EXECUTIVE SUMMARY

A 44 home residential development is proposed for Shadow Run Ranch in Pauma Valley. The property is currently the site of a 200 acre citrus and avocado grove. Under the proposed development the 44 homes will rely on individual septic systems and potable water from Yuima Municipal Water District. Additionally, grove acreage will be reduced to 144 acres under the proposed project.

Five water wells are located down gradient and across Highway 76 within the San Luis Rey River. These wells are owned by the applicant, but are not within the project site. Three of the wells are operated by Yuima Municipal Water District (YMWD). These wells are monitored for water quality by YMWD on a regular basis. Water quality monitoring information indicates that nitrate concentrations in groundwater samples collected from these wells is elevated and on rare occasions have exceeded the Maximum Contaminant Level (MCL) for nitrate (as nitrogen) of 10 milligrams per liter (mg/l). In May 2012, groundwater samples were collected from the four on-site irrigation wells, as well as one off-site irrigation well. Samples were analyzed for nitrate, as nitrogen. Nitrate concentrations ranged from below the reporting limit of 0.5 mg/l at the well located furthest up gradient at the site, to 8.9 mg/l at the well located furthest down gradient.

Because the proposed project will introduce a new source of nitrogen that will migrate to the water table, the San Diego County Environmental Health Department (DEH) requested an analysis of nitrogen loading. This analysis addresses both the addition of nitrogen to the site from the proposed septic systems, but also the reduction of nitrogen caused by the decrease in fertilizer application that will occur as a result of the planned reduction in grove acreage.

The study also characterizes the occurrence of groundwater at the site. Groundwater occurs beneath the site in saturated alluvial fan deposits. Alluvial fan deposits are generally highly permeable due to their coarse sediment texture. On-site well yields on the order of hundreds of gallons per minute indicate that the alluvial fan deposits at the site are permeable with respect to water. The alluvial fan deposits, along with the high annual rainfall rates that occur in the mountains upgradient and beyond the project boundaries, result in groundwater inflow to the property that likely is well in excess of groundwater recharge that occurs from direct rainfall infiltration on-site.

The change in land use is expected to result in about an 11 percent decrease in nitrogen loading under the new project, compared to current conditions. Hence, on-site nitrate concentrations in groundwater, measured as high as approximately 9 mg/l may be expected to eventually decline by about 1 mg/l. Because nitrate measurements in groundwater samples collected from the YMWD wells on a quarterly basis exhibit variations in excess of 1 mg/l it is not likely that the decline in nitrate concentrations will be readily evident. However, the analysis indicates that an increase in nitrate concentrations in groundwater at the site or at the YMWD wells is not expected as a result of the proposed project.

APPENDICES

1.0 INTRODUCTION

The project, known as "Shadow Run Ranch, LLC," (hereinafter "project") consists of 44 residential lots and three open space lots that are proposed to accommodate biological, agricultural, and recreational uses. The project site encompasses 248.26 acres (TRS, 2012) and is located in the unincorporated community of Pala/Pauma in north central San Diego County (Figure 1). Annexation to the local service district is also proposed for potable water and fire services and sewer service will be provided via individual septic systems on each lot.

This report documents an assessment of the change in nitrogen loading of groundwater from the existing citrus and avocado grove land use to the proposed land use that will not only include the new residences, but will also result in a reduction in grove acreage. Hence an increase in nitrogen loading will occur from the additional septic systems that will be introduced with the project and a decrease in nitrogen loading will also occur from the removal of grove acreage that is also associated with the new project.

2.0 SETTING

The following characterizes the topography, watershed boundaries, rainfall distribution, and general geologic setting near the site.

2.1 TOPOGRAPHY AND WATERSHED BOUNDARIES

As described by URS Consultants in their Updated Geologic Hazards Study (URS, 2009), the site is on an alluvial fan surface derived from the erosion of the nearby steep granitic mountain slopes of Agua Tibia Mountain, Crosley Saddle, and Eagle Crag to the north and northeast (Figure 2).

