model (eg, Kljun et al. 2004, Kormann and Meixner 2001).

Monitoring Requirements: Instrumentation for Eddy Covariance	
The monitoring report must include the following:	
MRR.70	Diagram or map of eddy covariance tower delineating the selected footprint area where flux was integrated from and the computed mean 80% footprint distance (including the footprint model used) from the tower during the period of analysis. A table of computed estimates for each of the following parameters: σ_w = standard deviation of the vertical velocity fluctuations (m/s) u^*= surface friction velocity (m/sec) z_m= measurement height (m) z_0= roughness length (m) (or canopy height and density to be used to estimate roughness length)
MRR.71	Description of the published model used to define the footprint.
MRR.72	Map showing the location of eddy covariance towers in the project area.
MRR.73	Documentation of adherence to manufacturer-recommended procedures for calibration of the methane analyzer.

The project proponent must use one of the software packages for eddy covariance data processing listed below. An inter-comparison of some of these software packages for eddy covariance data quality control was reviewed by Mauder et al. (2008), and any of these packages must be considered equally acceptable for computing GHG fluxes. Eddy covariance algorithms may be used in other commercial software, such as MatLab, but will require justification from the project proponent.

- EddyPro 4.0 (fully documented, maintained, and supported by LI-COR®, Inc.)
- ECO$_2$S (IMECC-EU)
- EdiRe (Rob Clement, University of Edinburgh)
- TK3 (Matthias Mauder and Thomas Foken, University of Bayreuth)
- ECPack (GNU Public License; Wageningen University);
- EddySoft (Olaf Kolle and Corinna Rebmann, Max-Planck Institute for Biogeochemistry)
- Alteddy (Jan Elbers, Alterra Institute in Wageningen)

The project proponent must plot a time series of 30 min data including methane concentration, surface friction velocity and temperature. Data points must be omitted based on the following thresholds:

- Methane concentration must not be less than ambient (< 1.7 ppm) or the regional average, which is available from the nearest NOAA ERSL laboratory field station.

- Surface friction velocities less than 0.10 m/s or greater than 1.2 m/s.

Upper and lower limits of daily temperature should be within norms of the nearest meteorological station.

Monitoring Requirements: Eddy Covariance Data Processing and Flux Computation
The monitoring report must include the following: **MRR.74** Frequency diagram of wind direction (0-359° with 30° intervals) and velocity (m/s) for the period of analysis. **MRR.75** Summary of the dates of data collection, the selected approach for averaging over each period, explicit formulas used for computing flux, number of 0.5-hr samples used in calculations. **MRR.76** Graphical plot of 0.5-hr GHG concentration (ppmv), wind velocity and direction, and temperature used for the flux calculations **MRR.77** Summary statistics (number of samples, mean, median, variance) of GHG flux for each averaging period.

9.2.2.4 Frequency of Measurement

The project proponent must monitor methane flux periodically during a sampling period. The frequency of measurement is dependent upon the measurement method selection (ie, chamber or eddy covariance).

9.2.2.4.1 Chamber Measurements

The sampling period must be defined by a chamber sampling type selected from Table 13; guidance on the appropriate seasons for sampling activities is given for the northern hemisphere. The chamber sampling type may change from monitoring period to monitoring period, but must never change within a monitoring period. The project proponent must justify their selection of the chamber sampling type every monitoring period.

Table 13: Measurement requirements for chambers

Chamber Sampling Type	Sampling Period	Frequency	Period Flux Calculation (tCO_2e/ac/d)	Annual Flux Calculation (tCO_2e/ac/yr)
Peak	June - August	Minimum of two sampling events. If only two, no less than 30 days between events.	Mean of all measurements during the sampling period.	Mean period flux * 365 days.
Seasonal	October – February (winter) March – May (spring) June – September (summer)	Minimum of four sampling events. Each season must have at least one event and the summer season must have at least two, with no less than 30 days between events.	Mean of all measurements per each sampling season.	SUM of the mean winter season flux * 151 days and the mean spring season flux * 92 days and the mean summer season flux * 122 days.
Monthly	January - December	Minimum of 12 sampling events with no less than seven days between events. Minimum of one event per each calendar month.	Mean of all monthly measurements during the sampling period.	Mean period flux * 365 days.

Methane production from wetland soils predominantly occurs when mean soil and water temperatures exceeds 20°C (Whalen 2005). Because the peak chamber sampling type is during the hottest months in the northern hemisphere, this sampling type is most conservative; it also requires the least amount of sampling. Seasonal and Monthly chamber sampling types may provide a more accurate estimate of seasonal and inter-annual fluxes.

Sampling must occur when water levels are within mean low and mean high water (ie, not during extended low water events).

Monitoring Requirements: Chamber Sampling for Methane	
The monitoring report must include the following:	
MRR.78	Table of sampling event dates for the monitoring period, including the time of day samples were collected, water level relative to the soil surface, soil temperature, and air temperature.
MRR.79	Copy of field data sheets documenting time intervals when samples were collected, sample identification number, and verification of the total number of samples received by the laboratory.

9.2.2.4.2 Eddy Covariance Measurements

The sampling period must be defined by the eddy covariance sampling type and the eddy covariance sampling type must be selected from Table 14; sampling periods are given for the northern hemisphere. The eddy covariance sampling type may change from monitoring period to monitoring period, but must never change within a monitoring period. The project proponent must justify their selection of the eddy covariance sampling type every monitoring period.

Flux measurements must not be verified during the sampling period if the selected eddy covariance sampling type is peak or seasonal.

Table 14: Measurement requirements for Eddy Covariance

Eddy Covariance Sampling Type	Sampling Period	Frequency	Period Flux Calculation ($tCO_2e/ac/d$)	Annual Flux Calculation ($tCO_2e/ac/yr$)
Peak	July 1 – September 30	Minimum of 21 days.	Mean of all measurements during the 21 cumulative days (or more).	Mean period flux * 365 days.
Seasonal	March 1 – May 30 (spring) July 15 – September 15 (summer)	Minimum of 21 days sampled in the spring and minimum of 21 days sampled in the summer.	Mean of all measurements during the 21 cumulative days (or more) per each season.	SUM of the mean spring season flux * 243 days and the mean summer season flux * 122 days.
Monthly	January - December	Minimum of 3 days sampled per calendar month. No less than 7 days between sampling events.	Mean of all measurements during the 36 days (or more).	Mean period flux * 365 days.

The following criteria establish the frequency of measurements within each day:

1) A sample interval is 0.5 hr.

2) A minimum of 12 samples must comprise a daily flux mean.

3) One missing sample between two samples may be linearly interpolated. No interpolation is allowed for time periods greater than 1 hr.

4) A list of interpolated samples must be recorded and provided to the verifier.

PD Requirements: Eddy Covariance Measurement	
The project description must include the following:	
PDR.69	The type of analyzer selected for direct measurements of methane, including a description of the resolution of measurements (in ppb) and the frequency at which measurements are to be taken (in Hz).
PDR.70	A table of meteorological variables selected for measurement. For each variable in the table, justification for its selection, the unit of measurement, resolution of measurement and frequency of measurement.
PDR.71	A description the eddy covariance tower configuration including the distances between sensors (vertical, northward and eastward separation).
PDR.72	A scale diagram of the eddy covariance tower configuration showing the relative location and distance of the anemometer relative to the methane sensor.
PDR.73	Plan view diagram or map of the eddy covariance tower delineating strata and the area of highest anticipated emissions within a 100m radius of the tower. Delineation of any patch vegetation (twice the dominant canopy height and occupying >100m^2 in area) occurring within the estimated 80% footprint area.
PDR.74	Description of dominant plant canopy height (in m) over an annual cycle. An estimate of the 80% flux footprint distance (in m) and parameter estimates, as follows: σ_w= standard deviation of the vertical velocity fluctuations (m/s) u_*= surface friction velocity (m/sec) z_m= measurement height (m) h_m= planetary boundary layer height (m) or 1000m z_m= roughness length (m) or 1/10th of the average canopy height

Monitoring Requirements: Eddy Covariance Measurement
The monitoring report must include the following: **MRR.80** A table of meteorological variables selected for measurement. For each variable in the table, an indication of whether the variable was measured, the make and model of the instrument used for measurement. **MRR.81** For each measured variable, a graphical plot or table of the data with respect to time during the monitoring period. A data table or plot must include at minimum: air temperature, methane concentration, methane flux. A list of interpolated/missing samples. **MRR.82** Documentation of calibration dates and zero checks for methane analyzer. Provide the date of last full calibration (0-10 ppm methane standard). Provide dates of carbon-free air gas checks for methane analyzer.

9.2.3 Monitoring Project Nitrous Oxide Flux

Nitrous oxide may be *de minimis* as determined per Section 8.4.3.2 and current VCS requirements. If it is not *de minimis*, the project proponent must monitor nitrous oxide flux $F_{P\,\Delta\,N20}^{[m]}$ using one of three approaches: applying default values (Section 9.2.3.1), proxy methods developed by the project proponent (Section 9.2.3.2) or direct measurement of flux from the project area (Section 9.2.3.3). All three approaches result in an estimate of flux in units of tCO_2e/day, which is then used in equation [G.13] to predict emissions as a result of project activities (see Section 8.2.3). Specific field methods for measuring nitrous oxide flux are described in Appendix B.

In deciding which monitoring approach to use, it should be kept in mind that direct measurement is usually the most demanding in terms of time and cost. If the project proponent is able to identify a default value or model that meets the requirements herein, these will likely be the most efficient methods.

Once an approach is selected, it cannot be changed after the first verification event.

PD Requirements: Monitoring Nitrous Oxide
The project description must include the following: **PDR.75** The selected approach for monitoring nitrous oxide.

9.2.3.1 Default Values

This section provides peer-reviewed estimates for nitrous oxide emissions flux in a variety of wetland ecosystems in several regions of North America (primarily Louisiana). The values provided in Table 16 may be used to determine a default value for nitrous oxide emissions.

If the project proponent demonstrates that the project area is not located within a direct 'outfall' of a NPDES major discharger (as described in this section) and is not located within a CWA Section 303d designated impaired water, the project proponent may use an applicable default value provided in Table 16 of Section 9.2.3.1.1, taking into consideration the issues described in this section in order to determine if the values in Table 16 are applicable to the project. If the project area is determined to be within the 'outfall' of a NPDES major discharger (ie, affected by external nitrate loading) or is located within a CWA Section 303d designated impaired water, the project proponent must either apply a proxy model (see Section 9.2.3.2) or conduct direct monitoring (see Section 9.2.3.3).

Prior to selecting a default value from Table 16, the project proponent must determine whether there exists an external nitrogen loading that is likely to influence gas fluxes in the project area. The project proponent must provide supporting evidence to show where major point sources of nitrogen are located relative to the project area and to define the hydrologic connections that lead to direct discharge into the project area. Major point sources of nitrogen may include state-authorized NPDES permits (industrial or municipal wastewater effluent) or public works projects resulting in the alteration of surface water flow into wetlands and estuaries (eg wetland restoration projects with freshwater/sediment river diversions). Major non-point nitrogen sources from surface runoff or wastewater – including agricultural, urban and suburban areas, leach fields, and leaking sewer pipes – also must be considered.

Specifically, the project proponent must demonstrate:

1. The project area is not located within a direct 'outfall,' nor is it downstream and in close proximity of a NPDES major discharger (>1 mgd) or public works project (river diversion) discharging elevated nitrogen effluent (>3 mg TN/L);

2. The project area is not located within a CWA Section 303d designated impaired water, where nitrogen (or 'nutrients') is the suspected causal factor of impairment; and

3. The project area does not receive direct surface runoff from agricultural, urban or suburban areas, and is not immediately adjacent to areas with sewer lines or leach fields.

Acceptable sources of supporting documentation to demonstrate the presence or absence of external nitrogen loading may include: state-authorized National Pollutant Discharge Elimination System (NPDES) documentation; Clean Water Act 303d Impaired Waters documentation; watershed-based Total Maximum Daily Load (TMDL) regulations; project-specific monitoring reports; first order, area-based water quality models; and ambient water quality monitoring data.

PD Requirements: Determining Project Area Exposure to Nitrogen Loading
The project description must include the following: **PDR.76** Location of the project area within a minimum definable watershed, using a USGS, EPA or state delineated watershed. **PDR.77** Locations of all NPDES major dischargers and public works projects producing > 1 MGD of elevated nitrogen effluent (>3 mg TN/L) discharging into the project area and located within the minimum definable watershed. **PDR.78** List of EPA CWA Section 303d designated impaired waters for the state.

Alternatively, other peer-reviewed estimates may be used, in which case the project proponent must demonstrate and justify the selected default value. Where default factors are used, they must be consistent with the current version of the VCS Standard's requirements for default factors (currently located in Section 4.5.6 of the VCS Standard version 3.3). The project proponent must calculate the selected default value in terms of tCO_2e/year and apply this calculated default to determine emissions in equation [G.13]. Models must be publicly available, though not necessarily free of charge, from a reputable and recognized source (eg, the model developer's website, IPCC or government agency).

PD Requirements: Default Values for Nitrous Oxide Monitoring
The project description must include the following if a default value is used to estimate nitrous oxide flux: **PDR. 79** Justification for the selected default value.

9.2.3.1.1 Default Factors in Absence of External Nitrate Loading

Under background wetland conditions, defined as those wetland areas not exposed to external nitrate loading sources (eg, a river diversion or wastewater treatment outflows, or other significant point sources), in the Mississippi River delta plain, nitrous oxide emissions flux to the atmosphere is ≤0.1 t CO2e/ac/yr (Smith et al. 1983). Under these conditions, the project proponent may use a value from Table 16, making sure to justify its applicability to the project area.

Table 15 shows annual estimates of nitrous oxide emissions fluxes from vegetated wetland and open water habitats across a salinity gradient in Louisiana (Smith et al. 1983),. The study was done over 2 years with samples taken on ~6 week intervals (17 sampling events) using static flux chambers at sites representative of background conditions for Louisiana wetlands (in the absence of external nitrate loading). The emissions fluxes are presented relative to an anticipated annual sequestration rate of 3 tCO_2e/ac/yr.

Table 15: Background annual nitrous oxide flux values from vegetated wetland and open water habitats across a salinity gradient in Louisiana (Smith et al. 1983)

Wetland Type	Annual mg N20-N/m2/yr	Annual $tCO_2e/ac/yr$	% of Benefit @ 3 $tCO_2e/ac/yr$
Salt marsh	31	0.06	2.0%
open water	10	0.02	
Brackish marsh	48	0.09	3.2%
open water	21	0.04	
Fresh marsh	55	0.11	3.6%
open water	34	0.07	

For projects in Louisiana, the values provided in Table 15 may be used to estimate nitrous oxide flux. For projects outside Louisiana, the project proponent must identify appropriate flux estimates from peer-reviewed literature and must demonstrate that they are applicable to the project.

The effects of river diversions on nitrous emissions flux to the atmosphere are less predictable than background conditions. Nitrous oxide emissions flux from freshwater wetlands near the outfall of river diversions may depend on whether the diversion is operating (positive flux to the atmosphere ~0.4 t CO2e/ac/yr; Yu et al. 2006) or not operating (flux from the atmosphere to the wetland -0.17 t CO2e/ac/yr; Table 15, Yu et al. 2006). The study of Lundberg (2012) conducted along a salinity gradient from the outfall of one river diversion showed that wetland nitrous emissions flux to the atmosphere are relatively low (< 0.07 t CO2e/ac/yr).

9.2.3.1.2 Projects in Presence of External Nitrate Loading

Exposure to high external nitrate loads may result in increased nitrous oxide emissions flux compared to background conditions. For project areas in the presence of external nitrate loading, the project proponent must either apply a proxy model (see Section 9.2.3.2) or conduct direct monitoring (see Section 9.2.3.3).

9.2.3.2 Proxy Modeling

Project proponents may develop new proxy models to predict nitrous oxide flux from wetland ecosystems. In building such a predictive model, the project proponent must measure or collect published data on response variables (nitrous oxide flux) using the guidance in Appendix B as well as possible covariates, consider a range of alternative models and select a model using statistically sound procedures, and apply the model at each verification event to predict nitrous oxide flux. Use Sections 9.2.3.2.1, 9.2.3.2.2, 9.2.3.2.3 and 9.2.3.2.4 to develop new proxy models.

Although the possible covariates to nitrous oxide flux must be reported at the time of validation, the selected model and data used to fit the model must be reported at the time of the first verification event.

9.2.3.2.1 Considering Covariates

In developing a statistical model, project proponents must first develop a list of possible covariates and list sources of potential data for those covariates, which may include direct field measurement, remote sensing, peer-reviewed scientific literature, and technical reports completed by government agencies. From the initially considered covariates, identify those whose data availability and expected relationship with methane flux are most relevant to the project needs.

Possible and selected covariates and sources for covariates must be validated.

PD Requirements: Covariates for Proxy Nitrous Oxide Models
The project description must include the following if an proxy model is used to estimate nitrous oxide flux: **PDR.80** A list of possible covariates and the sources of data available for each. **PDR.81** A list of selected covariates to be used for model fitting.

9.2.3.2.2 Collecting Data for Model Fitting and Response Variables

Data for model fitting may be collected from a combination of direct field measurements (see Appendix B), peer reviewed scientific literature and/or technical reports issued by government agencies. Field data must be collected to cover the entire range of nitrous oxide emissions flux potentially expected by the project, as well as the values of covariates that correspond to that range.

When data are collected directly by the project proponent in the field, a data collection plan (or protocol) must be prepared, detailing the data collection methods and referencing appropriate technical source documents.

Monitoring Requirements: Data Collection for Proxy Nitrous Oxide Model
The first monitoring report must include the following if an proxy model is used to estimate nitrous oxide flux: **MRR.83** Complete references to the source of any data collected from literature or reports. **MRR.84** Data collection procedures, plans or protocols for any data collected directly from the project area.

9.2.3.2.3 Model Fitting, Selection, and Goodness of Fit

This methodology is not prescriptive with regard to model form and fitting procedures, as various types of models may be appropriate depending on the observed relationship between covariates and response variables. However, the model must be fit using sound and well-documented statistical methods. The model must predict nitrous oxide flux in tCO_2e/day (or units that can be converted appropriately) from some combination of measureable covariates. The project proponents must consider a variety of model forms and data transformations as appropriate to the data collected. During model fitting, attention should be paid to outliers and overly influential data points. Residual plots should be analyzed to confirm that model fitting assumptions have been met. Model selection and goodness of fit must be evaluated as described in Appendix F.

PD Requirements: Model Fit for Nitrous Oxide
The project description must include the following if an proxy model is used to estimate nitrous oxide flux: **PDR.82** Justification that the proxy is an equivalent or better method (in terms of reliability, consistency or practicality) to determine the value of interest than direct measurement.

Monitoring Requirements: Model Fit for Nitrous Oxide
The first monitoring report must include the following if an proxy model is used to estimate nitrous oxide flux: **MRR.85** The form of the selected model. **MRR.86** Summary statistics of the model fit as appropriate to the fitting of the model. **MRR.87** The estimated model parameters. **MRR.88** A description of the range of covariate data with which the model was fit.

9.2.3.2.4 Predicting Nitrous Oxide Flux

When a proxy model is used, measurement of the selected covariates replaces direct measurement of nitrous oxide flux at each verification event. Covariates must be measured according to the procedures outlined by the project proponent in Section 9.2.2.2.1 and their actual values reported. Use the measured values as inputs to the statistical model. In the case that there is uncertainty about the value of a covariate model input, choose the value that results in the most conservative (ie, largest) estimate of nitrous oxide emissions flux. Models must not be extrapolated more than 10% (that is, no independent variables that exceed the range from which the model was fit by more than 10% must be input into the model).

Monitoring Requirements: Model Prediction for Nitrous Oxide
The first monitoring report must include the following if an proxy model is used to estimate nitrous oxide flux: **MRR.89** The values of any measured covariates. **MRR.90** The predicted nitrous oxide flux.

9.2.3.3 Direct Measurement

If using direct measurements, the project proponent must measure nitrous oxide flux using chambers. The project proponent may use the protocols prescribed in Appendix B as the basis for flux measurement in the monitoring plan.

Monitoring of gas fluxes is inherently uncertain when aggregated over space and time. This methodology addresses this uncertainty by providing requirements that ensure the fluxes are overestimated, rather than underestimated, using conservativeness as a mediator to accuracy. These requirements include guidelines for stratification, a requirement for making measurements in the stratum expected to have the highest emissions, and guidelines for the points in time during which measurements are made.

To convert monitoring data from flux per acre per day to flux per day as required in Section 8.2.3, use equation [G.12].

9.2.3.3.1 Stratification

Stratification must be used to determine the stratum that is likely to yield the greatest nitrous oxide emissions flux over the course of a year. Appendix A, Section A.1, provides general guidelines for stratifying the project area. Direct measurements must occur in the stratum that is likely to yield the greatest nitrous oxide emissions flux, and may optionally be made in other strata as well, using appropriate area-weighted stratification estimators as provided in Appendix A to determine a weighted-average estimate of flux for the project area. Strata boundaries may change over time. If this occurs, the project proponent must ensure that the stratum likely to yield the greatest nitrous oxide flux is always measured.

PD Requirements: Stratification for Nitrous Oxide Emissions
The project description must include the following if direct measurement is used to estimate nitrous oxide flux: **PDR.83** Description for how the strata were delineated. **PDR.84** Map(s) of the initial strata boundaries indicating which stratum is likely to yield the greatest nitrous oxide emissions flux. **PDR.85** Justification per the criteria in Section 9.2.2.3.1 for the stratum that is likely to yield the greatest nitrous oxide emissions flux.

Monitoring Requirements: Stratification for Nitrous Oxide Emissions
The monitoring report must include the following if direct measurement is used to estimate nitrous oxide flux: **MRR.91** Map(s) of the current strata boundaries. **MRR.92** A description of changes to the strata boundaries (if applicable).

9.2.3.3.2 Chamber Measurements

In most cases, chamber measurements for nitrous oxide flux will be collocated with methane flux. In the event that they are not collocated, the requirements of Section 9.2.2.4.1 must be used to identify the location of chambers for nitrous oxide.

9.2.3.4 Frequency of Measurement

There are two options for the frequency of nitrous oxide flux measurements:

1. In conjunction with chamber samples of methane flux per Section 9.2.2.4.1 (if applicable); or
2. Approximately once per calendar month, a minimum of 12 samples that are no less than seven days apart.

For either option, nitrous oxide flux must be calculated as the mean of all measurements.

Monitoring Requirements: Chamber Sampling for Nitrous Oxide
The monitoring report must include the following: **MRR.93** Table of sampling event dates for the monitoring period, including the time of day samples were collected, water level relative to the soil surface, soil temperature, and air temperature. **MRR.94** Copy of field data sheets documenting time intervals when samples were collected, sample identification number, and verification of the total number of samples received by the laboratory.

9.2.4 Monitoring Project Energy Consumption

Units of energy that are consumed as a result of project activities and monitoring activities must be monitored using the direct measurement approach or the cost approach (see Sections 9.2.4.1 and 9.2.4.2).

Monitoring Requirements: Energy Consumption Measurement Method
The monitoring report must include the following: **MRR.95** The selected approach to monitoring energy consumption.

9.2.4.1 Direct Measurement of Energy Consumption

If direct measurement is used, the project proponent must maintain separate records of energy consumption for each energy type listed in Table 10 (see Section 8.1.1). The total units of energy consumed during the monitoring period for each energy type is recorded as $G_{P\,\Delta\,(ty)}^{[m]}$.

Monitoring Requirements: Direct Measurement of Energy Consumption
The monitoring report must include the following: **MRR.96** Energy consumption for each energy type listed in Section 8.1.1. **MRR.97** References to records of energy consumption.

9.2.4.2 Cost Approach to Energy Consumption

The cost approach to estimating energy consumption assumes that the project proponent does not possess definitive, itemized records of energy expenditures, given that energy and fuel costs often are paid directly by dredging subcontractors and actual energy consumption is not often reported. If the cost approach is used, the project proponent must extrapolate energy consumption based on the project budget and historic energy costs. The project proponent must adhere to the following procedure:

1. Determine the proportion of the dredging budget estimated for fuel (or electricity) purchases,
2. Identify the energy type(s) likely to have been used in the course of dredging, and
3. Calculate the estimated energy consumption by energy type using published historic energy prices (eg, U.S. Energy Information Administration) at the time of dredging activities. The estimate of total units of energy consumed during the monitoring period for each energy type is recorded as $G_{P\,\Delta\,(ty)}^{[m]}$.

The project proponent must justify how the energy prices and proportion allocated to energy type is conservative; the most conservative scenario will always be to assume the lowest energy prices and allocate the highest emission factor for each type.

Monitoring Requirements: Cost Approach to Energy Consumption	
The monitoring report must include the following:	
MRR.98	Justification for the proportion of dredging budget allocated for fuel (or electricity) purchases.
MRR.99	Justification for choice of energy type(s).
MRR.100	Documentation of historic energy costs at the time of dredging activities.
MRR.101	Justification of estimate of energy consumption.

9.2.5 Monitoring Project Sediment Transport

Emissions from energy consumption are based upon the mass of sediment transported as a result of project activities. The mass of sediment transported is given by equation [G.2] where $M_{P\,\Delta}^{[m]}$ is the mass of sediment dredged from the sediment source as a result of project activities during the monitoring period, $V_{P\,\Delta}^{[m]}$ is the volume of transported sediment, and $d_{P\,\Delta}^{[m]}$ is the density of the transported sediment. The estimated volume of transported sediment must be based upon the volume of the catchment area to which dredged sediment is transported. Given that dredged sediment is likely to be a solid-liquid mixture, the density must be measured as equation [G.1].

Monitoring Requirements: Monitoring Sediment Transport	
The monitoring report must include the following:	
MRR. 102	Justification for the estimate of volume of dredged sediment transported.
MRR. 103	Justification for the estimate of the density of dredged sediment.
MRR.104	Estimated mass of sediment transported.

9.2.6 Monitoring Allochthonous Carbon

For projects that do not meet the criteria for the conservative exclusion of allochthonous carbon import (per Section 5.2.1), the project proponent must monitor allochthonous carbon sedimentation. Accretion measurements (ie, with a marker horizon technique) must be used to estimate the fraction of allochthonous mineral-associated carbon with sedimentation.

Based on literature values for the project area, a conservative deduction must be assessed according to the procedures described in Appendix E.6.4 and using equation [E.4]. Using regionally appropriate literature, the project proponent must use a peer-accepted correction factor (typically ≤3% of the mineral content is bound by organic matter, see Andrews et al. 2011) for the type of wetland system (eg, fluvial, non-fluvial) in order to compute the mass of the mineral-associated carbon that must be subtracted from total soil carbon accumulation during the monitoring period.

Monitoring Requirements: Monitoring Allochthonous Carbon	
The monitoring report must include the following:	
MRR.105	Reference(s) to the regionally appropriate literature used to determine the correct factor for mineral-associated carbon.

9.2.7 Monitoring Baseline Methane Flux

Baseline monitoring for methane must be conducted in a suitable reference area (as defined in Section 6.3.1). Methane monitoring (chamber or eddy covariance) must conform to the requirements in Sections 9.2.2 and must use the sampling designs and specifications outlined in Appendices B and C.

9.2.8 Procedures for Quality Control and Assurance

The monitoring plan must specify specific measures for quality control and assurance. These measures must conform to the requirements in Sections 9.2.8.1, 9.2.8.2 and 9.2.8.3.

9.2.8.1 Field Measurements

The project proponent must develop a monitoring plan that includes a detailed field sampling protocol. Field data must be spot-checked for errors in sampling, transcription, and analysis (see Section 9). The project description must describe the type and frequency of training for field personnel responsible for sampling carbon stocks, fluxes, and covariates. The monitoring report must document the type and training field personnel received during the monitoring period.

PD Requirements: Field Training for Field Sampling	
The project description must include the following:	
PDR.86	A description of the type and frequency of training of field personnel responsible for sampling carbon stocks, fluxes, and covariates.

Monitoring Requirements: Field Training for Field Sampling	
The monitoring report must include the following:	
MRR.106	The type and frequency of training of field personnel during the monitoring period.

9.2.8.2 Data Transcription and Analysis

Project proponents must document a procedure for ensuring high quality data is used in determining emissions reductions and removals. This procedure must include methods for recording and archiving data, checking data for errors, and analyzing data in a transparent manner. To the extent possible, analysis methods should be maintained throughout the lifetime of the project (eg, using the same spreadsheets, software, and computer code for all calculations made during the project lifetime). A percentage of any data entered manually should be randomly checked for transcription errors, preferably by a person not involved in the initial entry.

9.2.8.3 Carbon Stock Measurements

All carbon stock data from individual plots must be provided to the validation/verification body, along with all spreadsheets or computer code used to calculate project-level carbon stocks and associated uncertainties. Data analysis should be carefully checked for transcription or calculation errors. The distribution of biomass estimates by plot should be examined and compared to available literature to confirm that reasonable results have been achieved; a similar procedure must be followed for SOC. Any plots with unusually high or low biomass or SOC (ie, outliers) should be examined closely. It is good practice to re-measure a subset of biomass plots to verify the accuracy of field measurements when non-destructive sampling techniques are used. When destructive sampling is used, evidence of calibration of instruments (such as scales) must be provided.

Monitoring Requirements: Carbon Stock Measurements	
The monitoring report must include the following:	
MRR.107	Biomass and SOC carbon stock data for all plots, along with any ancillary spreadsheets or computer code used to generate these predictions.
MRR.108	List of outliers with unusually high or low biomass or SOC, including justification for their continued inclusion.
MRR.109	Results of accuracy assessment if non-destructive sampling techniques are used. Otherwise, justification for why accuracy need not be formally addressed.

9.2.8.4 Eddy Covariance Data

The project proponent must take direct measurements of methane flux using eddy covariance. The project proponent may use the protocols prescribed in Appendix C as the basis for flux measurement in the monitoring plan.. Refer to Section 9.2.2.4.2 for eddy covariance sampling requirements. Requirements for calibration are found in Section C.2.5.

PD Requirements: Quality Control and Assurance of Eddy Covariance Data	
The project description must include the following:	
PDR.87	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.

Monitoring Requirements: Quality Control and Assurance of Eddy Covariance Data
The monitoring report must include the following: **MRR.110** Description of processing software used, assumptions, and data quality control measures, which must include the selected method of coordinate rotation, detrending, and density fluctuation correction.

9.2.8.5 Laboratory Analyses

The analysis of methane and/or nitrous oxide from chamber samples (see Sections 9.2.2.3.2 and 9.2.3.3, Appendix B) must meet or exceed USEPA QA/QC requirements. The selected laboratory must provide written pre-analysis sample processing procedures, specific chemistry test methods and detection limits for the analysis.

Sample analyses must follow the EPA Method 3C (Determination of Carbon Dioxide, Methane, Nitrogen, and Oxygen from Stationary Sources). Instrument calibration must comply with EPA Protocol Gaseous Calibration Standards.

Soil samples must be analyzed for bulk density and SOC by a qualified laboratory following the methods of Nelson and Sommers 1996 and Ball 1964, respectively, or comparable methods. The chosen laboratory must have a rigorous Quality Assurance program that meets or exceeds the USEPA QA/QC requirements or similar international standards for laboratory procedures, analysis reproducibility, and chain of custody. The laboratory must also provide a document that defines the pre-analysis sample processing procedures, and the specific chemistry test methods they use at the laboratory, including the minimum detection limits for each constituent analyzed.

Monitoring Requirements: Laboratory Analyses
The monitoring report must include the following if samples are sent to a laboratory: **MRR.111** Documentation of the laboratory QA/QC protocols, the methods of sample analysis, and general calibration procedures used the laboratories conducting the analysis.

9.3 Data and Parameters Available at Validation

Data Unit / Parameter	A_{PA}
Data unit	acre
Description	Size of project area
Equations	[G.10], [G.12]
Source of data	GIS analysis prior to sampling
Justification of choice of data or description of measurement methods and procedures applied	-
Purpose of data	
Comments	

Data Unit / Parameter	$e_{(ty)}$
Data unit	tCO_2e/gal, tCO_2e/scf, tCO_2e/kWh
Description	Emissions coefficient for energy type *ty*
Equations	[G.3], [G.14]
Source of data	Emission factors in Section 8.1.1, Table 10
Justification of choice of data or description of measurement methods and procedures applied	Selected from published values
Purpose of data	
Comments	

Data Unit / Parameter	$g_{B\ (ty)}$
Data unit	gal/tonne, scf/tonne, kWh/tonne
Description	Energy consumed per metric tonne of sediment dredged in the baseline
Equations	[G.3]
Source of data	Documentation provided by project proponent
Justification of choice of data or description of measurement methods and procedures applied	Direct measurement

Purpose of data	
Comments	

Data Unit / Parameter	$p_{B\ (ty)}$
Data unit	proportion (unitless)
Description	Proportion of energy for energy type *ty* consumed in the baseline scenario
Equations	[G.3]
Source of data	Documentation provided by project proponent
Justification of choice of data or description of measurement methods and procedures applied	Calculated from direct measurement
Purpose of data	
Comments	

PD Requirements: Data and Parameters Available at Validation
The project description must include the following: **PDR.88** The value of each variable, data and parameter. **PDR.89** The units, descriptions, source, purpose and comments for each variable reported in the PD.

9.4 Data and Parameters Monitored

Data Unit / Parameter	$C_{P\ CS\ (c)}^{[m]}$
Data unit	tCO_2e
Description	Cumulative project carbon stock in pool *c* at end of monitoring period
Equations	[G.7]
Source of data	Sampling of carbon stocks
Description of measurement methods and procedures to be applied	See Appendix D
Frequency of	At least every five years

monitoring/recording	
QA/QC procedures to be applied	Independent review of equations and check against literature estimates. See Section 9.2.8.3
Purpose of data	
Calculation method	
Comments	

Data Unit / Parameter	$d_{LQD}^{[m]}$
Data unit	kg/m3
Description	Density of liquid in dredged sediment
Equations	[G.1]
Source of data	Direct measurement
Description of measurement methods and procedures to be applied	See Section 9.2.5
Frequency of monitoring/recording	Where sediment is transported, Every monitoring period.
QA/QC procedures to be applied	Compare data from multiple samples. See Section 9.2.8.1
Purpose of data	
Comments	

Data Unit / Parameter	$d_{SLD}^{[m]}$
Data unit	kg/m^3
Description	Density of solids in dredged sediment
Equations	[G.1]
Source of data	Direct measurement
Description of measurement methods and procedures to be applied	See Section 9.2.5
Frequency of monitoring/recording	Where sediment is transported, Every monitoring period
QA/QC procedures to be applied	Compare data from multiple samples. See Section 9.2.8.1
Purpose of data	

Comments	

Data Unit / Parameter	$f_{B\,\Delta\,CH4}^{[m]}$
Data unit	tCO_2e/ac/day
Description	Baseline methane emissions flux per unit area
Equations	[G.5]
Source of data	Static chamber or eddy covariance measurement
Description of measurement methods and procedures to be applied	See Section 9.2.7
Frequency of monitoring/recording	Every monitoring period
QA/QC procedures to be applied	Comparison of data from multiple samples and independent review of calculations. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
Purpose of data	
Comments	

Data Unit / Parameter	$f_{P\,\Delta\,CH4}^{[m]}$
Data unit	tCO_2e/ac/day
Description	Methane emissions flux per unit area within project area
Equations	[G.10]
Source of data	Static chamber or eddy covariance measurement
Description of measurement methods and procedures to be applied	See Section 9.2.2.3
Frequency of monitoring/recording	Every monitoring period
QA/QC procedures to be applied	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
Purpose of data	
Comments	

Data Unit / Parameter	$f_{P\,\Delta\,N2O}^{[m]}$

Data unit	tCO_2e/ac/day
Description	Nitrous oxide emissions flux per unit area within project area
Equations	[G.12]
Source of data	Static chamber or eddy covariance measurement
Description of measurement methods and procedures to be applied	See Section 9.2.3.3
Frequency of monitoring/recording	Every monitoring period
QA/QC procedures to be applied	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
Purpose of data	
Comments	

Data Unit / Parameter	$G_{P\,\Delta\,(ty)}^{[m]}$
Data unit	gal, scf, kW
Description	Energy consumed in project area for energy type *ty* over monitoring period
Equations	[G.14]
Source of data	Direct measurement approach or cost approach
Description of measurement methods and procedures to be applied	See Sections 9.2.4.1 and 9.2.4.2
Frequency of monitoring/recording	Every monitoring period when sediment is transported
QA/QC procedures to be applied	Independent review of calculations and monitoring records. See Sections 9.2.8.1 and 9.2.8.2
Purpose of data	
Comments	

Data Unit / Parameter	${p_{SLD}}^{[m]}$
Data unit	proportion (unitless)
Description	Proportion of solids by weight in the dredged sediment
Equations	[G.1]
Source of data	Direct measurement of dredged sediment

Description of measurement methods and procedures to be applied	See Section 9.2.5
Frequency of monitoring/recording	Every monitoring period when sediment is transported
QA/QC procedures to be applied	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1 and 9.2.8.2
Purpose of data	
Comments	

Data Unit / Parameter	$t^{[m]}$
Data unit	days
Description	Elapsed time from project start at the end of the monitoring period
Equations	[G.11], [G.13]
Source of data	Monitoring records
Description of measurement methods and procedures to be applied	N/A
Frequency of monitoring/recording	Every monitoring period
QA/QC procedures to be applied	N/A
Purpose of data	
Comments	

Data Unit / Parameter	$t^{[m-1]}$
Data unit	days
Description	Elapsed time from project start at the beginning of the monitoring period
Equations	[G.11], [G.13]
Source of data	Monitoring records
Description of measurement methods and procedures to be applied	N/A
Frequency of	Every monitoring period

monitoring/recording	
QA/QC procedures to be applied	N/A
Purpose of data	
Comments	

Data Unit / Parameter	$V_{P\,\Delta}^{[m]}$
Data unit	m^3
Description	Volume of sediment dredged from the sediment source over monitoring period
Equations	[G.2]
Source of data	Direct measurement
Description of measurement methods and procedures to be applied	See Section 9.2.5
Frequency of monitoring/recording	Every monitoring period when sediment is transported
QA/QC procedures to be applied	Independent review of calculations and monitoring records. See Section 9.2.8.2
Purpose of data	
Comments	

Monitoring Requirements: Data and Parameters Monitored
The monitoring report must include the following: **MRR.112** The value of each variable, data and parameter. **MRR.113** The units, descriptions, source, purpose, references to calculations and comments for each variable reported in the Monitoring Report. **MRR.114** For those variables obtained from direct measurement, a description of measurement methods and procedures. These may simply be references to components of the monitoring plan. **MRR.115** For those variables obtained from direct measurement, a description of monitoring equipment including type, accuracy class and serial number (if applicable). These may simply be references to components of the monitoring plan. **MRR.116** Procedures for quality assurance and control, including calibration of equipment (if applicable).

9.5 Grouped Projects

Grouped projects are allowable in order to permit the expansion of project activities after initial validation. For such projects, project documentation may differ by project activity instance with respect to carbon stock estimation, as stratification and plot location will vary. Otherwise, the same monitoring requirements set out in Section 9 apply.

As per Section 9.2.1.1, during the first verification including new project activity instances, all new plots must be measured.

If the original project area is stratified for SOC or biomass, then subsequent project activity instances must be similarly stratified as well, per Section 9.2.1.2.

Monitoring Requirements: Monitoring Grouped Projects	
The monitoring report must include the following when new project activity instances are added to the project:	
MRR.117	List and descriptions of all project activity instances in the project.
MRR.118	Project activity instance start dates.
MRR.119	Map indicating locations of project activity instances added to the group.
MRR.120	List of additional stratifications used for additional project activity instances; justification for why flux measurements are still located in the most conservative stratum (9.2.2, 9.2.3).
MRR.121	As project activity instances are added, the monitoring plan must be updated to reflect additional monitoring times and plot locations.

APPENDIX A: DEFAULT STRATIFICATION AND SAMPLE UNIT ALLOCATION METHODS

Stratification, in which a population to be sampled is divided into sub-populations of known size, can be used in measurements of many variables to improve sampling effectiveness, and can help reduce uncertainty when it would be cost-prohibitive to conduct statistical sampling of sufficient density to adequately represent the entire population. The default stratification methods, including guidelines for the stratification criteria of individual variables, are described in Sections 9.1, 9.2.1.2, 9.2.2.3.1, and 9.3.2.3.1. Here, formulas that can be used to estimate means and totals from stratified samples are provided, as well as guidelines for efficiently allocating sampling units to identified strata.

Stratification should always be done prior to measurement, such that the stratum sizes are known exactly. Stratification may be performed prior to any measurement event. Different stratification schemes may be used for estimating different variables according to the preferences of the project proponent.

A.1 Sample Size and Plot Allocation

In stratified random sampling, the following equations may be used to estimate the sample size required to attain a targeted precision level. Note that this methodology does not require that sample size be calculated in this way—these equations are provided solely for the convenience of the user. Estimating sample size as described here requires an estimate of the mean and standard deviation of the variable to be estimated. These quantities may be estimated from literature or from a pilot sample. The project proponent should recognize that actual standard error of a sampled statistic will be subject to random error, and that if the mean and standard deviation used to estimate the sample size differ significantly from those properties in the actual population, the sample size actually required for the targeted precision level will also from that estimated. The most efficient allocation of plots to strata depends on the relative sizes of the strata, the estimated means and within strata variability, and potentially the costs of sampling each stratum. Three methods are available for allocating sample units, which are described below. Actual sampling units within strata should be chosen systematically with a random starting point or randomly.

A.1.1 Proportional Allocation

Proportional allocation allocates sampling units to strata in proportion to their size. Given a targeted precision level, the total required sample size may be calculated as:

$$\hat{n}_{TOTAL} = \frac{1}{\left(\frac{\mathrm{E}\times\bar{x}}{Z\times\hat{\sigma}_{\bar{x}}}\right)^2 + \frac{\mathrm{n}}{\mathrm{N}}}$$ [A.1]	
Variables	E - The allowable degree of error (eg, 0.15 for +/- 15%) $\bar{x}$ - The estimated mean of the quantity to be estimated Z - Z statistic from a normal distribution associated with the desired confidence level (1.96 for 95% confidence). $\hat{\sigma}_{\bar{x}}$ - The estimated standard deviation of the quantity to be estimated $\frac{\mathrm{n}}{\mathrm{N}}$ - The relative size of a sampling unit with respect to the entire population to be sampled (for example, in sampling with fixed area plots, this is the ratio of the plot size to the total project area size)
Section References	9.2.1, Appendix D, Appendix E
Comments	The estimated required sample size

The plots are allocated to strata in proportion to strata size as follows:

$$\hat{n}_{(k)} = \hat{n}_{TOTAL}\frac{a_{(k)}}{A_{PA}}$$ [A.2]	
Variables	$\hat{n}_{TOTAL}$ - The estimated total required number of plots $a_{(k)}$ - The area of stratum *k* A_{PA} - The total project area
Section References	9.2.1, Appendix D, Appendix E
Comments	The number of plots to be allocated to stratum *k*

A.1.2 Neyman Allocation

Sometimes strata differ in their degree of within-stratum variability. In this case, the overall standard error will be minimized if sampling efforts are concentrated toward those strata with highest variability. If estimates of the standard deviation of each stratum are available, the following equations may be used to allocate sampling units:

$$w_{(k)} = \frac{a_{(k)}\hat{\sigma}_{(k)}}{\sum_{(j)\in\mathcal{S}} a_{(j)}\,\hat{\sigma}_{(j)}}$$	[A.3]
Variables	$a_{(k)}$ - The area of stratum *k* $\hat{\sigma}_{(k)}$ - The estimated standard deviation of the quantity to be estimated within stratum $\mathcal{S}$ - The set of all strata $a_{(i)}$ – The area $\hat{\sigma}_{(j)}$ – The standard deviation
Section References	9.2.1, Appendix D, Appendix E
Comments	The proportion of total sample size to be allocated to stratum k

$$\hat{n}_{TOTAL} = \frac{\sum_{(k)\in\mathcal{S}} \frac{a^2_{(k)}\hat{\sigma}^2_{(k)}}{w_{(k)}}}{\left(\frac{\mathrm{E}\times\bar{x}}{\mathrm{Z}} \times \frac{\mathrm{n}}{\mathrm{N}}\right)^2 + \sum_{(k)\in\mathcal{S}} a_{(k)}\, \hat{\sigma}_{(k)}{}^2}$$	[A.4]
Variables	${a^2}_{(k)}$ - $a_{(k)}$ - The area of stratum *k* ${\hat{\sigma}^2}_{(k)}$ - The estimated standard deviation of the quantity to be estimated within stratum $\mathcal{S}$ - The set of all strata E - The allowable degree of error (eg, 0.15 for +/- 15%) $\bar{x}$ - The estimated mean of the quantity to be estimated $w_{(k)}$ – proportion of total sample size to be allocated to stratum k Z - Z statistic from a normal distribution associated with the desired confidence level (1.96 for 95% confidence). $\frac{\mathrm{n}}{\mathrm{N}}$ - The relative size of a sampling unit with respect to the entire population to be sampled (for example, in sampling with fixed area plots, this is the ratio of the plot size to the total project area size)
Section References	9.2.1, Appendix D, Appendix E
Comments	The estimated total required number of plots

$$\hat{n}_{(k)} = \hat{n}_{TOTAL} w_{(k)}$$ [A.5]	
Variables	$w_{(k)}$ – proportion of total sample size to be allocated to stratum k $\hat{n}_{TOTAL}$ - The estimated total required number of plots
Section References	9.2.1, Appendix D, Appendix E
Comments	The number of plots to be allocated to stratum *k*

A.1.3 Optimal Allocation

A third allocation method incorporates both information about within strata variability and the potential for varying costs for sampling different strata:

$$w_{(k)} = \frac{a_{(k)}\hat{\sigma}_{(k)}/\sqrt{c_{(k)}}}{\sum_{(j)\in\mathcal{S}} a_{(j)}\,\hat{\sigma}_{(j)}/\sqrt{c_{(j)}}}$$ [A.6]	
Variables	$a_{(k)}$ - The area of stratum *k* $a_{(j)}$ – The area of stratum *j* $\hat{\sigma}_{(k)}$ - The estimated standard deviation of the quantity to be estimated within stratum $\mathcal{S}$ - The set of all strata E - The allowable degree of error (eg, 0.15 for +/- 15%) $c_{(k)}$ or $c_{(j)}$ - The cost of sampling stratum *k* or *j*
Section References	9.2.1, Appendix D, Appendix E
Comments	The proportion of total sample size to be allocated to stratum k

A.2 Totals and Standard Errors from Stratified Samples

The total of a quantity of interest may be estimated from a stratified sample

$$\hat{T} = \sum_{(k)\in\mathcal{S}} \frac{a_{(k)}}{n_{(k)}} \sum_{(j)\in\mathcal{P}_{(k)}} y_{(j,k)}$$ [A.7]	
Variables	$a_{(k)}$ - The area of stratum *k* $\mathcal{S}$ - The set of all strata $n_{(k)}$ – Number of sampling units in stratum k $\mathcal{P}_{(k)}$ – Set of all sampling units in stratum k $y_{(j,k)}$ - A quantity estimated for or measured on sampling unit j in stratum k
Section References	9.2.1, Appendix D, Appendix E
Comments	The estimated total quantity in the sampled area

$$\sqrt{\sum_{(k)\in\mathcal{S}} \left[\frac{a_{(k)}^2 \hat{\sigma}_{(k)}^2}{\#(\mathcal{P}_{(k)})}\left(\frac{N_{POSSIBLE\ (k)} - \#(\mathcal{P}_{(k)})}{N_{POSSIBLE\ (k)}}\right)\right]}$$ [A.8]	
Variables	$a_{(k)}$ - The area of stratum *k* $\hat{\sigma}_{(k)}^2$ - The estimated within-stratum variance of stratum *k* $\mathcal{S}$ - The set of all strata $\mathcal{P}_{(k)}$ – Set of all sampling units in stratum k $N_{POSSIBLE\ (k)}$ = total number of possible plots in stratum k
Section References	D.1, D.2
Comments	The estimated standard error of the total

APPENDIX B: DEFAULT STATIC CHAMBER MEASUREMENT METHODS

The project proponent may deviate from the methods provided in this appendix per the requirements of Section 9.

GHG emissions fluxes have been measured with the static (closed) or dynamic (with air circulation) chamber techniques on a wide variety of wetland sites (Moore and Roulet 1991). There are a number of chamber techniques that are used to isolate soil respiration or develop carbon budgets and sophisticated soil flux systems are commercially available. While there are acceptable variations in equipment and techniques, this guidance focuses on describing a static chamber method, with discrete time series of gas measurements during each monitoring period, to calculate methane flux for baseline and project monitoring. Nitrous oxide or carbon dioxide fluxes may be sampled in the same manner, depending on project requirements. With attention to minimizing chamber and soil disturbance, periodic sampling with static chambers can provide an estimate of project area GHG emissions on a daily time scale, which is then extrapolated to annual estimates.

The methods described here are specific to herbaceous marshes where vegetation heights are typically less than 1.0 m, and present optimal conditions to sample all contributions of GHG exchange, particularly soil diffusion, ebullition, and plant-mediated transport of methane. Closed chamber methods that only isolate soil processes, by excluding vegetation, may underestimate the contribution of methane release from plants (through xylem transport to the atmosphere), which can be considerable from certain wetland 'shunt' species that have well developed aerenchyma. Therefore, vegetation must not be excluded from wetland-based sampling, but an exception exists when open water sampling may be necessary for quantifying fluxes from this habitat type. Clipping of emergent plants above the water level to accommodate the dimensions of the flux chamber is allowable immediately prior to sampling. The technique of using dynamic chambers with semi-continuous measurements of GHGs may also be used but will require a justification of the technique and description by the project proponent.

B.1 Chamber Description

Chamber size or design must be scaled to accommodate the existing vegetation height and seal the soil surface so that plant-mediated, diffusion, and ebullition fluxes are captured. Chamber design guidelines described here follow that of Yu et al. (2008) and Parkin and Venterea (2010). A cylinder or box chamber must not have a cross-sectional area less than 200 cm^2. The base seals the soil column and is permanently installed and left in the field during the monitoring period. If the base is disturbed by natural or human causes, it must be reinstalled and allowed to equilibrate for a minimum of two weeks prior to additional sample collection.

The chamber top must be less than 1.0 m in vertical height, and is only installed or fit to the permanently installed base during sampling periods. It contains two or more sealed (syringe septa) gas collection ports that allow sampling when water levels are high or low. One port will have a tube that extends lower in the chamber for retrieving samples when water level is low, and the other port(s) must have a shorter tube(s) to collect samples higher in the chamber when water level is high. Where the chamber base and top seal together there must be a gas-impermeable gasket or water trough.

Cylinder or box chamber materials may consist of stainless steel, aluminum, PVC, polypropylene, polyethylene, or plexiglass. Opaque or clear chambers are acceptable. Black material must not be used given its potential for excessive heating of the chamber in sunlight. The chamber base must have drainage ports along its vertical length to eliminate chamber flooding between monitoring periods.

For sampling open water habitats, chamber specifications are the same as above; however, a permanent chamber base or collar is not required. Rather the chamber top may be outfitted with floatation that can form a seal with the water surface.

B.2 Plot Establishment for Chambers

B.2.1 Replication

Within a stratum, there must be a minimum of two plots comprising three replicate chambers per plot. Each plot must occur within a 100 m radius of a randomly chosen sampling location center point.

From the center point, chambers may be randomly located within a 100 m radius of habitat that is representative of the stratum. Factors that must be considered for plot location include dominant vegetation type and marsh surface elevation. In choosing sample locations, project proponents must justify that the locations chosen are conservative – that is, within a stratum, chambers should be located in areas in which methane flux is expected to be greatest (see section 9.2.2.3.1 for a description methane flux indications). Typically, this involves positioning chambers in areas that occupy lower elevations in the landscape that still support dense vegetation coverage. The arrangement of chambers within this radius will be dependent on the marsh topography and a suitable amount of existing habitat to re-locate chamber plots if needed in the future. There are no minimum or maximum distance requirements between replicate chambers but the chambers should be placed such that sampling can occur within the prescribed time intervals.

B.3 Chamber Installation

Most wetland conditions will require the construction of boardwalks to minimize soil disturbance during chamber deployment and subsequent sampling. Site specific conditions (water table depth, soil permeability) will dictate the depth to which the base of the chamber is fitted into the soil; the base should be installed to a depth no lower than the mean water table depth of the site. Installation of chambers may take place anytime of the year and should occur when water levels are at or below the soil surface.

The chamber base is installed to the soil by slicing and excavating a trench that will accommodate its dimensions. The base must capture representative vegetation cover and species and disturbance to vegetation in the chamber area must be minimized. To allow soil/plant disturbance effects to diminish, the chamber must equilibrate for a minimum of two weeks prior to any sampling. Drainage ports will remain open during the equilibration period and between verification events.

PD Requirements: Chamber Description	
The project description must include the following:	
PDR.90	A description of the chamber design, with its dimensions or total volume, and cross-sectional area.
PDR.91	Diagram of chamber plot randomization design and the resulting chamber locations within each stratum, with the chambers identified as replicates. Provide dates when chambers were deployed in each stratum. Provide a justification that the locations chosen are conservative (ie, that they are likely to predict methane emissions flux for the entire stratum for which they are representative.)

B.4 Chamber Sampling

Flux chamber measurements require collecting syringe gas samples of ambient air outside of the chamber, replicate samples within the chamber base prior to sealing with the chamber top, and then successive samples over an incubation period less than 2 hours after sealing the chamber. A minimum of three sample intervals should be collected: time = 0 hours (unsealed chamber), time = 0.5 hours (30 min after chamber sealed), t = 1.0 hours (60 min after chamber sealed). Exact sample times are recorded during sampling.

Steps:

1. Inspect the chamber base for any physical disturbance.
2. Drainage ports that are open to atmosphere are plugged before inserting the chamber top.
3. Sample vials are vacuumed with a 10 ml syringe.
4. Collect one ambient atmosphere gas sample outside of the chamber and inject into the sample vacuum vial.
5. Duplicate (n=2) gas samples are collected inside the chamber base prior to sealing with the top of the chamber.
6. The chamber top is sealed to the base. Stopwatch is started at t=0.
7. With the chamber sealed, duplicate samples are collected at 30 min intervals and injected into vacuum vials. One minute prior to each sample collection, a stirring procedure is done by

inserting a 30 ml syringe into the chamber septa and withdrawing and expelling the full volume twice.

8. After sampling is complete, the chamber top is removed and the drainage ports are unplugged.

Samples must be stored out of direct sunlight during transport to the laboratory. A chain of custody form should be completed by the field lead and submitted to the laboratory with the samples to be maintained with their records. The steps for open water sampling follow those for wetland-based sampling.

B.5 Data Processing and Analysis

Gas concentration data from lab analyses are in volumetric units (L trace gas : L total gas) and are corrected for chamber volume, cross-sectional area and linear change with time to yield flux volume (L trace gas m^{-2} hr^{-1}), according to the following equation:

$$f_v = v_{CHAM} * c_v * 1/a_{CHAM}$$ [B.1]	
Variables	f_v - flux of trace gas (volume basis) in the chamber headspace over the enclosure period, corrected for chamber volume and cross sectional area (L trace gas m^{-2} hr^{-1}) v_{CHAM} - chamber volume (L) c_v - change in gas concentration over the enclosure period, or slope of best fit line calculated from simple linear regression (L trace gas L^{-1} total gas hr^{-1}) a_{CHAM} - cross-sectional area of soil enclosed by the chamber base (m^2).
Section References	9.2.2.3
Comments	Guidance for assessing goodness of fit is provided in section F.3 of Appendix F. Curve fitting methods for non-linear rates of trace gas change are outlined in: Parkin, T.B. and R.T. Venterea. 2010. Sampling protocols. Chapter 3. Chamber–based Trace Gas Flux Measurements. In: Sampling Protocols R. F. Follett, ed. P.3-1 to 3-39. www.ars.usda.gov/research/GRACEnet

To convert from volumetric to mass flux basis, the ideal gas law is used in the following equation:

$$f_{P\,\Delta} = \frac{f_v * P}{R * T} * M * 24 * 0.000001 * GHGcf$$ [B.2]	
Variables	$f_{P\,\Delta}$ - mass of trace gas flux (tCO_2e ac/day) f_v - flux of trace gas (volume basis) (L trace gas m^{-2} hr^{-1}) *P* - barometric pressure (atm) *T* - air temperature (°K) *R* - universal gas constant (0.0820575 L atm/°K mol) *M* - molecular weight of trace gas (g/mol)
Section References	9.2.2.3
Comments	24 = conversion from hr to day 0.000001 = conversion from g to tonnes $GHGcf$ = GHG correction factor to CO2e, use 21 (CH_4) and 310 (N_2O)

With the series of repeated measures of gas concentration from a chamber, simple linear regression is used to compute the slope of gas concentration with time (c_t), which represents one replicate of gas flux (see equation [B.1]). A minimum of three replicate chambers (or plots) must be used to compute a mean flux (±1SEM) for a given location within a stratum for each verification event or sample date. Refer to Section 9.2.2.3 for chamber flux calculations.

APPENDIX C: DEFAULT EDDY COVARIANCE MEASUREMENT METHODS FOR METHANE

The project proponent may deviate from the methods provided in this appendix per the requirements of Section 9.

Eddy covariance or eddy correlation is a widely accepted micrometeorological technique to estimate flux of heat, water, atmospheric trace gases and pollutants and relies on turbulence to calculate fluxes. The semi-continuous nature of sampling allows for diurnal, seasonal, and annual budgets of energy and GHGs between the biosphere and atmosphere. Measuring carbon fluxes with the eddy covariance method has the advantage of covering broader space and more continuous measurements, unlike chamber flux techniques. The two methods may be used in concert in a heterogeneous landscape to evaluate flux contribution of distinct landforms (hummocks, hollows, ditches, open water; Teh et al. 2011, Baldocchi et al. 2011) to create a more accurate landscape or project area GHG budget.

Standard operating procedures for designing flux studies and data analyses are being unified by global and regional bio-meteorological communities, such as FLUXNET and AMERIFLUX, respectively. The information presented here draws from their basic guidelines for eddy covariance methods. Open source software is increasingly available for computing GHG fluxes that have been validated by a 'Gold Standard' (see AMERIFLUX, http://public.ornl.gov/ameriflux/sop.shtml) and a selection of the available software is given in Section 9.2.8.4.

Eddy flux is equivalent to the mean dry air density, multiplied by the mean covariance of instantaneous deviations of vertical wind velocity and the mixing ratio of a constituent (methane and carbon dioxide) in air. These covariances are corrected for density fluctuations due to water vapor (Baldocchi et al. 2011).

The eddy covariance technique, while applied in many different ecosystems, is most easily applied in areas where the canopy is relatively homogeneous and the terrain is horizontal. Thus herbaceous wetlands lend themselves well to this technique. Caution is needed when deploying eddy covariance stations, so that vertical disruptions (canopy height changes, trees, buildings) to the boundary layer of interest are minimized. The seven main assumptions for eddy covariance technique are outlined here (from Burba and Anderson 2007) and specific requirements to satisfy these assumptions are described throughout this appendix.

1. Measurements at a point represent an upwind area
2. Measurements are collected in the layer of interest (eg, constant flux layer)
3. The fetch is assumed to be adequate and measures the area of interest
4. Flux is fully turbulent
5. Terrain is horizontal
6. Average of vertical fluctuations is zero, density fluctuations are negligible, and flow convergence and divergence does not occur.

7. Instruments are capable of detecting small changes and measuring at a high frequency (>10 Hz).

There are sources of error that can affect flux computations; however, these errors, such as time lags in measurements and unleveled instruments, are adjusted according to accepted methods during data processing (see Section 9.2.8.4).

C.1 Eddy Covariance Instrumentation

Direct measurements of methane at high frequencies (10-20 Hz) are needed for eddy covariance calculations. For methane, laser absorption spectroscopy is common, and suitable instrumentation is equivalent to those of the closed path Los Gatos tunable diode laser spectrometer (DLT-100 Fast Methane Analyzer), the open path LICOR 7700 (Wave Modulated Spectroscopy), and the Campbell Scientific Trace Gas Analyzers. The chosen methane analyzer must have a resolution of ≤5 ppb methane at 10 Hz (@ 2000 ppb methane) and measurement frequencies must not be less than 10 Hz.

In addition to methane, other meteorological variables must be measured at a frequency (≥10 Hz) equivalent to the gas measurements, including wind and turbulence (three-dimensional sonic anemometer), water vapor, and air temperature. The chosen water vapor analyzer must have a resolution ≤ 0.005 mmol H20/mol air (@ 10 mmol H20/mol air). The sonic anemometer must have a resolution ≤ 0.01 m/sec (@ standard velocity of 12 m/sec). Water vapor measurements will be used to correct for air density fluctuations.

C.2 Tower Configuration

C.2.1 Orientation of Sensors and Equipment

A single tower must be used with the elevated array of eddy covariance instruments contained within a 3 m radius from the center of the tower. If a platform is used, the maximum footprint of the platform and support equipment (solar panels, flow modules, batteries) must not exceed a 5 m radius from the center of the tower base.

High frequency measurements of air properties for eddy covariance require short distances between sensors to minimize time response errors. Instrumentation on the tower must be integrated (ie, trace gas analyzers, anemometer, and temperature sensors) such that distance and orientation between sensors sample the representative air mass properties and allow frequency response corrections.

While configurations may vary depending on the wind direction of interest, the maximum horizontal distance of methane sensor or water vapor intake must not exceed 1.0 m from the center of the anemometer, unless the project proponent provides justification. The distance of the intake sensor for air density and methane sensor must be measured and recorded for elevation, in addition to the northward and eastward separation relative to the center of the sonic anemometer.