Land surface elevation at the site ranges from approximately 750 feet mean sea level (ft msl) to 1,620 ft msl. Land surface elevations within the watershed surrounding the site range from approximately 670 ft msl at the San Luis Rey River to nearly 4,780 feet at Agua Tibia Mountain (Figure 2). The local watershed encompassing the site covers approximately 6,700 acres (over 10 square miles).

2.2 RAINFALL DISTRIBUTION

Due to the steep mountain slopes and relatively high land surface elevations north of the site, the orographic effect of these slopes forces moist coastal breezes upward. As the air rises it is cooled. This process results in increasingly higher annual rainfall within the watershed as land surface elevation increases. An excerpt from the County of San Diego 30-Year Average Annual Precipitation Map overlaid on the USGS topographic map shows that average annual rainfall ranged from a low of 18 to 21 inches at the site to 33 to 35 inches at the upper reaches of the local watershed.

2.3 GEOLOGIC SETTING

As described by URS Consultants, the oldest rocks outcropping in the site vicinity are Cretaceous age intrusive igneous rock of Agua Tibia Mountain and older pre-Cretaceous metamorphic and metasedimentary rocks in the north-northeast portion of the site (URS, 2009). Rock units mapped in the area include the Woodson Mountain Granodiorite and the San Marcos Gabbro. The pre-Cretaceous metamorphic rocks are not named, according Kennedy, 2000 (URS, 2009). Erosion of the high relief Agua Tibia Mountain has generated broad, coalescing alluvial fans along the margins of the San Luis Rey River Valley. The site is underlain by alluvial fan deposits that include cobble to large boulder clasts of predominantly granitic rock. The alluvial fan deposits range in age from Pleistocene to Holocene age. Alluvium is present in the San Luis Rey River Valley and in the lesser on-site tributary drainages like Fry Creek (URS, 2009). Though alluvium in the lesser tributary drainages would not be expected to be saturated with groundwater as depth to groundwater is most likely greater than the relatively shallow alluvial deposits.

For reference, URS has prepared a detailed geologic map of the site and 7.5-minute quadrangle geologic maps, have been jointly published by the USGS and the California Geological Survey. The 7.5 minute quadrangle maps, specifically relevant to the project vicinity are Pala, Vail Lake, Boucher Hill, and Pechanga. These geologic maps can be obtained in PDF format on line at http://www.conservation.ca.gov/cgs/rghm/rgm/Pages/southern_region_quads.aspx.

The Elsinore Fault zone occurs within Pauma Valley and within the upper portion of the project site (URS, 2009). The fault zone is likely responsible for pronounced physiographic highs such as Agua Tibia Mountain and Palomar Mountain and hence is a causal factor in the development of the alluvial fans at the site.

3.0 HYDROGEOLOGY

Information regarding on-site water wells and water wells in the immediate vicinity of the project that are owned by the project applicant is summarized. A discussion of groundwater occurrence is presented including a qualitative discussion of local groundwater recharge processes, presentation of groundwater level and groundwater flow direction information, and a discussion of the relative contribution of groundwater inflow from the local watershed to groundwater flow along the San Luis Rey River. Lastly, nitrate concentrations in groundwater are presented.

3.1 WATER WELL INFORMATION

Four agricultural irrigation wells, PV-6 through PV-9 occur at the site (Figure 2). These wells will continue to provide irrigation water only for the project. Well PV-10, an irrigation well, is located just east of the project site and is owned by the Schoepe family. Five production wells, PV-1 through PV-5, are located along the San Luis River channel just south of the site (Figure 2). These wells are also owned by Schoepe family. Well PV-1 is inactive. Wells PV-2 through PV-4 are managed and pumped by the Yuima Municipal Water District (YMWD). Well PV-5 is

monitored by the YMWD but apparently has not been actively pumped for at least several years. The water wells were installed between 1972 and approximately 1992 (Table 1).
All ten wells are completed in the alluvial fan deposits and in some cases continue into the underlying fractured granitic rock (Table 1, Appendix A). Total depth of the wells ranged from 175 feet at PV-1 to approximately 1,000 feet at Wells 5 and 9. In some cases the quality of the driller's logs are questionable, in other cases the wells have gamma ray logs to support the driller's log.

Extended pump tests conducted by pump service contractors indicate that production rates at all the wells range between 200 gpm to 450 gpm. Specific capacity values range between 1.8 gpm per foot of drawdown to 6.0 gpm per foot of drawdown (Table 1).

3.2 GROUNDWATER OCCURRENCE

Unpumped groundwater depths measured in February 2012 for the YMWD wells and in April 2012 for the on-site wells ranged between 96 feet and 409 feet (Table 2). The 409 foot groundwater level was measured at well PV-7. It is uncertain if this anomalously deep measurement is accurate, a result of incomplete pumping recovery, or related to faulting along the Elsinore Fault Zone. The water level measurement at well PV-7 results in a localized deflection in the direction of groundwater flow (Figure 4) toward the southwest. However, this well is completed several hundred feet into bedrock while its neighboring wells are completed either above bedrock to 80 feet into bedrock according to hand drawn, draft logs prepared by an unknown author (Appendix A). Saturated alluvial sediment thicknesses are based on recent groundwater level measurements range between 30 to 77 feet for the YMWD production wells to approximately 190 to 365 feet for the on-site wells. The greater saturated alluvial sediment thicknesses on the property versus the river bed are attributable to reportedly deeper bedrock - alluvium contacts on the property (Appendix A). However, the quality of those lithologic interpretations are uncertain.

The overall direction of groundwater flow at the site is southward from the head of the alluvial fan toward the San Luis Rey River (Figure 4). Groundwater flow in the immediate vicinity of the YMWD wells is convergent as suggested by groundwater elevations at upstream wells PV-2 and 3 having somewhat lower static groundwater elevations than downstream wells, PV-4 and PV-5. The groundwater hydraulic gradient on-site is approximately 0.08 feet of groundwater elevation change per horizontal foot. As one approaches the YMWD water levels, the gradient flattens by nearly an order of magnitude to approximately 0.007 feet per foot. This change in gradient likely reflects the extended cone of depression associated with YMWD groundwater pumping.

In the western United States uplifted mountains, bordered by subsided valleys, often have alluvial fans that occur along the transition between these tectonic physiographic features. The alluvial fan deposits are typically coarser grained and higher in permeability closer to the mountain front and decrease in coarseness and permeability toward the valley. Runoff coming from the mountains can soak into the coarse deposits (Fetter, 1994). As demonstrated in Figure 2, rainfall occurs at significantly higher rates in the mountains. Hence infiltration of runoff into the alluvial fans is an important hydrogeologic process in delivering water to the water table and

most probably plays a greater role in groundwater recharge than infiltration of rainfall that falls directly on to the site.

Groundwater inflow into the San Luis Rey River of course is not limited to the alluvial fan deposits that are present at the site. The drainage area of the San Luis Rey River at the point where the river encounters the site encompasses hundreds of square miles, including extensive areas that occur at land surface elevations greater than 4,000 feet msl where rainfall rates are exceptional high. Similarly, Pauma Valley has extensive agricultural groves, hence nitrate sources off site and upgradient of the site are also extensive and subject to degrading groundwater pumped from the YMWD water wells.