C.2.2 Landscape Location of Tower

For conservative project emissions estimates, a primary requirement is to locate the tower within the strata where the highest emissions are anticipated, and at least one-half of the footprint area (as defined by the 80% mean footprint distance) must include the highest emitting strata (see Section 9.2.2.3.1, which defines criteria for determining areas likely to have highest emissions).

The slope of the site must not exceed 1% (1 m vertical /100 m horizontal distance) in any direction within a 200m radius of the eddy covariance tower. The tower may be positioned in the landscape to capture specified wind direction(s) or it may be centrally placed within a homogeneous habitat with adequate fetch to measure all wind directions. In either case, the terrain must be homogeneous with respect to the *mean 80% footprint distance*. Homogeneous terrain here is defined as an area that contains no more than 25% areal coverage of patch vegetation that exceeds twice the dominant plant canopy height. A patch is defined as ≥100 m^2 of species (twice the dominant plant canopy height) covering >70% of the 100 m^2.

C.2.3 Sensor Height

As a general rule a sensor height of 1.0 m above the canopy can integrate fluxes from 100 m upwind under turbulent conditions. Sensor height above the canopy must be no less than one and one-half greater than the dominant plant canopy height in the footprint area. It is permissible to increase or decrease sensor height on the tower to accommodate changes in plant canopy height, as long as the sensor height is maintained above twice the canopy height. Alternately, during data post-processing vegetation canopy height may be adjusted without changing sensor height. Physical changes in sensor height must be recorded and incorporated as offsets during data processing.

C.2.4 Fetch and Flux Footprint

Fetch is described as the horizontal extent from the tower where flux is sampled, whereas the flux footprint describes how much of the measured flux comes from an area at a given horizontal distance. Sufficient fetch is needed to develop an internal boundary layer where fluxes are constant with height (Baldocchi et al. 2001). For every 1.0 m increase in vertical plant structure above an effective surface, approximately 100 m of fetch is needed to readjust the internal boundary layer (Businger 1986, in Baldocchi et al. 1988). To provide adequate fetch, the effective surface (dominant canopy height of interest) must be provided by the project proponent and the sensor height must be twice the dominant canopy height within a minimum radius of 100 m from the tower. If patch vegetation is present it must not exceed the 25% area threshold identified in Section C.2.2.

C.2.4.1 Footprint Distance Estimation

The *mean 80% footprint distance* provides the verifier with information to confirm that flux measurements are being collected within an area that is homogeneous. Here, *mean 80% footprint distance* can be estimated with a predictive model and using daytime turbulence parameters that are typical of the region (ie, from a nearby meteorological station) and the characteristics of the site.

The predicted *mean 80% footprint distance* must be estimated by the project proponent based on the methodology by Klujn et al. (2004), which uses turbulence parameters to predict the location or distance that influences a percentage of the flux. In this case, the project proponent must provide parameter estimates and the results of the predicted footprint distance with 80% flux contribution (online footprint parameterization, http://footprint.kljun.net/varinput.php) to the verifier, based on data known for the project site or estimates from local meteorological stations for the time period of measurement. The parameter estimates must include:

σ_W = standard deviation of daytime vertical velocity fluctuations (m/s)
u_* = surface friction velocity (m/sec)
z_m = measurement height (m)
h_m = planetary boundary layer height (m) or 1000 m
z_m = roughness length (m) or 1/10th of the average canopy height

C.2.5 Calibration

Calibration of methane sensors must be performed by the factory or user according to manufacturer guidelines. When LICOR equipment is used, the intervals for checks and calibration are provided here, while detailed calibration/zero instructions can be accessed via the LICOR website. The methane analyzer (LI-7700) must be fully calibrated spanning a 0 and 10 ppm methane concentration standard at least once annually with standard gases (1% accuracy). Zero and 10 ppm checks of the methane analyzer with hydrocarbon-free and 10 ppm standard gases (accuracy for zero gases = <0.1 ppm Total Hydrocarbon Concentration; accuracy for 10 ppm methane = <0.5 ppm methane) must be conducted at a minimum of twice every six months over one year of data collection. The LI-7200, which measures water vapor and carbon dioxide, must be returned to the factory at least once every three years to confirm the stability of coefficient values on the factory drift table.

C.3 Scale to Project Area

Project field monitoring designs may fall into one of several general approaches that may embrace one uniform habitat type or multiple habitat types in a single location, periodic habitat sampling, or multiple eddy covariance towers contemporaneously measuring different habitats.

1. Stationary single habitat: The simplest case is restricting long-term measurements to a single location that maximizes flux estimates from a homogeneous habitat across seasonal atmospheric and environmental events. The assumption of this approach is that the range of project-scale variability in GHG emissions is adequately characterized over an annual period.

2. Stationary multiple habitats: The eddy covariance tower may be placed a single location that generates information from different habitats that have different source/sink effects. In this case,

data are isolated by the wind direction or quadrant that corresponds to the habitat (open water, scrub-shrub, herbaceous).

3. Complete or periodic coverage of multiple habitats: For project areas with diverse habitats, each habitat type is individually instrumented and measuring simultaneously for valid inter-habitat comparisons. Another approach is to make periodic movements to different habitats with an eddy covariance tower. The degree to which periodic deployments in different locations approximate average conditions must be demonstrated by the project proponent.

Regardless of the method chosen above to scale from the tower location to the project area, project proponents must justify that the tower locations selected result in conservative estimates of methane emissions flux. To do this, project proponents must:

1. Stratify the project area based on measureable factors expected to impact methane emissions flux. These factors may include but are not limited to elevation, vegetation cover, and salinity.

2. Calculate the percentage of the total project area that falls into each methane emissions flux stratum.

3. Using the mean 80% footprint distance defined above, calculate the percentage of the expected tower footprint that falls within each stratum.

4. Demonstrate that, if the proportion of the tower footprint area that falls within each stratum differs from the proportion of the total project area that falls within each stratum, the tower footprint area contains a proportionally greater area of strata expected to have high methane emissions flux. For example, if two strata are identified (low and high emissions flux), and the project area is 40% low and 60% high, a tower footprint that includes 70% high emissions flux strata and 30% low is acceptable, while a footprint that includes 55% high emissions flux strata and 45% low is not. If evidence can be presented that a tower footprint is completely homogenous and all strata are sampled separately, this requirement can be considered satisfied.

$$f_{P\,\Delta\,CH4} = (\,\overline{\rho a}\,\overline{w's'}) \times 5.61 \times 10^{-3} \times 21$$ [C.1]	
Variables	$f_{P\,\Delta\,CH4}$ = CH_4 daily flux (tCO_2e/ac/day) $\overline{\rho a}$ - mean air density for a 0.5 hour sample interval (μmol air/m^3) $\overline{w's'}$ - mean covariance of instantaneous vertical wind velocity and mixing ratio of CH_4 in air w' - instantaneous vertical wind velocity (m/sec) s' - instantaneous mixing ratio of CH_4 in air (μmol gas/μmol air)
Section References	9.2.2.3
Comments	5.61×10^{-3} = unit conversion of μmol CH_4/m^2/s to tCH_4/ac/day 21 = conversion of tCH4 to tCO_2e

C.4 Data Processing and Analyses

Decades of eddy covariance methodology research has resulted in some widely accepted sequences of processing steps and corrections that should be applied. As an evolving science, however, there are debatable topics under discussion. The traditional steps in eddy covariance data processing are outlined below and the project proponent is responsible for specifying how data processing conforms to accepted methods (adapted from Burba and Anderson 2007).

Table 16: Steps to eddy covariance data processing

	Step	Accepted methods	References
1.	**Raw data unit conversion**	- raw voltage to unit conversion	
2.	**Despike**	-signals greater than 6 times the standard deviation for a given averaging period (30 min) must be removed for vertical wind velocity and gas concentration	
3.	**Calibration coefficients**	-may be done during data post processing; or, -user input corrections embedded in the instrument software and metadata	
4.	**Coordinate rotation**	- rotation to mean vertical velocity is equal to zero over a 30 min sample interval; or, -planar fit method; or, -sonic tilt correction algorithms	
5.	**Detrending**	-30 min block averaging must be used -linear and non-linear de-trending should be justified by project proponent	
6.	**Frequency response corrections**	-corrections may include: sensor separation, scalar path averaging, high-low pass filtering.	Moore, C.J. 1986. Frequency response corrections for eddy correlation systems. Boundary Layer Meteorology, 37:17-35.
7.	**Density fluctuation**	WPL correction applied to uncorrected covariances or final fluxes.	Webb, E.K., Pearman, G., and Leuning, R. 1980. Correction of flux measurements for density effects due to heat and water vapor transfer. Quarterly Journal of the Royal Meteorological Society, 106:85-100.

C.5 Flux Footprint Calculations

Flux footprint calculations must employ one of the following methods: Klujn et al. 2004 or Kormann and Meixner 2001. With either method, the project proponent must provide a summary table describing the measured meteorological conditions and the mean 80% footprint distance for the monitoring period. See equation [C.1].

APPENDIX D: DEFAULT BIOMASS MEASUREMENT METHODS

The project proponent must develop a detailed sampling protocol for the purposes of field crew consistency and documentation. The project proponent may deviate from the methods provided in this appendix per the requirements of Section 9.

D.1 Above Ground Tree Biomass

Above ground tree (AGT) biomass includes only trees above a specified diameter and is estimated using allometric equations. For each tree within a given measurement plot, diameter at breast height (dbh) is measured and input into an equation to yield an estimate of above ground biomass. Some equations may also require tree height and/or wood density. Tree biomass is then summed for each plot, and plot biomass estimates are extrapolated across the entire project area to estimate total carbon stocks in AGT biomass.

Project proponents must choose plot size and design. For example, a nested plot configuration may be utilized in order to decrease sampling size necessary to obtain an acceptable level of error. The sampling protocol should reflect the selected sampling scheme.

In each plot, required measurements are taken on every tree falling within the plot based on the sampling protocol. The sampling protocol should explain how to determine whether a given tree is “in” or “out.” The project proponent may decide whether to collect height or wood density based on which metrics are required by selected allometric equations.

When a list of tree species present in the project area is available, allometric equations are to be compiled. Equations may be obtained from peer-reviewed scientific journals or developed by the project proponent, and may be species-specific, genus-specific, or generic form equations. Equations must be validated. When form equations are used, the project proponent must justify that they are conservative for species considered in the project. Since small errors in equations can lead to significant error in the biomass estimate across the entire project, it is important that equations are representative of the trees for which they are utilized—species, locale, and diameter range used to develop the equations should be considered when making selections. If equations require wood density, the project proponent may choose to employ species- or genus-specific values from peer-reviewed scientific journals instead of using field-collected data.

After field measurements are complete, the following steps are taken to calculate total project area carbon stocks in AGT:

- Using Equation [D.1], apply the appropriate allometric equation and convert the resulting biomass to carbon stocks for each tree.
- Using Equation [D.2], AGT carbon stocks are summed for each plot then divided by plot area to yield plot-wide carbon stock density.
- Using Equation [D.4], carbon stocks in each stratum are extrapolated from plot-wide carbon stock density and summed across all strata to yield average AGT carbon stocks for the project.

- Using Equations [A.8], calculate standard error of the average project carbon stock estimate.

D.2 Above Ground Non-Tree Biomass

Grasses, sedges, other herbaceous plants, shrubs, and trees smaller than the AGT pool minimum diameter are included in above ground non-tree (AGNT) biomass. Woody plants (small trees and shrubs) may be measured using either destructively-sampled clip plots or allometric equations, while herbaceous plants, if included, must be measured using clip plots. If a distinction in sampling is made between woody and herbaceous plants, a procedure to ensure that each plant is counted only once must be outlined in the sampling protocol.

Plot size will be chosen by the project proponent and will likely be much smaller than AGT plots. Though plots for AGNT sampling are separate measuring units from AGT plots, they may exist within AGT plots.

D.2.1 Destructive Sampling – Clip Plots

In the destructive sampling method, all plants in the sampling frame within a plot are cut and weighed to measure plot-wide AGNT biomass. Plants should be cut at a consistent height as close to the ground as possible. To aid in determining the extent of the plot, a sampling frame of the desired plot size must be laid on the ground and all plants within must be cut. If possible, biomass must be refrigerated as soon as possible after clipping in order to avoid mass loss due to respiration.

If the project proponent desires, woody and herbaceous plants may be destructively sampled separately, with a smaller plot size for herbaceous plants to improve sampling efficiency.

After harvest, all biomass should be placed in a drying oven at 70° C and weighed periodically until weight is static, indicating that drying is complete. Weigh all dry biomass to determine plot-wide dry weight.

Alternatively, the project proponent may elect to measure wet weight of all biomass in the field and collect a representative and well mixed subsample of which to measure dry weight. The ratio of dry-to-wet weight determined by the subsample would then be multiplied by the plot-wide wet weight to determine plot-wide dry weight.

After measurements are complete, the following steps must be taken to calculate total project area carbon stocks in AGNT:

- Using Equation [D.3], AGNT biomass is converted to carbon stocks and then divided by plot area to yield plot-wide carbon density.
- Using Equation [D.4], carbon stocks in each stratum are extrapolated from plot-wide carbon stock density and summed across all strata to yield average AGNT carbon stocks for the project.
- Using Equations [A.8], calculate standard error of the average project carbon stock estimate.

D.2.2 Allometric Equations

Allometric equations may be used to estimate biomass of trees smaller than the AGT minimum and small shrubs. It is not only less important but also potentially impractical for equations to be specific to the species level in this scenario. The project proponent may wish to destructively sample a subset of shrubs in order to develop one or more allometric equations since doing so for shrubs is far easier than for trees.

The same procedure used to estimate biomass through allometric equations used for AGT biomass must be used to find AGNT; refer to the AGT section. Note that shrub equations may use a different metric such as diameter near root collar (drc) as the independent variable.

D.3 Below ground Biomass

Below ground biomass must be estimated using proportional relationships between above ground and below ground biomass (ie, root-shoot ratios) or by SOC measurement, but not both.

D.3.1 Coarse roots

Coarse roots are defined as roots ≥ 2 mm in diameter, the IPCC suggested minimum diameter for below ground biomass. In partially or wholly forested wetlands, below ground biomass may be estimated with either root-shoot ratios or SOC measurement. In herbaceous wetland creation projects, carbon stock in coarse roots (> 2 mm) is captured by SOC measurement (see Appendix E); root-shoot ratios may not be used to calculate coarse root carbon stock in herbaceous wetlands.

D.3.1.1 Estimation using root-shoot ratios

Carbon stocks in below ground biomass may be estimated by applying a root-shoot ratio to the estimate of above ground tree and/or non-tree biomass yielded in Equation [D.4]. Root-shoot ratios from peer-reviewed literature (eg, Vadeboncoeur, Hamburg, & Yanai, 2007) in a comparable ecosystem and latitude must be used when available. If not available, the root-shoot ratios from the IPCC 2006 Guidelines may be used if appropriate for the ecosystem. The carbon concentration of roots may be determined by taking samples from roots leaving the tree base, using 50% carbon content, or by using the carbon content of above ground biomass.

If this approach is utilized, roots ≥ 2 mm must be removed from soil samples prior to analysis (see Appendix E).

D.3.1.2 SOC Measurement

In the case of herbaceous wetlands—and in forested wetlands, if the project proponent prefers—carbon stocks in coarse root biomass may be included in the SOC pool. If this approach is utilized, root-shoot ratios must not be used.

D.3.2 Fine roots

The carbon stock in fine roots (< 2 mm) is included in the SOC pool (see Appendix E).

D.4 Biomass Measurement Equations

$$x_{(i,j,k)} = \frac{44}{12} \times \frac{1}{1{,}000} \times f_{SPC}(\bullet) \times p_{(SPC)CF}$$ [D.1]	
Variables	$f_{SPC}(\bullet)$ - allometric equation for species SPC, with output in kg $p_{(SPC)CF}$ - carbon fraction for species SPC
Section References	D.1
Comments	Carbon stocks in the i^{th} tree in plot j in stratum k (tCO_2e). $\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. $\frac{1}{1{,}000}$ represents a conversion from kg to tonnes.

$$y_{(j,k)} = \frac{1}{a_{(j,k)}} \sum_{i \in \mathcal{X}_{(j,k)}} x_{(i,j,k)}$$ [D.2]	
Variables	$a_{(j,k)}$ - area of plot j in stratum k (ac) $x_{(i,j,k)}$ - estimated carbon stocks in the i^{th} tree in plot j in stratum k (tCO_2e) $\mathcal{X}_{(j,k)}$ - set of all measurements of a type in plot j in stratum k
Section References	D.1
Comments	Carbon stock density in above ground tree biomass in plot j in stratum k (tCO_2e/ac).

$$y_{(j,k)} = \frac{44}{12} \times \frac{1}{1{,}000} \times \frac{p_{(SPC)CF} \times md_{(j,k)}}{a_{(j,k)}}$$ [D.3]	
Variables	$p_{(SPC)CF}$ - carbon fraction for species SPC $md_{(j,k)\_}$ - dry mass of non-tree sample harvested from clip plots in plot j, stratum k (kg) $a_{(j,k)}$ - area of plot j in stratum k (ac)
Section References	D.2.1
Comments	Carbon stock density in above ground non-tree biomass in plot j in stratum k (tCO_2e/ha).

$$C_{P\ CS\ (c)} = \sum_{k \in \mathcal{S}} \frac{A_{(k)}}{n_{(k)}} \sum_{j \in \mathcal{P}_{(k)}} y_{(j,k)}$$ [D.4]	
Variables	$A_{(k)}$ - the area of stratum k (ac) $n_{(k)}$ - number of plots in stratum k $y_{(j,k)}$ - Carbon stock density in plot j in stratum k (tCO_2e/ac) $\mathcal{S}$ - set of all strata for monitoring period m $\mathcal{P}_{(k)}$ - set of all plots in stratum k
Section References	D.1, D.2
Comments	Carbon stocks in pool c in the sampled area (tCO_2e).

$$c_{BG\ (p,i)} = c_{AG\ (p,i)} \times r/s$$ [D.5]	
Variables	$c_{(p,i)AGx}$ - carbon in above ground biomass in pool p in stratum i for a given monitoring period r/s – root-shoot ratio selected
Section References	D.3
Comments	Carbon stock in below ground biomass for a given pool in stratum i.

APPENDIX E: DEFAULT SOC MEASUREMENT METHODS

Wetland soil carbon can comprise elemental (charcoal, soot), inorganic (carbonates) and organic states (dead and living plant-animal tissue). The organic form is dominant in alluvial soils which are typically poor in carbonate or calcite content. Elemental analyzers can provide direct measurements of total soil carbon, whereas the loss on ignition technique of organic matter combustion can provide an estimate of organic carbon. Chemical oxidation of organic carbon may also be used (Nelson and Sommers 1996).

Soil organic carbon (OC) in mature gulf coast wetlands is relatively constant with depth and averages 26 mg/ml (Gosselink and Hatton 1984). This vertical consistency develops as soils are saturated for extended periods and compaction/oxidation is minimal. Once wetland creation projects attain full plant coverage and long-duration hydroperiods, the process of organic matter vertical accumulation can proceed rapidly (1.0 cm/yr) both above the soil surface (via litter deposition and adventitious root growth) and within the emplaced soil (via root growth). Wetland creation projects will typically begin with a mineral-based soil that is homogeneous in elevation, soil texture, and relatively low in carbon content. The created wetland surface, or original project soil surface, becomes a long-lived marker where carbon accumulation rates can be estimated by measuring changes: (1) within the original project soil, and (2) in vertical accretion above the original project soil surface.

Accretion above the surface and within the original project soil compartments may have carbon infilling (via root growth) and vertical accretion rates. With time, the wetland soil in general may reach an equilibrium point with regards to carbon density. When this happens, changes in soil carbon stocks largely take the form of increasing vertical accretion and not necessarily increasing soil carbon density. A combined approach of soil coring and artificial marker horizons (such as feldspar clay; Knaus and Cahoon 1990) or reference devices (such as sediment reference pins; Steiger et al. 2003; USACE 1993) may be used to account for changes in carbon stocks within both compartments.

E.1 Sampling Design

Project proponents must choose plot size and design. For example, a nested plot configuration may be utilized in order to decrease sampling size necessary to obtain an acceptable level of error. The sampling protocol should reflect the selected sampling scheme.

Guidance for the design, allocation, and demarcation of core locations within a soil measurement plot is provided in VCS Module VMD0021: Estimation of Stocks in the Soil Carbon Pool.

E.2 Description of Soil Compartments

Two soil compartments may be monitored for changes in carbon stocks with time: (1) the original project soil, and (2) newly accreted material above the original project soil surface.

The project proponent may monitor both compartments, or choose to monitor stock changes only within a fixed soil sample depth, for the project lifetime. The project proponent must identify prior to the project start date either of these two methods:

1) fixed soil sample depth; or,

2) fixed soil sample depth *plus* accretion depth.

If for any reason during a monitoring event accretion measurements become unreliable, the fixed soil sample depth becomes the basis for detecting stock changes for the monitoring period.

E.2.1 Original Project Soil

Prior to the project start date, the project proponent must specify a fixed soil sample depth for the original project soil, and this depth will be fixed for the life of the project. The fixed soil sample depth must not exceed 100 cm. The fixed soil sample depth must be sampled in a manner to inventory carbon and bulk properties on a mass- volume basis. There is no requirement on the number of additional depth intervals from the original project soil that must be sampled and analyzed separately.

E.2.2 Accretion above the Original Project Soil Surface

Artificial marker horizons (described in Section E.4) must be used to assess the vertical depth ($d_{accretion}$) of material that has accreted above the original project soil from $t^{[m-1]}$ to $t^{[m]}$. Marker horizons must be deployed at a minimum of once every five years.

E.3 Coring Devices

When soils are sampled for carbon and bulk property analyses, coring devices must be used that are adequate to retrieve volumetrically intact samples. Accretion depth measurements may be taken on soil samples that are excavated with a knife or slicing instrument, but the accretion layer must be collected with a volumetrically controlled corer for carbon and bulk property analysis.

Soil density largely determines the smallest diameter corer than can be used without creating significant compaction. Highly compressible organic soils (bulk density ≤0.20 g/ cm^3) should be collected with a core tube diameter ≥7.6 cm. Soils with a bulk density >0.20 g/cm^3 can be sampled with a core tube diameter < 7.6 cm. Corer materials may consist of but are not limited to aluminum, stainless steel, PVC, or acrylic.

Core devices must allow inspection/measurement of vertical compaction of sample versus field condition. Piston corers should have a sampling base that limits the sample collection to the specified depth. McCauley peat augers may be used to collect organic soils and are designed to minimize compaction.

E.4 Artificial Marker Horizon Establishment

Marker horizons may be established with a feldspar marker technique (Knaus and Cahoon 1990; Folse et al. 2012), which consists of a 1-cm layer of white feldspar clay that is evenly sprinkled on the wetland sediment surface to create a white layer which is easily distinguishable from the natural substrate and can be used to measure surface accretion of sediments over time. Plot size must be approximately 0.25 m^2 or greater. A minimum of three marker horizon plots must be deployed in each stratum.

E.5 Soil Sample Collection

Soil from the accretion layer and the original project soil may be collected as one unit unless discrete horizons are identifiable within the sampling depth found in the original project soil, in which case the soil must be sampled in sub-increments of the sampling depth. However, the accretion layer formed from $t^{[m-1]}$ to $t^{[m]}$ must be separated from the original project soil. The accretion layer and the original project soil must be analyzed for bulk density and carbon content separately, except when an accretion layer is < 1.0 cm, in which case the accretion layer may be incorporated and analyzed for bulk density and carbon content with the original project soil. To properly adjust coring depth, a mean accretion estimate from a stratum must be known prior to sampling soil from the fixed soil sample depth. Thus, there are two soil sampling depth options available for monitoring.

- Soil Sampling Depth Option 1: fixed soil sample depth
- Soil Sampling Depth Option 2: fixed soil sample depth plus accretion depth.

Specific methods for efficient sampling will depend on local soil conditions, so prescriptive requirements for sample size, volume, and sampling depth are not provided in this methodology. Rather, project proponents must develop a locally appropriate sampling plan. In developing this plan, care must be taken that the sampling procedures employed across the depth profile do not bias the estimation of soil organic carbon. In the case that discrete soil horizons can be identified within the selected fixed soil sample depth, each horizon must be sampled separately. The volume of each soil sample taken should be large enough to capture inherent soil structure variability across the depth range represented by the sample.

In the case that a single sample is used to represent a depth range, the sample must be well homogenized prior to analysis, and care must be taken that the sample used for organic carbon determination and bulk density determination are representative of the same depth range. If multiple samples are taken across a vertical soil profile (such as by division of a core into segments), a weighted average should be used to estimate the mean carbon content across the entire depth profile, where the weights are proportional to the percentage of the total sample depth range represented by each subsample.

Refer to the most recent version of VCS Module VMD0021: Estimation of Stocks in the Soil Carbon Pool, the IPCC Good Practice Guidance for Land Use, Land Use Change, and Forestry, and Nelson and Sommers (1996) for more detailed guidance on establishing appropriate sampling protocols.

E.5.1 Accretion above the Original Project Soil Surface

The accretion depth will be measured from a minimum of three feldspar plots per sampling location within a stratum. The mean of the individual measurements from each plot will represent ($d_{accretion}$). The accretion depth from the marker horizons may be sampled by conventional coring, knife excavation, or cryogenic coring techniques. Regardless of technique, at least three measurements of the material thickness above the marker horizon must be taken with calipers or a ruler to the nearest 1.0 mm and recorded on a data sheet. The mean accretion depth will inform the total depth of subsequent soil sampling. The accretion depth must be known prior to determining the overall depth required for soil coring.

E.5.2 Original Project Soil

The original project soil must be sampled with a coring tube of an appropriate diameter (as described in Section E.3). The thickness of ($d_{accretion}$) sediment accretion above the original project soil must be accounted for, when applicable. Otherwise the original project soil is sampled to the fixed soil sample depth defined for the project.

Soil Coring Process:

1. Locate pre-determined sample plot. Remove emergent vegetation by clipping to the soil surface. Insert core tube and drive approximately 5-10 cm deeper than the fixed soil sample depth or the sum of the fixed depth and accretion depth.

2. Measure the vertical height of the soil surface relative to top of the core tube, both inside and outside of core tube to calculate compaction. If height difference is ≥ 10% of the sample depth, remove the core tube and re-sample. If height difference ≤ 10%, remove the core, aided by a cap on the top of the core tube to create a vacuum, or by inserting a hand at the base of the core tube. The core compaction estimate must be documented.

3. Transfer core to an extruding base, which may consist of a 'Meriwether extruder' (Folse et al. 2012) or equivalent device that permits extrusion from the base of the core, such that the upper soil is sectioned first, and deeper layers thereafter.

4. If the accretion depth ($d_{accretion}$) is ≤1 cm, it must be considered to be conservative to include this layer within the original project soil (ie, only core to the original fixed soil sample depth). If the accretion layer is > 1 cm, record the layer thickness as $d_{accretion}$.

5. Extrude the core to the mean accretion depth ($d_{accretion}$) as defined by the marker horizon technique (described in Section E.4 and E.5.1). The soil from this sample depth is removed and placed in a plastic bag labeled with sample location information and the sample depth to the nearest 1.0 cm.

6. After the surface accretion layer has been removed, continue the extrusion process to the original fixed soil sample depth, sectioning at the pre-defined intervals of the original project soil (as described in section E.2.1). Place the sample in a plastic bag with sample location information and deposit depth to the nearest 1.0 cm.

E.6 Soil Sample Analyses

All soil samples must be stored on ice following collection and during transport. A chain of custody form should be completed by the field lead and submitted to the laboratory with the samples to be maintained with their records.

Soil samples must be analyzed for bulk density and SOC by a qualified laboratory following the methods of Nelson and Sommers 1996 and Ball 1964, respectively, or comparable methods.

The chosen laboratory must have a rigorous Quality Assurance program that meets or exceeds the USEPA QA/QC requirements or similar international standards for laboratory procedures, analysis reproducibility, and chain of custody. The laboratory must also provide a document that defines the pre-analysis sample processing procedures, and the specific chemistry test methods they use at the laboratory, including the minimum detection limits for each constituent analyzed.

If root-shoot ratios are used to estimate carbon stocks in coarse roots (≥ 2 mm), such roots must be removed from soil samples prior to analysis. In this case, note that although coarse roots do not count toward mass or carbon content in SOC calculations, their volume should still contribute to soil core volume.

E.6.1 Bulk Density

For bulk density determination, core samples of known volume are collected in the field and oven dried to a constant weight at 105°C (for a minimum of 48 hours). The total sample is then weighed.

The bulk density of the soil core is estimated as:

$$\rho_{SOIL} = M_{soil} / V_{soil}$$ [E.1]	
Variables	M_{soil} - oven-dried mass of sample soil core (g) V_{soil} - volume of soil core (cm^3)
Section References	
Comments	Bulk density of soil core *j* in stratum *k* (g/cm^3)

Further guidance is provided in Nelson and Sommers (1996).

E.6.2 Direct Carbon Determination

For direct soil carbon determination, individual core samples collected in the field are oven dried to a constant weight at 105°C (for a minimum of 48 hours). Dried samples must be homogenized or ground with a Wiley Mill or ball grinder.

The prepared sample is analyzed for percent organic carbon or g C/g soil (cf_{soil}) using either dry combustion using a controlled-temperature furnace (eg, LECO CHN-2000, LECO RC-412 multi-carbon analyzer, or equivalent), dichromate oxidation with heating, or Walkley-Black method. Further guidance is provided in the IPCC LULUCF Good Practice Guidance (2003) and in Nelson and Sommers (1996).

E.6.3 Indirect Carbon Determination

Indirect carbon estimation techniques may be substituted for direct determination. Organic carbon (OC) can be estimated reliably with the loss-on-ignition (LOI) method, which combusts organic matter from a soil sample, leading to a direct relationship between soil organic matter content and organic carbon content. LOI lab techniques should adhere to those of described in Ball 1964 or Henri et al. 2001. While some variability may exist among samples, OC content should not exceed 50% of the OM content. Table 17 presents the relationships that are acceptable for converting from organic matter to organic carbon.