3.3 NITRATE CONCENTRATIONS

Groundwater samples are collected from YMWD water wells (PV-2 through PV-4) and analyzed for nitrate (NO_3^-), every 3 to 4 months. On-site, groundwater samples were collected from wells PV-6 through PV-10 on May 7, 2012 and analyzed for nitrate (as nitrogen), Total Kjedahl Nitrogen and Total Dissolved Solids (TDS) (Appendix B). TKN is a measure of the sum of the concentrations of organic nitrogen, ammonia (NH_3), and ammonium (NH_4+). Hence, with the exception of nitrite, Total Nitrogen in groundwater has been measured. The occurrence of nitrite (NO_2^-) in groundwater is highly unlikely as environmental conditions in the unsaturated zone and within an unconfined aquifer typically oxidizes the various reduced forms of nitrogen found in fertilizer as well as septic leachate completely to nitrate. TKN concentrations in the on-site groundwater samples were all below the laboratory reporting limit of 0.5 mg/l (Appendix B). Hence it is reasonably inferred that nitrate concentrations detected in groundwater is the only form of nitrogen occurring in groundwater.

The distribution of nitrate in groundwater across the site indicates that the grove operation is a likely source of nitrate as concentrations in the upgradient water wells are at or near the reporting limit. Nitrate concentrations at the site appear to increase as groundwater flows from the upgradient end of the grove to the down gradient end of the grove (Table 3 and Figure 5). Nitrate concentrations are greatest at the two most down gradient wells at the site, PV-9 and PV-10 at concentrations of 8.9 and 7.9 milligrams per liter (mg/l) compared to a state and federal maximum contaminant level (MCL) of 10 mg/l. Groundwater samples collected at YMWD wells, PV-2 through PV-4, in October and September 2011, ranged from 6.4 to 7.3 mg/l (Figure 5). The slightly lower nitrate concentrations suggest that groundwater inflow along the San Luis Rey River provides somewhat greater dilutive capacity for nitrate compared to groundwater flow beneath the site.

4.0 NITROGEN MASS BALANCE

A five year record of fertilizer purchases for the Shadow Run Ranch provides the basis for estimating the mass of nitrogen delivered to the soil from agricultural activity (Appendix C). A literature search for citrus tree uptake of nitrogen was researched on-line, through the San Diego County/University of California, Davis Agricultural Extension, and the University of California, Riverside (UCR) Library. On-line research identified research conducted by the University of Florida that estimated nitrogen uptake efficiency in citrus trees. Gary Bender, Ph.D. a farm

advisor from the San Diego County/University of California, Davis Agricultural Extension, who specializes in deciduous fruit trees, reviewed one of the University of Florida nitrogen uptake efficiency publications and indicated that there were no comparable studies in Southern California (Bender, 2012). A literature search at the UCR Library also did not provide any comparable studies.

Nitrogen uptake efficiency indicates how much of the nitrogen applied to the soil is taken up by the crop. A summary document prepared by the University of Florida reports that a well managed citrus grove planted in sandy soil will have a nitrogen uptake efficiency between 40 and 60 percent (University of Florida, 2006). Hence, approximately 50 percent of the nitrogen in fertilizer remains in the environment. Once oxidized to nitrate, nitrogen in soil is typically stable and is unlikely to leave the hydrogeologic environment other than through groundwater pumping.

Under the project, 44 residential lots equipped with septic systems will be developed at the property. As part of the development, grove acreage will decrease from 200 acres to 144 acres. Accordingly, nitrate loading will increase from one source and decrease from another.

4.1 CURRENT NITROGEN LOADING

Fertilizer purchase records for Shadow Run Ranch from 2007 through 2011 indicate that between approximately 8,300 kilograms (kg) to 20,100 kg of Total Nitrogen are purchased annually (Figure 6). Over the five year period Shadow Run Ranch Total Nitrogen purchases averaged 12,860 kilograms (Figure 6). Assuming a nitrate uptake efficiency of 50 percent, approximately 6,430 kg of nitrogen is expected to reach the water table from current agricultural practices.

4.2 NITROGEN LOADING UNDER THE PROPOSED PROJECT

Nitrogen loading to groundwater under the new project will differ from current conditions in two principal ways. The residential development will include 44 individual septic systems with nitrogen bearing septic effluent. The proposed project will also have less grove acreage. This will result in a decrease in the mass of nitrogen enriched fertilizer applied to the soil. The following provides an estimate of how each change in land use may affect the rate of nitrogen loading to groundwater.

4.2.1 Anticipated Nitrogen Loading from Septic Discharge

The addition of 44 residential homes will generate domestic wastewater containing reduced forms of nitrogen. The discharge of the wastewater via leach fields and infiltration through the unsaturated zone typically oxidizes the reduced forms of nitrogen to nitrate. The following provides an estimate of nitrogen loading from the proposed residential development.

Nitrogen loading from domestic wastewater is a function of the average septic wastewater flow rate and the average nitrogen concentration . Wastewater flow is generally a function of the number of people residing in the home. It is assumed that on average the homes in the

development will have five bedrooms and will populated with two residents in the master bedroom and one resident in the four remaining bedrooms. Hence on average it is assumed that for the purposes of estimating wastewater flow there will be six full time residents per home. The California Department of Water Resources estimates, for the purpose of urban water management planning, that indoor water use in newer homes is approximately 75 gallons per day per resident (DWR, 2011). However, this per capita rate of internal residential water consumption is considered very high by DWR and EPA (DWR, 2011 and EPA, 1980) and both agencies indicate most residences use approximately 55 gallons per day per resident.
Septic leachate was collected from suction lysimeters that were placed below several different San Diego County leach fields in a study conducted by San Diego State University. Nitrate concentrations detected in these samples ranged between 30 and 40 mg/l (Huntley, 1987).

Alternatively, the EPA Design Manual for Onsite Wastewater Treatment and Disposal (EPA, 1980) reports that approximately 11.2 grams of Total Nitrogen per day can be anticipated per individual resident. This approach permits bypassing an estimate of the average wastewater flow rate.

Applying both approaches, the estimated annual mass of Total Nitrogen applied to the site from the septic discharge of 44 homes ranges between 1,094 kg per year for the first approach to 1,079 kg per year for the second approach (Table 4). Hence the two approaches provide essential the same Total Nitrogen load estimate. This estimate will likely be on the high side relative to the actual nitrogen loading that will eventually occur at the site because the per capita rate of internal residential water use is considered quite high and the assumption that all 44 homes will have an average occupancy of six residents.

4.2.2 Reduction in Nitrogen Loading, Grove Acreage Decrease

Grove acreage is expected decrease from the current 200 acres to 144 acres after development. Assuming uniform fertilizer application rates across the grove it would be expected the Total Nitrogen application to the soil would decrease by (200-144) acres / 200 acres; or 28 percent. Since the average annual Total Nitrogen application to soil over the past five years is 12,860 kg, under the project one can anticipate Total Nitrogen applications to soil decreasing 28 percent to approximately 9,260 kg; a reduction of approximately 3,600 kg per year. Accounting for nitrogen uptake efficiency at a rate of 50 percent, nitrogen reaching groundwater from fertilizer application is anticipated to decrease by 1,800 kg per year under the project (Table 5).

4.2.3 Net Change in Nitrogen Loading

Under the proposed project, nitrogen loading to groundwater is expected to change from the current average of 6,430 kg per year through an increase of 1,094 kg of Total Nitrogen from septic discharge and through a decrease of 1,800 kg of Total Nitrogen caused by a planned decrease in grove acreage and fertilization (Figure 7). These changes in land use result in an estimated average nitrogen loading of 5,724 kg per year or a decrease of approximately 706 kg per year.

The anticipated reduction in nitrogen loading is approximately 11 percent of the current average nitrogen loading rate. Assuming that the sole source of nitrogen for on-site groundwater is on-site fertilizer applications, an 11 percent reduction in nitrogen loading would imply an eventual 11 percent reduction in nitrate concentrations in groundwater (Table 5). Hence a 9 mg/l nitrate concentration may eventually decline to approximately 8 mg/l. As both of these values fall within the normal range variability observed in nitrate concentrations measured at the YMWD wells, it is likely that decline in nitrate concentrations associated with the project would be difficult to detect. On the other hand, a potential future rise in nitrate concentrations in groundwater would not be expected to be attributable to the change in land uses discussed herein.