Table 17: Default equations for estimating organic carbon content from organic matter content with soil samples analyzed with the loss-on-ignition technique

Region	Relationship (OC and OM on a percent dry basis)	Reference
Atlantic	OC= 0.40 * OM + 0.0025 *OM^2	Craft et al. 1991
Gulf of Mexico	OC= 0.4541 * OM	Steyer et al. 2012
Pacific	OC= 0.38 * OM + 0.0012 *OM^2	Callaway et al. 2012

$$c_{SOC\ j} = \left[\sum_{l}^{1-x}\left(cf_{soil,l} * \rho_{soil,l} * \ d_{soil,l}\right) + \sum_{l}^{1-x}\left(cf_{soil,l} * \rho_{soil,l} * \ d_{accretion,l}\right)\right] * \frac{44}{12} * 40.47 - \ c_{alloch,j} \quad [E.2]$$

Variables	$c_{SOC\ j}$ = total soil carbon measured at plot *j* (tCO₂e ac⁻¹) *x* =number of soil layers *l* = soil layer cf_{soil} = organic carbon content of the soil sample in plot *j* in stratum *k* (g C/g soil) ρ_{soil} = soil bulk density of sample in plot *j* in stratum *k* (g/cm3) d_{soil} = depth of a soil sample collected below the surface of the original project soil surface in plot *j* in stratum *k* (cm) $d_{accretion}$ = depth of soil sample collected above a marker horizon (feldspar) or control rod or pin in plot *j* in stratum *k* (cm) $c_{alloch,j}$ = allochthonous soil carbon measured at plot *j* (tCO2e/ac). This quantity is zero if the project meets the criteria in section 5.2.1.
Section References	
Comments	$\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. 40.47= conversion to t/ac

$$C = \sum_{k \in \mathcal{S}} \frac{A_{(k)}}{n_{(k)}} \sum_{j \in \mathcal{P}_{(k)}} y_{(j,k)}$$	[E.3]
Variables	$A_{(k)}$ - the area of stratum k $n_{(k)}$ - number of plots in stratum k $y_{(j,k)}$ - a quantity estimated for or measured on plot j in stratum k $\mathcal{S}$ - set of all strata for monitoring period m $\mathcal{P}_{(k)}$ - set of all plots in stratum k
Section References	D.1
Comments	Estimated total SOC stock in the sampled area

E.6.4 Allochthonous Carbon Determination

Allochthonous carbon is estimated using a marker horizon technique in order to determine the amount of mineral matter that has been deposited over the monitoring period. The mineral-associated carbon is the component that is classified as allochthonous carbon.

1. Measure the total amount of soil accumulation (accretion depth) during the monitoring period.
2. From the accretion depth, collect soil sediment samples and analyze the samples for bulk density.
3. Calculate the mineral fraction of the soil sample.
4. Use a correction factor to estimate the amount of mineral-associated carbon (allochthonous carbon) to be deducted from the carbon stocks associated with recently deposited sediment.

Core samples of known volume are collected in the field, homogenized in the laboratory, and the homogenized material is sub-sampled for combustion (with the loss-on-ignition technique, described in Section E.6.3), which removes the organic matter/carbon. (The dry bulk density of total sample is measured first; then the organic and mineral content are separated by combustion.) The total remaining material is mineral, and mineral density of the sample is calculated from the original soil sample volume.

The mass of allochthonous carbon of the soil sample above the marker horizon is estimated as:

$$c_{alloch,j} = \sum_{l}^{1-x} (mcf_{soil,l} * \rho_{minsoil,l} * \ d_{accretion,l}) * \frac{44}{12} * 40.47$$	[E.4]
Variables	$c_{alloch,j}$- allochthonous soil carbon measured at plot *j* (tCO2e/ac) *x* =number of soil layers *l* = soil layer mcf_{soil} – mineral-associated carbon fraction of the soil sample in plot j in stratum k (%) $\rho_{minsoil}$ – mineral density of sample in plot j in stratum k (g cm^{-3}) $d_{accretion}$- depth of soil sample collected above a marker horizon (feldspar) or control rod or pin in plot j in stratum k (cm)
Section References	9.2.6
Comments	$\frac{44}{12}$ is the ratio of the mass of carbon dioxide to the mass of carbon and is used to convert to CO2e units. 40.47= conversion to t/ac Mineral associated carbon fraction of estuarine soils is typically less than 3% and a locally relevant data source may be used, or see, Andrews JE, Jickells TD, Adams CA, Parkes DJ, and Kelly SD (2011) Sediment Record and Storage of Organic Carbon and the Nutrient Elements (N, P, and Si) in Estuaries and Near-Coastal Seas. In: Wolanski E and McLusky DS (eds.) Treatise on Estuarine and Coastal Science, Vol 4, pp. 9–38. Waltham: Academic Press)

APPENDIX F: MODEL ASSESSMENT REQUIREMENTS

The project proponent may not deviate from the methods provided in this appendix because these methods are not related to monitoring or measurement. This appendix must be followed to select and assess proxy models from sections 9.2.2.2 and 9.2.3.2.

All models must be fit using a sample size of at least 30 measurements.

F.1 Model Selection

A candidate set of models to predict methane or nitrous oxide flux (the response) must be fit using an unbiased estimator of model parameters. All models must be fit to the same response data and covariate data. An estimate of Akaike Information Criterion (AIC) must be used for model selection. The model with the lowest AIC must be used to predict methane and nitrous oxide flux.

F.2 Checking Assumptions

The assumptions of the statistical methods used to fit the selected model must be listed. If ordinary least squares (OLS) is used to fit the model, this statistical method assumes the following:

1. Residuals are uncorrelated.
2. Residuals are homoscedastic.
3. Residuals are independent of each other.
4. Residuals are normally distributed.

The assumptions of the statistical method must be confirmed on the basis of sampling design, statistics and diagnostic plots. Diagnostic plots must be used to check for 'outlier' data points, which must be included in the model fitting unless they are determined to be erroneous. If the assumptions of the statistical method are not confirmed, then in some cases, a correction factor may be required. The correction factor must be applied from peer-reviewed literature or a statistical publication.

The selected model must not be used if the assumptions of the model are unconfirmed or if an appropriate correction factor has not been applied.

F.3 Determining Goodness of Fit

Goodness of fit must be determined based on the parameter values of the selected model. The parameter estimates must be unbiased and predictions must be monotonic on the interval of the range of plausible predicted emissions. The covariate and response data used to parameterize the model must be obtained per the requirements of Sections 9.2.2.3 or 9.2.3.3 to ensure conservativeness of model predictions. Because data for the parameterization of the model is derived from conservative measurements as described in these sections, there are no requirements on the precision of the model predictions or parameter estimates.

F.3.1 Estimates of Parameter Bias

Leave-one-out cross validation must be used to estimate the bias of parameter estimates. The estimated bias must not exceed 15% of the estimated parameter value, on average across parameters.

F.3.2 Confirmation of Monotonicity

In order to confirm that the selected model is conservative, the project proponent must provide graphical plots of the model predictions across the range of plausible input covariate values. Within this range, the function must be monotonic—that is, predictions must not change concavity and be increasing throughout the range of plausible predicted emissions. For example, if the function is increasing at a decreasing rate, it must continue to increase at a decreasing rate across the interval of plausible predicted emissions.

APPENDIX G: EQUATIONS IN METHODOLOGY

$$d_{P\,\Delta}^{[m]} = p_{SLD}{}^{[m]} d_{SLD}^{[m]} + (1 - p_{SLD}{}^{[m]}) d_{LQD}^{[m]}$$	[G.1]
Variables	$\boldsymbol{d_{P\,\Delta}^{[m]}}$, $\boldsymbol{p_{SLD}{}^{[m]}}$, $\boldsymbol{d_{SLD}^{[m]}}$, $\boldsymbol{d_{LQD}^{[m]}}$
Section References	9.2.5
Comments	Density of sediment dredged from sediment source.

$$M_{P\,\Delta}^{[m]} = \frac{V_{P\,\Delta}^{[m]} d_{P\,\Delta}^{[m]}}{1000}$$	[G.2]
Variables	$\boldsymbol{M_{P\,\Delta}^{[m]}}$, $\boldsymbol{V_{P\,\Delta}^{[m]}}$, $\boldsymbol{d_{P\,\Delta}^{[m]}}$
Section References	9.2.5
Comments	Mass of sediment dredged from the sediment source as a result of project activities.

$$E_{B\,\Delta\,EC}^{[m]} = -M_{P\,\Delta}^{[m]} \sum_{(ty)\in\mathcal{T}_{B\,EC}} e_{(ty)}\, g_{B\,(ty)}$$	[G.3]
Variables	$\boldsymbol{E_{B\,\Delta\,EC}^{[m]}}$, $\boldsymbol{M_{P\,\Delta}^{[m]}}$, $\boldsymbol{e_{(ty)}}$, $\boldsymbol{g_{B\,(ty)}}$
Section References	8.1.1
Comments	Total baseline emissions from energy consumption in the monitoring period (tCO_2e).

$$F_{B\,\Delta\,CH4}^{[m]} = A_{PA} \times f_{B\,\Delta\,CH4}^{[m]}$$ [G.4]	
Variables	$\boldsymbol{F_{B\,\Delta\,CH4}^{[m]}}$, A_{PA}, $\boldsymbol{f_{B\,\Delta\,CH4}^{[m]}}$
Section References	8.1.2, 9.2.2
Comments	Baseline methane emissions flux (tCO_2e/day).

$$E_{B\,\Delta\,CH4}^{[m]} = -\left(t^{[m]} - t^{[m-1]}\right)F_{B\,\Delta\,CH4}^{[m]}$$ [G.5]	
Variables	$\boldsymbol{E_{B\,\Delta\,CH4}^{[m]}}$, $\boldsymbol{t^{[m]}}$, $\boldsymbol{t^{[m-1]}}$, $\boldsymbol{F_{B\,\Delta\,CH4}^{[m]}}$
Section References	8.1.2
Comments	Total baseline methane emissions from methane over monitoring period (tCO_2e).

$$E_{B\,\Delta}^{[m]} = E_{B\,\Delta\,EC}^{[m]} + E_{B\,\Delta\,CH4}^{[m]}$$ [G.6]	
Variables	$\boldsymbol{E_{B\,\Delta}^{[m]}}$, $\boldsymbol{E_{B\,\Delta\,EC}^{[m]}}$, $\boldsymbol{E_{B\,\Delta\,CH4}^{[m]}}$
Section References	8.1
Comments	Total baseline emissions over monitoring period (tCO_2e). (If dredging is not included in the baseline scenario, emissions from energy consumption are zero (see section 6.2); if methane ebullition is not included in the baseline scenario, methane emissions are zero.)

$$C^{[m]}_{P\ CS} = \sum_{(c)\in\mathcal{C}} C^{[m]}_{P\ CS\ (c)}$$ [G.7]	
Variables	$\boldsymbol{C^{[m]}_{P\ CS}}$, $\boldsymbol{C^{[m]}_{P\ CS\ (c)}}$
Section References	9.2.1, 9.2.1.1
Comments	Cumulative carbon stocks in project area at end of monitoring period.

$$E^{[m]}_{P\ \Delta\ CS} = C^{[m]}_{P\ CS} - C^{[m-1]}_{P\ CS} - 0.131 E^{[m]}_{P\ \Delta\ CH4}$$ [G.8]	
Variables	$E^{[m]}_{P\ \Delta\ CS}$, $\boldsymbol{C^{[m]}_{P\ CS}}$, $\boldsymbol{C^{[m-1]}_{P\ CS}}$, $\boldsymbol{E^{[m]}_{P\ \Delta\ CH4}}$,
Section References	8.2.1
Comments	Total carbon stock emissions or emissions reductions and/or removals in the project area for the monitoring period (tCO_2e). For the first monitoring period $C^{[m-1]}_{P\ CS} = C^{[m=0]}_{P\ CS}$ or the carbon stocks in the project area prior to the project start date. Last term in equation ($0.131 E^{[m]}_{P\ \Delta\ CH4}$) is included in order to avoid double-counting of sequestered carbon that subsequently was released as a methane flux. The coefficient (0.131) represents a conversion for the differences in mass (44 CO_2 = 16 CH_4) and global warming potential (1 CO_2 = 21 CH_4): 1 ton CO2 = (44/16)*(1/21) = 0.131.

$$E^{[m]}_{P\,\Delta\,CS} = -0.131 E^{[m]}_{P\,\Delta\,CH4} + \sum_{(i)\in\mathcal{G}} C^{[m]}_{P\,CS\,(i)} - C^{[m-1]}_{P\,CS\,(i)}$$ [G.9]	
Variables	$\boldsymbol{E^{[m]}_{P\,\Delta\,CH4}}$, $\boldsymbol{C^{[m-1]}_{P\,CS}}$, $\boldsymbol{C^{[m]}_{P\,CS}}$ $\boldsymbol{E^{[m]}_{P\,\Delta\,CS}}$
Section References	8.2.1
Comments	Total carbon stock emissions or emissions reductions and/or removals in the project area for the monitoring period for project activity instances in a grouped project (tCO_2e). First term in equation ($0.131 E^{[m]}_{P\,\Delta\,CH4}$) is included in order to avoid double-counting of sequestered carbon that subsequently was released as a methane flux. The coefficient (0.131) represents a conversion for the differences in mass (44 CO_2 = 16 CH_4) and global warming potential (1 CO_2 = 21 CH_4): 1 ton CO2 = (44/16)*(1/21) = 0.131.

APPENDIX H: SUPPORTING INFORMATION ON DEVELOPMENT OF POSITIVE LIST

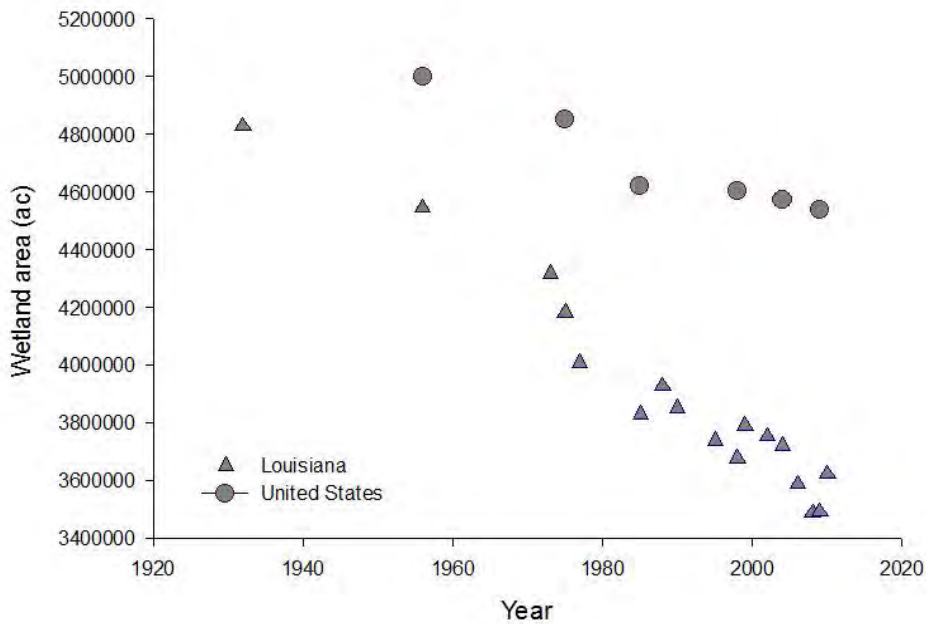
The methodology specifies a positive list for additionality based on activity penetration in specific geographic scopes. The level of activity penetration for a project activity in a given geographic region is determined using appropriate credible data, including from federal agencies (eg, USACE, USGS, USFWS). In order to define the activity and geographic scope for the positive list, the methodology developer demonstrated both the maximum adoption potential and the observed adoption of the project activity (eg, the number and extent of the activity which has been implemented). The calculated level of activity penetration of RWE project activities is currently determined to be less than 5 percent and the level of activity penetration of ARR+RWE project activities meeting the applicability conditions of this methodology is negligible.

The maximum adoption potential takes into account the relevant factors affecting the adoption of the activity within the applicable geographic scope, including implementation potential (ie, the extent of wetland loss within the geographic scope), resource availability (ie, the local supply of dredged sediments), technological capacity (ie, the amount of locally available dredging equipment), level of service (ie, the availability of dredging equipment), socio-economic conditions (ie, the presence of competing economic activities occurring in the coastal zone), and climatic conditions (ie, the incidence of hurricanes and extreme tidal fluctuations). In the case of socio-economic conditions and competing economic activities (eg, oyster farming), the methodology developers concluded that such competing activities are not common enough to limit or displace coastal wetland reestablishment activities, and moreover such economic activities do not vary significantly among regions within the geographic scope. The methodology developers also considered the spatial heterogeneity of climate conditions across the geographic scope, and concluded that regardless of the likelihood of such extreme climate events, the project proponent must demonstrate a long-term trend of wetland loss (see section 6.1). Further, once a project has been established, the methodology ensures that the impacts of a climate event will be captured by the monitoring activities and will be reflected in the carbon accounting. Maximum adoption potential does not consider cost of adoption, cultural or behavioral barriers, and laws, statues, regulatory frameworks or policies.

H.1 Synopsis

This methodology deems project activities as additional, and qualifies them for a positive list based on low rates of adoption in the United States. The total need or adoption potential for coastal wetland creation is conservatively ~1.482 million ac, based on historic loss in the lower 48 states since the 1930's (Figure 1). Approximately 2.7% (39,834) ac of the total coastal wetlands lost in the U.S. has been rebuilt. Therefore, creation of wetlands as described in this methodology, for both RWE and ARR+RWE projects, is deemed additional in accordance with VCS requirements.

Figure 1: Estimates of estuarine vegetated wetland in the U.S. and coastal land area in Louisiana



The following sections—*Analysis* and *Supporting Technical Information*—present the adoption potential analysis and summaries of national and region-specific wetland changes and creation efforts.

H.2 Analysis

This analysis demonstrates that the level of "activity penetration" for creation of coastal wetlands is currently much less than 5%. Substantial needs exist for rebuilding of wetlands lost due to various direct and indirect anthropogenic factors. However, due to funding constraints only a small fraction of the need has been satisfied as of the completion of this methodology.

The positive list for activities established under this methodology is based on a demonstration that the project activities have achieved a low level of penetration relative to their maximum adoption potential, in accordance with VCS requirements. This activity penetration level is estimated using the following equation:

$$AP_y = OA_y / MAP_y$$

Where,

AP_y = Activity penetration of the project activity in year y (percentage)

OA_y = Observed adoption of the project activity in year y (eg, total number of instances installed at a given date in year y, or amount of energy supplied in year y)

MAP_y = Maximum adoption potential of the project activity in year y (eg, total number of instances that potentially could have been installed at a given date in year y, or the amount of energy that potentially could have been supplied in year y)

The following analysis estimates penetration level, current as of 2012, for the conterminous United States. Since a key location for application of this methodology is Louisiana, it will also be demonstrated using state-specific data.

Given adequate time and funding, adequate supplies of sediment for wetland are available, either from rivers or nearshore/offshore locations where they are routinely dredged. Resource availability is not a constraint. As an ecosystem restoration activity, total demand, market access, and market price are not relevant factors in this analysis. Implementation potential is the need for wetland restoration and is therefore considered equal to maximum adoption potential.

In order to arrive at a conservative estimate for the maximum adoption potential, data from two studies are used. The first (Couvillion et al. 2012) provides data from Louisiana only and indicates that total coastal wetland loss in Louisiana amounted to 1,205,120 ac. This study provides a comprehensive and detailed estimate of wetland loss, including both coastal fresh and saltwater wetlands. The second is a national level study (Dahl 2000, 2006, 2011) that estimates total U.S. wetland loss of 461,000 ac, but includes only estuarine vegetated wetlands, thus excluding the losses of tidal freshwater wetlands. Because coastal Louisiana loss is commonly accepted to be 40% of the national total, the national vegetated estuarine wetland loss excluding Louisiana was estimated at 276,000 ac. Adding in the long-term historic wetland loss in Louisiana of 1,205,120 ac with the less-comprehensive national estimate of 276,000 ac yields 1,481,720 ac. The two studies used to derive the maximum adoption potential are described in more detail below.

Based on USGS data (Couvillion et al. 2012), approximately 1.205 million acres of Louisiana's coastal wetlands have been lost and converted to open water since the 1930's. Louisiana's Coastal Protection and Restoration Authority (CPRA) has tracked engineered wetland creation projects by the State, in addition to USACE beneficial use projects. CPRA estimates that approximately 16,137 acres have been created since 2005, including both the State's projects and USACE beneficial use projects (Table H3, *Supporting Technical Information*). Therefore, the current level of activity penetration in Louisiana is approximately 1.3% (16,137 ac created/1,205,000 ac lost).

At a national scale, the U.S. Fish & Wildlife Service Status & Trends reports (Dahl 2000, 2006, 2011) estimate that 461,000 acres of vegetated estuarine wetlands have been lost since the 1950s (Table H2, *Supporting Technical Information).* This estimate excludes the losses of tidal freshwater wetlands, which results in a conservative (underestimate) of total tidal and estuarine wetland loss (tidal freshwater wetlands are now reported as 'Palustrine,' which typically includes all inland freshwater systems). For example, a more detailed analysis by Stedman and Dahl (2008) showed that the *coastal watersheds* of the Gulf of Mexico and the Atlantic states lost a total of 370,760 ac and 14,980 ac, respectively, of freshwater and saltwater wetlands.

Given that total coastal wetland creation as described in Section H.3.5 was 39,834 ac and the maximum adoption potential is 1,481,720 ac, the resulting activity penetration level is approximately 2.7%. With observed adoption less than the need for replacement of wetlands, adoption potential is below the 5% threshold set by VCS requirements. Therefore, coastal wetland creation projects are deemed additional.

H.3 Supporting Technical Information

H.3.1 Estuarine Vegetated Wetland Loss in the United States

Estuarine vegetated wetland loss in the United States since the 1950's to 2009 has been estimated at approximately 461,000 ac (Table H1). Based on the most recent analysis from 2004-2009 (Dahl 2011), approximately 111,000 ac of estuarine vegetated wetlands were lost over the 4.5 year period, or approximately 25,000 ac/yr.

Wetland loss prior to the 1980's may have included direct conversion of wetlands to agriculture and coastal development. Since the 1980's, however, conversion of wetlands to deep open water has been responsible for wetland losses, as excerpted from Dahl's analyses:

> "[The 1998-2004 rate of loss] *was consistent with the rate of salt marsh loss recorded from 1986 to 1997 (Dahl 2000). Urban and rural development activities, and the conversion of wetlands to other upland land uses, accounted for an estimated loss of 1,732 acres (700 ha) or about 3.0 percent of all losses of estuarine emergent wetland. Most of the losses of estuarine emergent wetland were due to loss to deep salt water and occurred in coastal Louisiana*." (Dahl 2006)
>
> "[The 2004-2009 rate of loss] *of intertidal emergent wetland increased to three times the previous loss rate between 1998 and 2004. The majority of these losses (83%) was to deepwater bay bottoms or open ocean.*"

H.3.2 Vegetated Wetland Loss in Coastal Watersheds in the Atlantic and Gulf of Mexico

An analysis of *coastal watershed* vegetated wetland changes in the eastern United States (1998-2004) (Stedman and Dahl 2008) showed that the Gulf of Mexico and Atlantic states had net wetland losses in coastal watersheds totaling 370,760 ac and 14,980 ac, respectively, when including both fresh and saltwater wetlands. Total saltwater vegetated wetland loss was 64,970 ac, of which 96% (or 62,370 ac) was conversion to open saltwater.

Table H1: Historic and contemporary estimates of estuarine vegetated wetland acreage since the mid-1950's for the United States and Atlantic/Gulf of Mexico regions based on similar mapping techniques

Time period	**Conterminous US** Estuarine vegetated wetland (ac) (Dahl 2006, Dahl 2011)	**Atlantic Coastal Watershed** Vegetated wetland (ac) (Stedman and Dahl 2008)	**GOM Coastal Watershed** Vegetated wetland (ac) (Stedman and Dahl 2008)
1950's	5,000,000		
1970's	4,854,000		
1980's	4,623,000		
1998	4,604,200	1,842,320	3,108,110
2004	4,571,700	1,822,780	3,062,680
2009	4,539,700		
Notes	US wetland loss (1950's-2009) 461,000 ac	Atlantic wetland loss (98-04) 19,540 ac	GOM wetland loss (98-04) 45,430 ac

H.3.3 Wetland Loss in Louisiana

The most recent study by Couvillion et al. (2012) summarized wetland loss during 1932-2010 and intervals in between. Cumulative wetland loss in Louisiana from 1932-2010 was estimated at 1,205,120 ac. Trend analyses of comparable satellite imagery were limited to the 1985-2010[4] time period, which showed a loss rate of 10,605 ac/yr.

H.3.4 Proportion of Coastal Wetland Loss in Louisiana Compared to the U.S.

Based on a number of analyses, Louisiana wetland loss has been commonly accepted to be ~ 40% of the national total. This is supported by the recent analyses by Couvillion et al. (2012) and Dahl (2011), which showed that the annual loss rate in Louisiana (-10,605 ac/yr, from 1985-2010) was 42% of the national rate (-25,000 ac/yr 2004-2009).

[4] The calculation of wetland loss rates in Louisiana is sensitive to water level during imagery acquisition. More recent and frequent satellite imagery has allowed for a large number of images to be analyzed and reduced uncertainty.

H.3.5 Wetland Creation in the United States and Louisiana

The most significant nationwide wetland creation effort has been accomplished with beneficial placement of dredged sediments by the USACE (Table H2). More recently, a state wetland creation program has been developed in Louisiana by the Coastal Protection and Restoration Authority (CPRA) (Table H3).

Including Louisiana, marsh creation and nourishment by the USACE has totaled approximately 32,355 ac from 2007-2012 (Table H2). There are several reasons why these data produce a conservative overestimate of actual wetland creation. First, the USACE presents both wetland 'creation' and 'nourishment' together. Second, there are 11 non-coastal districts which are included in the statistics presented in Table H2 (although the non-coastal districts comprise only 5 percent of the total dredging conducted by the USACE). Third, the assumed conversion value of 1 ac = 6,250 CY may be low for some areas. For example, the actual CY of sediment needed for an acre of wetland creation ranges from approximately 6,000 CY to 16,000 CY (calculated from data in Table H3).

In Louisiana, engineered wetland creation projects have been tracked more precisely than USACE nationwide projects. Based on CPRA's data set, approximately 7,479 ac of wetlands have been created in Louisiana during FY 2005-2012 Table H3), not including the USACE's beneficial use projects (which are included in Table H2).

Combining both data sets results in an estimate of 39,834 ac (nationwide USACE = 32,355 ac; Louisiana state projects = 7,479 ac) of wetland creation and nourishment that has occurred nationwide through efforts of the USACE and the State of Louisiana, which comprise the most significant sources of wetland creation with dredged material.

Table H2: Estimated nationwide USACE wetland creation and nourishment from both coastal and non-coastal areas of the U.S. Acreage estimates are derived from dredge disposal statistics from the USACE Navigation Data Center: http://www.navigationdatacenter.us/dredge/drgdisp.htm (Disposal Type = Wetland Creation and Nourishment). APPENDIX I: JUSTIFICATION FOR THE EXCLUSION OF ALLOCHTHONOUS CARBON IN THE LOUISIANA COASTAL ZONE

I.1 Introduction

Many estuarine wetlands are exporters or sources of carbon to the continental shelf, typically termed 'carbon outwelling'. Net burial of carbon in tidal wetland soils is usually on the order of <200 g C/m^2/yr (McLeod et al. 2011), while an excess of 100-200 g C/m^2/yr of carbon is exported to inshore and offshore areas (Nixon 1980; also see Table 1). The source, transport and fate of carbon along the estuary-offshore gradient are complicated processes, but largely, estuarine wetland systems are typically understood as carbon sources to estuarine-offshore systems. High energy, macrotidal salt marshes may receive substantial mineral sediments (and associated carbon) near the mouth of the estuary. The source of carbon may come from upland habitats, which may be replenished, or within the estuarine system as wetlands are eroded or reworked.

Stevenson et al. (1988) raised the consideration of sea level rise and sediment supply as to why estuaries—especially southern microtidal systems—are susceptible to wetland loss. In addition to sea level rise, the authors maintain that sediment starvation through reductions in terrigenous sediment sources is a key factor of undernourishment of wetlands:

> From Stevenson et al. 1988*: Differences in tidal dynamics, seasonal changes in sea levels and higher temperatures may help explain why, in the U.S., southern marshes are more susceptible to export and eventual erosion than northern marshes. We hypothesize that another factor, the recent reductions of terrigenous sediment inputs from the southern river systems of the U.S., may also be critical. Sediment starvation may have led to undernourishment of wetland systems of the coastal zone over the last half century which may be reflected in the net export measured in the tidal marshes in this region. Furthermore, we postulate that changes in sediment inputs are more important than eustatic sea level rise in causing the past losses of marshes which are now undergoing mass erosion.*

There has been a systemic reduction in sediment delivery to coastal wetlands nationwide due to changes in land-use (European settlement and land clearing) and expansion of dam building on major rivers (Syvitski et al. 2009). The Chesapeake Bay area and Louisiana delta serve as examples of the observed modern sediment-driven degradation of wetlands to open water (Kirwan et al. 2011).

I.2 Support from the Literature

The literature from coastal Louisiana broadly supports the understanding that its wetlands are sources of carbon to the Gulf of Mexico (see estimates in Table I.1). Moreover, in the last century there has been a systematic reduction in allochthonous mineral sediment (with its associated carbon) to the wetlands due to construction of levees along the Mississippi River (Blum and Roberts 2009). As a consequence, the estuaries are not receiving substantial external sources of sediments or carbon. The following summary provides a description on carbon exchange in Louisiana estuaries and provides the rationale as to why accounting for the import of carbon to created wetlands projects is not relevant for the coastal region of Louisiana. Namely, there is an absence of real external sources of carbon to the coastal basins, most of the carbon is exchanged among habitats in the coastal basins, and any import of carbon in the project area will be substantially offset by the carbon that the project will export.

1. *Export of Carbon from Louisiana Estuaries*: Louisiana estuaries are ebb-dominated systems exhibiting a consistent pattern of exporting of Particulate Organic Carbon (POC) and Total Organic Carbon (TOC) to the Gulf of Mexico. This has been shown for most of the Louisiana coastal areas, including: Barataria Basin (Li et al. 2011; Das et al. 2010, 2011; Wilson and Allison 2008; Feijtel et al. 1985; Happ et al. 1977), Breton Sound (Wilson and Allison 2008), and Fourleague Bay (Stern et al. 1991; Madden et al., 1988; Perez et al. 2000). Wilson and Allison (2008) estimated that Barataria and Breton Sound estuaries export 3.7×10^4 and 4.6×10^4 MT POC annually, respectively, and the magnitude of these estimates was corroborated by Das et al. 2011. The magnitude of Dissolved Organic Carbon (DOC) that is exported is six fold greater than particulate forms (Das et al. 2011).

2. *External Sediment Supply Constraints to Louisiana Wetlands*: An allochthonous sediment deficit to Louisiana coastal wetlands occurred following the levee construction along the Mississippi River and persists today (Blum and Roberts 2009). In a review paper of mineral and organic contributions to tidal freshwater wetland accretion from Maine to Louisiana, Neubauer (2008) showed that Louisiana freshwater wetlands exhibited the lowest mineral accumulation rates. Much of the contemporary sediment deposition in Louisiana wetlands is a result of the redistribution of sediment and organic matter within the system. Organic matter (or carbon) can come from upper basin wetlands and be deposited in downstream project areas, or may arrive at the project site from lower in the basin with storms and fronts (Reed 1989). In any case, the source of the carbon comes from either the natural export of surrounding healthy wetlands or from shoreline erosion. DeLaune et al. (2013) described one example of how non-restored wetland erosion can serve as a source of sediments that are transported through the estuary: “as marshes degrade and erode, there is a loss of material through net transport of mineral and organic matter through tidal inlets to the coastal ocean (Li et al 2009, 2011). The translocation of organic and mineral material from the marsh to the coastal waters further exacerbates coastal land loss.”

3. *Carbon Quality, Storage, and Averting Emissions*: Das et al. (2011) proposed that “the fate of carbon from eroded wetlands remains incompletely known” but evidence from their study as well as another recent study (Wilson and Allison, 2008) “potentially suggest that about 40% of POC released from eroding marshes is exported to the coastal Gulf of Mexico”. Thus, organic matter storage is occurring within the estuary’s wetlands and bays. While the fate and transformation of organic matter from interior wetlands to the offshore environment isn’t entirely certain, there is reasonable evidence that the source of allochthonous carbon to a project area in Louisiana will be similar in quality to that which will be released from the project area (Wilson and Allison, 2008). That is, the source of carbon is largely derived within the system. There is also increasing

evidence that Mississippi River water, which could enter from the mouth of adjacent estuaries in Louisiana, has a higher fraction of labile carbon than previously assumed (Mayer et al. 2008).

The design and location of wetland creation projects offer benefits in the form of capturing organic sediments that could otherwise be lost offshore or potentially oxidized in shallow bay waters. The decay of organic matter in the emergent wetland environment is slower than the estuarine open water setting due to the presence of anaerobic conditions, acidic porewater, and the presence of decay inhibitors (secondary metabolic compounds or humic acids) (Bianchi et al. 2011). Along the terrestrial to marine gradient, the likelihood of emissions with organic matter decay is increased as exposure or residence time under oxic conditions is prolonged, a process termed 'diagenetic oxygen exposure time' (Bianchi et al. 2011). The combination of physical energy, photo-degradation, oxygen exposure, and strong ionic gradients can accelerate the carbon decay process along the estuarine-offshore gradient. Thus, under the project condition, allochthonous carbon has a greater likelihood of preservation in the wetland system.

In summary, for Coastal Louisiana, it can be conservatively assumed that transport of organic matter will not cause carbon accretion estimates to be significantly overestimated, and thus allochthonous carbon may be neglected.

Table I.1: Summary of carbon export from estuaries, with special consideration of Louisiana estuaries

Location	Carbon Export[6]	Habitat Type	Source
Review of estuaries	100-200	Salt marshes	Nixon 1980
Barataria Bay, LA	165	Forested upland-estuary interface	Hopkinson and Day 1979
Barataria Bay, LA	150-250	Entire estuary	Feijtel et al. 1985
Barataria Bay, LA	25-540 (150)[7]	Entire estuary	Happ et al. 1977
Barataria Bay, LA	57	Estuary open water area	Das et al. 2010

[6] Units: g C m^{-2} yr^{-1}

[7] Considering the magnitude of errors involved in the assumptions upon which the calculations were based, the study reported an organic carbon export of 25 to 540 g C m^{-2} yr^{-1} to inshore waters, with the most probable value around 150 g C m^{-2} yr^{-1}.

APPENDIX J: LIST OF VARIABLES

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
A_{PA}	acre	Area of project area	GIS analysis prior to sampling		[G.10], [G.12]	-	-
$b^{[m]}$	%	Buffer withholding percentage calculated as required by the VCS AFOLU Non-Permanence Risk Tool	VCS AFOLU Non-Permanence Risk Tool	N/A	[G.20]	Every monitoring period	N/A
$C_{P\ CS}^{[m]}$	tCO_2e	Cumulative project carbon stocks at end of current monitoring period	Sampling activities	[G.7]	[G.8], [G.9], [G.19]	At least every five years	Independent review of equations and check against literature estimates. See Section 9.2.8.3
$C_{P\ CS}^{[m-1]}$	tCO_2e	Cumulative project carbon at beginning of current monitoring period	Sampling activities	[G.7]	[G.8], [G.9]	At least every five years	Independent review of equations and check against literature estimates. See Section 9.2.8.3
$C_{P\ CS\ (c)}^{[m]}$	tCO_2e	Cumulative project carbon in pool *c* at end of current monitoring period	Sampling activities	Appendix D	[G.7]	At least every five years	Independent review of equations and check against literature estimates. See Section 9.2.8.3

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$d_{LQD}^{[m]}$	kg/m³	Density of liquid in dredged sediment	Monitoring records, direct measurement	9.2.5	[G.1]	Every monitoring period when sediment is transported	Compare data from multiple samples. See Section 9.2.8.1
$d_{SLD}^{[m]}$	kg/m³	Density of solids in dredged sediment	Monitoring records. direct measurement	9.2.5	[G.1]	Every monitoring period when sediment is transported	Compare data from multiple samples. See Section 9.2.8.1
$d_{P\,\Delta}^{[m]}$	kg/m³	Density of sediment dredged from sediment source	Monitoring records, direct measurement	9.2.5	[G.2], [G.1]	Every monitoring period when sediment is transported	Compare data from multiple samples. See Section 9.2.8.1
$E_{BA\,\Delta}^{[m]}$	tCO_2e	Emissions reductions and/or removals allocated to AFOLU pooled buffer account over current monitoring period	Monitoring records	8.4.2	[G.21], [G.20]	Every monitoring period	Independent review of equations and monitoring records. See Section 9.2.8.2
$E_{B\,\Delta}^{[m]}$	tCO_2e	Total baseline emissions over current monitoring period	Monitoring records	8.1	[G.6], [G.16]	Every monitoring period	Independent review of equations and monitoring records. See Section 9.2.8.2

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$E_{B\,\Delta\,CH4}^{[m]}$	tCO_2e	Total baseline emissions from methane over current monitoring period	Monitoring records	8.1.2	[G.5]	Every monitoring period	Independent review of equations and monitoring records. See Section 9.2.8.2
$E_{B\,\Delta\,EC}^{[m]}$	tCO_2e	Total baseline emissions from energy consumption over current monitoring period	Monitoring records	8.1.1	[G.6], [G.3]	Every monitoring period when sediment is transported	Independent review of equations and monitoring records. See Section 9.2.8.2
$E_{BR\,\Delta}^{[m]}$	tCO_2e	Total emissions reductions and/or removals for buffer release over current monitoring period	Monitoring records	8.4.2	[G.21]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2
$E_{GER}^{[m]}$	tCO_2e	Cumulative gross emissions reductions and/or removals at end of current monitoring period	Monitoring records	8.4.1.1	[G.17]	Every monitoring period	Independent review of GER calculations. See Section 9.2.8.2
$E_{GER\,\Delta}^{[m]}$	tCO_2e	Total gross emissions reductions and/or removals over current monitoring period	Monitoring records	8.4.1, 8.4.2	[G.16],[G.17], [G.19], [G.20], [G.21]	Every monitoring period	Independent review of GER calculations. See Section 9.2.8.2
$E_{NER\,\Delta}^{[m]}$	tCO_2e	Total net emissions reductions and/or removals over current monitoring period	Monitoring records	8.4.2	[G.21]	Every monitoring period	Independent review of NER calculations. See Section 9.2.8.2

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$E_{P\,\Delta}^{[m]}$	tCO_2e	Total project area emissions/ emissions removals over current monitoring period	Monitoring records	8.2	[G.15], [G.16]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2
$E_{P\,\Delta\,CH4}^{[m]}$	tCO_2e	Total methane emissions in project area over current monitoring period	Monitoring records	8.2.2	[G.15],[G.8], [G.9], [G.11]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2
$E_{P\,\Delta\,CS}^{[m]}$	tCO_2e	Total carbon stock emissions or emissions reductions and/or removals in project area over current monitoring period	Monitoring records	8.2.1	[G.15], [G.8], [G.9],	Every monitoring period	Independent review of calculations and monitoring records. See Sections 9.2.8.2 and 9.2.8.3
$E_{P\,\Delta\,EC}^{[m]}$	tCO_2e	Total emissions from energy consumption in project area over current monitoring period	Monitoring records	8.2.4	[G.15], [G.14]	Every monitoring period when sediment is transported	Independent review of calculations and monitoring records. See Section 9.2.8.2
$E_{P\,\Delta\,N2O}^{[m]}$	tCO_2e	Total nitrous oxide emissions within project area over current monitoring period	Monitoring records	8.2.3,	[G.15], [G.13]	Every monitoring period	Independent review of calculations. See Section 9.2.8.2

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$e_{(ty)}$	tCO_2e /gal, tCO_2e /scf, tCO_2e /kWh	Emissions coefficient for energy type *ty*	Emission factors in Section 8.1.1, Table 10	Selected from published values	[G.3], [G.14]		
$E_{U\,\Delta}^{[m]}$	tCO_2e	Confidence deduction for current monitoring period	Monitoring records	8.4.2.1	[G.19], [G.21]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2
$f_{B\,\Delta\,CH4}^{[m]}$	tCO_2e /ac/day	Baseline methane emissions flux per unit area	Monitoring records and static chamber or eddy covariance measurement	9.2.7	[G.5]	Every monitoring period	Comparison of data from multiple samples and independent review of calculations. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
$F_{B\,\Delta\,CH4}^{[m]}$	tCO_2e /day	Baseline methane emissions flux	Monitoring records and static chamber or eddy covariance measurement	9.2.7	[G.5]	Every monitoring period	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$f_{P\,\Delta\,CH4}^{[m]}$	tCO_2e /ac/day	Methane emissions flux per unit area within project area	Monitoring records and static chamber or eddy covariance measurement	9.2.2.3	[G.10]	Every monitoring period	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
$f_{P\,\Delta\,N2O}^{[m]}$	tCO_2e /ac/day	Nitrous oxide emissions flux per unit area within project area	Monitoring records and static chamber or eddy covariance measurement	9.2.3.3	[G.12]	Every monitoring period	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
$F_{P\,\Delta\,CH4}^{[m]}$	tCO_2e /day	Methane emissions flux within project area	Monitoring records and static chamber or eddy covariance measurement	9.2.2.3	[G.11], [G.10]	Every monitoring period	Comparison of data from multiple samples and independent review of calculations. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$F^{[m]}_{P\,\Delta\,N2O}$	tCO_2e /day	Nitrous oxide emissions flux within project	Monitoring records and direct measurement, default values, or proxy values developed by the project proponent	9.2.3	[G.13], [G.12]	Every monitoring period	Comparison of data from multiple samples and independent review of calculations. See Sections 9.2.8.1, 9.2.8.4, and 9.2.8.5
$g_{B\,(ty)}$	gal/tonne, scf/tonne, kWh/tonne	Energy consumed per metric tonne of sediment dredged in the baseline	Documentation provided by proponent	Direct measurement	[G.3]	-	-
$G^{[m]}_{P\,\Delta\,(ty)}$	gal, scf, kW	Energy consumed in project area for energy type *ty* over current monitoring period	Monitoring records and direct measurement or cost approach	8.2.4	[G.14]	Every monitoring period when sediment is transported	Independent review of calculations and monitoring records. See Sections 9.2.8.1 and 9.2.8.2
$M^{[m]}_{P\,\Delta}$	tonnes	Mass of sediment dredged from the sediment source over current monitoring period	Monitoring records	8.1.1, 9.2.5	[G.3], [G.2]	Every monitoring period when sediment is transported	Project verification and independent review of calculations. See Section 9.2.8.2

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$p_{B\,(ty)}$	proportion (unitless)	Proportion of energy for energy type *ty* consumed in the baseline scenario	Documentation provided by proponent	Calculated from direct measurement	[G.3]	-	-
${p_{SLD}}^{[m]}$	proportion (unitless)	Proportion of solids by weight in the dredged sediment	Sampling activities, direct measurement	9.2.5	[G.1]	Every monitoring period when sediment is transported	Comparison of data from multiple samples and review of monitoring records. See Sections 9.2.8.1 and 9.2.8.2
$t^{[m]}$	days	Elapsed time from project start at the end of the current monitoring period	Monitoring records	N/A	[G.11], [G.13]	Every monitoring period	N/A
$t^{[m-1]}$	days	Elapsed time from project start at the beginning of the current monitoring period	Monitoring records	N/A	[G.11], [G.13]	Every monitoring period	N/A
$U_{P\,CS}^{[m]}$	tCO_2e	Total standard error in project carbon stocks measured during the current monitoring period	Monitoring records	N/A	[G.19], [G.18]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2

Data / Parameter	Unit	Description	Source of Data	Measurement Method	Used in Equations	Frequency of Monitoring/ Recording	QA/QC
$U_{P\ CS\ (c)}^{[m]}$	tCO_2e	Total standard error in project carbon stocks for pool *c* measured during the current monitoring period	Monitoring records	[A.8]	[G.18]	Every monitoring period	Independent review of calculations and monitoring records. See Section 9.2.8.2
$V_{P\ \Delta}^{[m]}$	m^3	Volume of sediment dredged from the sediment source over current monitoring period	Monitoring records	9.2.5	[G.2]	Every monitoring period when sediment is transported	Independent review of calculations and monitoring records. See Section 9.2.8.2

APPENDIX K: SUMMARY OF PROJECT DESCRIPTION REQUIREMENTS

PDR#	Category	Requirements
PDR.1	Applicability Conditions	For each applicability condition, credible evidence in the form of analysis, documentation or third-party reports to satisfy the condition.
PDR.2	GHG Sources	A list of the included GHG sources.
PDR.3	Carbon Pools	A list of the selected carbon pools.
PDR.4	Allochthonous Carbon in Soil Carbon Pool	Narrative justification that the import of organic matter will not cause carbon accretion estimates to be significantly overestimated including citations to case studies, literature or models.
PDR.5	Allochthonous Carbon in Soil Carbon Pool	Description of the dominant sources of sediments with respect to external (ie, fluvial) inputs or internal (within estuary or tidal freshwater wetland) recycling.
PDR.6	Allochthonous Carbon in Soil Carbon Pool	Proximity of the project area with respect to direct fluvial inputs or near-shore sediment sources.
PDR.7	Allochthonous Carbon in Soil Carbon Pool	An annual mass estimate of the total carbon imported or exported from the estuary or tidal freshwater wetland where the project is located.
PDR.8	Allochthonous Carbon in Soil Carbon Pool	Description of the project area with respect to tidal energy (such as flood- or ebb-dominated) or tidal dispersive flux.
PDR.9	Delineating Spatial Boundaries	GIS-based maps of the project area with, at a minimum, the features listed above.
PDR.10	Delineating Spatial Boundaries	Documentation that the entire project area is/was open water at the project start date.
PDR.11	Delineating Spatial Boundaries	Evidence that the project area meets the definition of tidal or estuarine open water wetlands which once supported emergent wetland vegetation.
PDR.12	Delineating Spatial Boundaries	Evidence that the project area is compliant with the most current version of the VCS AFOLU Requirements regarding the clearing of native ecosystems.
PDR.13	Delineating Spatial Boundaries	If emissions from methane are included in the baseline scenario, an estimate of the average water depth in the project area prior to the implementation of project activities (see Section 6.3).
PDR.14	Delineating Spatial Boundaries	Documentation that the project proponent has control over the project area as described in most recent version of the VCS AFOLU Requirements, Section 3.4.
PDR.15	Delineating Spatial Boundaries	Documentation of the assessment of effects to hydrologically connected areas as further

		described in Section 8.3.1.
PDR.16	Delineating Spatial Boundaries	Documentation of projected sea level rise in the vicinity of the project area, evidence that existing landforms or constructed features are expected to withstand project sea level rise, and a description of the post-construction soil surface elevation relative to mean sea level.
PDR.17	Temporal Project Boundaries	The project start date.
PDR.18	Temporal Project Boundaries	The project crediting period start date and length.
PDR.19	Temporal Project Boundaries	The date by which mandatory baseline reassessment must occur after the project start date.
PDR.20	Temporal Project Boundaries	A timeline including the first anticipated monitoring period showing when project activities will be implemented.
PDR.21	Temporal Project Boundaries	A timeline for anticipated subsequent monitoring periods.
PDR.22	Grouped Projects	A list and descriptions of all enrolled project activity instances in the group at the time of validation.
PDR.23	Grouped Projects	A map of the designated geographic area within which all project activity instances in the group may be located, indicating that all instances are in the same region.
PDR.24	Grouped Projects	A list of eligibility criteria for project activity instances.
PDR.25	Baseline Scenario	Results of a comparative assessment of the implementation barriers and net benefits faced by the project and its alternatives, and justification for the most plausible baseline scenario.
PDR.26	Baseline Scenario	Documentation to demonstrate that the project area previously met the definition of a wetland before converting to open water or similar degraded state. Documentation must include hydrological data to show evidence of long-term patterns of wetland loss.
PDR.27	Baseline Scenario	The selected method for demonstrating the baseline scenario in the project area (regional land use change or spatial analysis).
PDR.28	Regional Land Use Change For Baseline Scenario	A reference to the document providing evidence of continued land loss or static condition in the basin for a period of 10 years prior to the project start date.
PDR.29	Regional Land Use Change For Baseline Scenario	A summary of the referenced document indicating where in the document the evidence is provided.
PDR.30	Regional Land Use Change For Baseline Scenario	Documentation of water management activities (eg, river diversions) that could influence the baseline scenario.
PDR.31	Spatial Analysis for Baseline Scenario	A report describing how the analysis was conducted, including data sources and dates, demonstration of conformance with the requirements listed in Section 6.1.2, and justification

		for the selection of the region in which the analysis was conducted.
PDR.32	Spatial Analysis for Baseline Scenario	A map of the region in which the analysis was conducted.
PDR.33	Spatial Analysis for Baseline Scenario	The quantified change in water area.
PDR.34	Determination of Dredging	Determination (yes or no) whether dredging is included in the baseline scenario.
PDR.35	Determination of Dredging	If dredging is included in the baseline scenario, a description of the single event or programmatic dredging projects, including the likely fate of dredged sediments in the baseline scenario.
PDR.36	Demonstration of Navigability	Map of dredging activities, including justification for planned dredging locations.
PDR.37	Demonstration of Navigability	Documents that demonstrate dredging would have occurred.
PDR.38	Determination of Baseline Energy Consumption	For each energy type in Table 11, the estimate of the unit of energy consumed per metric tonne of sediment dredged.
PDR.39	Determination of Baseline Energy Consumption	Description of equipment types and method or process of sediment dredging, transport, disposal, re-handling, sediment production rates, duration of operations and conveyance distances.
PDR.40	Determination of Baseline Energy Consumption	Estimates of cumulative sediment quantity excavated and re-handled, including temporary disposal and displacement activities, if applicable.
PDR.41	Determination of Baseline Energy Consumption	Source of procedures or data on which these estimates are based.
PDR.42	Determination of Baseline Methane Emissions	Description and justification for the selected reference area.
PDR.43	Demonstration of Project Additionality	Demonstration that pertinent laws and regulations have been reviewed and that none mandate the project activities.
PDR.44	Demonstration of Project Additionality	Evidence that project activities comply with all applicability conditions set out under Section 4.
PDR.45	Emissions or Emissions Reductions and/or Removals Events in Project Area	The selected definition of a significant disturbance.
PDR.46	Hydrologic Effects	Description of the expected impacts on hydrologically connected areas, and the agency process which is expected to take place prior to the commencement of project activities.
PDR.47	Monitoring Plan	A summary of carbon stock sampling procedures for the project area, with a copy of a sampling protocol used by field personnel to carry out measurements.
PDR.48	Monitoring Plan	A summary of flux measurement procedures for the project area, with a copy of a flux

		measurement protocol used by field personnel to carry out measurements.
PDR.49	Monitoring Plan	A reference to the monitoring plan.
PDR.50	Monitoring Plan	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.
PDR.51	Stratification	Justification for not stratifying carbon stocks.
PDR.52	Stratification for SOC	Description for how the strata were delineated.
PDR.53	Stratification for SOC	Map(s) of the initial strata boundaries.
PDR.54	Stratification for Biomass	Description for how the strata were delineated.
PDR.55	Stratification for Biomass	Map(s) of the initial strata boundaries.
PDR.56	Measuring Carbon Stocks	Proposed method for allocating plots to stratum.
PDR.57	Measuring Carbon Stocks	Description of plot sizes and layout (such as the use of nests and their sizes) for each carbon pool.
PDR.58	Soil Plot Design	Diagram of a soil plot showing the locations of artificial marker horizons and core samples within the plot over time.
PDR.59	Soil Plot Design	Description of the fixed soil sample depth.
PDR.60	Frequency of Carbon Stock Measurements	The anticipated frequency of monitoring for each plot and flux measurement location – all carbon stock plots should be measured for the first verification.
PDR.61	Monitoring Methane	The selected approach for monitoring methane.
PDR.62	Methane Models from Literature	Justification of methane flux model from the literature, per the requirements of Section 9.2.2.1.
PDR.63	Covariates for Proxy Methane Models	A list of possible covariates and the sources of data available for each.
PDR.64	Covariates for Proxy Methane Models	A list of selected covariates to be used for model fitting.
PDR.65	Stratification for Methane Emissions	Description for how the strata were delineated.
PDR.66	Stratification for Methane Emissions	Map(s) of the initial strata boundaries indicating which stratum is likely to yield the greatest methane emissions flux.
PDR.67	Stratification for Methane Emissions	Justification per the criteria in Section 9.2.2.3.1 for the stratum that is likely to yield the greatest methane emissions flux.
PDR.68	Instrumentation for Chambers	Diagram of chamber design.

PDR.69	Eddy Covariance Measurements	The type of analyzer selected for direct measurements of methane, including a description of the resolution of measurements (in ppb) and the frequency at which measurements are to be taken (in Hz).
PDR.70	Eddy Covariance Measurements	A table of meteorological variables selected for measurement. For each variable in the table, justification for its selection, the unit of measurement, resolution of measurement and frequency of measurement.
PDR.71	Eddy Covariance Measurements	A description the eddy covariance tower configuration including the distances between sensors (vertical, northward and eastward separation).
PDR.72	Eddy Covariance Measurements	A scale diagram of the eddy covariance tower configuration showing the relative location and distance of the anemometer relative to the methane sensor.
PDR.73	Eddy Covariance Measurements	Plan view diagram or map of the eddy covariance tower delineating strata and the area of highest anticipated emissions within a 100m radius of the tower. Delineation of any patch vegetation (twice the dominant canopy height and occupying >100m^2 in area) occurring within the estimated 80% footprint area.
PDR.74	Eddy Covariance Measurements	Description of dominant plant canopy height (in m) over an annual cycle. An estimate of the 80% flux footprint distance (in m) and parameter estimates, as follows: σw= standard deviation of the vertical velocity fluctuations (m/s) $u *$= surface friction velocity (m/sec) zm= measurement height (m) hm= planetary boundary layer height (m) or 1000m zm= roughness length (m) or 1/10th of the average canopy height
PDR.75	Monitoring Nitrous Oxide	The selected approach for monitoring nitrous oxide.
PDR.76	Determining Project Area Exposure to Nitrogen Loading	Location of the project area within a minimum definable watershed, using a USGS, EPA or state delineated watershed.
PDR.77	Determining Project Area Exposure to Nitrogen Loading	Locations of all NPDES major dischargers and public works projects producing > 1 MGD of elevated nitrogen effluent (>3 mg TN/L) discharging into the project area and located within the minimum definable watershed.
PDR.78	Determining Project Area Exposure to Nitrogen Loading	List of EPA CWA Section 303d designated impaired waters for the state.
PDR. 79	Default Values for Nitrous Oxide Monitoring	Justification for the selected default value.
PDR.80	Covariates for Proxy Nitrous Oxide Models	A list of possible covariates and the sources of data available for each.
PDR.81	Covariates for Proxy Nitrous Oxide Models	A list of selected covariates to be used for model fitting.

PDR.82	Model Fit for Nitrous Oxide	Justification that the proxy is an equivalent or better method (in terms of reliability, consistency or practicality) to determine the value of interest than direct measurement.
PDR.83	Stratification for Nitrous Oxide Emissions	Description for how the strata were delineated.
PDR.84	Stratification for Nitrous Oxide Emissions	Map(s) of the initial strata boundaries indicating which stratum is likely to yield the greatest nitrous oxide emissions flux.
PDR.85	Stratification for Nitrous Oxide Emissions	Justification per the criteria in Section 9.2.2.3.1 for the stratum that is likely to yield the greatest nitrous oxide emissions flux.
PDR.86	Field Training for Field Sampling	A description of the type and frequency of training of field personnel responsible for sampling carbon stocks, fluxes, and covariates.
PDR.87	Quality Control and Assurance of Eddy Covariance Data	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.
PDR.88	Data and Parameters Available at Validation	The value of each variable, data and parameter in Appendix I.
PDR.89	Data and Parameters Available at Validation	The units, descriptions, source, purpose and comments for each variable reported in the PD.
PDR.90	Chamber Description	A description of the chamber design, with its dimensions or total volume, and cross-sectional area.
PDR.91	Chamber Description	Diagram of chamber plot randomization design and the resulting chamber locations within each stratum, with the chambers identified as replicates. Provide dates when chambers were deployed in each stratum. Provide a justification that the locations chosen are conservative (ie, that they are likely to predict methane emissions flux for the entire stratum for which they are representative.)

APPENDIX L: SUMMARY OF MONITORING REPORT REQUIREMENTS

MRR#	Category	Requirements
MRR.1	Project Activities	Plan for establishment of permanent wetland plant community after project construction. Plan must include tracking aerial extent of emergent vegetation long-term monitoring of such communities, as well as plans for continued maintenance if necessary. This documentation must demonstrate that the project activity results in the accumulation or maintenance of soil carbon stock and that, upon completion of the project activities, the project area must meet the definition of a wetland.
MRR.2	Project Activities	Evidence that the project engineering and design takes into account local water level elevation, tidal range, geotechnical characteristics, sea level rise projections, and the range of plant growth within those constraints.
MRR.3	Substrate Establishment	Post-construction report, including an as-built drawing showing plan view and cross section of the project area along with an estimate of post-construction sediment elevation relative to a geodetic or tidal datum.
MRR.4	Substrate Establishment	Aerial image of the project area within three years prior to construction and an aerial image within one year post-construction.
MRR.5	Vegetation Establishment	A description of the quantity, species, date and location of vegetation establishment, and photographs of the operation. This documentation must demonstrate that the project activity results in the accumulation or maintenance of soil carbon stock.
MRR.6	Vegetation Establishment	Aerial image of the project area indicating where species were established.
MRR.7	Temporal Project Boundaries	The project start date.
MRR.8	Temporal Project Boundaries	The project crediting period start date and length.
MRR.9	Temporal Project Boundaries	Evidence of the start of monitoring per the frequency requirements described in Sections 5.4, 9.2.1.1, 9.2.2.4, and 9.2.3.4.
MRR.10	Grouped Projects	A list and description of all project activity instances in the group, including project activity instance start dates.
MRR.11	Grouped Projects	A map of the boundaries of all project activity instances in the group demonstrating that all instances are in the designated geographic region.
MRR.12	Baseline Emissions	Calculations of current baseline emissions $EB\ \Delta m$ as of the monitoring period.
MRR.13	Baseline Emissions	Calculations of baseline emissions $EB\ \Delta m - 1$ from prior monitoring periods.

MRR.14	Emissions Coefficients	Source and date of the emission coefficient.
MRR.15	Emissions Coefficients	Reference to the exact page number or worksheet cell in the source.
MRR.16	Project Emissions or Emissions Reductions and/or Removals	Calculations of current project emissions or emissions reductions and/or removals $EP\ \Delta m$ as of the monitoring period.
MRR.17	Project Emissions or Emissions Reductions and/or Removals	Calculations of project emissions or emissions reductions and/or removals $EP\ \Delta m - 1$ from prior monitoring periods.
MRR.18	Emissions or Emissions Reductions and/or Removals Events in Project Area	The selected definition of a significant disturbance.
MRR.19	Emissions or Emissions Reductions and/or Removals Events in Project Area	A map of the boundaries of any significant disturbance in the project area during the monitoring period.
MRR.20	Emissions or Emissions Reductions and/or Removals Events in Project Area	Evidence that plots were installed into these disturbed areas and were measured per Section 9.2.1.
MRR.21	Hydrologic Effects	Documentation that the project will not have a significant negative impact on hydrologically connected areas. This may include a Clean Water Act permit issued by the USACE, NEPA decision (ROD or FONSI) issued by the appropriate lead federal agency, or compliance documentation from local floodplain management agencies.
MRR.22	Quantification of GERs	Quantified GERs for the monitoring period including references to calculations.
MRR.23	Quantification of GERs	Quantified GERs for the prior monitoring period.
MRR.24	Quantification of GERs	A graph of GERs by monitoring period for all monitoring periods to date.
MRR.25	Quantification of NERs	Quantified NERs for the monitoring period including references to calculations.
MRR.26	Quantification of NERs	Quantified NERs for the prior monitoring period.
MRR.27	Quantification of NERs	A graph of NERs by monitoring period for all monitoring periods to date.
MRR.28	Confidence Deduction	The calculated confidence deduction and supporting calculations.
MRR.29	Confidence Deduction	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.

MRR.30	AFOLU Pooled Buffer Account	Reference to the VCS requirements used to determine the AFOLU pooled buffer account allocation.
MRR.31	AFOLU Pooled Buffer Account	Reference to calculations used to determine the AFOLU pooled buffer account allocation.
MRR.32	Buffer Release	Reference to the VCS requirements used to determine the release from the AFOLU pooled buffer account.
MRR.33	Buffer Release	Reference to calculations used to determine the buffer release.
MRR.34	Vintages	Quantified NERs by vintage year for the monitoring period including references to calculations.
MRR.35	Project Performance	Comparison of NERs presented for verification relative to those from *ex-ante* estimates.
MRR.36	Project Performance	Description of the cause and effect of differences from *ex-ante* estimates.
MRR.37	Monitoring Plan	Documentation of training for field measurement crews.
MRR.38	Monitoring Plan	Documentation of data quality assessment.
MRR.39	Monitoring Plan	References to plot allocation for carbon stock measurement.
MRR.40	Monitoring Plan	List of plot GPS coordinates for plots and flux measurement devices.
MRR.41	Monitoring Plan	Description and diagram of flux measurements devices for methane and/or nitrous oxide.
MRR.42	Monitoring Plan	The estimated carbon stock, standard error of the total for each stock, and the sample size for each stratum in the project area.
MRR.43	Monitoring Plan	Any methodology deviations. Such deviations must include the text that is being modified and the proposed new language.
MRR.44	Monitoring Plan	Frequency of monitoring for each plot and flux measurement location – all carbon stock plots should be measured for the first verification.
MRR.45	Stratification for SOC	Map(s) of the current strata boundaries.
MRR.46	Stratification for SOC	A description of changes to the strata boundaries (if applicable).
MRR.47	Stratification for Biomass	Map(s) of the current strata boundaries.
MRR.48	Stratification for Biomass	A description of changes to the strata boundaries (if applicable)
MRR.49	Measuring Carbon Stocks	Method for allocating plots to stratum.
MRR.50	Measuring Carbon Stocks	Map of the location of plots within strata.
MRR.51	Measuring Carbon Stocks	Description of plot sizes and layout (such as the use of nests and their sizes) for each carbon pool.