WATER WELL DRILLERS REPORT

(Sections 7079, 7080, 7081, 7082, Water Code)

THE RESOURCES AGENCY OF CALIFORNIA
DEPARTMENT OF WATER RESOURCES

Do Not Fill In

No 33683

State Well No.

Other Well No.

(1) OWNER:

Name Mr. Adolph Schoepe

Address 1800 Via Dawson

Escondido, California.

(2) LOCATION OF WELL:

County San Diego Owner's number, if any 2

Township, Range, and Section T10S, R1W, SW¼ of Sec 5.

Distance from cities, roads, railroads, etc. West End of Pauma Valley, S of Hwy 76.

(3) TYPE OF WORK (*check*):

New Well ☒ Deepening ☐ Reconditioning ☐ Destroying ☐

If destruction, describe material and procedure in Item 11.

(4) PROPOSED USE (*check*):

Domestic ☐ Industrial ☐ Municipal ☐

Irrigation ☒ Test Well ☐ Other ☐

(5) EQUIPMENT:

Rotary ☐

Cable ☒

Other ☐

(6) CASING INSTALLED:

STEEL: OTHER:

SINGLE ☒ DOUBLE ☐

From ft.	To ft.	Diam.	Gage or Wall	Diameter of Bore	From ft.	To ft.
+ 1	100	24"	¼"	34"	0	248'6"
+ 2	248'6"	6"/16"	5/16			

If gravel packed

Size of shoe or well ring:

Size of gravel: 1/4" to ½"

Describe joint Welded

(7) PERFORATIONS OR SCREEN:

Type of perforation or name of screen

From ft.	To ft.	Perf. per row	Rows per ft.	Size in. x in.
100'	244'	8	4	⅜ x 4
244'	248'6"	# 100 Slot Johnson		
Stainless Steel Well Screen				

(8) CONSTRUCTION:

Was a surface sanitary seal provided? Yes ☒ No ☐ To what depth 100 ft.

Were any strata sealed against pollution? Yes ☐ No ☐ If yes, note depth of strata

From ft. to ft.

From ft. to ft.

Method of sealing Cement Grout & Double Casing

(9) WATER LEVELS:

Depth at which water was first found, if known 25 ft.

Standing level before perforating, if known ft.

Standing level after perforating and developing 44 ft.

(10) WELL TESTS: Water Well

Was pump test made? Yes ☐ No ☐ If yes, by whom? Drillers Co.

Yield: 1,020 gal./min. with 88 ft. drawdown after 1 hrs.

Temperature of water Was a chemical analysis made? Yes ☐ No ☒

Was electric log made of well? Yes ☐ No ☒ If yes, attach copy

(11) WELL LOG:

Total depth 248' 6" ft. Depth of completed well 253' 6" ft.

Formation: *Describe by color, character, size of material, and structure*

ft. to ft.	
0' – 12'	Gray Sand
12' – 38'	Gray Sand & Bldr
38' – 63'	Bldr (Boulders No Boulders)
63' – 75'	Gray Cemented sand & Boulders
75' – 81'	Gray Granite Boulder Coarse
81' – 92'	Gray sand, Boulders and Clay No Boulders
92' – 164'	Gray Granite Boulder No Boulders Sand & Clay only
164' – 168'	Brown Cemented Sand, Clay and Boulders No B
168' – 245'	Gray Granite Boulder No Boulders Sand & Clay only
245' – 248'	Gray Cemented Sand, Gravel & Boulders No Boulders
248' – 248'6"	Gravel coarse with small amount of sand Coarse
	Extremely Hard Granite

Work started 9/8 1972, Completed 9/21 1972

Samples:

PA-8 (Fig Tree Well)

60'–100 – light color course granitic boulders

100–150' – brown course DG – fillings

150–210' – grey fine-course DG

210–220' – brown fine-course DG

220–300 – grey fine-course DG

300–310 – light grey fine course DG

310–320 – grey fine-course DG

320–340 – grey – light brown fine course DG

540–550 – light fine-course granite boulders

600–640' – grey fine-course DG fillings.