MRR.52	Soil Plot Design	For each measured soil plot, a diagram showing the location of installed artificial marker horizons and sampled cores.
MRR.53	Soil Plot Design	Field report describing soil sample depths (accretion depth and fixed soil sample depth) and coring devices used to collect samples. The report must also include number of soil samples and their identification in a chain of custody form submitted to the laboratory.
MRR.54	Frequency of Carbon Stock Measurements	List of plots measured during the monitoring period – all carbon stock plots should be measured for the first verification.
MRR.55	Methane Models from Literature	Demonstration that the selected model is applicable to the project area per the requirements of Section 9.2.2.1.
MRR.56	Methane Models from Literature	Description of how model predictions are converted to tCO_2e/day.
MRR.57	Data Collection for Proxy Methane Model	Complete references to the source of any data collected from literature or reports.
MRR.58	Data Collection for Proxy Methane Model	Data collection procedures, plans or protocols for any data collected directly from the project area.
MRR.59	Model Fit for Methane	The form of the selected model.
MRR.60	Model Fit for Methane	Summary statistics of the model fit as appropriate to the fitting of the model.
MRR.61	Model Fit for Methane	The estimated model parameters.
MRR.62	Model Fit for Methane	A description of the range of covariate data with which the model was fit.
MRR.63	Model Prediction for Methane	The values of any measured covariates.
MRR.64	Model Prediction for Methane	The predicted methane flux.
MRR.65	Processed Chamber and Eddy Covariance Flux Data	A table of chamber flux or eddy covariance emission summary statistics of the mean (±1SEM) and number of samples for each mean in tCO_2e/ac/day for each sample location within a stratum.
MRR.66	Stratification for Methane Emissions	Map(s) of the current strata boundaries.
MRR.67	Stratification for Methane Emissions	A description of changes to the strata boundaries (if applicable).
MRR.68	Instrumentation for Chambers	Diagram of chamber design.

MRR.69	Instrumentation for Chambers	Map showing the location of chambers in the project area.
MRR.70	Instrumentation for Eddy Covariance	Diagram or map of eddy covariance tower delineating the selected footprint area where flux was integrated from and the computed mean 80% footprint distance (including the footprint model used) from the tower during the period of analysis. A table of computed estimates for each of the following parameters: σ_w = standard deviation of the vertical velocity fluctuations (m/s) u^*= surface friction velocity (m/sec) z_m= measurement height (m) z_0= roughness length (m) (or canopy height and density to be used to estimate roughness length)
MRR.71	Instrumentation for Eddy Covariance	Description of the published model used to define the footprint.
MRR.72	Instrumentation for Eddy Covariance	Map showing the location of eddy covariance towers in the project area.
MRR.73	Instrumentation for Eddy Covariance	Documentation of adherence to manufacturer-recommended procedures for calibration of the methane analyzer.
MRR.74	Eddy Covariance Data Processing and Flux Computation	Frequency diagram of wind direction (0-359° with 30° intervals) and velocity (m/s) for the period of analysis.
MRR.75	Eddy Covariance Data Processing and Flux Computation	Summary of the dates of data collection, the selected approach for averaging over each period, explicit formulas used for computing flux, number of 0.5-hr samples used in calculations.
MRR.76	Eddy Covariance Data Processing and Flux Computation	Graphical plot of 0.5-hr GHG concentration (ppmv), wind velocity and direction, and temperature used for the flux calculations
MRR.77	Eddy Covariance Data Processing and Flux Computation	Summary statistics (number of samples, mean, median, variance) of GHG flux for each averaging period.
MRR.78	Chamber Sampling for Methane	Table of sampling event dates for the monitoring period, including the time of day samples were collected, water level relative to the soil surface, soil temperature, and air temperature.
MRR.79	Chamber Sampling for Methane	Copy of field data sheets documenting time intervals when samples were collected, sample identification number, and verification of the total number of samples received by the laboratory.
MRR.80	Eddy Covariance Measurement	A table of meteorological variables selected for measurement. For each variable in the table, an indication of whether the variable was measured, the make and model of the instrument used for measurement.
MRR.81	Eddy Covariance Measurement	For each measured variable, a graphical plot or table of the data with respect to time during the monitoring period. A data table or plot must include at minimum: air temperature, methane concentration, methane flux. A list of interpolated/missing samples.

MRR.82	Eddy Covariance Measurement	Documentation of calibration dates and zero checks for methane analyzer. Provide the date of last full calibration (0-10 ppm methane standard). Provide dates of carbon-free air gas checks for methane analyzer.
MRR.83	Data Collection for Proxy Nitrous Oxide Model	Complete references to the source of any data collected from literature or reports.
MRR.84	Data Collection for Proxy Nitrous Oxide Model	Data collection procedures, plans or protocols for any data collected directly from the project area.
MRR.85	Model Fit for Nitrous Oxide	The form of the selected model.
MRR.86	Model Fit for Nitrous Oxide	Summary statistics of the model fit as appropriate to the fitting of the model.
MRR.87	Model Fit for Nitrous Oxide	The estimated model parameters.
MRR.88	Model Fit for Nitrous Oxide Covariance Data	A description of the range of covariate data with which the model was fit.
MRR.89	Model Prediction for Nitrous Oxide	The values of any measured covariates.
MRR.90	Model Prediction for Nitrous Oxide	The predicted nitrous oxide flux.
MRR.91	Stratification for Nitrous Oxide Emissions	Map(s) of the current strata boundaries.
MRR.92	Stratification for Nitrous Oxide Emissions	A description of changes to the strata boundaries (if applicable).
MRR.93	Chamber Sampling for Nitrous Oxide	Table of sampling event dates for the monitoring period, including the time of day samples were collected, water level relative to the soil surface, soil temperature, and air temperature.
MRR.94	Chamber Sampling for Nitrous Oxide	Copy of field data sheets documenting time intervals when samples were collected, sample identification number, and verification of the total number of samples received by the laboratory.
MRR.95	Energy Consumption Measurement Method	The selected approach to monitoring energy consumption.
MRR.96	Direct Measurement of Energy Consumption	Energy consumption for each energy type listed in Section 8.1.1.
MRR.97	Direct Measurement of Energy Consumption	References to records of energy consumption.
MRR.98	Cost Approach to Energy	Justification for the proportion of dredging budget allocated for fuel (or electricity) purchases.

	Consumption	
MRR.99	Cost Approach to Energy Consumption	Justification for choice of energy type(s).
MRR.100	Cost Approach to Energy Consumption	Documentation of historic energy costs at the time of dredging activities.
MRR.101	Cost Approach to Energy Consumption	Justification of estimate of energy consumption.
MRR. 102	Monitoring Sediment Transport	Justification for the estimate of volume of dredged sediment transported.
MRR. 103	Monitoring Sediment Transport	Justification for the estimate of the density of dredged sediment.
MRR.104	Monitoring Sediment Transport	Estimated mass of sediment transported.
MRR.105	Monitoring Allochthonous Carbon	Reference(s) to the regionally appropriate literature used to determine the correct factor for mineral-associated carbon.
MRR.106	Field Training for Field Sampling	The type and frequency of training of field personnel during the monitoring period.
MRR.107	Carbon Stock Measurements	Biomass and SOC carbon stock data for all plots, along with any ancillary spreadsheets or computer code used to generate these predictions.
MRR.108	Carbon Stock Measurements	List of outliers with unusually high or low biomass or SOC, including justification for their continued inclusion.
MRR.109	Carbon Stock Measurements	Results of accuracy assessment if non-destructive sampling techniques are used. Otherwise, justification for why accuracy need not be formally addressed.
MRR.110	Quality Control and Assurance of Eddy Covariance Data	Description of processing software used, assumptions, and data quality control measures, which must include the selected method of coordinate rotation, detrending, and density fluctuation correction.
MRR.111	Laboratory Analyses	Documentation of the laboratory QA/QC protocols, the methods of sample analysis, and general calibration procedures used the laboratories conducting the analysis.
MRR.112	Data and Parameters Monitored	The value of each variable, data and parameter in Section 9.4.
MRR.113	Data and Parameters Monitored	The units, descriptions, source, purpose, references to calculations and comments for each variable reported in the Monitoring Report.
MRR.114	Data and Parameters Monitored	For those variables obtained from direct measurement, a description of measurement methods and procedures. These may simply be references to components of the monitoring plan.

MRR.115	Data and Parameters Monitored	For those variables obtained from direct measurement, a description of monitoring equipment including type, accuracy class and serial number (if applicable). These may simply be references to components of the monitoring plan.
MRR.116	Data and Parameters Monitored	Procedures for quality assurance and control, including calibration of equipment (if applicable).
MRR.117	Monitoring Grouped Projects	List and descriptions of all project activity instances in the group.
MRR.118	Monitoring Grouped Projects	Project activity instance start dates.
MRR.119	Monitoring Grouped Projects	Map indicating locations of project activity instances added to the group.
MRR.120	Monitoring Grouped Projects	List of additional stratifications used for additional project activity instances; justification for why flux measurements are still located in the most conservative stratum (9.2.2, 9.2.3).
MRR.121	Monitoring Grouped Projects	As project activity instances are added, monitoring plan must be updated to reflect additional monitoring times and plot locations.

APPENDIX M: SOURCE OF EMISSIONS FACTORS FOR ENERGY CONSUMPTION

		CO2		CH4		N20				
Fuel Type	Proponent reports as:	Emissions (kg/MMBtu)	tCO2 / MMBtu	Emissions (kg/MMBtu)	tCO2e / MMBtu	Emissions (kg/MMBtu)	tCO2e / MMBtu	Total Emissions (tCO2e/MMBtu)	Energy Content (MMBtu/unit)	**Emission Coefficient**

Sources:

- Emissions factors and energy content for fuels: EPA Final Mandatory Reporting of Greenhouse Gases Rule Table C-1, C-2 (http://www.epa.gov/ghgreporting/documents/pdf/2009/GHG-MRR-FinalRule.pdf). Emissions in kg/MMBtu are taken directly from the EPA Mandatory reporting Rule. Emissions in tCO2e/MMBtu apply a unit conversion to tons (1 ton = 1,000 kg) and multiply by the appropriate global warming potential (1 for CO_2, 21 for CH_4, 310 for N_2O – the project proponent must confirm the global warming potentials per the current version of VCS Standard). Total emissions are a simple sum of the emissions in tCO2e/MMBtu of each of the three covered gases. The emission coefficient is calculated as the product of the total emissions and the energy content of the fuel type.
  For updates to these factors, refer to the EPA website (http://www.epa.gov/ghgreporting/reporters/subpart/c.html) or the federal regulations (40 C.F.R. § 98, Subpart C, Tables C-1 and C-2).
- eGRID regional emissions factors for electricity: http://www.epa.gov/cleanenergy/documents/egridzips/eGRID2012V1_0_year09_GHGOutputrates.pdf ('annual total output emission rates'). Note the unit conversions required to calculate the emissions from electricity usage in terms of tCO_2e, given that eGRID factors are stated in terms of lb/MWh and lb/GWh, and in terms of CH_4 and N_2O emissions (vs. CO_2e).
  For the current version of emissions factors, refer to http://www.epa.gov/cleanenergy/energy-resources/egrid/index.html. Locate the eGRID GHG output summary file for the correct emission year (eg, eGRID2012 provides actual generation data from 2009). Because there is typically a lag of several years, if data for the current year or recent years are not available, use the most recent data (eg, if eGRID2012 is the most recent data available in 2013, then eGRID2012 with 2009 data should be used for all years 2009-2013). In the GHG summary file, use data for the appropriate eGRID subregion for 'annual total output emission rates.'

ACKNOWLEDGEMENTS

The creation of this methodology has relied upon the creative, critical insights from a wide range of stakeholder colleagues and their wider circle of colleagues whom they consulted. Our discussions have ranged from the initial inspiring conversations regarding the project activities included within this methodology, through the initial framing of this approach via our draft white papers, to the development of the performance benchmarks used in the methodology. Their generous guidance in the development of this methodology is greatly appreciated. Special thanks to Chevrolet for their generous sponsorship for the development of this methodology and to Pat Nye from Bonneville Environmental Foundation for his dedicated efforts.

The methodology uses the latest version of the following tools and guidance:

- VMD0038, Campus-Wide Module
- VMD0039, LEED-Certified Buildings Module
- US Environmental Protection Agency's ENERGY STAR Portfolio Manager® program[1]
- US Environmental Protection Agency's ENERGY STAR Target Finder tool[2]
- Clean Air Cool Planet Campus Carbon Calculator[3]
- CDM-EB67-A06-GUID Guidelines for sampling and surveys for CDM project activities and programme of activities

The methodology is based on approaches used in the following methodologies:

- VM0008 Weatherization of Single and Multifamily Homes (version 1.1)
- NM0302 Emission reductions in the cement production facilities of Holcim Ecuador S.A. (proposed CDM methodology)

The follow have also supported the development of the methodology:

- The American College and University Presidents' Climate Commitment (ACUPCC) GHG inventory reports[4]
- Efficiency Valuation Organization's International Performance Measurement and Verification Protocol (IPMVP) for guidance on methods determining energy savings (EVO-1000-1, 2010)[5]
- USGBC's LEED certification protocols[6]
- Portfolio Manager supporting documentation[7]

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

This methodology provides the procedures for quantifying reductions in scope 1 stationary combustion emissions and scope 2 electricity emissions achieved by college, university and school campuses in the United States. The methodology consists of two modules: *VMD0038, Campus-Wide Module*; and *VMD0039, LEED-Certified Buildings Module*, as follows:

1) Campus-Wide Module

   This module applies to projects targeting campus-wide emission reductions on existing college and university campuses in the United States (but does not apply to K-12 schools). Campuses may implement project activities that reduce scope 1 stationary combustion emissions and/or scope 2 electricity emissions. Campuses must meet the relevant additionality performance benchmark by applying a series of additionality benchmark tests. Emission reductions are quantified based on data from third-party GHG reporting programs (eg, ACUPCC, STARS and The Climate Registry) for each year relative to a three to five year adjusted baseline.

Additionality and Crediting Method	
Additionality	Performance Method
Crediting Baseline	Project Method

2) LEED-Certified Buildings Module

   This module applies to projects targeting emission reductions from LEED-certified New Construction or LEED-certified Existing Buildings located on college and university campuses and K-12 schools. The building must meet the relevant additionality performance benchmark. Emission reductions are quantified based on data generated using EPA's Target Finder tool for each year relative to a crediting benchmark or a three to five year adjusted baseline.

Additionality and Crediting Method	
Additionality	Performance Method
Crediting Baseline	Performance Method for New Construction and Existing Buildings B; Project Method for Existing Buildings A

This standardized methodology establishes multiple performance benchmarks which US colleges and schools can use to determine whether they have achieved a superior level of performance that would qualify as additional (additionality benchmark) and to quantify baseline emissions (crediting benchmark). Unlike project methods, performance methods are designed to identify the levels of performance (in terms of GHG emission reductions) in a given sector to allow for sector-wide benchmarking. Through extensive analyses of historical performance (outlined in the modules), this methodology establishes performance benchmarks for campus-wide emission reductions and LEED-certified building emission reductions that allow for a series of simple tests to be conducted to determine additionality and a crediting baseline. Stakeholder consultation was an important part of the development of this methodology, and the process and participants are described in Appendix 2.

Each module provides the detailed procedures for the given type of project activities, adding to the common requirements provided in this document. Each module has distinct specifications for applicability conditions, project boundary, baseline scenario, additionality, quantification of emission reductions, and monitoring. Where both campus-wide and building reductions are sought in combination for the same campus, both modules must be applied separately, and the relevant emission reductions netted out, as described in Section 8 below. Figure 1 below provides a conceptual route map illustrating how this methodology and its two modules are applied.

Projects must demonstrate right of use for any GHG emission reductions generated by the project, in accordance with the *VCS Standard* (for definition of *right of use* see VCS program document *Program Definitions*). Where right of use cannot be demonstrated for particular emission reductions (eg, for scope 2 emissions addressed by the project), the project proponent may choose to include only those emission reductions for which it can demonstrate right of use (eg, only include scope 1 emissions for LEED certified building projects). Emission reductions arising from a campus's third-party customer's use (eg, emission reductions achieved by a neighboring hospital which purchases energy from campus on-site energy generation) must be excluded from the project. Note that the consumption of energy services provided by off-site suppliers (eg, local industry) must be excluded from the scope 1 emissions and included in scope 2 emissions.

Where projects generate other forms of environmental credit (eg, renewable energy certificates (RECs)), the project must meet VCS rules and guidance on double counting (see *VCS Standard, Registration and Issuance Process,* and VCS guidance on double counting). For example GHG emission reductions that arise from the installation of renewable energy systems located on a campus, whose GHG-related attributes have been sold as RECs to other third parties must also be excluded from the quantification of emission reductions. Similarly, where RECs from off-site renewable installations are purchased by the campus, the lower GHG emissions or the respective grid emission factors associated with the RECs cannot be used to decrease project emissions in the quantification of emission reductions.

Emission reduction generated within a region subject to a carbon cap (eg, campuses' whose electricity emissions are included within a regulatory cap and trade program such as that in California) must meet the VCS rules regarding emission trading programs and other binding limits (ie, double counting) set out in the *VCS Standard*.

Where emission reductions are verified and intend to be issued as VCUs, project proponents must ensure that such VCUs are accurately reported in accordance with any procedures set out under any applicable third-party GHG reporting program under which the campus reports. The sale, transfer or retirement of any VCUs must be accurately reported to any applicable third-party GHG reporting program during the period where such sale, transfer or retirement occurs.

Figure 1: Conceptual Route Map for Methodology

Select project activities and determine appropriate module(s):

I. Campus-wide module for campus-wide activities
II. LEED-certified building module for LEED-certified building activities
III. Both modules for campus-wide *and* LEED-certified building activities

Campus-Wide	**LEED-Certified Buildings**
Applicability Conditions Determine whether activities qualify (eg, ACUPCC Carnegie classification of campus, use of third-party GHG reporting program, and activities implemented)	Applicability Conditions Determine whether activities qualify (LEED New Construction (NC), Existing Buildings A (EB-A), or Existing Building B (EB-B) and building classification higher education, higher education laboratory or K-12 School)
Project Boundary Determine the GHG sources, sinks and reservoirs for the project and whether new site areas can be excluded from the project boundary	Project Boundary Determine the GHG sources, sinks and reservoirs for the project
Baseline Scenario Determine the baseline scenario for the scope of GHG emission reductions that are additional, accounting for variance in square footage during the baseline period	Baseline Scenario Determine the baseline scenario for each building in the project by applying a crediting benchmark for NC and EB-B, or a historical baseline adjusted for energy efficiency improvements for EB-A
Additionality Determine which scope of emission reductions (ie, scope 1 stationary combustion emissions and/or scope 2 electricity emissions) are additional for the given project year, applying the regulatory surplus and performance benchmark tests, which account for variance in square footage during the baseline period and weather variances where necessary	Additionality Determine which buildings are additional for the given project year, applying the regulatory surplus and performance benchmark tests
GHG Emission Reductions Quantify the reductions for the relevant scope of emission reductions, adjusting for variance in square footage during the baseline period and project crediting period where necessary	GHG Emission Reductions Quantify the reductions for all additional buildings in the project using results generated from EPA's Target Finder tool anchored upon the appropriate property type and property use details

Monitoring Plan

Identify the data and parameters that need to be determined at validation, and those that need to be determined at each verification event.

Describe the plan for obtaining, recording, compiling and analyzing monitored data and parameters. Where both the campus-wide and LEED-certified buildings modules are applied, create a single monitoring plan.

Net GHG Emission Reductions

Where both the campus-wide and LEED-certified buildings modules are applied, quantify the net reductions by subtracting relevant LEED-certified building reductions from the campus-wide total.

3 DEFINITIONS

Definitions are specified in each of the modules referenced by this methodology.

4 APPLICABILITY CONDITIONS

This methodology applies to project activities that reduce emissions through the implementation of clean energy and/or energy efficiency activities at college and school campuses in the United States.

Projects applying this methodology must use the latest versions of one, or both, of the following modules:

1) VMD0038, Campus-Wide Module

2) VMD0039, LEED-Certified Buildings Module

Where the project applies one of these modules (ie, is implementing campus-wide activities *or* LEED-certified building activities), the project must meet the applicability conditions specified in the relevant module. Where the project applies both modules (ie, is implementing both campus-wide *and* LEED-certified building activities), the campus-wide activities must meet the applicability conditions set out in the campus-wide module, while the LEED-certified building activities must meet the applicability conditions set out in the LEED-certified buildings module.

Note that this methodology applies a standardized method and therefore must be used in preference to project methods (methodologies) available for the same project activities. Appendix 1 provides an indicative (non-exhaustive) list of project methods available for clean energy and energy efficiency projects.

5 PROJECT BOUNDARY

The procedures in the module being applied must be followed.

6 BASELINE SCENARIO

The procedures in the module being applied must be followed.

7 ADDITIONALITY

The procedures in the module being applied must be followed.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

The procedures in the module being applied must be followed.

Where both campus-wide and building reductions are sought in combination from the same campus (ie, both the campus-wide and LEED modules have been applied), then the building reductions must be subtracted from the campus-wide reductions, as follows:

$$ER_y = ER_{y,cw} - ER_{y,lcb} \quad (1)$$

Where:

ER_y = Net GHG emission reductions in year y for the project
$ER_{y,cw}$ = Net GHG emission reductions in year y from campus-wide module
$ER_{y,lcb}$ = Net GHG emission reductions in year y from LEED-certified building module

Only the relevant scope of emissions used in the quantification of campus-wide emission reductions must be subtracted (ie, only stationary combustion emissions reductions from LEED-certified buildings must be subtracted from projects quantifying campus-wide stationary combustion emission reductions). The LEED certification documents contain all the relevant information regarding the contributions that each source of energy (ie, stationary combustion or scope 2 electricity) contributed to the building's total energy consumption. These may be used, if sub-metering of the LEED-certified building is not accessible, to assess the total portion of the emission reductions from LEED-certified buildings that should be subtracted. For example, if a project sought emission reductions from both campus-wide stationary combustion and LEED-certified buildings, and the stationary combustion energy sources represent 40% of the LEED-certified building's energy consumption, then 40% of the LEED-certified building's emission reductions must be deducted from the campus-wide emission reductions.[8]

9 MONITORING

For campus-wide activities, the monitoring procedures set out in the campus-wide module must be followed. For LEED-certified building activities, the monitoring procedures set out in the LEED-certified buildings module must be followed. Where both modules are applied, monitoring procedures from both modules must be followed to provide a single monitoring approach for the project.

10 REFERENCES

None

[8] Given that LEED-certified building emission reductions will be small compared to a campus-wide emission reductions, this represents a reasonable estimation process, recognizing that the percent contribution of a given scope of energy emissions to the total is a reasonable proxy for the proportion of reductions that it contributed to a LEED-certified building emission reductions total.

APPENDIX 1: SIMILAR PROJECT METHODS

Standardized methods are designed to identify superior performance within a given sector and the performance benchmarks within the methodology have been developed to ensure such environmental integrity. Where project activities meet the applicability conditions of this methodology and its respective modules, such projects should apply the methodology in preference to project methods available for the same project activities. Project proponents should contact the VCSA at secretariat@v-c-s.org if additional guidance or clarification is necessary when selecting an appropriate methodology.

Table 1 below lists the identified approved and pending methodologies under VCS and approved GHG programs that target project activities that could be included under the *Campus Clean Energy and Energy Efficiency* methodology (ie, such methodologies may also be applicable to certain subsets of project activities covered by this methodology). Note that this is provided for indicative purposes only and does not necessarily represent an exhaustive list.

Table 1: Methodologies Targeting Similar Project Activities

Methodology	Title	GHG Program
AMS-I.A.	Electricity generation by the user	CDM
AMS-I.D.	Grid connected renewable electricity generation	CDM
AMS-I.F.	Renewable electricity generation for captive use and mini-grid	CDM
AMS-I.J.	Solar water heating systems (SWH)	CDM

APPENDIX 2: STAKEHOLDER CONSULTATION SUMMARY

The development of the methodology was generously sponsored by Chevrolet. Chevrolet's Carbon Reduction Initiative Environmental Advisory Board was instrumental in developing a draft white paper outlining the core framing and assumptions which would become this methodology. As part of this advisory board, a diverse group of stakeholders were consulted to refine the white paper and develop the performance benchmarks. This extensive stakeholder group included a diverse group of experts including AASHE, campus experts, environmental experts, college-focused NGO's, college sustainability officers, college business officers, carbon experts, and energy efficiency experts. A list of the experts involved with the stakeholder consultation is provided at the end of this appendix.

During the stakeholder consultation process many detailed questions relating to the design of the modules were discussed. These contributed to the refinements in the white papers, which were updated throughout this period. All stakeholders who reviewed the white papers therefore were able to review the performance benchmark. Particularly, detailed discussions of the following topics took place with the Environmental Advisory Board and USGBC:

- Baseline designs
- Project boundary definitions
- Applicability tests/conditions needed
- Provisions to avoid double counting
- Performance benchmark update processes
- Stratifications
- Performance benchmarks detailed analyses, based on performance curves, relative to percentile equivalents across each segment
- Carbon contribution to incremental capital analyses
- Refinements needed to fine tune the modules (eg, business as usual gains, square foot variances, inclusions/exclusions needed)
- Tests relative to attributable activities undertaken

The stakeholder dialogue was particularly helpful in confirming assumptions for key details and parameters in the modules. Not all discussions have been referenced here but, drawing upon key topics from the final white paper drafts, the main highlights in this category include:

Both modules:

- Refine performance benchmarks every five years – not sooner – to provide project proponents with sensible planning horizons; rather provide updated data on an interim basis to describe performance benchmark trends. Five years is consistent with VCS minimum requirements.
- Utility sign offs and other measures (especially regarding campus reporting of GHG reductions to ACUPCC, STARS etc.) to address double counting/double claiming.
- Project boundaries are appropriately specified to preclude GHG emission reductions resulting from RECs, energy services supplied to neighboring institutions etc.

Campus-wide module:

- The core foundation requires absolute reductions in both scope 1 and scope 2 electricity-based emissions.
- Selection of additionality benchmark as annual percentage improvement in stationary combustion emissions is appropriate. It conforms to VCS requirements, it closely aligns to campuses' ACUPCC reporting structures (which are over historical baselines) and thus encourages leadership capacity building in the sector, and it is consistent with precedent set by other performance methods under VCS.
- Stratify by Carnegie class, consistent with ACUPCC practice.
- Base the level of each additionality benchmark on the average annual percentage reduction by Carnegie class, not just a single percentile (eg, 85^{th}), to most accurately reflect superior performance achievement and minimize false positive/negatives.
- This approach generates performance benchmarks that are credible (around the 85^{th} percentile) relative to UNFCCC parameters and other VCS performance method precedents.
- Financial analysis of the carbon contributions was considered meaningful and providing leverage to deliver superior performance.
- Including a "positive" style test to document the steps taken to achieve the performances, based on leading campuses' ACUPCC Climate Action Reports, is credible and goes beyond other VCS performance method approaches.
- Screening for other potential drivers of performance has been thorough.
- Historical baselines are sound to use and well framed relative to variances for weather etc. Including variances to accommodate for weather changes makes sense if the historical reference period is short; otherwise, these variances are addressed by averaging over a longer historical reference period.
- It would be best to provide avenues in the module to accommodate variances for square footage outside reasonable parameters (declining or increasing more than 5 percent) rather than use an intensity style metric to determine additionality or quantify emission reductions. The latter introduces another orthogonal variable which then needs to be considered for variances relative to false positives and false negatives.
- Baseline adjustments reflecting US average energy efficiency gains should be made, not adjustments reflecting a five percent annual energy efficiency gain. The later would assume that campuses could go climate neutral very rapidly on a business as usual basis.

LEED-certified buildings module:

- Segmentations based on LEED proposed data is appropriate, using LEED overall averages where they feel the sample sets are otherwise too small.
- The average LEED-certified building Energy Star score is credible and the baselines selected make sense since the module then reflects a step-wise increase from national average ES score to average LEED-certified building Energy Star score.

- This approach generates performance benchmarks that are credible (around 86th percentile) relative to UNFCCC parameters and other VCS performance methodology precedents.
- Where EPA Portfolio Manager is not yet sufficiently robust for reporting/benchmarking purposes, it is appropriate to exclude campus laboratories from project consideration when comparisons need to be made to national benchmarks. However internal performance comparisons over time to an individual lab's performance improvements are appropriate. As a result, labs were excluded from EB-B pathway since ES 86 is a national benchmark, while labs are eligible to use EB-A (which compares the lab's EUI performance over time) and NC (where the building's EUI percent improvement over code has been independently assessed in detail through LEED certification). The exclusion of labs from the EB-B route may be reviewed again in year five when the performance parameters need to be updated.
- Including a "positive" style test to document the steps taken to achieve the performances, based on LEED's certification system, is credible and goes beyond other VCS performance method approaches.
- LEED Commercial Interior certifications could be included at a later stage but are too few and limited in energy efficiency scope to include at this stage.
- Baselines are well-defined and measurement approaches outlined in EPA Portfolio Manager are appropriate. Variances for many potential drivers are well-accommodated through Portfolio Manager's reporting system which accounts for such potential variances.
- Although EB-B could use the historical baseline for each building, since LEED does not collect this information for its certification system, it is appropriate to use ES 50 as the baseline.
- A one percent energy efficiency improvement factor is not needed as an adjustment for NC or EB-B to the baseline since EPA Portfolio Manager revises the ES 50 baseline each year to reflect current updated practices. It is only needed for EB-A which uses the project's historical baseline (but not needed for eligibility testing since the metric is EUI-based and thus already anchored on a per square foot basis).

The stakeholders consulted compromise the list of individuals acknowledged above in this methodology. Areas of expertise represented in this stakeholder group were as follows:

- Campus sustainability/energy/climate leadership (CSEC), 32 participants
- Campus financial leadership (CF), 30 participants
- Carbon methodology/project development (C), 23 participants
- Energy efficiency best practices (EE), 17 participants
- Business (B), 40 participants
- NGO (NGO), 6 participants
- Government/policy (G), 10 participants

1 SOURCES

The methodology was developed based on the requirements in the following documents :

- 2006 IPCC Guidelines for National Greenhouse Gas Inventories
- IPCC 2003 Good Practice Guidelines for Land Use, Land Use Change and Forestry
- IPCC 2000 Good Practice Guidance for Uncertainty Management in National Greenhouse Gas Inventories

This methodology uses the latest versions of the follow modules and tools:

- CDM *General Guidelines for Sampling and Surveys for Small-scale CDM Project Activities*
- CDM *Tool for Calculation of the Number of Sample Plots for Measurements within A/R CDM Project Activities*
- CDM *Tool for Estimation of Carbon Stocks and Change in Carbon Stocks of Trees and Shrubs in A/R CDM Project Activities*
- CDM *Tool for Identification of Degraded or Degrading Lands for Consideration in Implementing CDM A/R Project Activities*
- CDM *Tool for Testing Significance of GHG Emissions in A/R CDM Project Activities*
- VCS *AFOLU Non-Permanence Risk Tool*
- VCS methodology module *VMD0033 Estimation of Emissions from Market Leakage*
- VCS methodology module *VMD0040 Leakage from Displacement of Grazing Activity*
- VCS *VT0001 Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities*

2 SUMMARY DESCRIPTION OF THE METHODOLOGY

Additionality	Project Method
Crediting Baseline	Project Method

The methodology provides procedures to estimate the GHG emissions reductions and removals from the adoption of sustainable grassland management practices, such as improving the rotation of grazing animals between summer and winter pastures, limiting the timing and number of grazing animals on degraded pastures, and restoration of severely degraded land by replanting with perennial grasses and ensuring appropriate management over the long-term.

The methodology quantifies emissions reductions and removals from increases in soil organic carbon (SOC) stocks and reduction of non-CO_2 GHG emissions. Where biogeochemical models can be demonstrated to be applicable in the project region, they may be used in estimation of soil carbon pool changes. Where such models are not applicable, the methodology provides guidance for estimation of SOC pool changes using direct measurement methods. The methodology uses a project method to determine additionality and the crediting baseline.

3 DEFINITIONS

In addition to the definitions set out in VCS document Program Definitions, the following definitions and acronyms apply to this methodology:

3.1 Defined Terms

Baseline Period
A historical reference period over which the project's baseline emissions are calculated, which is representative of the most plausible baseline scenario and consists of five consecutive years occurring before the project start date

Baseline Year b
The year for which baseline emissions for a parameter are calculated as an average of emissions over the baseline period or as a result of sample surveys

Dry Matter (dm)
Biomass that has been dried to an oven-dry state, as defined by IPCC[1]

Grassland Parcel

A spatially discrete area of grassland that is owned and/or managed by a household or land user (and is identified by a unique geodetic polygon). Each household may have several parcels of land which may be categorized under the same land use stratum

Grazing Agent
An individual or organization responsible for decision-making regarding grazing management

Grazing Season
The period of time when a plot of grassland is available for grazing due to natural climatic and plant growth conditions and/or spatial and temporal management decisions of the grassland user[2]

Land Use Change

[1] IPCC, 2003
[2] Grazing plans typically allocate individual plots to be grazed in different seasons, which may be identified differently in different locations (eg, two season systems, three season systems, four season systems) and some grazing plans may identify shorter periods of time when a specific plot is available for grazing.

Conversion of land from one land use category to another. In this methodology, land use change is conversion of grassland to cropland, forest or wetland

Land Use Stratum (Stratum)
A distinct sub-type of land use. When land use is not homogeneous but instead consists of several sub-types which are known (or thought) to vary with reference to the indicator of interest (eg, with-project carbon stock change), then each sub-type may be treated separately as a land use stratum

Significance
A term used to determine whether an increase or decrease in carbon pool or GHG source can, or cannot, be deemed de minimis (ie, amounts to less than five percent of the total GHG emission reductions generated by the project)

Sustainable Grassland Management (SGM)
Activities on land that meets the definition for grassland under the VCS rules and that reduce net GHG emissions by increasing carbon stocks and/or reducing non-CO_2 GHG emissions

3.2 Acronyms

AEZ	Agroecological Zone
AFOLU	Agriculture, Forestry and Other Land Use
ALM	Agricultural Land Management
dm	dry matter
SGM	Sustainable Grassland Management
SOC	Soil Organic Carbon
VCS	Verified Carbon Standard

4 APPLICABILITY CONDITIONS

This methodology applies to Agricultural Land Management (ALM) project activities that introduce sustainable grassland management practices such as improving the rotation of grazing animals between grassland areas, limiting the number of grazing animals on degraded grassland, and restoring severely degraded grasslands by replanting with grasses and ensuring appropriate management over the long-term into a grassland landscape.

This methodology is applicable under the following conditions:

- The project area is grassland at the start of the project. The project area is land that is degraded at the start of the project and degradation will continue in the baseline scenario on the basis that degradation drivers or pressures are still present in the baseline scenario. The procedures outlined the latest version of the CDM *Tool for Identification* *of Degraded or Degrading Lands for Consideration in Implementing CDM A/R Project Activities* must be used to determine both that the land is degraded at the start of the project and that in the baseline scenario the land will continue to degrade.[3]

- The project area is subject to livestock grazing, burning, and/or nitrogen fertilization in the baseline scenario.
- In the baseline scenario, more than 95 percent of animal dung from grazing animals deposited on grassland is allowed to lie as is, and is not managed, and in the project scenario no more than 5 percent of the animal dung from grazing animals within the project area is managed with alternative manure management systems.
- The project area must not have been cleared of native ecosystems within the 10 year period prior to the project start date.
- The project area is located in a region where precipitation is less than evapotranspiration for most of the year and leaching is unlikely to occur.
- If a biogeochemical model is selected for estimation of change in soil carbon stocks, the following conditions must be met:
  - The model must comply with the requirements for models as set out in the VCS rules.
  - The model must be appropriate for the region within which the project is situated. There must be studies by appropriately qualified experts (eg, scientific journals, university theses, local research studies or work carried out by the project proponent) that demonstrate that the use of the selected biogeochemical model is appropriate for the IPCC climatic regions (see *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, Volume 4, Chapter 3), or the agroecological zone (AEZ) in which the project is situated (see Section 9.3.2).
- Project activities must not include land use change. Note that seeding perennial grasses or legumes on degraded grassland is not considered a land use change activity.
- Project activities must not lead to an increase in the use of fossil fuels and fuel wood from non-renewable sources for cooking and heating.
- Project activities must not occur on wetlands or peatlands.

5 PROJECT BOUNDARY

The geographic project boundary delineates the location of grasslands where the project implements sustainable grassland management. The projectmay be implemented on more than one discrete areas of land. The following must be specified in the project description:

[3] Such procedures were specified in Section II and III of version 1 of the tool which became inactive 3 Oct 2013

- Each discrete area of land must be identified by a unique geodetic polygon that must be recorded in a KML file.
- Aggregation of grassland parcels with multiple landowners is permitted under the methodology, with aggregated areas treated as a single project area.

Table 1 and Table 2 identify the GHG sources, sinks and reservoirs included or excluded from the project boundary.

Where the increases in greenhouse gas emissions from any project emissions or leakage source, and decreases in carbon stocks in carbon pools, is less than five percent of the total net anthropogenic GHG emission reductions and removals due to the project, such sources and pools may be deemed de minimis and may can be ignored (ie, their value may be accounted as zero). The significance of emissions and removals must be tested using the latest version of the CDM *Tool for Testing Significance of GHG Emissions in A/R CDM Project Activities*.

Table 1: Selected Carbon Pools under Baseline and Project

Carbon Pools	Included	Justification / Explanation
Aboveground woody biomass	Yes	SGM may reduce aboveground woody biomass.
Aboveground non-woody biomass	No	The increase of aboveground non-woody biomass resulting from SGM is transient in nature and can be conservatively excluded.
Belowground biomass	Optional	In calculating the baseline net greenhouse gas removals by sinks and/or actual net greenhouse gas removals by sinks, project proponent can choose not to account for below-ground biomass. This is subject to the provision of transparent and verifiable information that the choice will not increase the expected net anthropogenic greenhouse gas removals by sinks.
Dead wood	No	None of the applicable SGM practices decrease dead wood. Thus it can be conservatively excluded.
Litter	No	None of the applicable SGM practices decrease the amount of litter. Thus it can be conservatively excluded.
Soil organic carbon	Yes	A major carbon pool affected by grassland management practices that is expected to increase after adoption of SGM practices.
Wood products	No	None of the applicable SGM practices increases or decreases wood products. Because carbon changes in aboveground woody biomass is considered, it can be conservatively ignored.

Table 2: GHG Sources Included In or Excluded From the Project Boundary

Source		Gas	Included?	Justification/Explanation
Baseline	Use of fertilizers	CO_2	No	Not applicable.
		CH_4	No	Not applicable.
		N_2O	Yes	Main gas for this source. This includes direct and indirect N_2O emissions from synthetic nitrogen fertilizer use. Indirect N_2O emissions from leaching and runoff a can be excluded from the project boundary, following guidance in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 4, Chapter 11* given that this methodology is only applicable in regions where annual precipitation is less than or equal to annual potential evapotranspiration.
		Other	No	Not applicable.
	Use of N-fixing species	CO_2	No	Not applicable.
		CH_4	No	Not applicable.
		N_2O	No	N_2O is the main gas for this source, but in the baseline N_2O emissions from this source are conservatively excluded.
		Other	No	Not applicable.
	Burning of biomass	CO_2	No	CO_2 emissions from biomass burning in grassland are not reported since they are largely balanced by the CO_2 that is reincorporated back into biomass via photosynthetic activity, within weeks to a few years after burning.
		CH_4	Yes	Non-CO_2 emissions from the burning of biomass.
		N_2O	Yes	Non-CO_2 emissions from the burning of biomass.
		Other	No	Not applicable.

	Manure deposition on grassland	CO_2	No	CO_2 emissions from biomass decomposition are not reported because net CO_2 emissions from this source are assumed to be zero – the CO_2 photosynthesized by plants is returned to the atmosphere as respired CO_2.
		CH_4	Yes	Significant emission source.
		N_2O	Yes	Main gas for this source.The baseline N_2O emissions from manure management include direct N_2O emissions from manure and urine deposited on grassland soil during the grazing season and indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season. Indirect N_2O emissions from leaching and runoff can be excluded from the project boundary, following guidance in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 4, Chapter 11* given that this methodology is only applicable in regions where annual precipitation is less than or equal to annual potential evapotranspiration.
		Other	No	Not applicable.
	Farming machine	CO_2	Yes	CO_2 emissions from fossil fuels used in farming machinery is the main gas for this source. Where project emissions from this source are larger than baseline emissions, project proponent may choose to account for this source in the baseline or may choose to conservatively exclude baseline emissions from this source.
		CH_4	No	Not main gas for this source. Excluded for simplification.
		N_2O	No	Not main gas for this source. Excluded for simplification.
		Other	No	Not applicable.
	Animal	CO_2	No	CO_2 emissions from animal respiration are

	respiration / Enteric fermentation			not reported because net CO_2 emissions from this source are assumed to be zero – the CO_2 photosynthesized by plants is returned to the atmosphere as respired CO_2.
		CH_4	Yes	Main gas for this source.
		N_2O	No	No N_2O emission from enteric fermentation.
		Other	No	Not applicable.
Project	Use of fertilizers	CO_2	No	Not applicable.
		CH_4	No	Not applicable.
		N_2O	Yes	Main gas for this source. This includes direct and indirect N_2O emissions from synthetic nitrogen fertilizer use. Indirect N_2O emissions from leaching and runoff a can be excluded from the project boundary, following guidance in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 4, Chapter 11*, given that this methodology is only applicable in regions where annual precipitation is less than or equal to annual potential evapotranspiration.
		Other	No	Not applicable.
	Use of N-fixing species	CO_2	No	Not applicable.
		CH_4	No	Not applicable.
		N_2O	Yes	Main gas for this source. Where the area cropped with N-fixing species in the project is more than 50 percent larger than the area cropped with N-fixing species in the baseline, the project N_2O emissions from the use of N-fixing species must be calculated.
		Other	No	Not applicable.
	Burning of biomass	CO_2	No	CO_2 emissions from biomass burning in grassland are not reported since they are largely balanced by the CO_2 that is reincorporated back into biomass via photosynthetic activity, within weeks to a

				few years after burning.
		CH_4	Yes	Non-CO_2 emissions from the burning of biomass.
		N_2O	Yes	Non-CO_2 emissions from the burning of biomass.
		Other	No	Not applicable.
	Manure deposition on grassland	CO_2	No	CO_2 emissions from biomass decomposition are not reported since they are largely balanced by the CO_2 that is reincorporated back into biomass via photosynthetic activity, within weeks to a few years after burning.
		CH_4	Yes	Significant emission source.
		N_2O	Yes	Main gas for this source.The project emissions from manure and urine deposited on grassland soil during the grazing season include direct and indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season. Indirect N_2O emissions from leaching and runoff a can be excluded from the project boundary, following guidance in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories, Volume 4, Chapter 11*, given that this methodology is only applicable in regions where annual precipitation is less than or equal to annual potential evapotranspiration.
		Other	No	Not applicable.
	Farming machine	CO_2	Yes	CO_2 emissions from fossil fuels used in farming machinery is the main gas for this source. Where project emissions from this source are larger than baseline emissions, project proponent must account for this source of project emissions.
		CH_4	No	Not main gas for this source. Excluded for simplification.
		N_2O	No	Not main gas for this source. Excluded for simplification.

		Other	No	Not applicable.
	Animal respiration / Enteric fermentation	CO_2	No	CO_2 emissions from enteric fermentation are not reported since they are largely balanced by the CO_2 that is reincorporated back into biomass via photosynthetic activity, within weeks to a few years after burning.
		CH_4	Yes	Main gas for this source.
		N_2O	No	No N_2O emissions from enteric fermentation.
		Other	No	Not applicable.

6 BASELINE SCENARIO

This methodology uses a project method to determine the baseline scenario. The following steps must be followed to identify the most plausible baseline scenario.

Step 1. Identification of alternative land use scenarios to the proposed SGM project

Sub-step 1a) Identify and list all credible alternative land use scenarios to the proposed SGM project: The project proponent must identify and list all realistic and credible land use scenarios that could have occurred within the project area in the absence of the SGM project. At a minimum, the identified land use scenarios must include:

1) Continuation of current land uses (ie, the land uses immediately prior to initiation of project activities); and

2) Any previous land use practiced within the project area in the ten years prior to initiation of project activities.

All current land uses c must be deemed realistic and credible. The project proponent must refer to the VCS *Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities* for guidance on identification of realistic and credible alternative land uses. The project proponent must justify that each of the identified alternative land uses is realistic and credible on the basis of verifiable information sources, such as documented management records of land users, agricultural statistics reports, published studies of grazing behavior in the project region, results of Participatory Rural Appraisals and other documented stakeholder discussions, and/or surveys conducted by or on behalf of the project proponent prior to the initiation of project activities.

Sub-step 1b) Check the consistency of credible alternative land use scenarios with enforced mandatory applicable laws and regulations: The project proponent must check whether all alternative land use scenarios identified in sub-step 1a) are either:

1) In compliance with all mandatory applicable legal and regulatory requirements, or

2) Where an alternative does not comply with all mandatory applicable legal and regulatory requirements, it must be shown that on the basis of current practice in the region to which the mandatory law or regulation applies that those laws or regulations are not systematically enforced or that non-compliance is widespread.

Where an alternative land use scenario identified does not meet either of these two criteria, the alternative land use scenario must be removed from the list. The resulting revised list is a list of credible alternative land use scenarios that are consistent with enforced mandatory applicable laws and regulations.

Step 2: Select the most plausible baseline scenario.

Sub-step 2a) Barrier analysis: Taking the list of credible alternative land use scenarios resulting from sub-step 1b, a barrier analysis must be conducted to identify realistic and credible barriers that prevent implementation of these land use scenarios following the procedures described in Step 3 of the VCS *Tool for the Demonstration and Assessment of Additionality in VCS AFOLU Project Activities.* The project proponent must indicate which of the alternative land use scenarios would face which identified barrier, and provide verifiable information to support the presence of each particular barrier in relation to each alternative land use scenario.

Sub-step 2b) Eliminate alternative land use scenarios that face a barrier to implementation: All land use scenarios that face a barrier to implementation must be removed from the list.

Sub-step 2c) Select most plausible baseline scenario (if allowed by barrier analysis): Where there is only one alternative land use remaining in the list, this must be selected as the most plausible baseline scenario.

Where there is more than one alternative land use remaining in the list, and one of these alternatives includes continuation of current land use (ie, land use immediately prior to commencement of the project), continuation of current land use must be chosen as the most plausible baseline scenario where the following conditions are met:

1) The grazing agent(s) has not changed in the five years prior to initiation of project activities;
2) The current land uses have not changed in the five years prior to initiation of project activities; and
3) There have been no changes in mandatory applicable legal or regulatory requirements during this five year period and no such changes are currently under legal review by the relevant authorities.

Where there is more than one alternative land use remaining in the list and the most plausible land use has still not been chosen, then proceed to Step 2d.

Step 2d) Assess the profitability of alternative land use scenarios: Taking the list resulting from Step 2b of alternative land use scenarios that face no barriers to implementation, document the costs and revenues associated with each alternative land use and estimate the profitability of each alternative land use. The profitability of alternative land uses must be assessed in terms of the net present value of net incomes over the project crediting period. The key economic parameters and assumptions used in the analysis must be justified in a transparent manner.

Step 2e) Select the most plausible baseline scenario: The most profitable alternative land use among the land uses assessed in Step 2d must be selected as the most plausible baseline scenario.

Where, the most plausible baseline scenario selected conforms to the applicability conditions that pertain to the baseline scenario as specified in Section 4 of this methodology the project will be eligible to apply this methodology.

7 ADDITIONALITY

The project proponent must demonstrate the additionality of the project using the most recent version of the VCS *Tool for the Demonstration and Assessment of Additionality in VCS Agriculture, Forestry and Other Land Use (AFOLU) Project Activities*. When applying Steps 2, 3 and 4 of that tool, the most plausible baseline scenario identified through application of procedures in Section 6 of this methodology must be assessed together with the project scenario.

8 QUANTIFICATION OF GHG EMISSION REDUCTIONS AND REMOVALS

8.1 Baseline Emissions

8.1.1 Baseline N_2O emissions due to fertilizer use

Baseline N_2O emissions due to fertilizer use equals baseline direct N_2O emission plus indirect N_2O emission, as described using the following:.

$$BE_{N_2O_{SN},b} = GWP_{N,O} \times (BE_{D,N_2O_{SN},b} + BE_{ID,N_2O_{SN},b}) \quad (1)$$

Where:

$BE_{N_2O_{SN}\,b}$ = Baseline N_2O emissions due to fertilizer use in baseline year b (t CO_2e)

$BE_{D,N_2O_{SN}\,b}$ = Baseline direct N_2O emissions from synthetic nitrogen fertilizer use in baseline year b (t N_2O)

$BE_{ID,N_2O_{SN}\,b}$ = Baseline indirect N_2O emissions from synthetic nitrogen fertilizer use in baseline year b, (t N_2O)

GWP_{N_2O} = Global-warming potential for N_2O (t CO_2e/t N_2O)

1) Baseline direct N_2O emissions from synthetic nitrogen fertilizer use:

Baseline direct N_2O emissions from synthetic fertilizer use in year *b*, $BE_{D,N_2O_{SN},b}$, must be calculated following Chapter 11, Volume 4 of the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, as described using the following:

$$BE_{D,N_2O_{SN},b} = F_{SN,b} \times EF_{Nfert} \times 44/28 \quad (2)$$

Where:

$BE_{D,N_2O_{SN}\,b}$ = Baseline direct N_2O emissions from synthetic nitrogen fertilizer use in baseline year b (t N_2O)

$F_{SN,b}$	=	Annual amount of synthetic fertilizer N applied to grassland soils in baseline year *b*, adjusted for volatilization as NH_3 and NO_x (t N)
EF_{Nfert}	=	N_2O emission factor for synthetic N fertilizer use (kg N_2O-N/kg N applied)
44/28	=	Conversion of N_2O-N to N_2O

$$F_{SN,b} = \sum_{i=1}^{I} M_{SNi,b} \times NC_{SNi,b} \times (1 - Frac_{GAS,F}) \quad (3)$$

Where:

$F_{SN,b}$	=	Annual amount of synthetic fertilizer N applied to grassland soils in baseline yearb, adjusted for volatilization as NH3 and NOx (t N)
$M_{SNi,b}$	=	Mass of synthetic N fertilizer type *i* applied in baseline year *b* (t fertilizer)
$NC_{SNi,b}$	=	Nitrogen content of synthetic N fertilizer type *i* applied in baseline year *b* (g N/g fertilizer)
$Frac_{GAS,F}$	=	Fraction of synthetic N fertilizer that volatilizes as NH_3 and NO_x (kg N volatilized/kg N applied)
I	=	Index of synthetic N fertilizer types

2) Baseline indirect N_2O emissions from synthetic N fertilizer use:

The N_2O emissions from the atmospheric deposition of N volatilized as NH_3 and NO_x after fertilizer is applied to grassland soils in baseline year b, is calculated using the below equation. Indirect N_2O emissions from leaching and runoff are excluded from the project boundary as described in Section 5:

$$BE_{ID,N_2O_{SN},b} = \sum_{i=1}^{I} (F_{SNi,b} \times Frac_{GAS,F}) \times EF_{4,SN} \times 44/28 \quad (4)$$

Where:

$BE_{ID,N_2O_{SN}\,b}$	=	Baseline indirect N2O emissions from synthetic nitrogen fertilizer use in baseline year b, (t N2O)
$F_{SNi,b}$	=	Annual amount of synthetic N fertilizer type *i* applied to grassland soils in baseline year b, adjusted for volatilization as NH_3 and NOx (t N)
$Frac_{GAS,F}$	=	Fraction of synthetic N fertilizer that volatilizes as NH_3 and NO_x (kg N volatilized/kg N applied)
$EF_{4,SN}$	=	N_2O emission factor for atmospheric deposition of synthetic N on soils and water surfaces (kg N_2O-N/(kg NH_3-N + NO_x-N volatilized)).

8.1.2 Baseline emissions due to the use of N-fixing species

N_2O emissions due to the use of N-fixing species in the baseline are excluded from the project boundary as described in Section 5.

8.1.3 Baseline emissions due to burning of biomass

The baseline emissions due to burning of biomass, $BE_{BB,b}$, include CH_4 emissions from biomass burning plus N_2O emissions from biomass burning in baseline year *b*, as described using the following:

$$BE_{BB,b} = BE_{CH_{4BB},b} + BE_{N_2O_{BB},b} \quad (5)$$

Where:

$BE_{BB,b}$ = Baseline GHG emissions from biomass burning in baseline year *b* (t CO_2e)

$BE_{CH_{4BB},b}$ = Baseline CH_4 emissions from biomass burning in baseline year *b* (t CO_2e)

$BE_{N_2O_{BB},b}$ = Baseline N_2O emissions from biomass burning in baseline year *b* (t CO_2e)

1) CH_4 emissions from biomass burning:

CH_4 emissions from biomass burning in baseline year *b* must be calculated using the following:

$$BE_{CH_{4BB},b} = \frac{A_{B,b} \times M_{B,b} \times C_f \times EF_{CH_4} \times GWP_{CH_4}}{1000} \quad (6)$$

Where:

$BE_{CH_{4BB},b}$ = Baseline CH_4 emissions from biomass burning in baseline year b (t CO_2e)

$A_{B,b}$ = Area burned in baseline year *b* (ha)

$M_{B,b}$ = Aboveground biomass burned in baseline year *b* (t biomass/ha)

C_f = Combustion factor (t dry matter burnt/t biomass)

EF_{CH_4} = CH_4 emission factor for biomass burning (g CH_4/kg dry matter burnt)

GWP_{CH_4} = Global-warming potential for CH_4 (t CO_2e/t CH_4)

2) N_2O emissions from biomass burning:

N_2O emissions from biomass burning in baseline year *b* must be calculated using the following:

$$BE_{N_2O_{BB},b} = \frac{A_{B,b} \times M_{B,b} \times C_f \times EF_{N_2O} \times GWP_{N_2O}}{1000} \quad (7)$$

Where:

$BE_{N_2O_{BB},b}$ = Baseline N_2O emissions from biomass burning in baseline year b (t CO_2e)

$A_{B,b}$ = Area burned in baseline year *b* (ha)

$M_{B,b}$	=	Aboveground biomass burned in baseline year *b* (t biomass/ha)
C_f	=	Combustion factor (t dry matter burnt/t biomass)
EF_{N_2O}	=	N_2O emission factor (g N_2O/kg dry matter burnt)
GWP_{N_2O}	=	Global-warming potential for N_2O (t CO_2e/t N_2O)

8.1.4 Baseline CH_4 emissions due to enteric fermentation

Baseline CH_4 emissions from enteric fermentation must be calculated based on the approach in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, with the addition of a parameter to reflect the proportion of the year that livestock are present inside the project area, as described using the following:

$$BE_{CH_{4EF},b} = \frac{GWP_{CH4} \times \sum_{l=1}^{L} P_{l,b} \times EF_l \times Days_{l,b}}{1000 \times 365} \quad (8)$$

Where:

$BE_{CH_{4EF},b}$	=	Baseline CH_4 emissions from enteric fermentation in baseline year *b* (t CO_2e)
GWP_{CH_4}	=	Global-warming potential for CH_4 (t CO_2e/t CH_4)
$P_{l,B}$	=	Population of grazing livestock type *l*, in baseline year *b* (head)
l	=	Index of livestock type
EF_l	=	Enteric CH_4 emission factor per head of livestock type *l* per year (kg CH_4/(head*year))
$Days_{l,b}$	=	Grazing days inside the project area for each livestock type *l* in baseline year *b* (days)

8.1.5 Baseline N_2O and CH_4 emissions due to manure management

Baseline emissions from manure management include N_2O and CH_4 emissions from manure and urine deposited on grassland soil during the grazing season.

$$BE_{GHG_{MD},b} = BE_{N_2O_{MD},b} + BE_{CH_{4MD},b} \quad (9)$$

Where:

$BE_{GHG_{MD},b}$	=	Baseline GHG emissions from manure management in baseline year *b* (t CO_2e)
$BE_{N_2O_{MD},b}$	=	Baseline N_2O emissions from manure and urine deposited on grassland soil in baseline year *b* (t CO_2e)
$BE_{CH_{4MD},b}$	=	Baseline CH_4 emissions from manure and urine deposited on grassland soil in baseline year *b* (t CO_2e)

1) Baseline N_2O emissions from manure management

Baseline N_2O emissions from manure and urine deposited on grassland soil in baseline year b are the sum of direct and indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season and is calculated as described using the following:

$$BE_{N_2O_{MD},b} = GWP_{N_2O} \times (BE_{D,N_2O_{MD},b} + BE_{ID,N_2O_{MD},b}) \quad (10)$$

Where:

$BE_{N_2O_{MD},b}$	=	Baseline N_2O emissions from manure and urine deposited on grassland soil in baseline year b (t CO_2e)
GWP_{N_2O}	=	Global-warming potential for N_2O (t CO_2e / t N_2O)
$BE_{D,N_2O_{MD},b}$	=	Direct N_2O emissions from manure and urine deposited on grassland soil during the grazing season in baseline year *b* (t N_2O)
$BE_{ID,N_2O_{MD},b}$	=	Indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season in baseline year *b* (t N_2O)

2) Baseline direct N_2O emissions from manure and urine deposited on grassland soil:

Baseline direct N_2O emissions from manure and urine deposited on grassland soil must be calculated using the methodology recommended in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, as described in the following equations. Equation 11 calculates direct N_2O emissions from livestock types classified as cattle (dairy, non-dairy and buffalo), poultry and pigs. Equation 12 calculates direct N_2O emissions .from livestock types classified as sheep and other animals. Where both kinds of livestock are present the following equations must be summed.

$$BE_{D,N_2O_{MD},b} = \sum_{l1=1}^{L1} F_{MD,l1,b} \times EF_{3,PRP,CPP} \times 44/28 \quad (11)$$

and/or

$$BE_{D,N_2O_{MD},b} = \sum_{l2=1}^{L2} F_{MD,l2,b} \times EF_{3,PRP,SO} \times 44/28 \quad (12)$$

Where:

$BE_{D,N_2O_{MD},b}$	=	Direct N_2O emissions from manure and urine deposited on grassland soil during the grazing season in baseline year b (t N_2O)
$F_{MD,l1,b}$	=	Annual amount of nitrogen in cattle, poultry and pigs manure and urine deposited on grassland soil during the grazing season in baseline year *b*, adjusted for volatilization as NH_3 and NO_x (t N)
$F_{MD,l2,b}$	=	Annual amount of nitrogen in sheep and other animals manure and urine deposited on grassland soil during the grazing season in baseline year *b*, adjusted for volatilization as NH_3 and NO_x (t N)
$EF_{3,PRP,CPP}$	=	N_2O emission factor for cattle, poultry and pigs manure and urine deposited on grassland soil during the grazing season (kg N_2O-N/kg N input)

$EF_{3,PRP,SO}$	=	N_2O emission factor for sheep and other animals manure and urine deposited on grassland soil during the grazing season (kg N_2O-N/kg N input)
L_1	=	Index of livestock cattle, poultry and pigs
L_2	=	Index of livestock sheep and other animals

$F_{MD,l1,b}$ and $F_{MD,l2,b}$ must be calculated using equation for each livestock type *l*.

$$F_{MD,l,b} = \frac{P_{l,b} \times W_{l,b} \times Nex_l \times H_{l,b} \times Days_{l,b} \times (1 - Frac_{GAS,MD})}{1000_a \times 24 \times 1000_b} \quad (13)$$

Where:

$F_{MD,l,b}$	=	Annual amount of manure and urine deposited on grassland soil from livestock type *l* during the grazing season in baseline year b, adjusted for volatilization as NH_3 and NO_x (t N)
$P_{l,b}$	=	Population of livestock type *l* in baseline year *b* (head)
$W_{l,b}$	=	Average weight of livestock type *l* in baseline year *b* (kg livestock mass/head)
Nex_l	=	Nitrogen excretion of livestock type *l* (kg N deposited/(t livestock mass*day))
1000_a	=	Conversion factor for t livestock mass to kg livestock mass
$H_{l,b}$	=	Average grazing hours per day for livestock type *l* in baseline year *b* (hour)
24	=	Conversion factor for days to hours
$Days_{l,b}$	=	Grazing days for livestock type*l*inside the project area in baseline year *b* (days)
1000_b	=	Conversion factor for tonnes N to kg t N
$Frac_{GAS,MD}$	=	Fraction of volatilization from manure and urine deposited by grazing animals as NH_3 and NO_x (kg N volatilized/kg of N deposited)
L	=	Index of grazing livestock types

3) Baseline indirect N_2O emissions from urine and manure N deposited on grassland soils:

The indirect N_2O emissions from the atmospheric deposition of N volatilized as NH_3 and NO_x after urine and manure N is deposited on grassland soils in baseline year *b,* are calculated using the following equation. Indirect N_2O emissions from urine and manure N deposited on grassland soils excludes N_2O emissions from leaching and runoff in regions.

$$BE_{IDV,N_2O_{MD},b} = \sum_{l=1}^{L} F_{MD,l,b} \times Frac_{GAS,MD} \times EF_{4,MD} \times 44/28 \quad (14)$$

Where:

$BE_{ID,N_2O_{MD},b}$	=	Indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season in baseline year b (t N_2O)

$F_{MD,l,b}$	=	Annual amount of manure and urine deposited on grassland soil from livestock type *l* during the grazing season in baseline year b, adjusted for volatilization as NH_3 and NO_x (t N)
$Frac_{GAS,MD}$	=	Fraction of volatilization from manure and urine deposited by grazing animals as NH_3 and NO_x (kg N volatilized/kg of N deposited)
$EF_{4,MD}$	=	N_2O emission factor for atmospheric deposition of urine and manure N on soils and water surfaces, (kg N_2O-N/(kg NH_3-N + NO_x-N volatilized))
L	=	Index of grazing livestock types

4) **CH_4 emissions from manure management**:

The Tier 1 approach recommended by the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* must be used to calculate CH_4 emissions from manure management, as described using the following:

$$BE_{CH_{4MD},b} = \frac{GWP_{CH4} \times \sum_{l=1}^{L} EF_{lM} \times P_{l,b} \times H_{l,b} \times Days_{l,b}}{24 \times 365 \times 1000} \quad (15)$$

Where:

$BE_{CH_{4MD},b}$	=	Baseline CH_4 emissions from manure and urine deposited on grassland soil in baseline year b (t CO_2e)
GWP_{CH_4}	=	Global warming potential for CH_4 (t CO_2e / t CH_4)
EF_{lM}	=	CH_4 emission factor from manure of livestock type *l* (kg CH_4/(head*year)
$P_{l,b}$	=	Population of grazing livestock type *l*, in baseline year *b*, head
$H_{l,b}$	=	Average grazing hours per day for livestock type *l* in baseline year *b* (hour)
$Days_{l,b}$	=	Grazing days for livestock type *l* inside the project area in baseline year *b* (days)
24	=	Conversion factor for days to hours
365	=	Conversion factor for years to days
1000	=	Conversion factor for t CH4 to kg CH4

8.1.6 Baseline CO_2 emissions due to the use of fossil fuels for grassland management

If project emissions from this source are larger than baseline emissions, the project proponent may choose to account for this source in the baseline or may choose to conservatively ignore baseline emissions from this source. The following is applied to calculate CO_2 emissions from consumption of fossil fuels for SGM in baseline year *b*.

$$BE_{FC,b} = \frac{\sum_{p=1}^{P} \sum_{j=1}^{J} \sum_{k=1}^{K} FC_{p,j,k,b} \times EF_{CO_2,k} \times NCV_k}{1000} \quad (16)$$

Where:

$BE_{FC,b}$	=	Baseline CO_2 emissions from farming machine fossil fuel consumption in baseline year *b* (t CO_2)
$FC_{p,j,k,b}$	=	Fuel consumption by fuel type *k*, by machine type *j* , on parcel grassland *p*, in baseline year *b* (kg fuel/year)
$EF_{CO_2,k}$	=	CO_2 emission factor by fuel type *k* (t CO_2/GJ)
NCV_k	=	Thermal value of fuel type *k* (GJ/t fuel)
1000	=	Conversion factor for tonnes fuel to kg fuel
K	=	Index of fuel type
J	=	Index of machine type
P	=	Index of grassland parcel

8.1.7 Baseline emission removals from existing woody perennials

Where the project proponent includes above and below ground woody biomass pools as a selected carbon pool, baseline removals from existing woody perennials ($BRWP_b$) are calculated using the latest version of the CDM A/R tool for *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities*. Where the project proponent chooses not to include above and below ground woody biomass pools, baseline removals, $BRWP_b$, are assumed to be zero.