PA-9

30–60' boulder light color coarse granite with pink color

60–100 light grey DG. ~~calcite~~ beta separated from other minerals.

100–140 light color with pink boulders and DG. calcite seperated from others

140–150' dark grey fine DG fillings between boulders

150–160' grey with pink course DG iron stain.

160–170 same as 140–150'

170–200 light pink color boulders

200–230 dark ~~red~~ color fine DG – fillings

230–290 – light pink course DG and boulders. iron stain

290–299 – grey ~~tan~~ color fine DG fillings

299–310' – light pink DG. ~~Calcite seperated from others~~

310–320 – 50% black gabbro 50% granite DG

320–330 – same as 299–310'

330–357 – course DG 80% dark grey gabbro 20% granite

RV-9

350 – 390. brown grey course DG and boulders

390 – 410. brown grey course DG & boulders

410 – 460 course granite boulders

460 – 470 – dark grey course granodiorite with many granitic grains

Lithology of 7*7 (PV-7)

Shadow Run Ranch, Pauma
November, 90--January, 91
By Zhouping Guo

Location: Frey Creek--Aluvine fan overlay and granite bedrocks environment.

Footage	Lithology
50	95% light grey course quartz-granite. Quartz grains have rose color coating. In granite: 50% quartz, 45% Na-feldspar and 5% biotite. 5% dark grey diorite
50-60	" "
60-70	80% light grey course granite (grains have iron coating), 20% dark grey fine course diorite.
70-80	80% light grey course granite, 20% dark grey diorite. Iron coating disappears, but see quartz from quartz vein with iron coating.
90-90	90% light grey course granite, 10% dark grey diorite.
90-100	90% light grey course granite, 10% diorite, <1% quartz vein.
100-105	100% light grey course granite: 60% feldspar and quartz, 40% biotite. Some grains have iron coating.
105-110	" "
110-115	100% grey course biotite-granite: 60% feldpsar and quartz, 40% biotite.
115-120	" "
120-125	" "
125-130	90% grey-course biotite-granite, 10% quartz from quartz vein. Quartz grains size from 1-5 mm.
130-135	" "
135-140	95% grey course biotite-granite, 5% quartz vein. Some of the quartz grains have iron coating.
140-145	100% grey course biotite-granite.

145-150 100% light grey course granite: 80% feldspar and quartz, 20% biotite, <1% quartz vein.

150-155 " "

155-160 " "

160-165 100% grey course biotite-granite: 50% feldspar and quartz, 50% biotite.

165-170 " "<1% quartz vein

170-175 100% grey course biotite-granite: 40% feldspar and quartz, 60% biotite and hornblend.

175-180 60% grey course granite, 40% dark grey fine course diorite.

180-185 50% light yellow clay (first time clay has appeared), 50% course granite, <1% quartz vein. The clay more likely acts as cement material between the boulders.

1850190 100% light grey quartz-granite: 90% quartz and feldspar, 10% dark minerals (biotite), <1% dark grey granite or diorite.

190-195 100% light grey quartz-granite: 90% quartz and feldspar, 10% dark. Some grains have iron coating.

195-200 100-% light grey quartz-granite: 10% rose color K-feldspar.

200-205 100% grey biotite-granite. Some grains have iron coating.

205-210 " "

210-215 " "

215-220 " "

220-225 " "

225-230 " "

230-235 80% dark grey course biotite-granite, 20% yellow clay.

235-240 100% grey course biotite-granite: 60% feldspar and quartz, 40% biotite.

240-245 " "

245-250 100% light grey quartz-granite. Some grains have iron coating.

250-255 100% light grey (quartz-granite) : 80% quartz and Na-feldspar, 15% rose color K-feldspar, 5% biotite.

255-260 " "

260-265 60% light grey quartz-granite, 10% dark grey, fine course diorite, 30% clay. In granite, rose color K-feldspar is 20% of all minerals.

265-270 70% clay, 15% light grey quartz-granite, 15% dark grey diorite.

270-275 90% dark grey fine course diorite, 10% light grey quartz-granite. Diorite chips range from 0.5-20 mm.

275-280 50% clay, 30% light grey course quartz-granite, 20% dark grey fine course diorite.

280-285 70% dark grey fine course diorite, 30% light grey quartz-granite, <1% clay.

285-290 99% light grey course quartz-granite, 1% dark grey diorite. 80% of grains have iron coating.

290-300 85% light grey course quartz-granite, 15% dark grey diorite. 50% of granite grains have iron coating.

300-310 90% light grey course granite (80% feldspar & quartz, 20% biotite), 10% dark grey fine course diorite. 5% of granite grains have iron coating.

310-320 80% green-gray clay, 15% light grey course granite, 5% dark grey diorite.

320-330 60% light grey course quartz-granite, 30% dark grey fine diorite, 10% red clay.

330-340 100% light grey course quartz-granite. 90% grains have iron coating.

340-350 " "

350-360 100% light grey course quartz-granite: 70% of granite grains have iron coating.

360-370 " "

370-380 90% dark grey fine course diorite, 10% light grey course quartz-granite with iron coating.

380-390 100% light grey course mozonite (?) (may be gneiss) with 50% rose color K-feldspar, 40% Na-feldspar & quartz, 10% dark minerals. It is very similar to gneiss.

390-400	98% light grey course quartz-granite, 2% dark grey fine diorite. 90% of granite grains have an iron coating.
400-410	100% decomposed granite (DG). Some grains have iron coating. <1% of diorite.
410-420	95% DG -- course quartz-granite, 5% dark grey diorite.
420-430	100% DG -- course quartz-granite.
430-440	no sample
440-450	100% DG -- course quartz-granite.
450-460	85% DG (of which 80% grains are coated by iron), 15% dark grey diorite.
460-470	99% light grey course quartz-granite, 1% Calcium chips. 40% of grains have an iron coating.
470-480	99% DG, 1% Calcium chips. 90% of grains have an iron coating.
480-490	100% DG, <1% Calcium chips. 20% of grains have an iron coating.
490-500	50% DG-course granite, 50% dark grey diorite.
500-510	70% DG-course granite, 30% dark grey diorite, <1% calcium chips.
510-520	100% DG-course granite, <1% diorite. 100% grains have iron coating.
520-530	" "
530-540	" "
540-550	100% DG-course granite, 40% grains have iron coating.
550-560	50% light grey course quartz-granite, 50% dark grey course grained diorite. 90% of granite grains have an iron coating.
560-570	99% light grey course quartz-granite, 1% dark grey granodiorite.
570-580	97% course quartz-granite.
600-610	30% course quartz-granite, 70% dark grey course grained diorite.
610-620	90% grey course granite, 10% grained diorite.

Notes and Definitions

QM-05	The spike recovery was outside acceptance limits for the MS and/or MSD due to matrix interference. The LCS and/or LCSD were within acceptance limits showing that the laboratory is in control and the data is acceptable.
ND	Analyte NOT DETECTED at or above the reporting limit
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference

Notes and Definitions

W-02	The sample for nitrate analysis was preserved with H2SO4 after the nitrite portion of the analysis was completed to extend the holding time for the sample. Nitrate results are corrected for the nitrite contribution per the method.
ND	Analyte NOT DETECTED at or above the reporting limit
NR	Not Reported
dry	Sample results reported on a dry weight basis
RPD	Relative Percent Difference