The carbon gain-loss approach must be applied to estimation of baseline removals from existing woody perennials.

Baseline removals by existing woody perennials in baseline year *b* ($BRWP_b$) must be calculated using the following:

$$BRWP_b = \sum_{j=1}^{J} \Delta C_{BG,j} - \Delta C_{BL,j} \quad (17)$$

Where:

$BWRP_b$	=	Baseline removals from existing woody perennials in baseline year *b* (t CO_2)
$\Delta C_{BG,j}$	=	Average annual increase in carbon stocks of existing woody biomass for species *j*, under the baseline scenario (t CO_2)
$\Delta C_{BL,j}$	=	Average annual loss of carbon stocks of existing woody biomass for species *j*, under the baseline scenario (t CO_2)
J	=	Index of species

As noted under the assumptions used in developing this methodological tool, no explicit accounting of the term representing stock losses, $\Delta C_{BL,j}$, is included in this tool. That is, $\Delta C_{BG,j}$ is assumed to be a measure of net growth increment and thus to implicitly accounts for $\Delta C_{BL,j}$.

The average annual increase in carbon stocks in existing live woody biomass for each species must be calculated using the following:

$$\Delta C_{BG,j} = \sum_{s=1}^{S} A_{B,j,s} \times G_{B,j,s} \times CF_j \times \frac{44}{12} \quad (18)$$

Where:

$\Delta C_{BG,j}$	=	Average annual increase in carbon stocks of existing woody biomass for species *j*, under the baseline scenario (t CO_2)
$A_{B,j,s}$	=	Area of species *j* in stratum s under the baseline scenario (ha)
$G_{B,j,s}$	=	Average annual increase in existing woody biomass of species *j* in stratum *s*, under the baseline scenario (t dm/(ha)
CF_j	=	Carbon fraction for species *j* (t C/t dm)
S	=	Index of stratum
44/12	=	Ratio of molecular weights of CO_2 and C

The average annual increase in existing live woody biomass stocks for each species in a vegetation class in a stratum must be calculated from:

$$G_{B,j,s} = G_{AB,B,j,s}(1 + R_j) \quad (19)$$

Where:

$G_{B,j,s}$	=	Average annual increase in existing woody biomass of species *j* in stratum *s*, under the baseline scenario (t dm/ha)
$G_{AB,B,j,s}$	=	Average annual increase in existing above-ground woody biomass of species *j* in stratum *s* (t dm aboveground biomass/ha)
R_j	=	Root to shoot ratio of species *j* (t dm belowground biomass/t dm aboveground biomass)

Since below ground biomass is an optional carbon pool (Table 1), the term $(1 + R_j)$ may be removed from the above equation if this carbon pool is not included in the project boundary.

8.1.8 Baseline emission removals due to changes in soil organic carbon

Since the applicability conditions limit the project to land that is degraded and is continuing to degrade, it can be conservatively assumed that the changes in SOC in the baseline scenario is zero. Therefore:

$$BRS = 0 \quad (20)$$

Where:

BRS	=	Baseline removals due to changes in SOC under the baseline scenario (t CO_2e)

8.1.9 Baseline emissions and removals

The emissions and removals in baseline year *b* are given by:

$$BE_b = BE_{N_2O_{SN},b} + BE_{BB,b} + BE_{CH_{4EF},b} + BE_{GHG_{MD},b} + BE_{FC,b} - BRWP_b \quad (21)$$

Where:

BE_b	=	Baseline emissions and removals in year *b* (t CO_2e)
$BE_{N_2O_{SN}\,b}$	=	Baseline N_2O emissions due to fertilizer use in baseline year b (t CO_2e)
$BE_{BB,b}$	=	Baseline GHG emissions from biomass burning in baseline year *b* (t CO_2e)
$BE_{CH_{4EF},b}$	=	Baseline CH_4 emissions from enteric fermentation in baseline year *b* (t CO_2e)
$BE_{GHG_{MD},b}$	=	Baseline GHG emissions from manure management in baseline year *b* (t CO_2e)
$BE_{FC,b}$	=	Baseline CO_2 emissions from farming machine fossil fuel consumption in baseline year *b*, (t CO_2)
$BWRP_b$	=	Baseline removals from existing woody perennials in baseline year *b* (t CO_2)

8.2 Project Emissions

8.2.1 Project N_2O emissions due to fertilizer use

Project N_2O emissions due to fertilizer use equals the sum of project direct and indirect N_2O emissions, as described using the following:

$$PE_{N_2O_{SN},t} = GWP_{N_2O} \times (PE_{D,N_2O_{SN},t} + PE_{ID,N_2O_{SN},t}) \quad (22)$$

Where:

$PE_{N_2O_{SN},t}$	=	Project N_2O emissions due to fertilizer use in year *t* (t CO_2e)
$PE_{D,N_2O_{SN},t}$	=	Project direct N_2O emissions from synthetic nitrogen fertilizer use in year *t* (t N_2O)
$PE_{ID,N_2O_{SN},t}$	=	Project indirect N_2O emissions from synthetic nitrogen fertilizer use in year *t* (t N_2O)
GWP_{N_2O}	=	Global-warming potential of N_2O

1) Project direct N_2O emissions from synthetic nitrogen fertilizer use:

Project direct N_2O emissions from synthetic fertilizer use is calculated using IPCC methodology recommended in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, as described using the following:

$$PE_{D,N_2O_{SN},t} = F_{SN,t} \times EF_{Nfert} \times 44/28 \quad (23)$$

Where:

$PE_{D,N_2O_{SN},t}$	=	Project direct N_2O emissions from synthetic nitrogen fertilizer use in year *t* (t N_2O)
$F_{SN,t}$	=	Annual amount of synthetic fertilizer N applied to grassland soils in year *t*, adjusted for volatilization as NH_3 and NO_x (t N)
EF_{Nfert}	=	N_2O emission factor for synthetic N fertilizer use (kg N_2O-N/kg N applied)
44/28	=	Conversion of N_2O-N to N_2O

$$F_{SN,t} = \sum_{i=1}^{I} M_{SNi,t} \times NC_{SNi,p} \times (1 - Frac_{GAS,F}) \qquad (24)$$

Where:

$F_{SNi,t}$	=	Annual amount of synthetic fertilizer N applied to grassland soils in year t, adjusted for volatilization as NH_3 and NO_x (t N)
$M_{SNi,t}$	=	Mass of synthetic N fertilizer type *i* applied in year *t* (t fertilizer)
$NC_{SNi,p}$	=	Nitrogen content of synthetic N fertilizer type *i* applied (g-N/g fertilizer)
$Frac_{GAS,F}$	=	Fraction of synthetic N fertilizer that volatilizes as NH_3 and NO_x (kg N volatilized/kg of N applied)
I	=	Index of synthetic N fertilizer types

2) Project indirect N_2O emissions from the synthetic N fertilizer use:

The N_2O emissions from the atmospheric deposition of N volatilized as NH_3 and NO_x after fertilizer is applied to grassland soils under the project scenario in year t, is calculated using the below equation. Indirect N_2O emissions from leaching and runoff are excluded from the project boundary as described in Section 5.

$$PE_{ID,N_2O_{SN},t} = \sum_{i=1}^{I} (F_{SNi,t} \times Frac_{GAS,F}) \times EF_{4,SN} \times 44/28 \qquad (25)$$

Where:

$PE_{ID,N_2O_{SN},t}$	=	Project indirect N_2O emissions from synthetic nitrogen fertilizer use in year t (t N_2O)
$F_{SNi,t}$	=	Annual amount of synthetic fertilizer N applied to grassland soils in year t, adjusted for volatilization as NH3 and NOx (t N)
$Frac_{GAS,F}$	=	Fraction of synthetic N fertilizer that volatilizes as NH_3 and NO_x (kg N volatilized/kg of N applied)
$EF_{4,SN}$	=	N_2O emission factor for atmospheric deposition of synthetic N on soils and water surfaces (kg N_2O-N/(kg NH_3-N + NO_x-N volatilized)$^{-1}$)
I	=	Index of synthetic N fertilizer types

8.2.2 Project emissions due to the use of N-fixing species

Project emissions from N-fixing species must only be accounted for. if the area cropped with N-fixing species in the project is more than 50 percent larger than the area cropped with N-fixing species in the baseline.

The project emissions from the use of N-fixing species, $PE_{N_2O_{NF},t}$, must be calculated using the following equations:

$$PE_{N_2O_{NF},t} = F_{CR,t} \times EF_{Nfix} \times 44/28 \times GWP_{N_2O} \quad (26)$$

Where:

$PE_{N_2O_{NF},t}$	=	Project N_2O emissions as a result of N-fixing species within the project area in year *t* (t CO_2e)
$F_{CR,t}$	=	Amount of N in N-fixing species (above and below ground) and from forage/pasture renewal, returned to soils under project in year *t* (t N)
EF_{Nfix}	=	Emission factor for N_2O emissions from N inputs of N-fixing species to grassland soil (kg N_2O-N/kg N input)
GWP_{N_2O}	=	Global-warming potential for N_2O (t CO_2/t N_2O)

$$F_{CR,t} = \sum_{g=1}^{G} Area_{g,t} \times Crop_{g,t} \times N_{content,g} \quad (27)$$

Where:

$F_{CR,t}$	=	Amount of N in N-fixing species (above and below ground) and from forage/pasture renewal, returned to soils under project in year t (t N)
$Area_{g,t}$	=	Annual area of N-fixing species *g* in year *t* (ha)
$Crop_{g,t}$	=	Annual dry matter, including aboveground and below ground, returned to grassland soils for N-fixing species *g* under project in year *t* (t dm/ha)
$N_{content,g}$	=	Fraction of N in dry matter for N-fixing species *g* (t N/t dm)
G	=	Index of N-fixing species

8.2.3 Project emissions due to burning of biomass

The project GHG emissions equals CH_4 emissions from biomass burning plus N_2O emissions from biomass burning under the project, as described using the following:

$$PE_{GHG_{BB,t}} = PE_{CH_{4BB},t} + PE_{N_2O_{BB},t} \quad (28)$$

Where:

$PE_{GHG_{BB,t}}$	=	Project GHG emissions from biomass burning in year *t* (t CO_2e)
$PE_{CH_{4BB},t}$	=	Project CH_4 emissions from biomass burning in year *t* (t CO_2e)
$PE_{N_2O_{BB},t}$	=	Project N_2O emissions from biomass burning in year *t* (t CO_2e)

1) CH_4 emissions from biomass burning under project:

CH_4 emissions from biomass burning must be calculated using the following:

$$PE_{CH_{4BB},t} = \frac{A_{B,t} \times M_{B,t} \times C_f \times EF_{CH_4} \times GWP_{CH_4}}{1{,}000} \quad (29)$$

Where:

$PE_{CH_{4BB},t}$	=	Project CH_4 emissions from biomass burning in year *t* (t CO_2e)
$A_{B,t}$	=	Area burned under project in year *t* (ha)
$M_{B,t}$	=	Aboveground biomass burned, excluding litter and dead wood under project in year *t* (t biomass/ha)
C_f	=	Combustion factor (t dry matter burnt/t biomass)
EF_{CH_4}	=	CH_4 emission factor for biomass burning (g CH_4/kg dry matter burnt)
GWP_{CH_4}	=	Global-warming potential for CH_4 (t CO_2e/t CH_4)

2) N_2O emissions from biomass burning under project:

N_2O emissions from biomass burning must be calculated using the following:

$$PE_{N_2O_{BB},t} = \frac{A_{B,t} \times M_{B,t} \times C_f \times EF_{N_2O} \times GWP_{N_2O}}{1{,}000} \quad (30)$$

Where:

$PE_{N_2O_{BB},t}$	=	Project N_2O emissions from biomass burning in year *t* (t CO_2e)
$A_{B,t}$	=	Area burned under project in year *t* (ha)
$M_{B,t}$	=	Aboveground biomass burned, excluding litter and dead wood under project in year *t* (t biomass/ha)
C_f	=	Combustion factor (t dry matter burnt/t biomass)
EF_{N_2O}	=	N_2O emission factor (g N_2O/kg dry matter burnt)
GWP_{N_2O}	=	Global-warming potential for N_2O (t CO_2e/t N_2O)

8.2.4 Project CH_4 emissions due to enteric fermentation

Project CH_4 emissions from enteric fermentation are calculated based on an IPCC methodology recommended in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, with the addition of a parameter to reflect the proportion of the year that livestock are present inside the project area, as described using the following:

$$PE_{CH_{4EF},t} = \frac{GWP_{CH_4} \times \sum_{l=1}^{L} P_{l,t} \times EF_l \times Days_{l,t}}{1000 \times 365} \quad (31)$$

Where:

$PE_{CH_{4EF},t}$	=	Project CH_4 emissions from enteric fermentation in year *t* (t CO_2e)
GWP_{CH_4}	=	Global-warming potential for CH_4 (t CO_2e/t CH_4)
$P_{l,t}$	=	Population of grazing livestock type *l* in year *t* under project (head)
L	=	Index of livestock type
EF_l	=	Enteric CH_4 emission factor per head of livestock type *l* per year (kg CH_4 head*year)
$Days_{l,t}$	=	Grazing days inside the project area for each livestock type *l* in the project year *t* (days)
1000	=	Conversion factor for t CH_4 to kg t CH_4
365	=	Conversion factor for years to days

8.2.5 Project N_2O and CH_4 emissions due to manure management

The project emissions from manure management include N_2O and CH_4 emissions from manure and urine deposited on grassland soil during the grazing season.

$$PE_{GHG_{MD},t} = PE_{N_2O_{MD},t} + PE_{CH_{4MD},t} \quad (32)$$

Where:

$PE_{GHG_{MD},t}$	=	Project GHG emissions from manure management in year *t* (t CO_2e)
$PE_{N_2O_{MD},t}$	=	Project N_2O emissions from manure and urine deposited on grassland soil in year *t* (t CO_2e)
$PE_{CH_{4MD},t}$	=	Project CH_4 emissions from manure and urine deposited on grassland soil in year *t* (t CO_2e)

1) Project N_2O emissions from manure management

The project emissions from manure and urine deposited on grassland soil during the grazing season include direct and indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season. Project N_2O emissions from manure and urine deposited on grassland soil are calculated as described in the following:

$$PE_{N_2O_{MD},t} = GWP_{N_2O} \times (PE_{D,N_2O_{MD},t} + PE_{ID,N_2O_{MD},t}) \quad (33)$$

Where:

$PE_{N_2O_{MD},t}$	=	Project N_2O emissions from manure and urine deposited on grassland soil in year *t* (t CO_2e)
GWP_{N_2O}	=	Global warming potential for N_2O (t CO_2e/t N_2O)
$PE_{D,N_2O_{MD},t}$	=	Project direct N_2O emissions from manure and urine deposited on grassland soil during the grazing season in year *t* (t N_2O)

$PE_{ID,N_2O_{MD},t}$	=	Project indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season in year *t* (t N_2O)

2) Project direct N_2O emissions from manure and urine deposited on grassland soil

Project direct N_2O emissions from manure and urine deposited on grassland soil are calculated using IPCC methodology recommended by *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, as described using the following Equations 34 and 45. Equation 34 calculates direct N_2O emissions from livestock types classified as cattle (dairy, non-dairy and buffalo), poultry and pigs and Equation 35 calculates direct N_2O emissions from livestock types classified as sheep and other animals. Note that where both kinds of livestock are present the following equations must be summed.

$$PE_{D,N_2O_{MD},t} = \sum_{l1=1}^{L1} F_{MD,l1,t} \times EF_{3,PRP,CPP} \times 44/28 \quad (34)$$

and/or

$$PE_{D,N_2O_{MD},t} = \sum_{l2=1}^{L2} F_{MD,l2,t} \times EF_{3,PRP,SO} \times 44/28 \quad (35)$$

Where:

$PE_{D,N_2O_{MD},t}$	=	Project direct N_2O emissions from manure and urine deposited on grassland soil during the grazing season in year t (t N_2O)
$F_{MD,l1,t}$	=	Annual amount of nitrogen in cattle, poultry and pigs manure and urine deposited on grassland soil during the grazing season in year *t*, adjusted for volatilization as NH_3 and NO_x (t N)
$F_{MD,l2,t}$	=	Annual amount of nitrogen in sheep and other animals manure and urine deposited on grassland soil during the grazing season in year *t*, adjusted for volatilization as NH_3 and NO_x (t N)
$EF_{3,PRP,CPP}$	=	N_2O emission factor for cattle, poultry and pigs manure and urine deposited on grassland soil during the grazing season (kg N_2O-N/kg N input)
$EF_{3,PRP,SO}$	=	N_2O emission factor for sheep and other animals manure and urine deposited on grassland soil during the grazing season (kg N_2O-N/kg N input)
L_1	=	Index of livestock cattle, poultry and pigs
L_2	=	Index of livestock sheep and other animals

$F_{MD,l1,t}$ and $F_{MD,l2,t}$ must be calculated using the following equation for livestock type *l*.

$$F_{MD,l,t} = \frac{P_{l,t} \times W_{l,p} \times Nex_l \times H_{l,t} \times Days_{l,t} \times (1 - Frac_{GAS,MD})}{1000_a \times 24 \times 1000_b} \quad (36)$$

Where:

$F_{MD,l,t}$	=	Annual amount of manure and urine deposited on grassland soil from livestock type l during the grazing season in year *t*, adjusted for volatilization

as NH_3 and NO_x (t N)

$P_{l,t}$	=	Population of grazing livestock type*l*in year *t* (head)
$W_{l,p}$	=	Average weight of livestock/under project (kg livestock mass/head)
Nex_l	=	Nitrogen excretion of livestock typ *l* (kg N deposited /(t livestock mass*day))
1000_a	=	Conversion factor for t livestock mass to kg livestock mass
$H_{l,t}$	=	Average grazing hours per day during grazing season in year *t* (hours)
24	=	Conversion factor for days to hours
$Days_{l,t}$	=	Grazing days for livestock type *l* inside the project area in year t (days)
1000_b	=	Conversion factor for t N to kg N
$Frac_{GAS,MD}$	=	Fraction of volatilization from manure and urine deposited by grazing animals as NH_3 and NO_x (kg N volatilized/kg of N deposited)
L	=	Index of grazing livestock types

3) Project indirect N_2O emissions from urine and manure N deposited on grassland soils

Indirect N_2O emissions from rine and manure N deposited on grassland soils excludes N_2O emissions from leaching and runoff in regions as set out in Section 5.

Indirect N_2O emissions from the atmospheric deposition of N volatilized as NH_3 and NO_x after urine and manure N is deposited on grassland soils under the project in year t, are calculated using the following:

$$PE_{ID,N_2O_{MD},t} = \sum_{l=1}^{L} F_{MD,l,t} \times Frac_{GAS,MD} \times EF_{4,MD} \times 44/28 \qquad (37)$$

Where:

$PE_{ID,N_2O_{MD},t}$	=	Project indirect N_2O emissions from manure and urine deposited on grassland soil during the grazing season in year t (t N_2O)
$F_{MD,l,t}$	=	Annual amount of manure and urine deposited on grassland soil from livestock type l during the grazing season in year *t*, adjusted for volatilization as NH_3 and NO_x (t N)
$Frac_{GAS,MD}$	=	Fraction of volatilization from manure and urine deposited by grazing animals as NH_3 and NO_x (kg N volatilized/kg of N deposited)
$EF_{4,MD}$	=	N_2O emission factor for atmospheric deposition of urine and manure N on soils and water surfaces, (kg N_2O-N/(kg NH_3-N + NO_x-N volatilized))

4) CH_4 emissions from manure management

Project CH_4 emissions from manure management must be calculated using the Tier 1 approach, recommended by the *2006 IPCC Guidelines for National Greenhouse Gas Inventories*, as described using the following:

$$PE_{CH_{4MD},t} = \frac{GWP_{CH4} \times \sum_{l=1}^{L} EF_{lM} \times P_{l,t} \times H_{l,t} \times Days_{l,t}}{1000 \times 365 \times 24} \quad (38)$$

Where:

$PE_{CH_{4MD},t}$	=	Project CH_4 emissions from manure and urine deposited on grassland soil in year t (t CO_2e)
$P_{l,t}$	=	Population of livestock type *l* in year *t* (head)
EF_{lM}	=	CH_4 emission factor from manure of of livestock type *l* (kg CH_4/(head*year))
$H_{l,t}$	=	Average grazing hours per day during grazing season in year *t* (hours)
$Days_{l,t}$	=	Grazing days for livestock type *l* inside the project area in year t (days)
1000	=	Conversion factor for t CH_4 to kg CH_4
365	=	Conversion factor for years to days
24	=	Conversion factor for days to hours

8.2.6 Project CO_2 emissions due to the use of fossil fuels

If project emissions from this source are larger than baseline emissions, the project proponent must account for this source of project emissions. The following equation is applied to calculate CO_2 emissions from consumption of fossil fuels for management practices implemented as part of the project.

$$PE_{FC,t} = \frac{\sum_{p=1}^{P}\sum_{j=1}^{J}\sum_{k=1}^{K} FC_{p,j,k,t} \times EF_{CO2,k} \times NCV_k}{1000} \quad (39)$$

Where:

$PE_{FC,t}$	=	Project CO_2 emissions from farming machine fossil fuel consumption in year *t* (t CO_2)
$FC_{p,j,k,t}$	=	Fuel consumption by fuel type *k*, by machine type *j*, on grassland parcel *p*, in year *t* (kg fuel/year)
$EF_{CO_2,k}$	=	CO_2 emission factor by fuel type *k* (t CO_2/GJ).
NCV_k	=	Thermal value of fuel type *k* (GJ/t fuel)
1000	=	Conversion factor for tonnes fuel to kg fuel
K	=	Index of fuel type
J	=	Index of machine type
P	=	Index of grassland parcel

8.2.7 Project removals from woody perennials

Where the project proponent chooses to include the aboveground woody biomass pool, project removals from woody perennials ($PRWP_t$) is calculated using CDM A/R tool for *Estimation of carbon stocks and change in carbon stocks of trees and shrubs in A/R CDM project activities*. Where the project proponent chooses not to include the aboveground woody biomass pool, with-project removals, $PRWP_t$, are assumed to be zero.

The carbon gain-loss approach must be applied to estimation of the project removals from woody perennials. Project removals from woody perennials must be calculated using the following:

$$PRWP_t = \sum_{j=1}^{J} \Delta C_{PG,j,t} - \Delta C_{PL,j,t} \qquad (40)$$

Where:

$PRWP_t$	=	Project average net change in carbon stocks of existing woody biomass in year *t* (t CO_2)
$\Delta C_{PG,j,t}$	=	Project average increase in carbon stocks of existing woody biomass for species *j*, in year *t* (t CO_2)
$\Delta C_{PL,j,t}$	=	Project average loss in carbon stocks of existing woody biomass for species *j*, in year *t* (t CO_2)
J	=	Index of species

As noted under the assumptions used in developing this methodology, no explicit accounting of the term representing stock losses, $\Delta C_{PL,j,t}$, is included in this methodology. That is, $\Delta C_{PG,j,t}$ is assumed to be a measure of net growth increment and thus to implicitly account for $\Delta C_{PL,j,t}$.

The average increase in carbon stocks in existing live woody biomass for each species must be calculated using the following:

$$\Delta C_{PG,j,t} = \sum_{s=1}^{S} A_{P,j,s,t} \times G_{P,j,s,t} \times CF_j \times 44/12 \qquad (41)$$

Where:

$\Delta C_{PG,j,t}$	=	Project average increase in carbon stocks of existing woody biomass for species *j*, for year *t* (t CO_2)
$A_{P,j,s,t}$	=	Area of species *j* in stratum *s* under project in year *t* (ha)
$G_{P,j,s,t}$	=	Project average increase in existing woody biomass for species *j* in grassland management stratum *s* in year *t* (t dm/ha)
CF_j	=	Carbon fraction for species *j* (t C/t dm)
S	=	Index of stratum
44/12	=	Ratio of molecular weights of CO_2 and C

The average annual increase in existing live woody biomass stocks for each species in a vegetation class in a stratum must be calculated using the following:

$$G_{P,j,s,t} = G_{AB,P,j,s,t}(1+R_j) \qquad (42)$$

Where:

$G_{P,j,s,t}$	=	Project average increase in existing woody biomass for species *j* in grassland management stratum *s* in year *t* (t dm/ha)
$G_{AB,P,j,s,t}$	=	Project average increase in existing above-ground woody biomass for species *j* in grassland management stratum *s*, in year *t* (t dm/ha)
R_j	=	Root to shoot ratio of species *j* (t dm belowground biomass/t dm aboveground biomass)

Since below ground biomass is an optional carbon pool (see Table 1), the term (1 + R_j) may be removed from the above, Equation 42, if this carbon pool is not included in the project boundary.

8.2.8 Project removals due to changes in soil organic carbon

Soil carbon is a major pool affected by changes in grassland management practices. In this methodology, proponents may either make direct measurements of SOC, or use a modeling approach. If there are peer-reviewed studies (eg, scientific journals, university theses, or work carried out by the project proponent) that demonstrates that the use of the selected model is valid for the project region, the model can be applied for estimating of carbon stock changes (Option 1 below). Otherwise, direct measurement of carbon stocks will be carried out (Option 2 below).

Option 1: Estimate of project removals due to changes in SOC using a validated model

Using a biogeochemical model that has been accepted in peer-reviewed scientific publications and validated for the project region (eg, CENTURY soil organic matter model[4]) estimate SOC stocks at equilibrium ($SOC_{m_G,s,Equil}$) and the time to reach the equilibrium ($D_{m_G,s}$) under each of the identified management practices of stratum s. The details of each management practice that are recorded will depend on the choice of the soil model selected and the type of activity being promoted.

If $D_{m_G,s}$ is longer than the length of the project crediting period, it means that the SOC will not reach equilibrium during the project implementation. The annual changes of SOC stock ($\Delta SOC_{m_G,s}$) and project removals due to changes in SOC (PR_t) in year t must be calculated using the following:

$$\Delta SOC_{m_G,s} = \frac{SOC_{m_G,s,Equil} - SOC_{s,Baseline}}{D_{m_G,s}} \qquad (43)$$

4 Parton et. al., 1987

Where:

$\Delta SOC_{m_G,s}$	=	Annual changes of SOC stock under management practice m_G in stratum *s* (t C/(ha * year)
$SOC_{m_G,s,Equil}$	=	Estimated SOC stocks in the top 30 cm of soil layer (or greater depth if required) at equilibrium, under management practice m_G in stratum *s* (t C/ha)
$SOC_{s,Baseline}$	=	Baseline SOC stock in the top 30 cm of soil layer (or greater depth if required) in stratum *s* (t C/ha)
$D_{m_G,s}$	=	The time to reach equilibrium under management practice m_G in stratum *s* (years)

The annual project removals due to changes in SOC in year *t* must be calculated using area-weighted average values of model input parameters for each management practice identified.

$$PR_t = \sum_{m_G} \sum_{s} PA_{m_G,s,t} \bullet \Delta SOC_{m_G,s} \times \frac{44}{12} \qquad (44)$$

Where:

PR_t	=	Project removals due to changes in SOC in year *t* (t CO_2e)
$PA_{m_G,s,t}$	=	Project areas with management practice m_G in stratum s in year *t* (ha)
$\Delta SOC_{m_G,s}$	=	Average annual changes of SOC stock under management practice m_G in stratum s (t C/(ha*year))
S	=	Index of stratum
m_G	=	Index for grassland management types
